In traditional engineering curricula, senior design or capstone courses emphasize structured design processes aimed at "the application of scientific and technical knowledge" (Atman et al. 2014, 210), mainly from textbook-based knowledge (Qattawi et al. 2021). These courses often follow one of two formats: students are either directed by one or two instructors who propose specific ideas for student exploration, or students are guided by academic faculty members who, while advising students, also derive benefits from the faculty's own research projects, treating student contributions as a form of free labor. These approaches raise ethical concerns/questions about effectiveness in enhancing students' design capabilities, especially because design problems are pre-defined. In contrast, we believe the primary objective of these courses should be to develop students' abilities to tackle real-world engineering problems through design for the benefit of people. Like Miska et al. (2022), our teaching team endorses "expand[ing] the curriculum beyond the theoretical and technical core concepts to an application-focused, holistic approach" (618) that fuses students' technical and professional skills in an effort to close a gap between academia and industry.

1.2 Student Outcomes Fostered by Multidisciplinary Teaching Team

Our goal in describing each instructor's service design teaching intervention is to outline how we fostered the Accreditation Board for Engineering and Technology (ABET) student outcomes by weaving together our multidisciplinary expertise. For the purposes of this paper, we limit attention to the broader ABET student outcomes, but each of our courses identifies more specific student learning outcomes that align with ABET. We provided instruction stemming from our respective areas of expertise to enable student teams to ideate, prototype, and iterate upon designs that more closely matched user needs. Here we endeavor to show how the engineering curriculum can be improved by a multidisciplinary teaching collaboration such as ours that intersects multiple ABET student outcomes.

ABET requires engineering programs to meet educational objectives that include seven student outcomes (SO), and we argue that our partnered courses, BEE and ENGRC 4590, achieve all seven. Briefly, ABET outcomes that prepare "graduates to enter the professional practice of engineering" include the abilities to:

1. solve complex engineering problems
2. apply engineering design

3. communicate effectively
4. recognize ethical and professional responsibilities
5. function effectively on a team
6. develop and conduct appropriate experimentation, analyze and interpret data, and use engineering judgment to draw conclusions
7. acquire and apply new knowledge ("Criteria for Accrediting Engineering Programs, 2024 - 2025," n.d.)

In particular, SO 4 relates to environmental contexts, which we focused on more in the most recent semester by directing the physical design toward the Environmental Protection Agency's People, Prosperity and the Planet (P3) Student Design Competition. The EPA P3 grant offers funding to "benefit people, promote prosperity and protect the planet by designing environmental solutions that move us toward a sustainable future" (US EPA 2015).

When the teaching partnership between the Biological Engineering Department and the Engineering Communications Program first began, student teams documented their physical design project by writing a patent. The United States Patent and Trademark Office's stringency and highly complex requirements are perhaps well-known, and students often struggled to meet both technical writing and engineering design aspects of patent documents. The anecdote in the introduction also signaled to us that wastefulness and sustainability needed to figure more prominently in the curriculum. Therefore, in 2023, our teaching team discussed another, more suitable lens for the physical design project, and the student teams instead wrote design proposals targeted toward the EPA P3 grant.

2 SERVICE DESIGN AS A CURRICULAR INTERVENTION

After hearing multiple instances of over-engineered designs, Allison Hutchison, the communication instructor, applied her research experience with service design methodology by revising course materials to introduce students to concepts and tools that connect design more carefully to users and their needs, not just technological innovation. We draw upon Polaine, Løvlie, and Reason's definition of service design as a methodology that "is about designing *with* people and not just *for* them" (2013, 41). Service design "is commonly used in the service economy, such as restaurants and hotels, in order to design or redesign services" (Hutchison 2019, ii), but its applicability to engineering design has been treated nominally. According to Kaner and Karni, service design and service engineering hold similar practices (2007). While user-centered design (UCD) or user experience (UX) might be thought of as umbrella terms, service design differs in that it incorporates research to identify service interactions, allowing the researcher to "experience things for themselves that may be hard for someone to describe to them" (Polaine, Løvlie, and Reason 2013, 57). All three methodologies employ research methods such as interviews, surveys, and observations, but service design frames its approach around three main areas: *props, processes*, and *people*. Props consist of any physical or digital artifacts needed to execute the service, processes refer to "Workflows, procedures, or rules needed to perform the service successfully," and people include anyone involved in or affected by the service (Gibbons 2017).

2.1 Communication Instruction

Students in ENGRC 4950 created service blueprints that visualized the props, processes, and people involved in their proposed physical design, as well as a user persona for whom the design was created. Student teams first incorporated their service blueprint in a design proposal. The instructions stated, “The service blueprint shows your persona's user journey, including what is frontstage (what the user interacts with) and what is backstage (what goes on behind the scenes). Consider people, processes, and props in this service blueprint.” For instance, a team who dubbed themselves the Manure Buddies mapped out the user journey of an “environmentally conscious farmer” who “wishes to better understand their manure storage’s volume and environmental impact” (see Figure 1). They identified applicable props, processes, and people in their proposed design to “construct a camera-based device for measuring depth” of manure storage on a dairy farm, including:

- **Props:** manure, livestock, manure storage, camera-based device
- **Processes:** install device in manure storage system, obtain accurate storage volume measurement, obtain emissions estimate
- **People:** dairy farmers, agricultural scientists, agricultural researchers

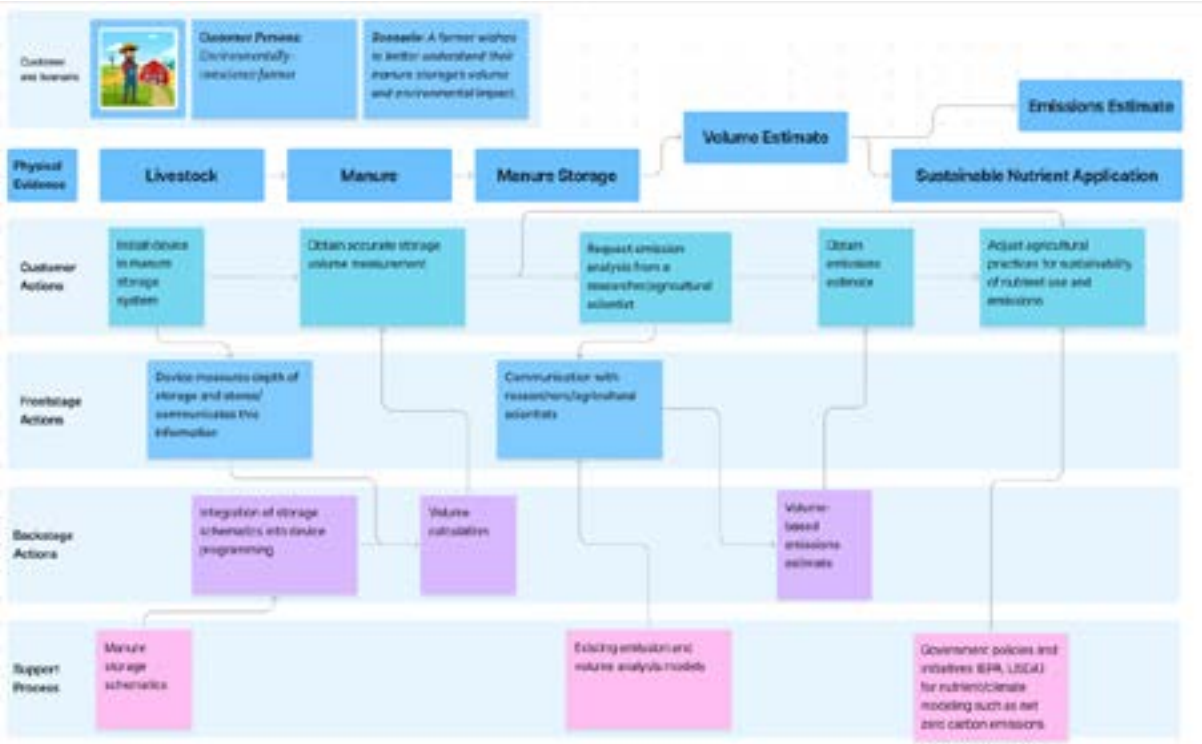

Fig. 1. The Manure Buddies’ Service Blueprint for a Manure Storage Measuring Device. Net zero carbon emissions appear as a support process (bottom right corner, in pink).

Not only did the service blueprint serve as a communication deliverable, evidencing SO 3, but it also showed how the students planned to solve the problem of safely measuring manure storage (SO 1); visualized how they applied engineering design principles through frontstage, backstage, and support processes (SO 2); and incorporated their recognition of the design’s attention to reducing harmful emissions

(SO 4). The team researched several processes in their proposals that particularly relate to sustainability (SO 4), described in more detail in the next section.

2.2 Information Literacy Instruction

The information literacy component was introduced into the BEE/ENGRC 4590 course in 2021 and has progressively increased from research consultations in the library to embedded instructional support to Hutchison by co-teaching the communication course. Initially, Sheley conducted research appointments so students could better understand how to integrate secondary sources that "positioned" their evolving designs in the marketplace, explored features appropriate for particular user groups and environments, and identified similar, existing technologies. However, during our conversations, it became clear that students also needed to stretch their understanding of the real-world contextual factors that could impact their thinking and approach. For example, Sheley prompted discussion about geopolitical factors, data collection methods and evaluation, and potential ethical and moral implications of an engineer's design (SO 1, 4, 7).

To embed information literacy instruction in the communication course, Sheley developed learning outcomes focused on the iterative nature of research and the contextual evaluation of information (SO 7). To achieve these outcomes, they gave lectures on the real-world factors mentioned in the above paragraph and demonstrations on researching the problem central to the design and end user. Additionally, they attended every class to support each phase of the research process, particularly after students were given feedback from course instructors. When students gave presentations about various aspects of their technologies to the class, the assessment rubric included a scoring area focused on using evidence to support their claims, thereby signaling how important research and information were to their design process.

One pain point at this time was the students' tendency to focus heavily on the technology and design, while excluding the problem and the user. Course instructors repeatedly brought those elements frontstage, so Sheley suggested adding user personas to the communications component. Personas are typically defined as "fictional, detailed archetypical characters that represent distinct groupings of behaviors, goals, and motivations" (Calde, Goodwin, and Reimann 2002), and act as stand-ins for real users to help guide decisions about functionality and design (Robertson 2024). They are often used when designers cannot engage directly with end users, due to time, money, or other project constraints (Marshall et al. 2015) and are based on knowledge of real users garnered from user research that identifies customer motivations, expectations, and goals about the target product segment (Bryant and Wrigley 2014, 76). Additionally, personas bring empathy into the design process because engineers focus on the intricacies of a user's journey and behavior (SO 1, 4). One class period was dedicated to introducing this concept and providing suggestions on secondary sources that provided demographic, behavioral, and psychographic information for generating a persona.

As Sheley moved into a co-instructor role, the communication course retained the previously introduced information literacy instruction and research support; however, additional emphasis was placed on user personas to address the *people* element of the service design framework. We also embedded this concept in several places across the course to ensure the user stayed central and to provide scaffolding for the storyboard and video assignments. Each team produced a user persona based on initial research using the secondary sources outlined above. For example, the Manure Buddies team initially identified two users: farmers and researchers. Many teams then talked to a user about their projects and specific needs. This generated new information that was then used to refine their persona and overall design.

We incorporated in-class activities that scaffolded teamwork (SO 5), such as the one depicted in Figure 2, where the Manure Buddies teammates individually sketched storyboard drafts. The goal here was to give all teammates a chance to convey their ideas about the design project to one another, as well as support a subsequent video assignment for the design course. The team then turned these individual storyboards into a unified storyboard that outlined their video. The video demonstrated how their proposed design would allow their intended user persona to measure the volume of a manure storage more safely and, consequently, support more accurate calculations of methane emissions.

Fig. 2. The Manure Buddies Team Drawing Storyboards During ENGRC 4590.

The Manure Buddies' awareness of the effect of methane emissions on climate change increased as the semester progressed. By examining props, processes, and people relevant to their proposed design, they more intentionally matched their design to a user persona and offered an innovative, sustainable solution. The team's initial design proposal stated that their device "would help agricultural researchers reliably estimate CH_4 emissions and see how they change annually," but how gathering more accurate manure measurements could lead to reducing greenhouse gas emissions was unclear. Later, in their EPA P3 proposal, the team expanded their literature review to connect the larger problem of greenhouse gas emissions to the more localized problem of underestimated methane emissions from livestock manure. In that way, gaining a greater understanding of two *processes* (gathering measurements and estimating emissions) allowed them to better situate how their *prop* (an autonomous stereo camera-based device) works for specific *people* (dairy farmers and agricultural researchers). In their words, they developed a "device that can autonomously, continuously, and accurately measure manure storage volumes," fostering cooperation among two groups of people with different areas of expertise to reduce methane emissions that contribute to global warming.

2.3 Biological Engineering Instruction

In the design capstone course, Sunghwan Jung extended invitations to researchers affiliated with the university’s Cooperative Extension. These extensions bridge communities with the university's research, enhancing and empowering neighbors, local businesses, and urban and rural areas. While academic faculty members have proposed various design project ideas in recent years, Jung noted these projects often stem from faculty's own curiosity or research interests, rather than focusing on specific user needs. In contrast, extension researchers have consistently informed design challenges to students, which are directly relevant to agricultural fields and environmental contexts, informed by feedback from farmers, environmental activists, and governments. By consulting with Jason Oliver, PhD, Senior Extension Associate, students gained access to practical knowledge and real-world challenges that are related to community needs and environmental considerations. Therefore, the project they worked on became not only technically viable (SO 1) but also socially relevant and impactful to communities (SO 4).

Adhering to Oliver’s advice, the Manure Buddies implemented service design’s concentration on *people*. The extension researcher’s advisory role significantly informed the Manure Buddies’ development of a user persona for the design and centered the user’s perspective. During Oliver’s initial conversation with the Manure Buddies, the team thought their design would be “just a researcher tool,” so Oliver sought to increase their appreciation of the reality of weekly, state-required manure storage measurements (Jason Oliver, phone call to Hutchison, April 1, 2024). Therefore, in addition to showing the Manure Buddies the manure storage facility on campus, Oliver also connected them to “a farmer with a couple thousand cows to bounce ideas off of” because he “wanted them to have a genuine conversation.” According to Oliver, visiting the campus farm and speaking to a New York dairy farmer “helped students *see* the system and understand the context of why farms invest in manure storages.” This combination of activities enacted service design methodology in that students got their hands (a little) dirty and experienced the problem beyond Oliver’s explanations (cf. Polaine, Løvlie, and Reason 2013, 57).

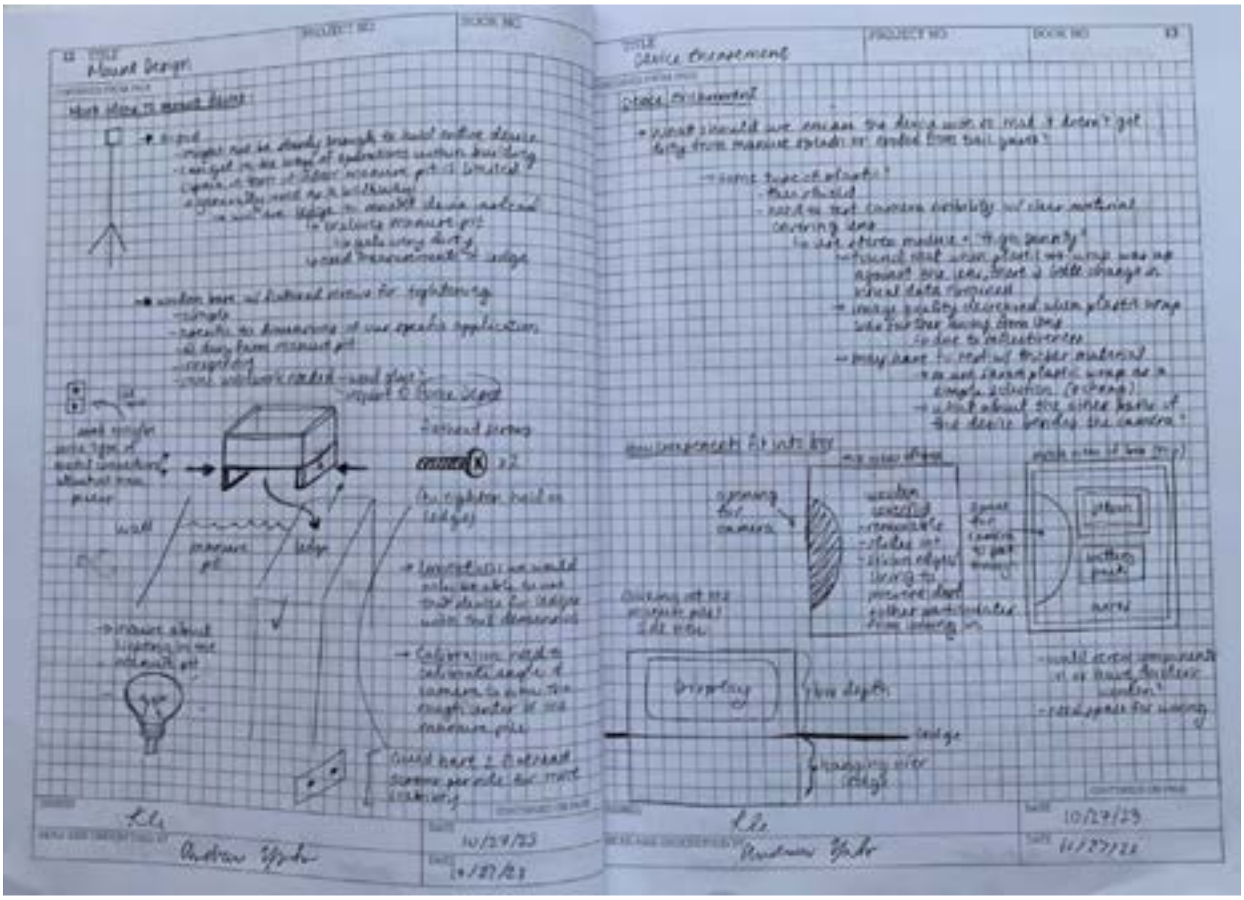

Fig. 3. A Page from Kathy Le's Lab Notebook. It showcases the student's critical analysis and thinking of potential issues (such as sturdiness) related to a simple design (a stereo camera on a tripod) that the Manure Buddies team initially drafted.

Our course emphasizes the maintenance and significance of student laboratory notebooks (see Figure 3). Each student kept an individual notebook and recorded their weekly work along with their team members. After completing their write-ups, peers reviewed and validated the content by signing the bottom of each page. This process allowed students to summarize collaborative work to ensure alignment with their teammates' work. In addition, students documented their data collection and analysis methods, recorded discussions with teammates, advisors, and users, and outlined next steps or potential solutions using their engineering knowledge (SO 6). Instructors examined these notebooks to check students' thought processes during the design phase and practical application of their engineering knowledge (SO 2).

3 COLLABORATIVE TEACHING REFLECTIONS

For undergraduate biological engineering majors to solve complex engineering problems (SO 1) and apply engineering design (SO 2), our experience has shown that embedding communication and information literacy instruction in the curriculum enhances opportunities for students to practice communication (SO 3) and teamwork (SO 5) within the situated context of a hands-on learning environment. We forward this model to improve the engineering curriculum by better responding to growing concerns about sustainability and preparing engineering students to take increased responsibility for socially and environmentally informed designs. An area of future research for our teaching team is seeking student responses to this intervention, such as how service design might impact their work as professional engineers. On the communication course's evaluations, one student shared, "There was a strong emphasis on inventing for a user group, which I found very useful." Another student wrote, "I think that this course is strong in guiding engineers to start with the user in mind rather than simply finding a problem to solve. I liked that the emphasis was creating something useful, rather than just inventing for the sake of inventing."

Finally, we conclude by offering steps for the next partner course design iteration.

Throughout a twelve-year period of teaching the capstone design course at two US-based universities along with instructors in engineering communication programs at both institutions, the biological engineering instructor has modified and advanced the course, transitioning from solely academic, research-driven projects to user-centric projects. This transition reflects the need to develop the course to educate students to address real-world problems and to ensure students not only acquire technical skills but also develop user awareness. With instructors in two engineering communication programs, the design instructor's development and modification of the course will continue to help students to be ready to face and solve the complexities of modern engineering challenges.

Because the focus of the biological engineering design course is moving from research-driven to more user-centered projects, the information literacy component will continue to lean heavily on the user persona within the service design framework. Future instruction will address how to conduct primary, user research (both qualitative and quantitative) to outline a user's nuanced journey. Additional exploration here adds to the information students receive in class and from outside advisors/stakeholders and can be consulted during the design prototyping and testing phases. Furthermore, additional instruction on searching for prior art to identify a wider variety of possible solutions that meet user needs before picking a particular direction will be given. Ideally, this work also supports a more sustainable engineering design process, as students will identify gaps in the marketplace and/or flaws in existing designs earlier and not replicate what is currently available.

4 ACKNOWLEDGEMENTS

We thank the Manure Buddies for their permission to include their coursework artifacts in this paper: Kathy Le, Peter Wei, Mingyang Xu, and Andrew Yonko.

ABSTRACT

Micro-credentials offer flexible and targeted approaches to skill development. However, their international exchange and utilization are hindered by a lack of standardization. Herein, we propose a hierarchical architecture and reference framework for Micro-credentials. The hierarchical architecture integrates educational systems with information technology for secure storage, issuance, and exchange of learning records. The framework establishes a common definition of Micro-credentials, reference descriptors for describing them, and quality assurance guidelines. By standardizing these elements, the framework enables learners to compare credentials, employers to evaluate skills, and institutions to design high-quality Micro-credentials. This comprehensive approach paves the way for a global learning ecosystem in which Micro-credentials empower lifelong learning and workforce mobility.

1 INTRODUCTION

1.1 Background

To develop human resources who can respond to rapid changes in industrial structures and promote digital transformation (DX) and green transformation (GX), learning must continue beyond the knowledge acquired in the university. There is a need for reskilling to acquire knowledge and skills in different fields and upskilling to enhance competence in one’s area of expertise.

Micro-credentials have attracted attention in many countries as complementary education to master’s and bachelor’s degree programs, in which students acquire skills in a specific study area in a relatively short period with certified results. Flexible teaching methods, such as online or blended teaching, are employed (OECD2021).

Micro-credentials comprise an educational system, which assures the quality of education, and information technology, which allows learners to securely store and share their learning history. These are interrelated but are considered by different organizations. Educational systems are first developed at the national or regional level (Australia 2021) (European Union 2022) (MQA 2020) (JMOOC 2023), and international mutual recognition can be included. Information technology for the digital issuance of academic records is developed by international standard organizations, such as 1EdTech Consortium (1EdTech 2024).

To design Micro-credentials, share and stack them locally and internationally, and implement their operation with digital data, the roles of educational systems and information technology, as well as their interdependencies, must be well defined.

Herein, we define the structure of an educational system and information technology and propose a system architecture for hierarchically structured Micro-credentials to ensure that Micro-credentials acquired by learners are internationally recognized and used.

1.2 Definition of Micro-credential

A Micro-credential comprises two aspects: the educational program and a proof of its academic record. The definition of Micro-credential varies among countries and regions. Based on the various definitions in various countries, UNESCO reported the following (UNESCO 2022):

(1) A Micro-credential is a record of focused learning achievement verifying what the learner knows, understands or can do.

(2) It includes assessment based on clearly defined standards and is awarded by a trusted provider.

(3) It has standalone value and may also contribute to or complement other micro-credentials or macro-credentials, including through recognition of prior learning.

(4) It meets the standards required by relevant quality assurance.

1.3 Micro-credential architecture that hierarchically structures educational systems and information technology

Micro-credentials comprise educational systems and information technologies that allow learners to securely store and share their academic history.

Herein, we propose an overall system comprising three layers of educational systems (Layers 1–3 on the top) and three layers of information technologies (Layers 4–6 on the bottom). These layers are as follows:

Layer 1: Individual Micro-credentials

Layer 2: National Qualifications Framework and Skill Standards

Layer 3: Micro-credential framework

Layer 4: Interface between the Micro-credential framework and digital certificate issuance technology

Layer 5: Digital certificate. Technology for digital issuance of academic records

Layer 6: Digital format for exchanging academic records. Comprehensive storage and international exchange of academic records.

The rest of this paper is organized as follows; Chapter 2 presents the framework of the Micro-credential (Layer 3), Chapter 3 presents the technical layer of issuing digital certificates (Layer 5), and Chapter 4 describes the details of the Micro-credential architecture.

2 MICRO-CREDENTIAL FRAMEWORK

2.1 Micro-credential framework and the current state of the world

A framework is required to enable learners to compare Micro-credentials issued by various institutions and make appropriate choices, employers to appropriately evaluate Micro-credentials, and guide the design of issuing institutions.

The framework provides a common set of Micro-credential guidelines for learners who want to decide what to study, organizations and institutions issuing and accrediting Micro-credentials, and employers and professional organizations seeking to understand the learning outcomes and competency of their learners and employees. The framework facilitates the development, acquisition, and use of high-quality Micro-credentials.

The standard elements used to objectively and clearly describe various Micro-credentials are called descriptors. Descriptors are the basic building blocks of a Micro-credential framework. Table 1 compares the major international Micro-credential descriptors. The bolded and red items are required descriptors and must be included when describing a Micro-credential. The title of the Micro-credential, awarding body, and learning outcomes and their assessment (type of assessment) are defined, the teaching method (form of participation) and the amount of learning (Total learning time) (Learner Effort). These are prerequisites for a Micro-credential. The rest are recommended descriptors, and their inclusion is optional.

Descriptors in each country are similar but expressed differently. Therefore, translation between descriptors is necessary for the international use of Micro-credentials.

2.2 Proposed Micro-credential reference framework

To facilitate the international exchange of Micro-credentials, we propose a reference framework for Micro-credentials. The reference framework comprises (1) the definition of a Micro-credential, (2) reference descriptors for expressing a Micro-credential, and (3) quality assurance guidelines. Reference descriptors are included in Table 1 to clarify the correspondence between Micro-credential descriptors in each country. The reference descriptors allow for international comparison and reference of Micro-credentials and promote their use across countries by developing a reference framework for collaboration among countries.

Table 1. Proposed reference descriptors for micro-credentials

3 Technology for the Digital Issuance of Academic Records

This chapter describes the relationship between Micro-credentials as a system of education and information technology that issues academic records.

Academic credentials include traditional degrees, such as bachelor's and master's degrees, and nonformal credentials, such as Micro-credentials. Education can be recorded and certified using both paper-based and digital certificates. Figure 1 shows the relationship between these types of certificates.

Digital certificates can be issued as electronic files (e.g., PDF) or digital badges. Digital certificates issued as PDF files with digital signatures are commonly issued for bachelor's, master's, and other degrees. A digital badge is issued for a visual record of knowledge, skills, or experience that can be visually communicated. Digital badges are a popular digital proof of academic achievement, such as Micro-credentials, but they can also be used for participation in events, awards, skills, credentials, and other noneducational applications. An international standard for digital badges developed by the 1EdTech Consortium, an international association, is Open Badges.

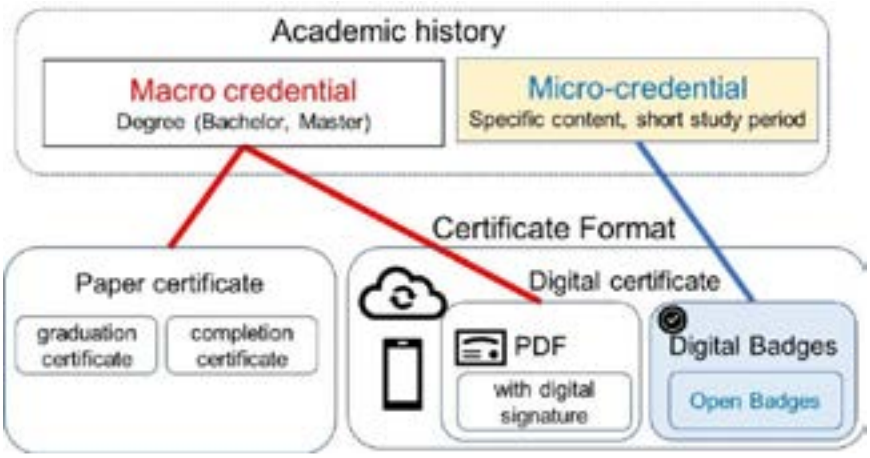

Fig. 1. Relationship between academic history and its means of certification

4 Proposed Micro-credential Architecture

Micro-credentials comprise a mechanism for quality assurance of education and information technology for learners to securely store and share their academic history. To share and accumulate micro-credential internationally and implement its operation with digital data, it is necessary to define the roles of education systems and information technology and design and collaborate internationally on the architecture.

Herein, we propose a hierarchical architecture comprising three layers of educational systems (Layers 1–3) and three layers of information technologies (Layers 4–6), as shown in Figure 2. The following sections describe the layers.

Layer 1: Individual Micro-credentials. Systematically designed individual Micro-credentials are deployed.

Layer 2: National Qualifications Framework and Skill Standards. The levels of Micro-credentials are defined according to the national qualifications framework and contrasted with the skill standards for each discipline. In addition, the size of Micro-credentials (scope of study) is systematically defined so that Micro-credentials issued by different institutions can be combined and studied without duplication or omission.

Layer 3: A framework for Micro-credentials

Layer 4: Interface layer for issuing digital Micro-credentials. This interface layer inserts the standard descriptors of Micro-credentials (Layer 3) into the metadata of digital technology (Layer 5).

Layer 5: Digital certificate. This is the layer of technologies for digital issuance of academic credentials. Examples include The 1EdTech Consortium's specification, Open Badges, and the European specification, Open European Digital Credential.

Layer 6: Digital format for exchanging academic records. This layer indicates comprehensive learner records, including Micro-credentials and degrees, such as bachelor's and master's degrees. This layer enables comprehensive academic records to be stored and used internationally.

5 MICRO-CREDENTIALING INITIATIVES IN JAPAN AND INTERNATIONAL COLLABORATION

In 2007, Japan approved the "certificate of completion program" to certify the completion of educational programs that aim at the acquisition of systematic knowledge and skills with a duration of 120 h or more, which is shorter than the time required for a degree. In 2019, the requirement for certification programs was reduced from 120 to 60 h, and universities can now recognize the completion of certification programs as credits toward a degree.

Figure 3 shows the current Micro-credentialing efforts in Japan. The Japan Virtual (JV) Campus, a project subsidized by the Ministry of Education, Culture, Sports, Science and Technology (MEXT), established the Badge and Credential Subcommittee in April 2022, and the Japan Council for Open Online Education (JMOOC) established the Micro-credential Working Group in June 2023. The subcommittee of JV-Campus and the JMOOC working group formed a Micro-credential joint working group in August 2023 (JV-Campus 2023) and published "Micro-credential Framework" and "Guidelines for Issuing Micro-credentials Digitally" (JMOOC 2023) (MCJWG 2024).

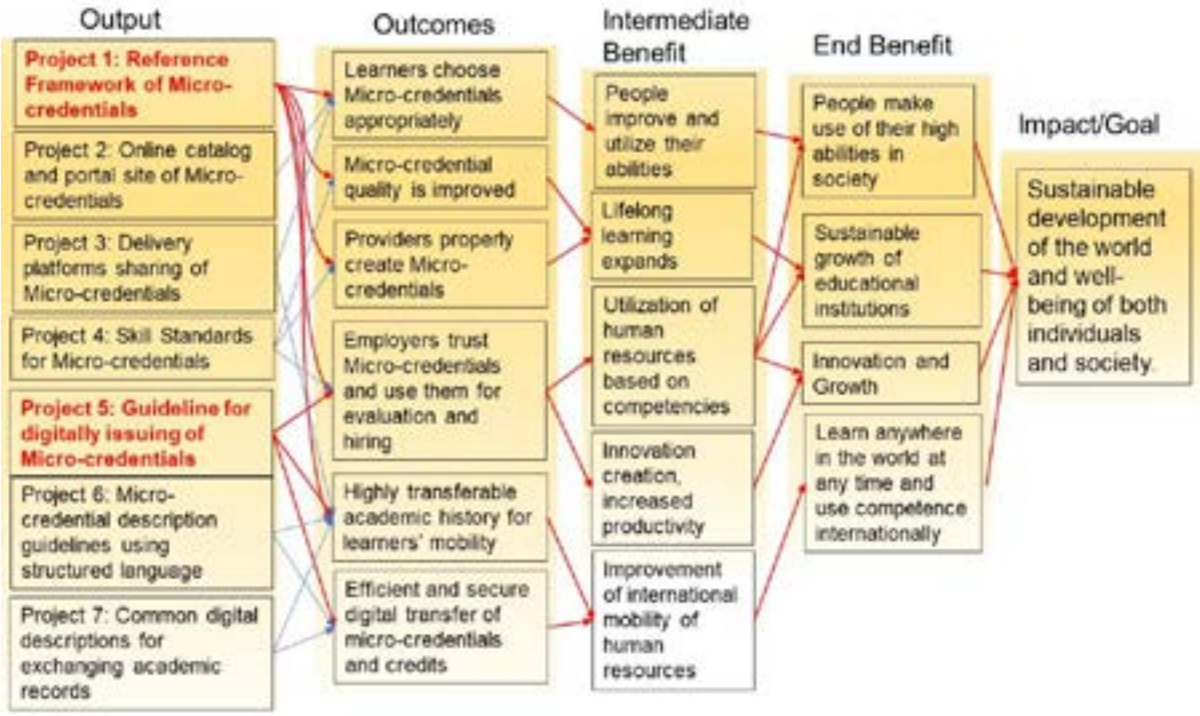
6 DISCUSSION

6.1 Value and Impact of Micro-credentials and their Architecture



(1EdTech 2024a) (JMOOC 2023) (MCJWG 2024)

Fig. 4 Value and Impact of Micro-credentials and their Architecture

Figure 4 shows the impact of promoting Micro-credential projects along the proposed architecture and reference framework. Projects 1 and 5 are promoted by the JV-Campus/JMOOC Micro-credential joint working group, and the results was made public in April 2024. They also promote international collaborative activities. Micro-credentials and their architectures promote global sustainable development and the well-being of both individuals and society.

6.2 Structuring educational systems and information technologies

To structure educational and information systems and evaluate the adequacy of their architecture, conditions and cases that affect the architecture are investigated, and the responses of to such cases are elucidated. Several cases are presented and discussed below.

(1) Cases in which information technologies differ by country or region

The U.S. and Japan use 1Edtech's Open Badges as their information technology, whereas Europe uses the Open European Digital Credentials.

If micro-credentials are built on equivalent educational systems and have equivalent descriptor schemes, then micro-credentials can be shared and transferred. However, because of differences in information technology standards, digital data differs between the U.S./Japan and Europe. There are two responses to this case. (a) The international postal and mail model: In this model a micro-credential is relayed as a payload to different information technology standards. In this case, each user only needs to support the local technology standard. (b) The Internet model: On the Internet, users use multiple applications such as e-mail and social networking services. In this case, the user simultaneously has multiple information technology standards to handle micro-credentials. A user's wallet contains multiple micro-credentials, which use multiple information technology standards.

(2) Cases where the framework differs by country or region

Micro-credentials are translated using a reference framework. Each country has a different framework. When transferring micro-credentials across national borders, the originating side sends data that is converted using a reference descriptor. The receiving side receives the data with the reference descriptor and converts it into the home country's descriptor if required.

7 Conclusion

The proposed architecture establishes a hierarchical structure with three educational system layers and three information technology layers. The educational system layers define individual Micro-credentials, ensure alignment with national qualifications frameworks and skill standards, and establish a Micro-credential framework. The information technology layers address the digital issuance and exchange of learning records. This design facilitates the international recognition and use of Micro-credentials.

To promote global adoption, we propose a Micro-credential reference framework comprising a common definition of Micro-credentials, standardized descriptors for describing them, and quality assurance guidelines. This standardization enables learners to effectively compare credentials, employers to accurately evaluate skills, and institutions to design high-quality Micro-credentials.

By integrating these educational systems and technologies, the proposed architecture would pave the way for a global ecosystem for effective lifelong learning. Micro-credentials issued under this framework can empower individuals to continuously develop their skillsets, remain competitive in the workforce, and pursue their learning goals throughout their lives.

ABSTRACT

We introduced Care Ethics to enhance empathy and perspective taking in a second-year Engineering and Society course. Care is a practice and a mindset, so we guide students to move from self interest to caring: identifying the need for care, taking responsibility for care, developing competence to care, and receiving and assessing care (from Tronto, 1998). Situating care ethics in discussion of artificial intelligence (AI) opens concepts of moral distance and interconnectedness, while examining care ethics in the context of sustainability allows students to consider the extension of care to more-than-human actors. Activities help students consider perspectives including the environment or most vulnerable.

Our experience suggests (1) starting from an interest enhances engagement and uptake. (2) Students struggle to enact care because they see it as just "something you do". (3) Empathy and care require emphasis to enable students to permit themselves to enact empathy and care in professional work.

Although activities in a course are distinct from developed ethical practice, we create the potential for moral and ethical growth. Helping students to integrate empathy into their ethical reflexes can help develop a mindset of care.

1 INTRODUCTION

While care is embedded formally in professions such as medicine and nursing, it has received less explicit emphasis in engineering, despite the relationship between engineering work and critical social issues (Campbell et al, 2012). This paper explores our experience integrating care ethics into a mandatory second-year course about Engineering and Society at a large North American university. The course serves as students' first experience with social sciences in their engineering education through an in-depth consideration of the impact of technology on society and the environment. It also builds on their first-year experience in engineering design. We have situated care ethics in discussions of ethics in Artificial Intelligence due to interest in the field and the future career paths of students in the class, and in discussions of sustainability given the critical nature of the climate crisis and our collective responsibility to consider it. The goal of the paper is to explain how learning outcomes are being achieved thereby improving our ability to support students in developing into caring engineers.

The course involves lectures, readings, and weekly small-group discussion seminars. For the past eight years, we have incorporated ethical reasoning into the course as part of the over-arching conceptual structure that gets enacted throughout the course, i.e. it is not just taught and dropped, but becomes central to our examination of all sociotechnical issues. Our motivation to build the ethical framework in the course derives from an understanding that "effective ethical reasoning requires both some specific knowledge of morality and ethical frameworks as well as some reasoning skills" (Beever and Brightman, 2016: p.278). This pedagogical underpinning requires reaching past ethics education as case-based, code-based, or theory-based. Students need to develop a character of ethical awareness and understanding; that is, they require virtue with its emphasis on the character of the decision maker.

Care has emerged more recently in engineering education because it seems well situated to enhance empathy and perspective taking to address ethical concerns in design (Pantazidou and Nair, 1999). In practice, human-centred design approaches entail empathetic perspective taking through listening, identifying underlying causes of needs, and increasing resources and opportunities for those in need (Leydens et al, 2014), so virtue and care ethics offer appropriate means to develop necessary engineering attributes.

2 DEFINING ETHICS OF CARE

Care ethics is related to virtue ethics in that both are concerned with character. "A care ethic emphasizes the importance of responsibility, concern, and relationship over consequences or rules" (Nair and Bulleit, 2020: 78). Essentially, virtuous relations guide right action, rather than right action demonstrating virtuous character. Care ethics received its first unique articulation by Carol Gilligan (1982) as a feminist response to the unempathetic, utilitarian, analytical reasoning in favour at the time.

Tronto (1998) has offered a usable articulation of care ethics, as evidenced by its relevance across a range of engineering contexts including teaching design and problem-solving methodologies (Pantazidou and Nair, 1999), sustainability (Campbell 2013), and as a critical component of professional practice (Kardon 2005). Further, the application of care ethics to engineering provides an opportunity to reinforce a motivation towards equity, and to broaden interest in participating in engineering if it is framed as a caring profession (Campbell, 2013).

Tronto articulates four moral elements of care – attentiveness, responsibility, competence and responsiveness – which correspond to four phases of a practice of care, noting the development and deepening of commitment to community that they entail:

- recognizing the need for care. At this point, empathy shapes the caring act as the individual sees an opportunity to care: "They need help/care."
- taking responsibility for care. The second stage becomes more personal as the individual takes ownership of the care: "I need to provide care."
- having competence to care. This level is the most challenging aspect because the individual must assess their own assets and abilities to help (and not harm) in a situation: "I can provide care."
- receiving care. Here, the caregiving individual can assess the efficacy of the care as received. In relationship with the party receiving care, they can ask questions: "Is this helpful? Does the nature of care need to change?

Care starts in character but is embodied in praxis. The caring mindset involves recognizing one's place in a network of actors and developing an orientation toward responsiveness that moves beyond rules or calculated outcomes to consider the vulnerable and the voiceless (Villegas-Galaviz & Martin, 2023). Further, Tronto (1998) suggests an integration of phases to deepen the practice of care and working through the possibility of conflicts unique to the context.

3. OUR APPROACH

Developing care through a balance of theory and application should bolster students' ability to begin to make ethical judgments. We begin with ethical reasoning to ground our approach to ethics. Then, we define care ethics simply "an act is right if it promotes deeper attentiveness to each other and the community" including the environment (Whyte & Cuomo, 2015). Using Tronto's framing and specific examples ranging from micro to macro ethics, we seek to build an understanding of care ethics in our students and given them an ability to enact care in their ethical reasoning process.

3.1. Building Care Ethics from Ethical Reasoning

Our commitment to ethical reasoning led us to adopt Beever and Brightman's 'reflexive principlism' (2016). The approach comes from applied medical ethics and specifies a limited set of virtues (principles), which allow for focused reasoning. The iterative aspect is aimed specifically at engineering. Stated briefly, reflexive principlism offers structured ethical reasoning using four principles:

- respect for autonomy, upholding the rights and the dignity of individuals,
- beneficence, actually doing good,

- justice, ensuring an appropriate sharing of risks and benefits across the actors in the ethical situation, and
- non-maleficence, avoiding doing harms.

From these principles, reasoning involves specification and balancing. Specification is the process of moving from the abstract to more determinate understanding of the principle in each situation. Balancing, in turn, is a process of adjudicating conflicts between principles as they have gained power through specification (Beever and Brightman, 2016). We have found that, through reading Beever and Brightman's paper and classroom discussion, students easily grasp the four principles and see their reasoning power in action. They are less able to reach to the stage of balancing between conflicts—a factor that could result from students' lack of ethical commitments or the limitations of the classroom (including time, subject knowledge, and our teaching of the concept).

We began to incorporate care ethics into our discussion for three main reasons: first, we saw it as a way to expand students' awareness of justice beyond the obvious actors in a network. Second, we sought to use it to engage the students with other voices particularly Indigenous ways of knowing. Third, we saw care as complementary to reflexive principlism, encouraging specific types of balancing to help the students consider the process of ethical action-taking as a human activity requiring care within relations.

Since engineering remains a largely analytical field, we looked for means to allow students to develop care, including permission to feel. Indigenous writer, Kyle Whyte notes that: "Feminist and indigenous conceptions of care ethics offer a range of ideas and tools for environmental ethics that are helpful for unearthing deep connections and moral commitments, and for guiding environmental decision making" (Whyte and Cuomo, 2015, p.243). Since the environment and sustainability are already well-integrated into the course, we saw this as a meaningful point of connection. More recently, we have extended the incorporation of care to concerns about AI.

3.2. Introducing Care Ethics to Students

After students are introduced to ethics and ethical reasoning, including virtue ethics and reflexive principlism, we commence a week of study on the concept of care ethics. In lectures, key concepts are introduced, alongside examples so students can start to apply these concepts.

To support our discussion of care ethics, we recently added the reading, "Moral distance, AI, and the Ethics of Care" by Villegas-Galaviz and Martin (2023) to connect care ethics to computational technologies and artificial intelligence, which are areas of interest to many of our students. The article wrestles with the concept of moral distance with respect to AI, something the students see as worthwhile and important. So, it creates buy-in to the concept of care. Additionally, it provides a specific orientation to ethical reasoning that links our interconnectedness with the need to attend to the vulnerable and voiceless. Then, as we begin to explore sustainability, students read an article that raises the concern of care for more-than-human actors through the lens of Indigenous ways of knowing (Todd, 2017). These two readings in particular offer an overview of care as a concept and expand student understanding of to what and whom care should be extended.

In the first seminar on care ethics, we use a sequence of cases that allow students to move outwards from their immediate circle to understand the nature, benefits and limits of care. Students were encouraged to use the framing of care ethics from Villegas-Galaviz and Martin (2023), which draws from Tronto's elements and phases of care, to consider care in the cases. For each of Villegas-Galaviz and Martin's four framings, we developed a set of questions to prompt student thinking and discussion, and to scaffold a 'way of being' that can be difficult to articulate.

- Interdependent Relationships: who or what is in the context (or web of relations), and what are the key relations? Who needs to be considered? How can we act in a way that is responsive to the needs of others?
- Context and circumstances: What is unique about the context/circumstances that requires care? How might another circumstance require a different response? How do we need to be responsive to the needs of "particular" others?
- Vulnerability: Who is vulnerable in the context/circumstance? What are the risks to those who are vulnerable? How can those risks be mitigated?
- Voice: who or what needs to be given a voice? How can we give voice to every affected part of this context/circumstance? How do we engage in the relational act of listening and bringing close?

In seminar, we start our exploration of care with a microethics case relevant to their own life as an engineering student:

> *Your friend in (your program) is having a rough go of things – they are dealing with some major family challenges and trying to balance the tough workload of (the program) with a part-time job. It's week 4 of the semester and suddenly, things have gotten really busy. They ask you to copy your thermodynamics problem set, which your professor has asked you to complete independently.*

After considering a 20 second "gut decision", students are asked to map out the actors in the network and consider the prompting questions noted above, giving them scaffolding to articulate how they have considered care in their decision-making. After this, students are invited to participate in a brainstorm to share the ways they "show care" in their lives: as a person and as an engineer-in-training. These warm-up activities provide an opportunity for students to connect care to familiar experiences. The brainstorm exposes how care is something we consider more easily for those in "close proximity" to us, drawing from the concept of moral distance in the reading. In these activities, students value the opportunity to share their own notions of care and how they extend care to those around them.

Next, we move to a case beyond their own sphere of direct experience, using a classic robotics ethical dilemma (Open Roboethics Institute, 2015):

Emma is a 68-year-old woman and an alcoholic. Due to her age and poor health, she is unable to perform everyday tasks such as fetching objects or cooking for herself. Therefore, she purchased a care robot. Her doctor advises her to quit drinking to avoid worsening her condition. When Emma commands the robot to fetch her an alcoholic drink, should the care robot fetch the drink for her? (A second version of the case has the robot provided to Emma through a funded healthcare program).

Students are initially introduced to this case in lecture while discussing reflexive principlism, which elucidates interesting perspectives around the principles of justice and autonomy. In re-examining this case, students are encouraged to consider whether a specific attention to care ethics changes their approach, and what actions might lead to a caring/ethical result. It's worth noting that as students examine this case, they don't necessarily change their response to the question of whether the robot should fetch the drink but do generate new considerations about how to approach this challenge in a way that demonstrates care, for example: programming the robot to respond in a way that demonstrates care, re-considering the relationship between the robot, Emma and her care team, or generating new ideas on the resources Emma may need to live a healthy life.

Finally, students are re-introduced to macroethics case studies that were shared in the previous week: one exploring the use of AI to create "griefbots" based on the personalities and communication patterns of the deceased, and one on use of AI in recidivism. However, this time, rather than consider care ethics as an alternative to reflexive principlism, we encouraged students to consider how reflexive principles and care ethics can be brought together in service of the development of responsible AI, giving them the scenario that they are hired by a large AI firm to head up the "responsible AI" initiative at the company, and are responsible for creating a set of guidelines for company management on how to encourage ethical thinking.

As students move further away from their personal sphere of "care", they are more challenged to apply the concept. However, the concept of moral distance helps them to make sense of this, acknowledging that as we find ourselves further removed, through distance, time, bureaucracy or otherwise, we struggle to understand the reciprocity that exists between, for example, those who design an algorithm or a care robot, and those who implement that robot in the field.

3.3 Application through the Course

Early in our discussion of sustainability, we engage in a critical examination of the role of oil and gas in our sociotechnical world. To provide immediacy to the discussion—and create a context in which care becomes important—we introduce the students to the case of the Coastal Gaslink (CGL) Pipeline Project, a recent and contentious oil and gas project in Western Canada. The multi-billion-dollar project involves construction of a pipeline to transport fracked and liquified natural gas (LNG) from a gas field in northeastern British Columbia, Canada, to the small coastal city of Kitimat, BC. From there, LNG is shipped to international destinations. The pipeline is contentious because it traverses land claimed by indigenous peoples. Most significantly, it crosses the land of the Wet'suwet'en people. This land was never ceded to Canada under any treaty and remains the subject of land claim disputes in Canadian courts. Indigenous protesters have resisted and blocked the pipeline construction. In turn, they have been arrested and subjected to police violence and intimidation. In working through the case in lectures, we provide detailed background on numerous stakeholders—the company, elected and the hereditary Wet'suwet'en chiefs, local, provincial and federal politicians, and various environmental systems.

We also look at the conflict within Wet'suwet'en society with its elected and hereditary chief structures (the former a fixture of colonialism, the latter traditional self-government). Whereas the elected chiefs have approved the pipeline seeing employment opportunities and financial benefits, the hereditary chiefs have opposed the pipeline because it violates sacred lands and relationships with more-than-human actors.

In the seminars, we have a set of activities for the students. In groups of two, they are assigned to examine the case using either reflexive principlism or ethics of care. They try to determine the key ethical considerations by either approach. Then, paired with a team using the other approach they look for commonalities and differences in findings. The students are prompted with questions to deepen their thinking:

- What challenges came up in balancing dimensions of the case?
- Can care be applied across all actors? Did you find yourself prioritizing care for a particular group or need?
- Do we need to consider the possibility that coercion is used to greenlight projects like this? How does this differ from consent?
- Several more-than-human (environmental) actors were included in the network. How far are you willing to spread inclusion of other species?

In the process of these discussions, students begin to confront their own limits of care, as many prioritize LNG extraction over the environment and struggle to accept the idea that more-than-human actors have any standing in ethical considerations. Students want to claim that they care for the vulnerable, but when confronted by the moral distance of a different species (plants, animals) or remote people (the Wet'suwet'en) they struggle to care. The mere fact of this struggle reveals the students' ethical commitments to petro-capitalism rather than (broadly speaking) environmental care. Of course, some students do incorporate care for others and other species into their ethical reasoning, and in doing so they become advocates for care, and exemplars of a deeper care ethic.

As a second example, later in the course, we explore technological unemployment as a byproduct of the pace of technological development. Through examining case studies of technological job loss due to automated manufacturing or self-driving cars, students are encouraged to apply care ethics to investigate particular dimensions of the cases; for example, what roles/functions should be automated and what should remain the work of humans? How should we best support people whose work is displaced through technological unemployment? And should we mitigate economic inequality and labour disruption caused by technological development? Our impression is that framing ethical thinking as "care" helps learners broaden their thinking about what and who to attend to in such circumstances. It has particular salience for students to conceive of their own work as displacing others.

Throughout the course, we encourage students to broaden their perspective and to see the "particular other" (Schmidt, 2014), who needs care for reasons of vulnerability or lack of voice. By opening students to building their basis for empathy, we hope to engender (or more often legitimize pre-existing) compassion that can be enacted as caregiving when the situation is appropriate.

4 OUTCOMES AND REFLECTIONS

We acknowledge that activities in a course are a long way from an embodied mindset lived out in praxis. Empathy and care are learnable but require development. Our activities help students build a process to actualize care. They consider other perspectives and discuss the challenges in the perspective of the "particular other"—the person, group, or entity (including the environment) most vulnerable in any situation. While taking such perspectives may be new, it encourages students to understand the situation more holistically.

Our experience suggests three insights. The first should probably have occurred to us before we started with care ethics, as it is a truism of teaching. It is this: rooting the concept in an area of known interest to students deepens engagement. Specifically, placing care ethics in questions around AI enhanced interest and willingness to reason through a "care lens". Initially, we only considered care ethics in terms of the environment, but we found the students less disposed to engage in the personal challenge of considering others in need of compassionate care. By reframing the questions to focus first on AI using the reading from Villegas-Galaviz and Martin, we have found students more open to asking questions and considering their own ethical positions. Given that care ethics involves developing a mindset, openness is critical to engagement.

Second, even when willing, students struggle to apply care to engineering work, in part due to an implicit belief that care is just "something you do". As such, it does not feel as rigorous as a code that can be assiduously applied or a theory that can be referenced. Ironically, this "caring" thing we just do, asks more of us because it asks us to be particular kinds of people with particular ethical commitments. Developing such commitments as an undergraduate student takes time and awareness. We can only begin to help students along that process.

Finally, unlike other concepts, care seems to require emphasis to validate it with students—and often the question is how to permit themselves to bring their empathy and care into the professional sphere. Schmidt (2014) offers strong grounding for doing so as he focuses on the aspirational goal of engineering as being contributing to everyone's "material well-being." Framing that as the goal of engineering creates an opening for students to examine what ethical character such an objective requires.

Because care ethics emphasizes attentiveness to the various actors requiring care, we argue it helps students to cast a wider net in understanding who must be considered. This is especially important in complex systems like the environment or artificial intelligence with various actors and relations to consider, widely variable moral distance, and ethical decisions being made in significant uncertainty and ambiguity.

5 CONCLUSIONS

Activities in a course are distinct from developed ethical practice; however, by providing an opening to explore and enact care ethics, we create the potential for moral and ethical growth. Helping students to integrate care into their ethical reflexes can help them to acknowledge the moral distance and seek to minimize it through empathy and care.

Validating care is an ongoing challenge. So much of engineering education is concerned with analytical "doing", while care ethics asks students to develop ways of "being"—that alone makes ethical development uncomfortable and unfamiliar to students. We have sketched several different ways of framing care ethics (Tronto, Villegas-Galaviz and Martin, Whyte and Cuomo), but we continue to struggle to reconcile the different framings and guide students into a coherent means to deepen their sense of care. Even so, we can see it infiltrate students' ethical reasoning processes through assignments, through course discussion, and even through their design work in a subsequent design course.

We need further interrogation how to connect care to other approaches to engineering ethics, how to bring it into engineering work. We trust that if you hold care and consider others with care you are doing something important, worthwhile and relevant to engineering. Like Carol Gilligan, we are attempting to give language and conceptual richness to something that is taken for granted by, but little embodied in students. By seeking to elevate a different voice—many different voices—we aim to encourage students to hear the vulnerable and pay attention to the voiceless in the pursuit of the highest aspirations of engineering as a noble profession.

Project-based learning (PBL), as one of the effective teaching and learning approaches in engineering education, can create opportunities for students to address problems with real-world applications, integrate and apply knowledge, and practice and develop transversal competencies such as teamwork and communication. However, with the common emphasis on final products and a lack of explicit attention to transversal competencies in designing and teaching PBL courses, the benefit of PBL in facilitating the development of transversal skills is under question. In this paper, we use a critical lens to examine a project-based course offered at a polytechnic university in Switzerland, EPFL, and explore structural elements that are important in facilitating the development of transversal competencies. We describe the structure of the PBL course, Mechanical Product Design and Development, that was recently conceived and received positive feedback from students, report on ways transversal competencies were addressed, and reflect on lessons that can be learned from the praxis, informed by the literature, to avoid missing opportunities to support students in developing transversal competencies.

1 INTRODUCTION

Within the last three decades, there has been growing attention to the importance of effective teaching and learning approaches to help engineering students develop the competencies required to address problems in work settings and live in today's world. Initially, in response to outcome-based education and later with the increasing evidence from learning sciences as well as funding opportunities for engineering education research, students' learning became the center of attention in pedagogical design and development, and incorporating student-centered approaches became common within engineering curricula. Project-based learning (PBL) is one such approach that has been frequently used, especially in the context of first-year engineering courses and capstone design. In this practice paper, we focus on a project-based course offered at EPFL, discuss how the course provides opportunities for enhancing transversal competencies, and reflect on limitations and possible improvements for incorporating PBL in engineering curricula, more specifically concerning transversal skills.

PBL is centered around a project that students need to address through collaborative work by applying and integrating knowledge and skills to arrive at final products (or artifacts). The project has two major components: a question or problem that organizes a set of activities and those activities that will lead to the creation/construction of final products (Blumenfeld et al. 1991). Learning is relevant and engaging as students face problems similar to real world settings that are open-ended, complex, ambiguous, and ill-structured, often with conflicting goals (Jonassen et al. 2006). The appropriate driving question then needs to inspire and motivate students, which will help them to better understand and monitor what they are learning (Barron et al. 2014). Among the major features of PBL are "learning by doing", students' agency, teamwork, opportunities for assessment and revision, and the creation of artifacts (Barron et al., 2014; Chen and Yang, 2019; Guo et al., 2020).

Conceptually supported by constructivism, PBL involves students, actively, in the process of learning by creating mental models and constructing and reconstructing knowledge through which they understand what they experience (Prince and Felder, 2006; Lattuca and Stark, 2006). Proper implementation of PBL that provides a connection with students' prior knowledge and gives them agency in the process of learning with opportunities for reflection improves metacognition, which facilitates the transfer of learning to new settings (Barron et al. 2014; NRC, 2005; Prince and Felder, 2006). From another perspective, inspired by the design profession and ways by which designers think and work, the practice of PBL is in line with design thinking discourses where there is an emphasis on the creation of artifacts, reflection, and problem-solving (Johansson-Sköldberg et al. 2013). PBL courses very often provide structure for students to move through the major steps of design (engineering design) by emphasizing elements of problem definition, ideation, prototyping, and testing (Dym et al., 2005; Seidel and Fixson, 2013). More recently, several studies illustrated the integration of PBL and design thinking in designing and teaching project-oriented courses (Jiang and Pang, 2023; Kuo et al. 2021).

Prior literature emphasized the benefits of PBL in relation to persistence and improving students' performance in subsequent courses (Nguyen et al. 2020), improving students' motivation (de Graaff and Kolmos, 2003; Prince and Felder, 2006), and creating opportunity for learning transversal competencies including teamwork and collaboration (Boelt et al. 2022; de Graaff and Kolmos, 2003; Guo et al. 2020; Llorens et al. 2017; Miranda et al. 2020; Uotila et al. 2023). While it is challenging to pinpoint a specific list of skills/sub-skills, PBL learning environments provide potential settings for enhancing students' transversal competencies. Within the engineering education literature, PBL has been portrayed as an effective approach to help students develop transversal competencies (Boelt et al. 2022; Uotila et al. 2023; Vogler et al. 2018). That is why it is not surprising that the benefits of PBL courses in developing professional skills have been taken for granted in the majority of case studies and examples of PBL demonstrated in the literature. The underlying assumption is that creating opportunities for teamwork or presentation of the project outcomes, for instance, facilitates the development of corresponding competencies. But, can we make a conclusive argument about the impact through mere exposure of students to such opportunities? In this paper, we grapple with this question and address some structural elements necessary for promoting transversal competencies.

In a recent review of students' perceptions of the development of generic/transversal competencies in PBL and problem-based learning environments, Boelt et al. (2022) argued that research should uncover how alignment and scaffolding of different activities contribute to intended learning outcomes concerning transversal competencies. Considering the importance of explicit instruction in addressing transversal competencies (Isaac et al. 2023; Picard et al. 2023) on one hand and considerable time and efforts in implementing PBL (Chen et al. 2021; Chen and Yang, 2019) on the other hand, it is less clear how educators prioritize and operationalize opportunities to help students develop professional skills. Among a few studies that explicitly addressed the development of transversal competencies in PBL, we can highlight the following strategies discussed: regular supervision of the groups (MacLeod and van der Veen, 2020); lectures on professional skills (Uotila et al. 2023); opportunities for feedback from different stakeholders including industrial partners (Shekar, 2007; Uotila et al. 2023); and the integration of learning contracts (Llorens et al. 2017). In general, there is an underrepresentation of studies examining practices in PBL environments to facilitate students' development of transversal competencies.

In what follows, we briefly describe the structure of a PBL course that was recently conceived and received positive feedback from students, report on ways transversal competencies were addressed, and finally reflect on challenges and limitations and provide ideas for improvement applicable in similar settings.

2 SETTING: MECHANICAL PRODUCT DESIGN AND DEVELOPMENT

2.1 Overall structure of the course

The course is a five-credit elective course (3 hours of contact hours that are a mix of lectures, exercises, and project sessions) offered by the Mechanical Engineering Department. The course was originally developed by one of the authors of this paper with the major goal of immersing students in “A to Z” product development. While there may seem to be similar existing courses in other departments and other universities, often as a Capstone project, there are two distinctive characteristics of this class worth noting: 1) the curriculum ensures to stretch the engineering mind without only relying on the intuitions, 2) it requires the students to building a truly a full robotic system.

Concerning the first characteristic, sharpening engineering minds, the curriculum and the project deliverables focus on students to question their intuitions and create concrete reasonings for their design choices. Not only that, they are asked to create measurable and quantitative benchmarks to which they compare their designs. This means that it cannot be based on aesthetics, popular opinions, or even SWAT tables. While still important, the students were asked to focus on the mechanical and physical functionalities of the design and their reproducible results that can be quantified. Regarding the second characteristic, a comprehensive system development of a working robotic prototype, while building a new robotic platform in a class is not new, building a brand-new prototype with specific metrics to achieve and deliver a working prototype during a period less than 14 weeks has novelty. The fast-paced nature of the program encouraged students to make hard choices during the first 3 weeks of their design and that point on, focus on the “transferable knowledge” of the sub-components of their design (i.e., control architecture, working principles, motor and sensor characterizations). What these “transferable knowledge” packages allow students to gain was not the time, but any learnings that they have accumulated could be maintained even if they were to change some aspects of the product design such as dimensions, materials, and even applications.

Each year, up to 30 students from different engineering disciplines (Master students in mechanical engineering, electrical engineering, computer science, and micro-engineering) enroll in the course, where they work in groups of 4-5 to conduct an in-depth analysis of the operation principles and apply knowledge on advanced meso-scale technologies (kinematics, structural design, mechatronics, sensors and actuators, etc). The theme of the problem given to students is wearable technology and related mechatronic components and systems. Consistent with the PBL approach, a high emphasis is given to creative solutions, working concepts, and functioning prototypes. Students’ assessment is based on the final project outcomes (70%), including final report, final presentation, and working prototype, designed over 12 weeks, and weekly presentation and participation (30%). Following the recommendations by Helle et al. (2006) on the necessity of addressing the details of project-based courses, it is worth noting that each group has 2 teaching assistants

(TAs) who follow their work throughout the semester. A budget of about 500 CHF (fluctuated due to annual institutional budget) is given to each group on top of a starting kit that includes a microprocessor kit, basic mechanical hand tools and electronic components. They have access to mechanical and additive manufacturing ateliers (workshops) where they can create/ machine their own components or have it machined by the mechanics.

2.2 Course design and implementation

A comprehensive robotic platform development in under 14 weeks requires a clear outline of deliverables. Normally these are courses offered for over 30-week classes with a larger group of student teams. What has been unique in creating the class and keeping it within such a tight running schedule is to put the emphasis in the 1) concrete decision making processes based on quantifiable measurements - not based on surveys nor opinions 2) giving weekly feedback on the set of specific questions and deliverables that are pertinent to keeping i) the manufacturing feasible, ii) control algorithm relevant, and iii) prototyping and assembly to function. These questions and comments were streamlined using the accumulated FAQs from the previous years as well. What made these FAQ more reliable was that the “transferable knowledge” was clearly defined and communicated every session for each group.

The course facilitates the iterative process of engineering design where students need to develop a new robotic product (robot - as it is defined by having a motor, sensor and a microcontroller to control the movement), where in the process they choose methods and tools for the development, modeling and simulation, and the analysis of alternatives in designing the chosen functional product. They are expected to refine and update their motivations, understanding of the problem, and the state-of-the-art. As such, there are several points throughout the course that students need to reflect on their decision making. With the emphasis on planning earlier in the semester, students are given opportunities to reflect on what they do, reconstruct knowledge, and adjust their future decisions and actions (Helle et al. 2006; Miranda et al. 2020). In terms of student weekly presentations, they were presenting based on the given format (form and contents) that followed defining/redefining the problem statement, product specification, concept generation, concept selection, simulation, experiment design for validation, prototyping, and testing. From a technical standpoint, products developed by teams should include i) actuators (any type of motors, i.e. smart materials, electro/ magnetic/ electric/ ultrasonic/pneumatic/ etc); ii) structures (origami, cable-pulled underactuated system, 3D printed modular blocks); iii) model (analytical, numerical, simulation tool based); iv) working prototype (benchtop prototype, scaled version, or a display of a working principle. Therefore, students need to apply knowledge, concepts and principles related to mechanics, electronics, robotics, advanced manufacturing, sensors, motors, and programming into a real-world problem. Among examples of final prototypes/artifacts developed by student teams we can refer to are post-surgical scar rehab massager, zero-shock baby carrier, auto-launching cleats, automatic bicycle transmission, rowing synchronizer, automated contractor knee-pad, auto-compensating foot orthosis, free-hug squeeze doll for the stressed, auto focusing lens for surgeons, noise-limiting device, and haptic mouse (Figure 1).

Fig. 1. Two examples of artifacts produced by students

Students are given the theme of the project in the first class - it needs to be an active wearable / portable device that must contain at least one motor and a sensor to be controlled by a microcontroller. Students brainstorm product ideas and form groups based on the common project idea. Each team is required to define their own specific scenarios with existing problems and challenges that in turn translate into a clear purpose and desired functions. In other words, considering the categorization of de Graaff and Kolmos (2003), the type of project is the discipline project where the instructor provides some degree of planning and direction in terms of required design iterations (functionality design, mechanical design, mechatronics design, and program design), while at the same time, students have the autonomy to identify and define specific problems in line with the theme that is given. Within the first few weeks of the semester, students are given a tour of the university infrastructure supporting PBL, which provides access to tools, machines, and space for prototyping. The overall structure of the course is presented in Table 1.

Students' feedback about the course has been really encouraging. For instance, in Spring 2023, 19 students (out of 29) completed the final course evaluation where all of the respondents strongly agreed to the statement "I find this course interesting." and 18/19 strongly agreed that "In my opinion, the project complements and adds value to the theoretical knowledge of the course."

Table 1. Overall structure of the course

	Week	Topics	Student tasks and deliverables
Theory and application	1	Introduction to the course and project: general wearable tech; product development, fabrication methods, project brainstorming.	› Forming groups. › Think of 3 product ideas.
	2	Core components for wearable tech: electronics	› Choose 3 potential solutions. For each, define functionality of product, quantifiable metrics, motor, and sensor choices.
	3	Performance & Challenges for wearable tech: core challenges and performance metrics (qualitative and quantitative measures). Motors; actuators and sensors.	› Revisit state-of-the-art and choose the final design. › Compare 3 solutions: calculations / metrics. › Choose a motor. › Sketch of the product
	4	Functionality considerations of wearable tech: choices of design and performance; evaluation metrics; cost estimation.	› Improve the functionality/engineering specification of one of the parameters in the chosen solution.
	5	Considerations for prototyping and demos: core components of automated product functionality	› Test actuator and sensor solutions. › Plan the demo.
Refining prototypes	6	Weekly feedback and comments to the progress of the project.	› Controller for sensor and actuator
	7		› Finalize platform design
	8		› Finalize the solution presentation – metric performance
	9		› Polish the demo scenario
	10		› Flyer, poster, presentation, and report
	11		› Finish the project and communication formats
Final deliverables	12	Presentation of the project and prototype to the wide public	
	13	Presentation of the project and prototype to all the class and teaching team (graded).	
	14	Recap and feedback to all projects, presentations, and prototypes.	

3 TRANSVERSAL SKILLS

In this section, we summarize the elements and practices that have been integrated into the course design and implementation to address specific transversal skills.

3.1 Communication

Recognizing the importance of students' ability to communicate with different stakeholders, the course provides a structure for practicing communication in different formats and at different times. Students are required to have a weekly presentation where they provide systematic and intermediate updates about their progress with their project and how they applied what they have learned conceptually, for instance, on product specification or functionality. Among the major aspects, students need to address motivation, the latest updates, and proof of working principle. The last aspect is emphasized later in the semester when students made progress with conceptual and detailed design and incorporated demo presentations. At the end of the semester, student teams need to prepare presentations in three different formats: poster presentation, final in-class presentation, and public presentation with live function demonstrations. The first two formats follow academic guidelines in which students address elements such as motivation, state-of-the-art, design process, performance and results, and future direction. Students' audience is their peers, TAs, and instructor. As such, the instructor expects students to use i) technical details, ii) precise scientific language, and iii) quantified data. For the public presentation, students are required to focus on prototype demos using real prototypes, highlighting the need and application. Students are instructed to use i) accessible language, ii) accessible plots, and iii) qualitative representations of results.

3.2 Feedback

Continuous stream of feedback is crucial for every project. One of the distinct elements of the course is weekly presentations. Every class opens up with the teacher recapping the structure and progress of the project: the lecture always ends with summary slides "by this week, your group should have completed 1,2,3.." and "this week, your group should aim to achieve…". The contents reflect the general outcome of the week before but is adjusted to the fixed demo day schedule and the syllabus. With these slides, all the groups are reminded of their pace and progress. Based on the given slides, each group also presents their weekly progress to the whole class (3 slides under 5 minutes). This is when formal feedback takes place. Students have the opportunity to both provide and receive feedback from their peers, the teacher, and TAs. The continual aspect of weekly presentations creates a learning environment where the emphasis is on process rather than the final product. Through exchanges about the evolution of the project, students receive input and suggestions on their choices and decisions. As such, this process allows students to i) learn and reflect on what other groups are progressing; ii) make decisions that may not be the "ideal" and have some space for failure; and iii) incorporate the feedback received in improving their work. Among different means incorporated to encourage feedback, peer-feedback was fruitful when it was in a verbal form, but also the instructor witnessed its longer effect: it was apparent from the follow-up questions and slide updates that students made auto-corrections based on watching their peers presenting. The aspect of active and continuous feedback continues between the TAs and the teacher as well. After each class, the round-table discussion with the TAs allows the instruction team to share the common challenges both TAs and students face and solutions and strategies to communicate approaches.

Students value these interactions and opportunities for feedback, as we can observe in the data collected at the survey at the end of the semester, where 90% of the students agree or strongly agree with the statement, “I could get advice and useful feedback on my work during the semester.” However, while integrating arrangements for seeking and providing feedback is a unique and valuable component of the course, we cannot make a conclusive argument about how students used the opportunities, what the perceived benefits are, and whether there has been an impact on students' capacity to appreciate feedback, making judgment, managing affect, and taking action as major components of feedback literacy (Carless and Boud, 2018). How can educators systematically rely on peer feedback that is beyond impressions and curiosity-driven comments to a more educational and thought-through practice? Considering the possible benefits of repeated exposure to peer feedback on teamwork skills and confidence in evaluating and communicating about other performances (Donia and O'Neill, 2018), creating a more formal and standardized structure for feedback may contribute to team effectiveness and the development of transversal skills.

It is also worth noting that student teams start prototyping during the first few weeks of the semester. In other words, they are encouraged to use the opportunity as a springboard for communication and feedback. The use of tangibles, in general, and prototyping, in particular, facilitates visualizing and materializing ideas that can help students in improving and refining the concepts (Jalali et al. 2023; Stigliani and Ravasi, 2012).

3.3 Teamwork and collaboration

One major feature of PBL approach is the emphasis on teamwork and collaboration. In the context of this course, student teams are formed at the beginning of the semester based on their initial interest and field of study. The instructor of the course is intentional in creating teams with multiple disciplinary backgrounds so that students have the opportunity to collaborate across different boundaries. Prior literature on teamwork highlights the benefits of diversity in skills and expertise (Williams and O'Reilly, 1998). In addition, the fact that students share an interest in a given project aligns with the documented benefit of deep-level diversity in work teams that has been highlighted in social psychology literature (Harrison et al. 1998). In other words, in terms of structural elements, teams have the potential to flourish and function effectively. Further, considering teamwork processes, course activities, and assignments facilitate team communication and coordination. With the need for weekly interactions and discussions in advancing product design and preparing presentation materials, and the accountability of individual students in presenting and prototyping, there are more opportunities for informal discussion, cohesion, and integration within the group to improve.

It is also inevitable when working in groups, there are discrepancies in the division of the workload. While monitoring the team dynamics every week helped minimizing catastrophes (disappeared member, declaration of alienating a single member, etc), what made it more concrete was making an official disclaimer to the groups in the beginning of the semester. The teacher dedicated the time to explain the importance of having a “functional group” - it is not the excellence of individuals that make a strong group, but it is the teamwork that builds a group. Therefore, the teacher put the responsibility to every member for creating a working relationship: if there is a problem, it was their responsibility to seek help immediately. Whether students acquire specific teamwork competencies that they could apply in different settings is subject to speculation. For instance, members within a team may be exposed to disagreements and conflict; how they navigate and resolve the issues is critical to the team's effectiveness and performance; importantly, as it relates to the focus of our discussion, a question should be asked: Do students learn teamwork competencies from the experience?

4 DISCUSSION AND CONCLUSION

In this paper, we described a novel PBL course focusing on product design and development and explained how the course provides opportunities for students to practice and develop transversal competencies. One of the central themes in students' comments to open-ended questions on the course evaluation questionnaire has been on learning “doing a project.” By going through different stages of design process and acquiring and applying knowledge into practice, students indeed, first and foremost, enhance their problem-solving skills.

Instructor’s attempts to facilitate appropriate collaboration and teamwork (Chen and Yang, 2019) and deliberate integration of opportunities for giving/receiving feedback and presentation are essential features of this course regarding transversal competencies. Students can diagnose and correct errors in their project work process (Blumenfeld et al. 1991) in formal and informal interactions with their peers and instructor teams. Importantly, they need to frequently reflect on their design choices, where they are, and what they have learned to formulate and discuss their progress weekly. They also need to reflect on their experience with the exchanges to adjust future decisions and actions and comparing to the accumulated FAQ lists. This reflective process is an important feature of PBL (Barron et al. 2014; Miranda et al. 2020), and the course uses creative ways to operationalize it. Do all students take these chances seriously and learn from the overall process? In contemplating this question, we shall recognize the need for more explicit attention to reflection. For students to learn with understanding and be able to transfer what they have learned to new settings, there should be opportunities for thinking about the goals, where they are in the process of learning, and how they should make adjustments (Barron et al. 2014). A potential advancement to the course is to incorporate explicit prompts or opportunities for self-assessment/reflection linked with discussion within the group (team, with the instructor, or with the whole class). What is critical is to unfold the meaning process of reflection by expressing it to others; in other words, it needs to happen in a community and interact with others (Rodgers, 2004).

Moving from reflection that is applicable to learning in general to more specific skills and competencies highlighted in this paper, communication, feedback (literacy), and teamwork, what can we learn? First, as briefly addressed earlier, the course may benefit from explicit instruction on specific skills. Time and resources are a major challenge in ensuring that students learn new competencies. Prior literature highlighted the significant investment for students in PBLs (Du et al, 2021; Guo et al. 2020; Miranda et al. 2020) and closely related demands on facilitators/instructors to properly help students to navigate the complexities and uncertainties in the process (Du et al. 2021; Bissett-Johnson and Radcliffe, 2021; Guo et al. 2020; Miranda et al. 2020). Adding new elements to existing courses might be challenging, but it can be really rewarding. Now, the question is whether we should expect instructors in PBL courses to lead the designing and implementing new modules and materials on transversal competencies. In fact, one of the fruitful outcomes of the collaboration of the authors of this paper is unfolding the potential of the course in addressing transversal competencies and envisioning potential interventions where students can first appreciate the importance of specific skills, gain conceptual knowledge and understanding about frameworks underlying specific skills, practice in applying those skills in a meaningful way, and reflect on their experience to develop an awareness of their abilities and what needs to be improved.

A closely related issue to what has been discussed is difficulties with assessment in PBLs in general (Miranda et al. 2020), and more specifically related to transversal competencies. To examine students' learning and/or the influence of particular interventions addressing specific transversal competencies, it is critical to take advantage of different tools and measures. For instance, designing and integrating rubrics for presentation skills is a mainstream educational practice; evaluating teamwork skills, on the other hand, is more challenging considering a variety of factors that may influence the dynamics and the process of collaboration and complexities in unfolding behavioral components of teamwork skills. In this case, for instance, educators can benefit from incorporating peer evaluation or assessing students' self-efficacy beliefs. As a measure of learning, students' beliefs about their abilities may demonstrate their tendency to apply what they have learned to the new settings.

Reflecting on what has been discussed on explicit integration of transversal competencies, while enhancement in design and delivery of the course is desired, we should acknowledge once again the amount of investment and efforts instructors of PBLs need to make despite major institutional challenges in recognition of such courses, including financial support (Chen et al. 2021). As such, instructors often have to deal with broader contextual and structural issues when offering such courses. Nevertheless, as illustrated in this paper, lessons can be learned from the praxis to avoid missing opportunities to support students in developing transversal competencies.

ABSTRACT

FIBER (Flexible Interactive Bioreactor for Experimentation and Research), a novel bioreactor platform designed to bridge the gap between theoretical understanding and practical application in bioengineering education. Bioreactors are fundamental technologies in various fields, but their inherent practical nature can make theoretical introduction challenging for students. FIBER tackles this issue by fostering active learning experiences through modular and adaptable design. The platform's modular components allow students to conduct multiple experiments simultaneously and tailor FIBER to fit specific experimental requirements. Affordability is a key consideration, with FIBER utilising readily available materials and 3D-printed parts, making it accessible for educational institutions with budgetary constraints. Additionally, FIBER boasts a compact design with a base station smaller than 10x10 cm for convenient benchtop operation. FIBER is further enhanced by interactive software that facilitates real-time monitoring and control of experiments. Students can use this software to compare different bioreactor operating modes, customize and investigate how various parameters influence cell growth. For increased versatility, FIBER integrates sensor slots for bacterial growth measurement. The design includes attachments for simple integration of Optical Density (OD) and fluorescence sensors, allowing for adaptation to diverse experimental needs. While the primary focus of FIBER lies in its educational applications, its ability to run multiple simultaneous experiments with its modular and cost-effective design holds potential for researchers as well. FIBER promotes active learning and responsible research practices by educating students to build socially and environmentally sustainable society.

1 INTRODUCTION

Bioreactors are cornerstone technologies across diverse industries, enabling the production of enzymes, proteins, microbial biomass, vaccines, biofuels such as ethanol, biodiesel and much more (Regonesi, 2023). This widespread use necessitates a well-equipped and educated engineering workforce. However, the inherently practical nature of bioreactors can pose a challenge in traditional, theory-heavy educational settings. This practice paper introduces FIBER (Flexible Interactive Bioreactor for Experimentation and Research), a novel device designed to bridge this gap and enhance bioengineering education. FIBER fosters active learning by providing a hands-on platform for students to apply theoretical concepts in a practical environment. They can explore different bioreactor operating modes, investigate the impact of parameters like temperature on bacterial growth, and gain a deeper understanding of the many disciplines that are integrated in bioreactors design and experiments such as fluid mechanics, biology and chemistry. This approach aims to assist in the education of students to build a more socially and environmentally sustainable society.

Recent research offers some promising avenues for bioreactor development. A morbidostat bioreactor was developed to continuously monitor bacterial growth and drug resistance of these bacteria (Toprak et al. 2013). Another example is the creation of a low-cost, customisable, turbidostat for use in the characterisation of synthetic circuits (Takahashi et al. 2015). This device proposed a system that could measure Optical Density (OD) and Fluorescence in alternating times. A more complex solution that makes use of a modular reactor with a microfluidic plate is the eVOLVER (Wong et al. 2018). A more comprehensive view on miniature size bioreactors can be seen in the review by Betts and Baganz (Betts and Baganz 2006. In education, bioreactors have been incorporated to provide students with an introduction to bioreactors and its uses, the EVE (Evolutionary Bioreactor, Gopalakrishnan et al. 2022) is a device proposed to be a low-cost morbidostat used in educational settings to demonstrate real-time examples of bacterial evolution. However, the most common solution to teaching students about operational modes of bioreactors is through virtual labs due to the high cost of equipment (Martín-Lara and Ronda 2020, Seidel, Eibl-Schindler, and Eibl 2022). Hence, by introducing FIBER, we present a solution to some of the issues of bioengineering education such as the high costs of bioreactors and the extensive training that usually is required to operate them (Seidel, Eibl-Schindler, and Eibl 2022). FIBER's strength lies in its user-friendly, affordable, and modular platform with multiple cells. This innovative design empowers students to delve into the fascinating world of bioreactors and explore diverse bioprocesses. Unlike traditional bioreactor setups FIBER allows exploration in novel settings fostering a deeper understanding and opening doors to exciting discoveries.

2 FIBER'S UNIQUE FEATURES

Traditionally, grasping bioreactor concepts can be challenging for students due to the inherent complexity of these systems. FIBER addresses this issue by focusing on a student-centered design. The platform tackles these challenges by prioritising features that enhance learning, such as modularity for flexibility in experimentation and affordability to make it accessible for educational institutions. FIBER user-friendly, small-scale, and modular platform empowers students to directly interact and experiment, fostering a deeper understanding of bioprocesses. This hands-on approach lets them design and test experiments for optimal growth conditions, building not only bioreactor knowledge but also valuable experimental skills. Ultimately, FIBER bridges the theory-practice gap crucial for industry, where diverse biological needs demand precise optimization (Enes Kadic and Heindel, 2014).

2.1 Modular and Compact

Ensuring student collaboration in labs with limited space is a key consideration for FIBER's design. With an entire setup occupying less than 50 x 10 cm for four bioreactor cells, multiple FIBER units can be simultaneously used on a standard lab bench with a base station measuring under 10 x 10 cm. In addition, FIBER is designed so that by adding or removing individual bioreactors cells from the base station, students can run multiple experiments simultaneously to gather data under various conditions. This focus on modularity and compactness saves not only valuable lab space and time, but also allows for more efficient data collection and analysis of different experimental conditions.

2.2 Affordability and Accessibility

Ensuring widespread adoption in educational settings was a core principle behind FIBER's design. Affordability was paramount, with a focus on readily available components that can be purchased in bulk for cost-effectiveness. 3D printing forms the backbone of FIBER, allowing for easy replication of parts and construction at any location. This not only makes FIBER accessible to institutions with varying budgets, but also empowers them to customize and adapt the platform for specific educational needs. The final design for FIBER aims to be at least 25% cheaper than any current market alternatives when two experimental cells are considered. This difference further increases with a higher number of cells to run parallel experiments, with FIBER being at least 40% and 50% cheaper for 3 and 4 cells respectively, with an increase in functionality.

2.3 Adaptable

FIBER prioritises user-friendliness and adaptability for both educational and research applications. The intuitive software offers presets for fundamental bioreactor control systems, including turbidostats, batch-fed, chemostats, and retentostats. These form the foundation for more complex systems like luminostats and morbidostats. While these advanced systems are not currently supported, FIBER's source code allows users to customize the software for their specific needs. Furthermore, the platform's adaptability extends to sensor selection. Users can modify sensor components, such as the LED for fluorescence experiments, to align with the specific wavelength of interest. This allows FIBER to accommodate diverse educational curriculums and research projects, empowering both students and researchers.

3 THE BIOREACTOR

It's important to acknowledge that FIBER is a continuously evolving platform. While this practice paper details its current design and functionalities, ongoing development efforts may introduce refinements in the future. This transparency allows for open discussion and potential collaboration as FIBER's capabilities continue to expand.

3.1 The design

FIBER's core design philosophy prioritises user flexibility. To facilitate a wide range of experiments, the platform is divided into two key components: a base station and interchangeable experimental cells. The base station acts as the central control hub, managing data collection, fluid distribution, and communication with connected cells. Each base station, also referred to as a feeding station, can support up to four experimental cells simultaneously. These cells connect to the base station for data exchange and power supply.

Figure 1 illustrates the current FIBER design. Figure 1a) shows the 3D-printed components of the current prototype, with the blue part in Figure 1b) corresponding to the base station. This section, covered in detail later (section 3.2), manages the flow of fluids to individual experimental cells. The red components in Figure 1b) represent the experimental cells, currently under development (section 3.3). These cells, where microorganisms will be grown, connect and communicate with the base station. This modular design allows users to tailor FIBER to their specific needs by easily adding or removing experimental cells for parallel experiments.

FIBER's impact extends beyond the hardware. We have developed an open-source software that empowers students to tailor experiments by adjusting parameters and visualizing data with automatic growth calculations. Researchers can access raw sensor data and write custom scripts. This opens doors for a wider range of modifications, ensuring FIBER adapts to the specific needs of each experiment.

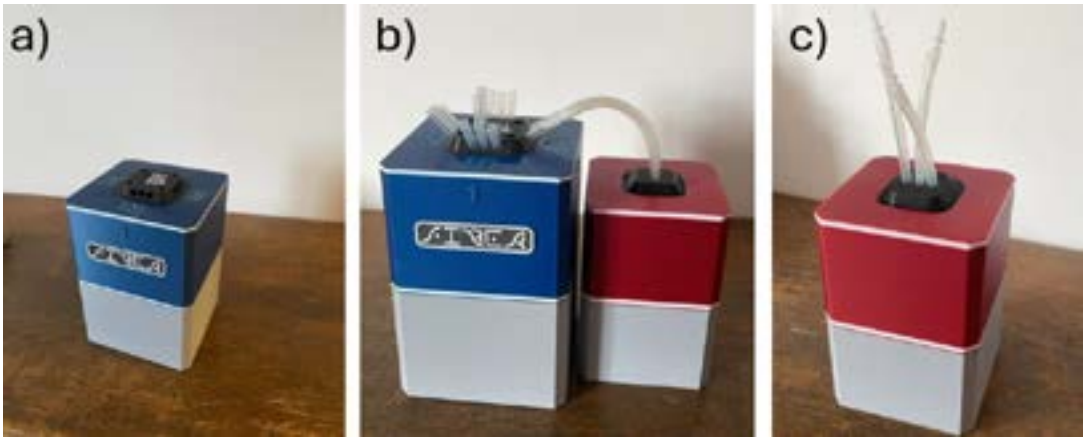

Fig 1. Images of the prototype of FIBER. a) is a picture of the 3D-printed base station of the system without the tubing attached. b) is a picture of FIBER. In blue is the base station, with the tubing leaving through the top. The tubing will be connected to each one of the experimental cells (red) which are shown in c).

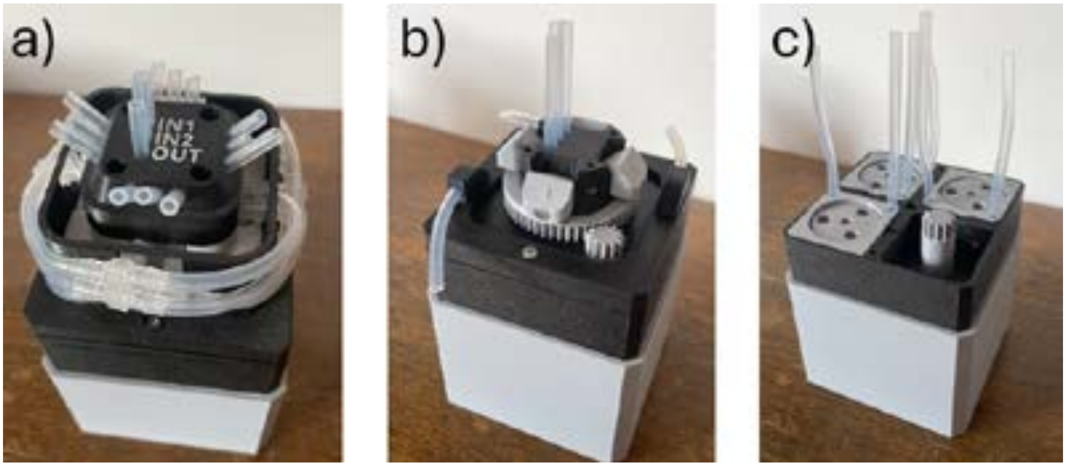

Fig 2. Pictures of the base station. All images correspond to sections of the base station, a) shows the tubing of the pinch valve that controls the amount of fluid distributed to the cells. b) shows a clearer picture of the pinch valve mechanism that distributes fluids to the cells. c) shows the stepper motors that control the pinch valve and the peristaltic pumps. The part presented in c) is on the bottom of the tubing shown in a) and b).

3.2 Base station

As the central control unit, the base station plays a critical role in coordinating and managing experiments. It houses a powerful microcontroller for advanced regulation and user-defined calculations. However, the core functionality lies in its sophisticated fluidic control system. Equipped with four stepper motors, the base station operates peristaltic pumps and a fluid pinch valve to precisely regulate the flow of fluids to each connected experimental cell. Figures 2a and 2b illustrate the pinch valve system. By compressing or relaxing tubing wrapped around the base, the valve controls fluid flow based on requests from the experimental cells. The remaining three stepper motors drive the peristaltic pumps. One pump acts as an output, removing fluids from the cells, while the other two function as inputs, allowing for the introduction of two distinct fluids into the same experiment. This configuration, depicted in Figure 2c, empowers students and researchers to investigate various scenarios, such as how different substrate concentrations impact cell growth. A picture of this system is shown in Fig. 2c), where there are three peristaltic pumps and a stepper motor that controls the pinch valve. This robust fluidic control system empowers FIBER to conduct diverse and controlled experiments.

3.3 Experimental cell

The experimental cell, arguably the heart of FIBER where experiments take place, is meticulously designed for flexibility and user customisation. Currently, the Team's focus is on integrating core sensors like the Optical Density (OD) sensor for measuring total cell concentration. A dedicated slot is planned for a future fluorescence sensor, though not currently prioritised due to the complexity of fluorescence-based measurements. Additionally, an infrared temperature sensor slot will be included for precise temperature control within the cell. However, true to FIBER's modular philosophy, users can modify the cells to add, remove, or adjust sensors to suit specific experimental needs. As the OD sensor relies on light intensity reaching a photodetector, external light can impact readings. To minimise this background error for light-based sensors, the cell will be equipped with a removable lid (the red compartment in Figure 1c). This lid not only protects against light interference but also allows for easy access for adjustments to LEDs or other experimental configurations. This combination of core sensors and user-customisable options empowers students and researchers to conduct a wide range of experiments within the FIBER platform.

4 RESULTS

While FIBER's development is ongoing, an initial experiment has yielded promising results for the sensor design. This preliminary test aimed to evaluate the functionality of the fluorescence sensor alongside the Optical Density (OD) sensor. *Escherichia coli* (*E. coli*) bacteria engineered with Green Fluorescent Protein (GFP) were used in the experiment (Figure 3).

The data collected indicates that the sensor placement and design function are as expected. The figure shows variations in light intensity measured by the phototransistor, corresponding to bacterial growth. The OD (red line), measured using a red LED, exhibits an exponential increase until approximately 10 hours into the experiment, when it reaches its stationary phase of growth. Similarly, the blue line, representing the fluorescence intensity, shows an exponential increase until the 10-hour mark, signifying stable bacterial growth.

The agreement between OD and fluorescence readings suggests that growth stabilises after 10 hours, which is a strong indication of successful sensor design for FIBER. These encouraging initial results pave the way for further development and testing of FIBER's functionalities. The results displayed have been confirmed by multiple experiments developed, thus further increasing the viability of the sensor design.

FIBER is currently undergoing testing and refinements. Following completion of testing, we will gather feedback from researchers and conduct student learning sessions to evaluate FIBER's educational potential after the ethical approval for student trials is granted. We anticipate FIBER's evolving capabilities hold immense promise for future collaborations.

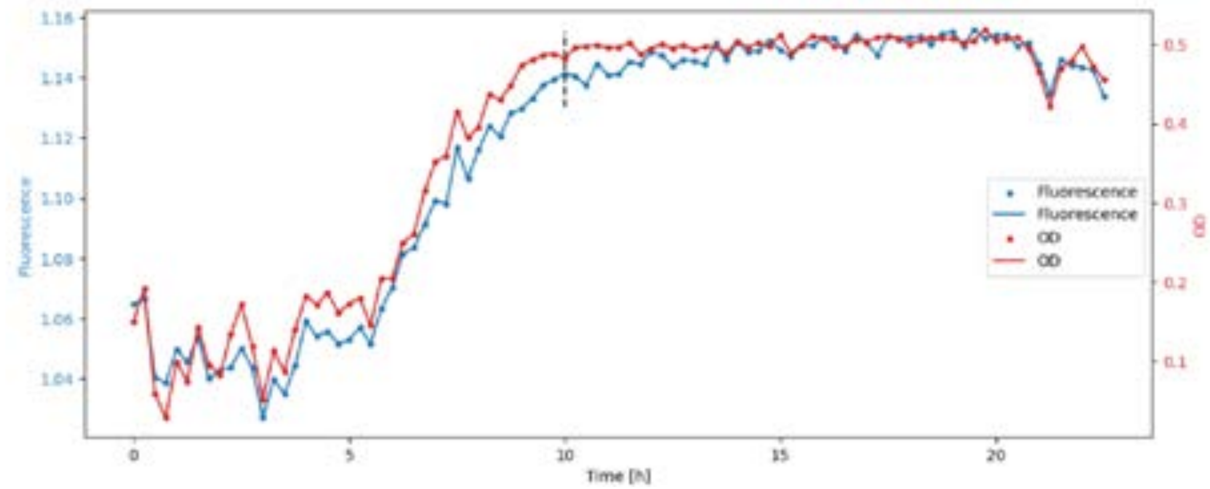

Fig 3. Data collected during preliminary tests of the OD and fluorescence sensors for FIBER. The graph presents the readings for the light intensity registered by the photodetector for OD (red) and fluorescence (blue). Both the OD and Fluorescence data show exponential growth until around t = 10h. After t = 10h, both measurements present stability and no significant relevant variations.

5 APPLICATIONS OF FIBER

FIBER's impact transcends the realm of education, offering valuable applications for research as well. The platform's modular design and ability to run multiple experiments simultaneously make it a cost-effective tool for students and researchers. This translates to several benefits: increased experimental throughput through faster data collection and analysis, optimised culture conditions by allowing researchers to efficiently explore various parameters for maximising cell growth or product yield, and the flexibility to tailor FIBER to specific research questions through its modular design. These functionalities, coupled with its primary focus on enhancing bioengineering education, solidify FIBER as a versatile and valuable tool for both learning and scientific exploration.

5.1 Educational Institutions

FIBER is designed to revolutionise bioengineering education at various levels. For university students, particularly those in Chemical and Biological Engineering disciplines, FIBER offers a hands-on platform to apply theoretical concepts in cell manipulation and production, crucial aspects of these fields. Research has been conducted on how to incorporate bioreactors in education and it was suggested to use of virtual bioreactors as opposed to their physical counterparts due to the high cost of equipment (Martín-Lara and Ronda 2020, Seidel, Eibl-Schindler, and Eibl 2022). Meanwhile (Gopalakrishnan et al. 2022) present a new bioreactor that focuses on helping biologists to understand bacterial evolution using a Morbidostat. FIBER attempts to innovate on the principles presented by helping students to gain a deeper understanding of complex bioreactor control systems by conducting experiments that compare different operating modes for an affordable price.

Additionally, FIBER allows them to investigate how various variables, like temperature or nutrient concentration, impact the growth of living cells. At the school secondary level, FIBER can be introduced as a captivating lab experiment exploring bacterial growth. This could spark student interest in biotechnology and potentially steer them towards STEM careers. Furthermore, FIBER can be seamlessly integrated into various curriculum topics, providing students with the opportunity to practice scientific investigation and visually understand concepts related to bacterial growth. Its adaptability also extends to higher education institutions beyond engineering, empowering undergraduate students in other disciplines to develop research skills and conduct their investigations. By fostering active learning across multiple educational levels, FIBER bridges the gap between theory and practice, fostering a deeper understanding of bioengineering principles which could facilitate the transitions of students from university to industrial settings where complex bioreactors are used.

5.2 Research

While education remains our primary focus, FIBER's potential extends to aiding researchers in diverse biological fields. The platform's key strengths - user-friendliness and adaptability - make it a valuable tool for biologists of varying experience levels to conduct simultaneous experiments. This adaptability goes beyond hardware; the customisable control system opens doors for exciting applications like developing an algorithm for simultaneous growth characterisation of different bacterial strains. FIBER's cost-effectiveness positions it as an attractive option for researchers with budgetary constraints. Additionally, researchers with some understanding of control systems engineering could further tailor FIBER to their specific needs. In fact, discussions with PhD students at the University revealed their enthusiasm for FIBER's potential to automate the creation of growth curves for microorganisms - a task currently performed manually. In addition to the feedback provided by the PhD students, mini bioreactors, the category where FIBER lies, are needed to be adaptable due to the large range of conditions required by different biological species (Betts and Baganz 2006). Therefore, as one of FIBER’s focus is its adaptability, it can be used in a variety of situations in research without the requirement of expensive purchases for simple tests. The points raised underscores FIBER's ability to streamline research processes and enhance efficiency for biologists beyond the educational realm.

6 SUMMARY AND ACKNOWLEDGEMENTS

FIBER addresses the critical need for a user-friendly and affordable bioreactor platform to bridge the gap between theory and practice in bioengineering education. This modular system prioritises affordability through readily available materials and 3D printing, making it accessible for institutions with varying budgets. The compact design ensures efficient use of lab space, while the interactive software empowers students to actively participate in experiments, monitor parameters in real-time, and analyse the impact of different variables on cell growth. Sensor integration with options for customisation further enhances FIBER's adaptability to diverse experimental needs. Beyond education, FIBER's potential extends to research, offering researchers the ability to run multiple simultaneous experiments, optimize culture conditions, and tailor the platform to address specific research questions. This versatility, coupled with its focus on active learning, positions FIBER as a valuable tool for both bioengineering education and research. FIBER is not just a bioreactor, it is an educational bridge to empowers students to explore bioprocesses through hands-on experimentation, fostering a generation equipped to tackle future ethical and sustainability challenges.

ABSTRACT

Ethics education is crucial for civil engineers due to the far-reaching impact of their work. This article presents the Chapter on Civil Engineering that is part of the forthcoming "Routledge International Handbook of Engineering Ethics Education". In

[1] *I. Josa*
i.josa@ucl.ac.uk

particular, it explores how ethical considerations should be integrated throughout civil engineering in a project's lifecycle, from design to decommissioning. Ethical considerations like professionalism, social responsibility, sustainability, and safety are addressed throughout. Each of these considerations is analysed across project phases, including planning, construction, operation, and decommissioning. Contents related to different civil engineering disciplines are examined (i.e., construction, energy, environment, water, transportation, urbanism). The chapter presented herein aims at fostering discussions around ethics in civil engineering classrooms, with a view of educating new generations of civil engineers that are strong not only technically, but holistically, thus ensuring that their projects prioritise safety, sustainability, and societal well-being.

1 INTRODUCTION

Unlike other engineering disciplines with a more recent origin, civil engineering has a long history dating back to ancient civilisations. From the Roman Empire's roads and viaducts to the achievements in Egypt, Greece, and China, civil engineering has demonstrably shaped societies and improved quality of life by providing essential infrastructure. This rich history is accompanied by the establishment of professional bodies like the American Society of Civil Engineers (ASCE) and the Institution of Civil Engineers (ICE) to ensure ethical practices that benefit society.

Ethics education is crucial for engineers, and it is increasingly being incorporated into engineering programs around the world. However, the importance that civil engineering has for society has not traditionally been reflected in the education of civil engineers. While civil engineers have the potential to solve pressing global challenges and enhance quality of life, undesired outcomes can arise if safety, sustainability, and public well-being are not prioritised. News headlines about infrastructure collapses and corruption cases highlight the importance of ethical considerations.

To avoid these adverse effects, future civil engineers must be equipped to understand and solve ethical dilemmas. Engineering ethics education is vital for this purpose. In addition to technical expertise, a well-rounded civil engineering education should include a comprehensive exploration of ethical questions, real-world case studies that showcase the ethical challenges faced by professionals, and opportunities for ethical decision-making and reflection.

Considering the above, this article presents the Chapter on Civil Engineering (Josa et al.) that is part of the forthcoming "Routledge International Handbook of Engineering Ethics Education" (Chance et al.). It aims to provide an overview of the ethical issues, dilemmas, and challenges that are included in the chapter, which addresses how these issues can be tackled by both students and practicing civil engineers.

2 CONTEXT: THE HANDBOOK

The Routledge International Handbook of Engineering Ethics Education (Chance et al.) is an open-source handbook on Engineering Ethics Education (EEE), which has been compiled by a diverse team of scholars. This handbook aims to be a comprehensive resource for both new and experienced researchers in the field.

The content of the book is organised into six main sections, each focusing on a different aspect of EEE. These sections cover the foundations of the field, explore contributions from other disciplines, delve into various teaching methods, and address the role of accreditation. Additionally, the handbook explores ethical issues specific to different engineering disciplines and provide guidance on assessing various aspects of EEE programs. Each section contains multiple chapters that review existing research and present the different perspectives and dilemmas surrounding each topic.

3 DETAILS OF THE CIVIL ENGINEERING CHAPTER

3.1 Development of the chapter

This chapter's development involved an iterative process through a series of meetings. The first meeting served as an initial discussion, laying the groundwork for the chapter's content and direction. Following this, a matrix was developed to structure the chapter (as will be further detailed later). The matrix then underwent refinement to ensure it effectively captured the intended content. Once finalised, the next phase involved filling the matrix with specific concepts and relevant case studies to illustrate the ethical considerations within the chosen framework.

The review process of the chapter involved discussions with the teams writing the chapters on other engineering disciplines, as well as three rounds of reviews by authors of other chapters and the handbook editors.

3.2 Contents of the chapter

Figure 1 shows how the chapter is organised. The structure of the chapter emphasises that ethical thinking should be integrated from the very beginning of a project and continue through to its completion.

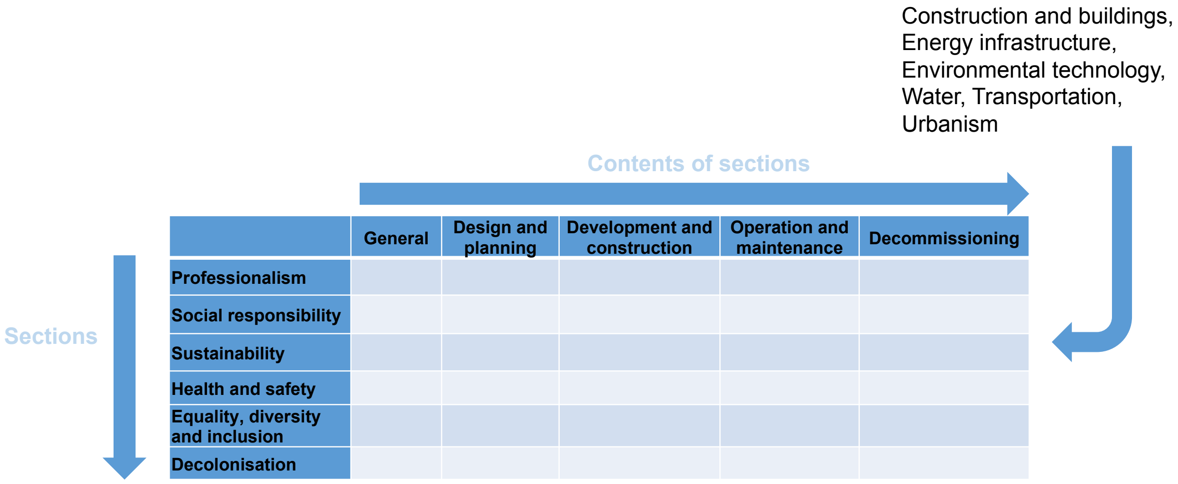

Fig. 1. Structure of the chapter

The chapter focuses on six main areas: construction and buildings, energy infrastructure, environmental technology, water, transportation, and urbanism. Each section is further divided into subsections that explore different stages of a project's life cycle, from general planning and design to construction, operation, and eventual decommissioning.

Then, running alongside the project phases are additional considerations that highlight the importance of ethics throughout the entire process. These ethical considerations include professionalism, social responsibility, sustainability, health and safety, as well as equality, diversity, inclusion, and decolonisation.

There is a part of the Handbook dedicated to methods through which these contents can be integrated into the curricula (e.g., case studies, problem-based learning). In the chapter presented herein, examples of potential case studies are included, together with questions that can be used in class to guide discussions. The titles of the case studies included are: the National Society of Professional Engineers Board of Ethical Review Case 97-13, Saadiyat Island Abu Dhabi and Worker Rights, Powerhouse Kjørbo, La Scala Opera House Asbestos Deaths, Trans-inclusive sanitation, and The Central Corridor, Tanzania.

In what follows, the main contents included for each of the ethical considerations (organised in sections) are presented.

3.2.1 Professionalism

This section discusses the ethical expectations of engineers throughout a project's journey. It starts with foundational concepts, exploring professionalism and its significance in construction. Also, the section delves into established codes of conduct, outlining the principles that guide ethical practice.

As a civil engineering project progresses, the focus shifts to ethical considerations within specific phases. During design and planning, the section discusses maintaining design integrity, avoiding conflicts of interest, and considering the long-term social and environmental impact of projects. A particularly challenging scenario, clashes of obligations, is also addressed here. This involves situations where client confidentiality clashes with public safety, and the section provides questions to critically think about navigating these conflicts while prioritising ethical duties.

The section then continues to the construction phase, emphasising ethical considerations like quality control, adherence to safety regulations, and responsible material sourcing. It also tackles the sensitive issue of corruption and bribery within the industry, offering strategies for identifying and avoiding such practices.

Finally, the section explores the ethical responsibility of whistleblowing. This involves those cases where engineers witness unethical or potentially harmful practices.

3.2.2 Social responsibility

This section dives into the ethical obligations engineers have towards society and the far-reaching consequences of their work. In particular, it opens with a discussion on the concept of social responsibility in engineering drawing on Chance et al. (2021), moving beyond technical considerations to explore the impact projects have on communities and the environment.

The section discusses the ethical principles guiding this responsibility, such as fairness, justice, and the well-being of future generations. It then tackles the distribution of responsibility, identifying who bears the ethical burden for different project aspects. This could involve engineers, contractors, clients, and governments.

The concept of Corporate Social Responsibility (CSR) is explored, examining how engineering firms can integrate social responsibility into their practices. Strategies for minimising negative project impacts and maximising positive contributions are discussed.

Moving into specific project phases, the section focuses on ethical considerations during design and planning. This involves considering the needs of vulnerable communities, minimising environmental disruption, and ensuring equitable access to the project's benefits. Recognising the potential downsides of new technologies, the chapter explores how to identify and mitigate unintended consequences during design. It emphasises the importance of considering the long-term social and ethical implications of innovation.

Regarding ethical considerations during construction, fair labour practices, responsible sourcing of materials, and minimising the project's impact on local communities are addressed. Highlighting the ethical complexities of global supply chains, the section dives into responsible sourcing practices and avoids human rights abuses or environmental exploitation within these chains. A real-world case study, the Saadiyat Island Abu Dhabi and Worker Rights (Human Rights Watch, 2009), is used to illustrate the challenges of social responsibility in construction projects.

Regarding operation and maintenance, this involves ensuring proper infrastructure upkeep to prevent disasters, such as bridge inspections or ensuring proper dam maintenance. The section also delves into the ethical complexities of who bears responsibility when a project fails. Additionally, effective communication with stakeholders throughout the project's life cycle is crucial for social responsibility.

Finally, ethical considerations for decommissioning involve responsible dismantling of structures, recycling or repurposing materials, and minimising the environmental impact of the decommissioning process.

3.2.3 Sustainability

This section dives deep into the environmental impact of engineering projects and how to minimise it throughout the entire process. This section explores the challenges of climate change and the ethical obligation to future generations (intergenerational justice). The section introduces frameworks like the Sustainable Development Goals (SDGs) and the capabilities approach to guide sustainable practices. It also touches on the concept of "Net Zero" emissions.

For design and planning, the focus is on incorporating sustainability principles from the very beginning (Engineering Council, 2021). This involves using design criteria that prioritise energy-efficient buildings, sustainable materials selection, and minimising resource consumption. The section also explores the concept of a circular economy, where materials are reused or recycled, and discuss potential criticisms of this approach.

Ethical sourcing of materials takes centre stage during the development and construction. The section discusses strategies for identifying and using materials with minimal environmental impact, including recycled content or those produced through responsible practices (Cole & Fedoruk, 2015).

As for operation and maintenance, the focus shifts to sustainable operation of the completed project. This involves strategies for maximising energy efficiency throughout the life of the building or infrastructure. A real-world example, the

Powerhouse Kjørbo, a highly energy-efficient office building in Denmark, is used to illustrate these concepts (UNFCCC, n.d.).

The end of a project's life also has sustainability implications. The last part of this section explores the challenges of obsolescence and waste generation during decommissioning. Strategies for minimising waste and promoting repurposing or recycling materials during demolition are discussed (Lawlor, 2015).

3.2.4 Health and safety

The "Health and Safety" section prioritises the well-being of everyone involved in a project, from conception to completion. The section emphasises the importance of identifying and mitigating potential hazards throughout a project's lifecycle.

For design and planning, the focus is on integrating safety considerations from the earliest stages. This involves discussions around incorporating safety features during design, evaluating cheaper versus safer alternatives, and prioritising long-term safety over short-term cost savings (Toole, 2007).

The development and construction section prioritises the safety of workers on the construction site. The section delves into mitigating accidents and risks through proper safety protocols, adequate worker training, and providing the necessary personal protective equipment.

Once the project is operational, the safety of users becomes paramount (Lukhele et al., 2022). This section explores strategies for ensuring safe building or infrastructure use, including emergency protocols and ongoing maintenance to avoid potential hazards.

In the dismantling of a project, safety requires careful consideration. This section discusses the challenges of dealing with harmful materials like asbestos during decommissioning. Strategies for safe removal and disposal of these materials are explored. A real-world example, the La Scala Opera House Asbestos Deaths case, is used to illustrate the potential consequences of neglecting safety during decommissioning (ACTS FACTS, 2016).

3.2.5 Equality, diversity and inclusion

The "Equality, Diversity and Inclusion" section emphasises the importance of creating a level playing field for everyone affected by a project. The section introduces the concepts of inclusive design and how it can address the needs of diverse populations. It discusses the medical vs social model of disability, highlighting the importance of designing for user capability rather than focusing on limitations (Field et al., 2022; Hao et al., 2023).

In design and planning phases, the focus is on designing with accessibility in mind from the start. This involves considering the needs of people with disabilities during building, transportation, and urban planning projects. The section uses a real-world case study, "Trans-inclusive sanitation", to illustrate the importance of inclusive design for all genders and identities.

As for development and construction, the section discusses potential gender inequalities within the construction sector. Then, for operation and maintenance, the focus shifts to ensuring equitable access to the benefits of a project throughout its operation. This involves discussions around energy poverty and strategies for ensuring affordable access to energy for all communities. Additionally, the section explores the ethical obligation to provide universal access to clean water, a basic human right.

The decommissioning stage part addresses the potential negative impacts of demolition on socio-economically disadvantaged communities. Strategies for mitigating these impacts and ensuring a just decommissioning process are discussed.

3.2.6 Decolonisation

This section delves into the historical and ongoing power imbalances within the engineering profession. It examines how engineers can approach their work ethically in a globalised world. It raises questions about the ethical implications of engineering projects in former colonies and explores how to avoid perpetuating power imbalances.

For design and planning, the focus is on ethical considerations when working in foreign settings. This involves discussions about understanding the local context, respecting cultural norms, and acknowledging existing power imbalances between the Global North and South.

For development and construction, the chapter tackles the ethical challenges of modern slavery and global exploitation within the construction industry. Strategies for ensuring fair labour practices and preventing human rights abuses during project development and construction are explored.

Additionally, the ethical dilemmas surrounding the maintenance of colonial-era urban and infrastructure projects are addressed. The section discusses the challenges of balancing historical preservation with the need for modernisation, and how to ensure these projects benefit the local population. A real-world example, the Central Corridor project in Tanzania, is used to illustrate these complexities.

Finally, this section concludes by discussing issues related to minimising environmental impact and ensuring responsible disposal of materials during decommissioning in formerly colonised countries.

4 SUMMARY AND ACKNOWLEDGEMENTS

This article explored ethical issues in civil engineering across project stages, as included in the Chapter on Civil Engineering of the Routledge International Handbook on EEE. While vast and complex, it serves as a starting point for considering ethical responsibilities in education and practice. The chapter emphasises the full project life cycle and key factors for ethical decision-making. Civil engineers need to navigate individual and collective ethics in a changing world.

This chapter is just a glimpse into a complex topic. For responsible practice, a deeper understanding of these ongoing challenges is crucial. We hope that the chapter inspires further exploration and a commitment to ethical and sustainable engineering.

The authors are grateful for the financial support of the BSSC Conference Support Fund to attend the SEFI2024 conference. The authors are also grateful to the editors of the Routledge International Handbook on Engineering Ethics Education (Chance, S.; Børsen, T.; Martin, D.; Tormey, R.; Lennerfors, T.; and Bombaerts) for the opportunity to contribute to the book and present it in this conference.

ABSTRACT

Within higher education, integrating gender perspectives into teaching is crucial for inclusivity and addressing gender disparities. This article presents a guideline from

[1] *I. Josa*
i.josa@ucl.ac.uk

the "Xarxa Vives Guides," a resource offering educators strategies for incorporating gender considerations across disciplines. In particular, the civil engineering guideline contains general and specific actions aimed at creating a more inclusive learning environment. General recommendations focus on teaching methods, classroom dynamics, assessment, and content. The emphasis is on using diverse methods, promoting respectful dialogue, and employing fair assessments. Additionally, course content should integrate the contributions of underrepresented groups and address gender-related issues within civil engineering. The guideline delves into specific recommendations for various subject areas within civil engineering education. Examples illustrate how to integrate gender perspectives, from considering gendered needs in water access projects to incorporating them into transportation planning. Finally, the chapter presented in this article explores fostering research with a gender lens. This includes supporting students in conducting gender-sensitive research projects and integrating gender considerations throughout the research cycle. By following these recommendations, civil engineering educators can empower students to challenge gender inequalities and contribute to a more equitable and inclusive profession.

1 INTRODUCTION

Teaching with a gender lens in higher education institutions is imperative to promote inclusivity, address gender disparities, and prepare students to navigate diverse professional environments.

Recognising the importance of integrating gender perspectives into teaching methodologies, Xarxa Vives has developed comprehensive guidelines aimed at educators across multiple disciplines. These guidelines serve as a framework for incorporating gender-sensitive approaches into course content, pedagogy, and assessment, fostering critical thinking about gender biases and their implications in various fields of study.

For engineers, competencies acquired by students upon completing their studies should extend beyond technical skills. In the realm of civil engineering, the chapter developed by Xarxa Vives offers practical strategies for educators to integrate gender considerations into the curriculum and final degree dissertations.

By incorporating these guidelines, educators can empower students to recognise and challenge gender inequalities, ultimately contributing to more equitable and inclusive practices within the field of civil engineering and beyond.

2 CONTEXT: THE “XARXA VIVES” GUIDES

2.1 The “Xarxa Vives” guides

The "Guidelines for University Teaching with a Gender Lens" is a collection of guidelines from diverse disciplines and knowledge fields that provide guidance on reviewing courses from a gender perspective. The guidelines present recommendations and indications related to objectives, content, examples, language used, and selected sources, as well as teaching, evaluation, and learning environment management methods and their results.

The resource has become a pioneer in the European Higher Education Area and has received recognition from the European Institute for Gender Equality, which has included it as an example of good practice in its Guide to Tools for Gender Equality in Academy and Research.

The following are the fields of knowledge and disciplines of the collection:

- Arts and Humanities: Anthropology, Philology and Linguistics, Philosophy, History, Art History, Museology and Museography, Translation and Interpretation.
- Sciences: Physics, Mathematics.
- Social and Legal Sciences: Communication, Law and Criminology, Education and Pedagogy, Sociology, Economics, and Political Science, Geography, Tourism, Business Administration and Management, Social Work.
- Life Sciences: Biology, Nursing, Medicine, Human Nutrition and Dietetics, Psychology, Sports Science and Physical Activity, Podiatry.
- Engineering and Architecture: Architecture, Computer Science, Telecommunications Electronic Engineering, Industrial Engineering, Multimedia Engineering, Agricultural Engineering, Naval, Marine, and Nautical Engineering, Civil Engineering.

Each year, this list grows bigger as guidelines are added to the collection. During year 2023, one of the guidelines developed was the civil engineering one, which is presented here (Josa & Real, 2024). Note that, at the moment of preparing this article, the guideline is only available in Catalan. However, the versions translated to Spanish and English are currently being prepared.

2.2 Gender and Civil Engineering

Over the years, the number of female students and professionals in civil engineering has been increasing. However, differences between men and women are still present. According to the 4th UPC Equality Plan 2022-2026 (Universitat Politècnica de Catalunya, 2022), the percentage of new female students in UPC degrees (mainly engineering and architecture degrees) in the 2021/22 academic year was 31%. This represents an increase from the 2016/17 academic year, when it was 24.4%. The Civil Engineering degree is around the average of all STEAM degrees at the UPC, below degrees related to health and environmental sciences and technology, but above degrees related to Information and Communication Technologies (ICT), where percentages are much lower.

The same pattern is reproduced globally. For example, Imperial College London currently has 29% female students studying Civil Engineering (Imperial College London, 2023), around 31% at École des Ponts (ParisTech) (École des Ponts ParisTech, 2023), between 30% and 40% at the National University of Singapore (National University of Singapore, n.d.) and 30% at the University of Sydney (The University of Sydney, n.d.).

Regarding the differences that exist between men and women who enrol in engineering studies, several studies have found that women are often more attracted to studies that are related to "people", while men tend to choose careers more related to "things" (Su et al., 2009). In addition, other studies have highlighted that women's greater interest in more socially oriented careers is motivated by altruism and a desire to help others and benefit society (Freund et al., 2013).

In addition to the differentiated interests between men and women, it is important to consider aspects related to the work environment. Some work environments and cultures can be unwelcoming for women. The lack of diversity and gender equality in organizations and cases of discrimination, harassment, or unequal treatment can create an unfavourable environment for female civil engineers, which can negatively affect their motivation and job satisfaction, and even lead to them leaving the profession. In this context, it is important to note that there are significant salary gaps between men and women in the civil engineering sector (Manesh et al., 2020; Shrestha et al., 2020).

3 CONTENTS OF THE GUIDE

The guide delves into this mainstreaming, proposing the inclusion of gender perspective through the implementation of actions in all stages of teaching: teaching methods, teaching dynamics, evaluation, and content. One of the main innovations it brings is the addition of four levels of complexity of the actions to be implemented: fundamental, easily applicable, advanced, and expert.

3.1 General recommendations for teaching with a gender lens

The gender lens may be introduced through actions in four basic pillars: teaching methods, teaching dynamics, assessment, and content. Furthermore, the actions that can be taken may cover four different levels (see Figure 1).

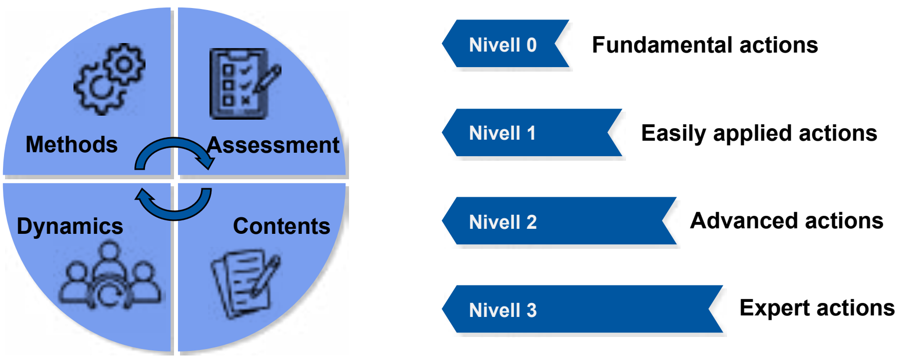

Fig. 1. Structure of the contents of the guideline

Below are general teaching recommendations for each of the pillars:

- Teaching methods: that different backgrounds will result in diverse prior experiences and knowledge. Therefore, based on this, the more diverse the classrooms are (including women, for example), the more varied teaching and learning methods must become – otherwise, the majority group will become dominant and privileged. This emphasis on using varied teaching and learning methods is not just a matter of inclusion. Although active and cooperative learning experiences are inclusive, they are also recommended as strategies to improve learning and motivation for all students, regardless of their characteristics (e.g., gender, socio-economic status, cultural background, prior knowledge, etc.).

- Teaching dynamics: when a gender perspective is applied to teaching dynamics, it implies a reflection on the dynamics that occur in the classroom and in the learning environment. It is important to consider these dynamics to ensure that they are equitable and respectful of diversity. This involves being aware of power relations, promoting inclusive participation, encouraging dialogue and collaboration, and fostering a supportive and inclusive atmosphere where all students feel valued and respected. Some strategies to achieve this include: encouraging students to reflect on their own assumptions and biases, promoting inclusive language and communication, providing opportunities for students to share their experiences and perspectives, and creating a safe and supportive learning environment where all students feel comfortable expressing themselves and participating actively in discussions and activities.
- Assessment: assessment is a crucial aspect of teaching and learning, as it provides feedback on students' progress and achievements and informs future teaching and learning activities. When applying a gender perspective to assessment, it is important to ensure that assessment tasks are fair, equitable, and inclusive of all students. This involves using a variety of assessment methods that allow students to demonstrate their learning in different ways, considering students' diverse backgrounds and experiences, and avoiding bias and stereotypes in assessment tasks and criteria. Some strategies to achieve this include: using a mix of assessment methods (e.g., essays, presentations, projects, exams, etc.), providing clear and transparent assessment criteria and expectations, offering opportunities for students to receive feedback and improve their work, and being mindful of the language and examples used in assessment tasks to ensure they are inclusive and respectful of diversity.
- Content: content refers to the subject matter or material covered in a course or curriculum. When applying a gender perspective to content, it is important to ensure that the content is inclusive, representative, and relevant to all students. This involves integrating gender perspectives into the curriculum and course materials, highlighting the contributions and experiences of women and other underrepresented groups in the field, and addressing gender-related issues and topics in the subject matter. Some strategies to achieve this include: including diverse perspectives and voices in readings and case studies, using examples and illustrations that reflect the diversity of the student body, and exploring gender-related topics and themes in the curriculum. Additionally, it is important to provide opportunities for students to critically reflect on gender-related issues and to engage in discussions and activities that promote awareness and understanding of these issues.

3.2 Specific recommendations for teaching with a gender lens

The specific recommendations related to content are given grouped as shown in Figure 2.

Fig. 2. Organisation of recommendations given for content

3.2.1 Basic subjects

This group of subjects encompasses competencies and content of basic training subjects, namely mathematics, physics, chemistry, and business and legislation. Mathematics is fundamental for structural analysis, force and motion calculations in structures, and the study of hydraulics. Physics is used to understand the fundamental principles of material and fluid behaviour, while chemistry is important for understanding material reactions, properties of construction materials, or water treatment processes.

Despite these subjects appearing gender-neutral at first glance, it is crucial to recognise that gender inequalities can manifest within these areas, influencing participation, academic performance, and student perceptions. Hence, it is important to introduce such issues from the beginning, gradually raising students' awareness throughout their studies. While topics like differential equations or the first law of thermodynamics are gender-neutral, technical content can be taught in different ways, considering gender, learning environment, types of assessment, teaching methods, etc. Additionally, although the theoretical basis remains unchanged, the examples used to illustrate it and the projects proposed in class can be more inclusive than those traditionally used in engineering classrooms.

3.2.2 Scientific and technologic subjects

The scientific and technological group of subjects focuses on applying scientific principles to engineering problems. Subjects like hydraulics emphasise real-world challenges, such as providing clean water access, particularly in rural areas where women often bear the burden of water retrieval. Implementing water distribution networks could greatly improve quality of life and gender equality by relieving women of this responsibility and allowing them to engage in other activities. In addition to technical considerations, it is crucial to consult affected communities to ensure interventions align with their needs and perspectives.

Furthermore, disciplines like materials resistance and geotechnics address gender-related factors in engineering design and analysis. For instance, considering how gender inequalities may affect terrain or landslide risk perception and responses can lead to more inclusive and effective solutions. The integration of gender perspectives extends to statistical analysis and spatial techniques, aiming to uncover hidden disparities and improve decision-making processes.

3.2.3 Applied technologies

This group of subjects encompasses subjects directly applicable to the profession, focusing on specialised content in various areas such as civil engineering and construction, including structures, water, and transportation/urban planning. For instance, within the realm of structural engineering and foundations, the emphasis lies on designing and calculating structures supporting different types of buildings and infrastructure, with a unique opportunity to delve into techniques ensuring safety, reliability, and sustainability. Incorporating a gender perspective in the conception and construction of structures and foundations is highlighted to ensure projects address diverse population needs, promoting equitable and safe access to buildings and infrastructure. Activities like debates and practical cases, such as the Citicorp Center's structural issues and seismic vulnerability, underscore the importance of understanding gender implications in engineering and fostering discussions on integrating gender perspectives in design, calculation, and construction processes.

Furthermore, in water technology and transportation, mobility, and urban planning, the significance of considering gender perspectives in addressing water management, transportation infrastructure, and urban planning challenges is emphasized. By analyzing gender dynamics, especially concerning travel patterns and access to resources like water and transportation, engineering education aims to design inclusive solutions responsive to diverse population needs. Practical cases, like designing water supply systems for rural communities with a gender focus, highlight the importance of equitable access to resources and involving communities in the design process. Debates on gender perspectives in public and private transportation usage aim to explore challenges women face in daily mobility and discuss strategies to enhance gender inclusivity in transport planning and policy-making, fostering collaboration among various stakeholders to integrate gender perspectives effectively.

3.3 Recommendations for doing research with a gender lens

To encourage students to conduct gender-sensitive research, it is essential to integrate aspects of research into teaching. Various methods can be employed to introduce research and its connection with gender in the classroom, such as showcasing research projects and practical cases that have considered gender implications in the field of civil engineering. Additionally, fostering critical reflection on gender biases in civil engineering and how they can affect professional and research decisions is crucial. Supporting research with a gender perspective, whether in academic assignments or final projects, is also vital. It is important to identify the level at which gender aspects are being introduced into research projects, with considerations ranging from blindness to transformation. However, while not all research can be transformative, this shouldn't serve as an excuse to limit gender-sensitive analysis.

Incorporating gender perspective throughout all stages of the research cycle, from conceptualization to analysis, report writing, and conclusions, is crucial and should not be left until the end of the research process, as is often the case. Various conceptual frameworks have been developed to integrate gender considerations into projects, including the Harvard Analytical Framework, Moser's Framework, Gender Analysis Matrix, and others. Integrating gender perspective into research design from the outset is emphasized to fully realize its potential, considering gender as an analytical category or variable rather than the sole focus of research.

Considerations at different stages of a research project include identifying research areas and generating ideas, defining research objectives, conducting research, drawing conclusions, and dissemination. Strategies such as using gender-sensitive methodologies, participatory approaches, and considering gender-specific risks are recommended. Additionally, it is crucial to report data sensitively, analyze gender implications, propose recommendations to address gender biases, and use inclusive language in reporting and dissemination.

Moreover, in various types of final degree projects, such as construction projects, laboratory experiments, simulations, and literature reviews, specific recommendations are provided to integrate gender perspectives effectively. For example, in construction projects, factors like accessibility, lighting, comfort, and signage should be designed considering the needs of all users, while in laboratory experiments, attention should be paid to ensuring equal participation of all students to enrich their learning experiences. Overall, integrating gender into research projects not only benefits the research outcomes but also inspires students and contributes to a more inclusive academic environment.

4 SUMMARY AND ACKNOWLEDGEMENTS

This article presented a guideline from the Xarxa Vives guides that promotes integrating gender perspectives into civil engineering education. This approach aims to create a more inclusive learning environment and address gender disparities in the field.

The guideline suggests incorporating gender considerations throughout the curriculum, from teaching methods and classroom dynamics to assessment and course content. It emphasizes using diverse teaching methods, fostering respectful dialogue, and employing fair assessments.

The content itself should integrate the contributions of underrepresented groups and address gender-related issues within civil engineering. Specific examples are provided on how to consider gender in various subjects, like water access projects and transportation planning.

Finally, the guideline encourages research with a gender lens. This includes supporting students in conducting gender-sensitive research projects and integrating gender considerations throughout the research cycle.

The authors are grateful for the financial support of the BSSC Conference Support Fund to attend the SEFI2024 conference. The authors are also grateful to Xarxa Vives for the opportunity to contribute to the collection of guidelines and present it in this conference.

ABSTRACT

Higher Education Institutions (HEIs) face the ongoing challenge of effectively engaging students in the learning process. Traditional methods often fail to fully capture students' attention and foster the necessary entrepreneurial skills for their professional development. This paper presents a new method of engaging students in a university study module and discusses the results of a student survey. A novel Financial Investment Method (FIM) is introduced to enhance student engagement in a graduate course and to develop their entrepreneurial mindset, critical thinking, and overall attentiveness. The survey was conducted to evaluate the impact of FIM on student learning, competency development, and skill acquisition. Of the students who participated in the course, 91% responded to the survey, totalling 53 respondents from three study programs. The survey included both open-ended and closed questions. The results revealed that students were familiar with engagement methods such as group work, team-building sessions, active discussions, and checkpoint presentations. Most importantly, the survey indicated that the new Financial Investment Method increased students' attention and concentration during the course. Although some students did not perceive significant added value, a majority (73%) recommended its continuation in future courses.

1 INTRODUCTION

1.1. Student engagement methods

In recent decades, Higher Education Institutions (HEIs) have experienced a paradigm shift in which students became partners in the learning community rather than 'consumers' (Robinson 2012). This shift has encouraged HEIs to develop new student engagement practices and support students' involvement in educational processes. Since then, many scientific works have been published exploring the phenomenon and proposing various methods to increase student engagement (Tight 2020). In this study, the definition of student engagement is adapted from Bond et al. 2020: *"Student engagement is the energy and effort that students employ within their learning community, observable via any number of behavioural, cognitive or affective indicators across a continuum. It is shaped by a range of structural and internal influences, including the complex interplay of relationships, learning activities and the learning environment. The more students are engaged and empowered within their learning community, the more likely they are to channel that energy back into their learning, leading to a range of short- and long-term outcomes."*

There are three commonly recognized dimensions of student engagement: behavioural, emotional, and cognitive(Bond et al. 2020). Behavioural engagement involves observing students' actions and behaviours in the learning environment. Emotional engagement pertains to students' reactions and attitudes towards learning. Cognitive engagement examines the mental effort students invest in learning activities. Ideally, strategies to enhance student engagement should encompass all three aspects.

One of the most effective methods for student engagement, which significantly increases students' focus during group work, is peer assessment. (Weaver and Esposto 2012). To date, several studies have analyzed the impact of peer assessment on the learning process (Li et al. 2020). Specific peer assessment methods have been introduced to higher education (HE) engineering students by Conde et al. 2017, O'moore and Baldock 2007, and Dominguez et al. 2012.

Conde et al. 2017 proposed a method based on *Moodle Workshop,* which includes a workshop tracking panel with setup, submission, assessment and grading phases. The method improved student's participation in assignments, their motivation and even increased their grades. O'moore and Baldock 2007 introduced a method called "Peer Assessment Learning Sessions (PALS)" that using peer assessment enable frequent, efficient and timely evaluation of large student groups. The method was tested in several courses for Civil Engineering students and received 75-90% of the students recommendations to be extend further. Dominguez et al. 2012 also worked with Civil Engineering students and proposed an online peer assessment algorithm using commonly known tools such as *Google Docs*. Their study highlights the importance of good preparation and supporting guidelines for similar methods.

However, there is still a lack of quantitative and experimental studies examining the assumptions and practical implications of such approaches (Double, McGrane, and Hopfenbeck 2020). Moreover, student engagement can manifest in various shapes and forms, so there is no doubt that introducing unconventional, novel pedagogical approaches or techniques that spark surprise and interest, and thus engagement, is beneficial.

1.2. Entrepreneurial education of engineers

In the fast-developing world, engineering students are generally expected to develop their entrepreneurial skills and innovative thinking. Entrepreneurial education (EE) is a type of education that aims to develop students' entrepreneurial intention (EI). Numerous researches have been carried out on the contribution of education in fostering an entrepreneurial mindset in society, i.e. how EE impacts EI. This raises an important question: can entrepreneurship be taught? Some authors, such as Mueller (2011) and Packham et al (2010) argue that the impact of EE on IE is strongly positive. However, for others, such as Colette et al (2005) and Matlay (2005) this effect remains unclear. In any case, as noted by Sun et al (2016), Lortie and Castogiovanni (2015), and Nabi et al (2016), there is a lack of research on the exact mechanism on how specific educational components enhance EI in students.

Academic EE research is usually aimed at secondary school or business school students, and rarely at students from HEIs. As noted by Mäkimurto-Koivumaa and Belt (2016), this type of education is difficult to implement in engineering study programs, due to the fact that it is easier for lecturers to impart only engineering-specific technical knowledge, leaving less space for entrepreneurial education.

For this reason, Sun et al (2016) conducted an extensive investigation with engineering students on the influence of various education components (know-what, why, who and how) on the three EI areas (or determinants), namely entrepreneurial attitudes, social norms and self-efficacy. The influences were studied on the basis of the Theory of Planned Behaviour (TPB).

Similarly, Barba-Sánchez and Atienza-Sahuquillo (2016) investigated the EE and EI in the case of engineering students, and the results revealed that, among the possible motivations for acquiring EI (need for independence, need for achievement and financial motivation), the need for independence was the most important. Furthermore, the study confirmed the positive effect of EE on students' EI, presumably due to increased self-efficacy. Finally, the authors provided some guidelines on how to improve the EE effect on engineering students including engineering start-up exhibitions, idea generation workshops, business plan creation workshops and organization of inter-university business plan competitions.

Mäkimurto-Koivumaa and Belt (2016) also discussed effective ways of implementing EE in university engineering programs, suggesting a framework in which various aspects of EE are emphasised in the later years of the study program. Action-based learning activities are recommended in the first year to foster personal growth and boost the entrepreneurial mindset. Gradually, in the later years, once students have a basic knowledge of engineering, specific business and entrepreneurship content can be included in related courses.

From the reviewed literature, it becomes clear that encouraging EI through EE in HEI's engineering study programs is still a challenge. Therefore, this paper presents an investigation on the effectiveness of action-based learning activities on the learning outcomes and entrepreneurial mindset of Civil Engineering students.

This study introduces a novel Financial Investment Method, which allows students to invest virtual funds, under a specifically described set of rules, into other students' work based on their initial plan and pitch presentations. In turn, they can earn benefits at the end of the course if their investments prove to be sound. This method was created to engage students and maintain their interest in the work of their peers, as well as foster creative solutions to engineering problems and students' EI.

This paper describes the Financial Investment Method and provides results of a questionnaire survey from graduate students.

2 METHODOLOGY

2.1 The Financial Investment methodology pilot

This study introduced and evaluated a novel method designed to enhance student engagement by incorporating a financial investment element into an educational setting. The method was applied in a course titled "Research Project 1", designed to provide graduate students with the knowledge and research skills to analyse a problematic Civil Engineering task (Fig. 1). During the course, student teams tackled problem-based research challenges on topics such as energy efficiency, novel building materials, structures, construction management and indoor climate. The process involved several stages: defining the research problem, formulating hypotheses and questions, reviewing relevant literature, developing methodology and research design, and preparing and presenting a research article. In addition, the learning outcomes of the course included critical interpretation of research results (from literature analysis to result processing); application of the interactive process to research problem solving; learning to present research work in various formats: oral, research paper, poster presentation. Oral presentations were given in two formats: brief pitches and a poster session at the end of the course.

Fig. 1. Student participants of "Research Project 1" course who took part in Financial Investment Method testing.

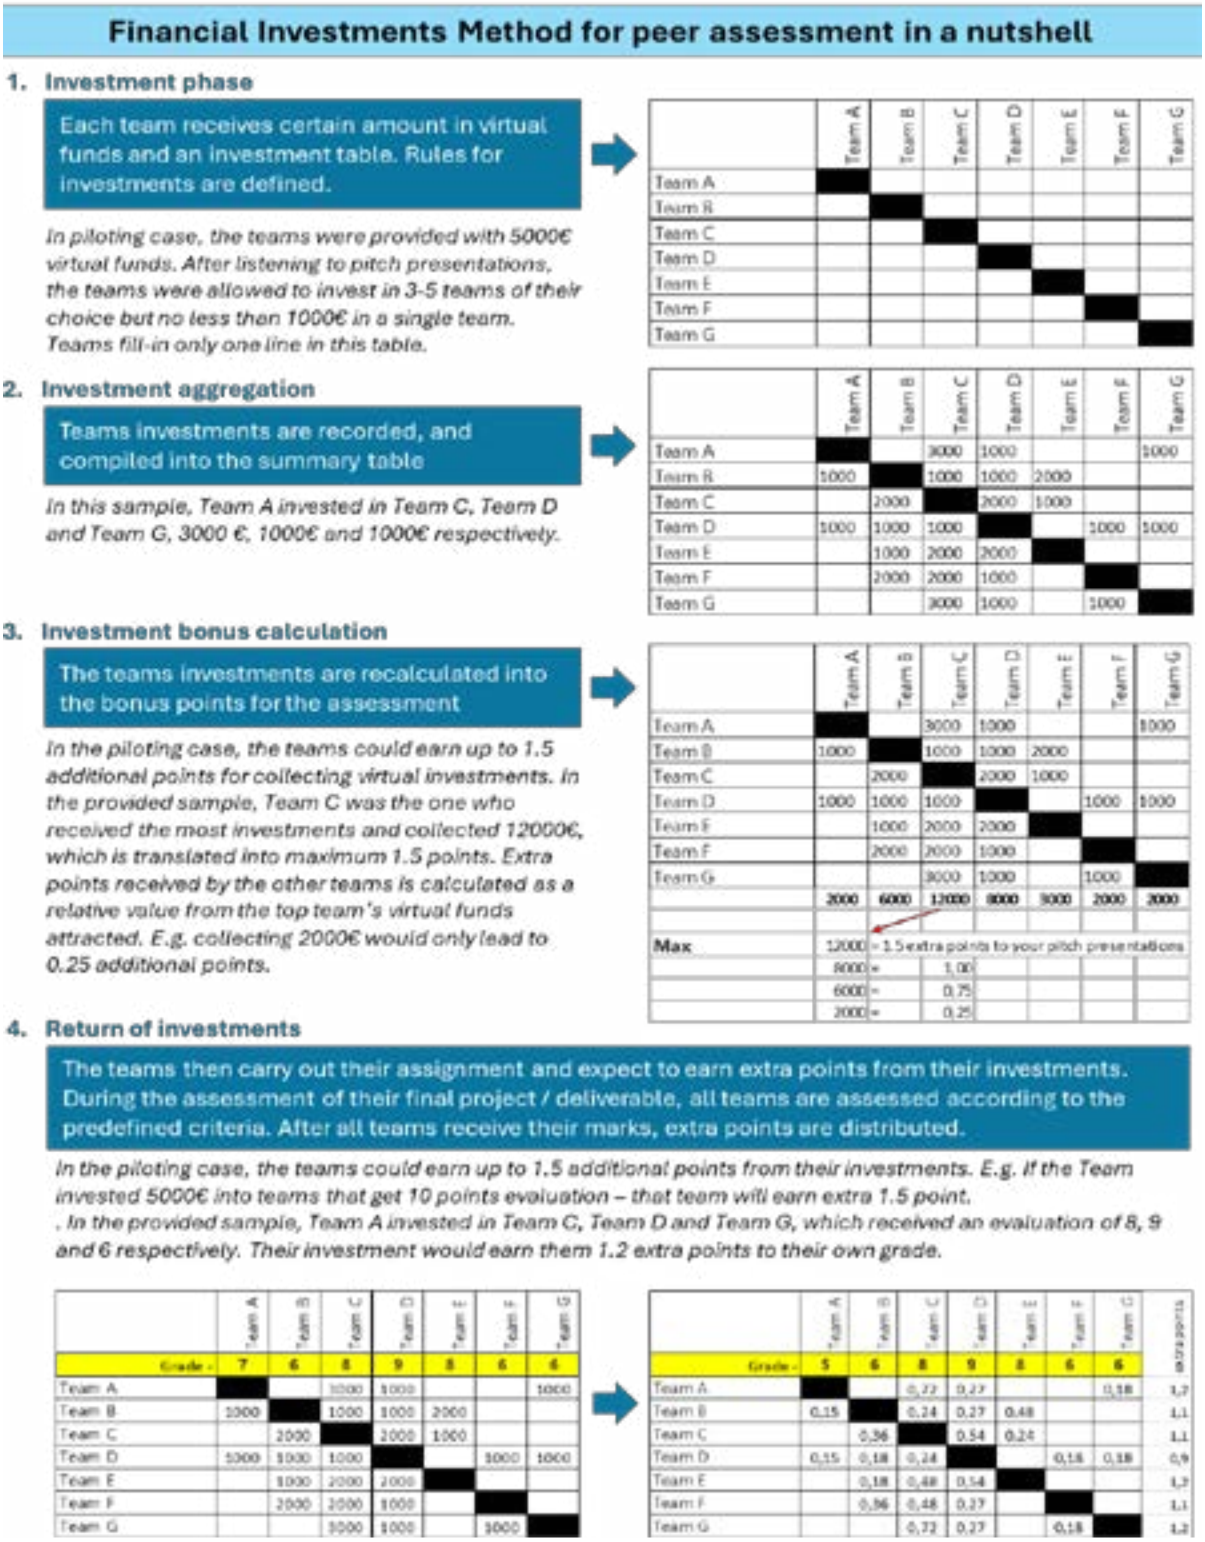

Fig. 2. Financial Investment Method for peer assessment: Implementation workflow with sample calculations

The course included 15 teams (3-5 students per team) from three Civil Engineering master's programmes. After a literature review and definition of their research problem, the teams developed their methodology and research design, leading to a checkpoint where each team presented a 7-minute pitch. These pitches outlined the research problem to be addressed, literature review findings, chosen research methodology, and expected results.

To encourage greater engagement, a Financial Investment Method was introduced, where student teams were given "virtual funds" to invest in other teams based on pitch presentations. This approach aimed to develop students' entrepreneurship, communication skills and critical thinking. It encouraged them to ask insightful questions, particularly about other teams' research plans, and to assess their validity and expected results. The Financial Investment Method had a twofold benefit for the teams. Attracting investments translated into additional points for the pitch presentation evaluation. Therefore, the more investments a team managed to attract, the more bonus points it received for the pitch presentation assessment. On the other hand, successful investments could earn points in the long run - for the subsequent evaluation of their research paper. This innovative methodology, which to the authors' knowledge has not been used before in engineering education, is depicted in Figure 2.

It is worthwhile to note that the main strength of this method lays on the fact that it engages the students through all three dimensions described in Section 1.1: cognitive engagement is achieved when evaluating the research of other teams; emotional engagement takes place when students have to "sell" their own research in an attractive way to their peers; behavioural engagement is addressed in the process of deciding the investments towards the other teams. In this way, Financial Investment Method is suggested as a powerful tool to deeply engage the students in the learning process.

2.2 Questionnaire survey methodology

A total of 58 students took part in Research Project 1 course. The course was completed in January 2024 and the survey was carried out immediately after the completion of the course. A total of 53 participants took part in the survey, with 91% participation rate. The questionnaire included both open and closed-ended questions, ensuring that both quantitative and qualitative analysis can be performed.

3 RESULTS

3.1 Familiarity and effectiveness of student engagement methods

A questionnaire was provided to students who participated in Research Project 1. The first part of the questionnaire aimed to evaluate their previous experience with student engagement methods and didactics aimed to strengthen their entrepreneurial mindset, and the results are provided in Figure 3. Students indicated that, so far, they had been mostly exposed to engagement methods such as group work, team-building sessions, active discussions, and checkpoint presentations where they had to present their progress to their peers and lecturers. The three dimensions of student engagement mentioned earlier (behavioural, emotional, and cognitive) were also reflected in the results. For example, over 40 % of students selected that they had experience in group work and team building – this can be attributed to the behavioural dimension. Group work and team building encourages students to actively participate and collaborate with others, fostering face-to-face communication and collaboration with colleagues. "Active discussions" were also highly ranked in the questionnaire and it can be assigned to all three dimensions. It not only encourages student participation, but also motivates to engage in the discussions, exchange ideas and analyse, which are clearly related to the cognitive dimension.

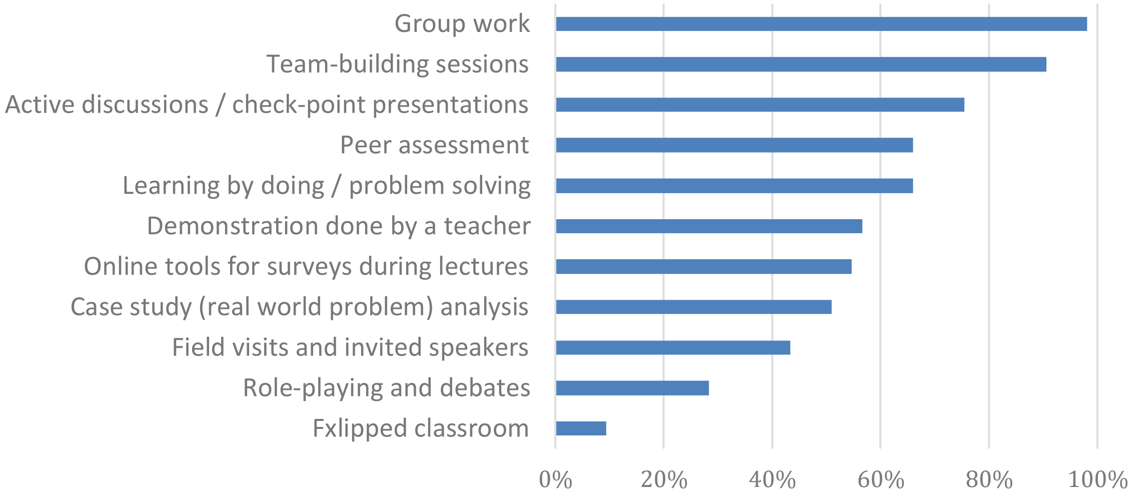

Fig. 3. Results of the questionnaire survey indicating students' familiarity with engagement methods and didactics.

The survey also asked students to indicate which factors contributed most to their engagement during the lectures (see Figure 4). The results revealed that ~80% of the students agreed or strongly agreed that all of the listed engagement methods were effective. The most effective methods were the clarity of content and the use of visual aids. Moreover, students indicated that they were least affected by interactive elements in the classroom, such as online surveys during lectures. They also noted that the variety of engagement methods was not that important.

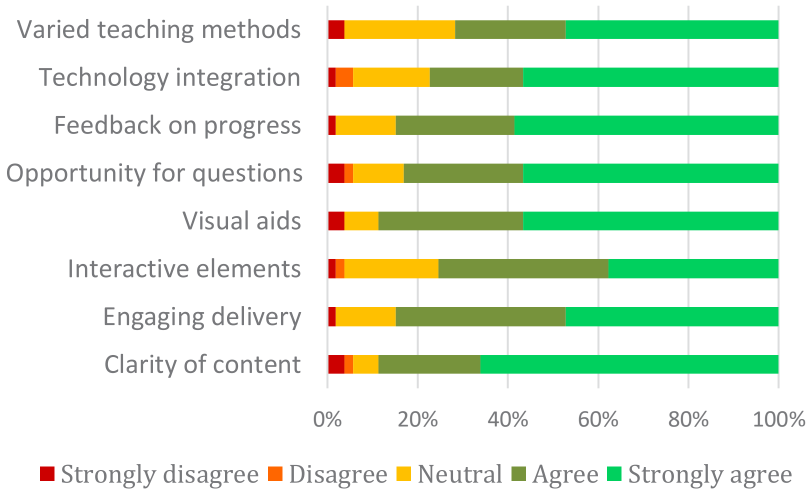

Fig. 4. The importance of factors for engagement in lectures

From a wider perspective, Figure 5 shows the effectivity of the various applied engagement methods in enabling students to acquire the learning outcomes of "Research Project 1". According to the surveyed students, the most effective ones were active discussions and checkpoint presentations in class. They further noted that the initial team-building session and the Financial Investment Method were the least important contributors. However, it is worth noting that the learning outcomes of this course were primarily focused on the development of research competencies, which include conducting systematic literature review, research design preparation, research implementation and presentation in various formats. The benefits of Financial Investment Method are discussed in the next subsection.

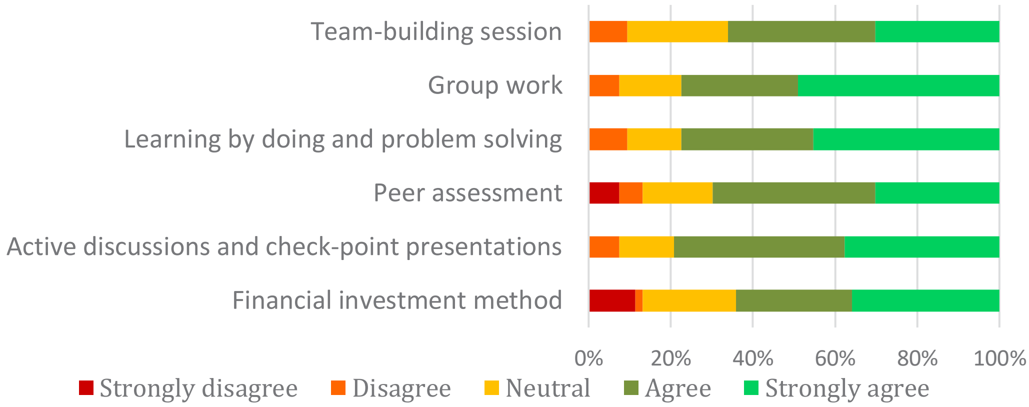

Fig. 5. Engagement method contributed to the achievement of learning outcomes

3.2 The impact of Financial Investment Method on students' learning

In the questionnaire students were asked to evaluate the Financial Investment Method and to indicate which skills it helped to strengthen the most (Fig. 6). More than 50% of the students indicated that the method has made a significant contribution to their skills, with the biggest impact being the increased attention during peer presentations. Only a few students indicated that method did not contribute to their respective skills.

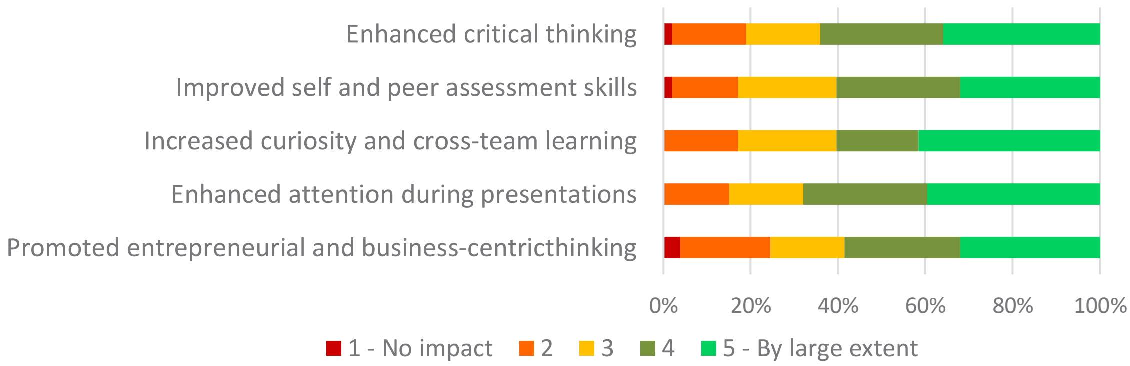

Fig. 6. Contribution of the Financial Investment Method towards skills and competencies

Table 1. Overall experience with the student engagement through financial investments methodology and its impact on learning

Category of responses	**Percentage of responses**	**Summarized comments**
Positive	62%	*Helped to be more active; Encouraged to perform better and pay more attention to presentations; A good method to better prepare for pitch; A new method encouraged to put more effort into preparation for the lecture and to be more active.*
Neutral	21%	*No comments were provided*
Negative	17%	*New method was a little bit confusing, could have been explained better; The methodology of financial investments did not engage*

		me in the course; Really good and interesting method, but it did not increase my engagement.

The survey also included open-ended questions where students could comment on their choices. Table 1 presents a summary of the students' comments, classifying their responses into positive, negative, and neutral categories. As can be seen from the table, 62% of the students responded that this method positively affected their learning, and only 17% of the respondents felt that the method was not well communicated or did not contribute significantly to the learning outcomes of the course.

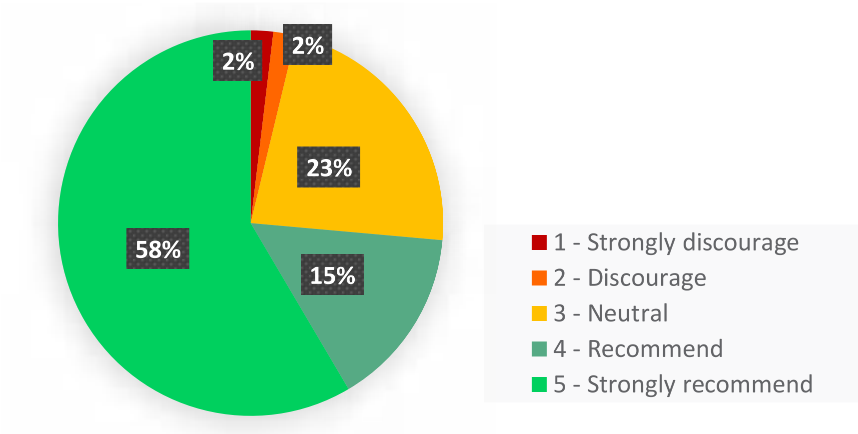

Fig. 7. Student feedback on the recommendation of the Financial Investment Method for the upcoming semester of the "Research Project 1" course.

Although some students did not support the Financial Investment Method, the vast majority would endorse its inclusion in the next semester's course of the "Research Project 1" (Fig. 7). 73% of students would recommend or strongly recommend incorporating this methodology, demonstrating overall satisfaction with this innovative approach for peer assessment that fosters entrepreneurial mindset, and enhances engagement.

This study provides empirical support for the findings presented by Motta and Galina (2022), which underscore the importance of diverse pedagogical methods to enhance student engagement and foster an entrepreneurial mindset. According to Motta and Galina, there has been a significant increase in scholarly attention towards experiential learning methods, as evidenced by the rise in publications on the topic between 2015 and 2019. This trend suggests a growing recognition of the need for innovative engagement strategies in educational settings.

4 SUMMARY AND CONCLUSIONS

- The literature review demonstrated that student engagement methods increase students' focus on courses. A novel Financial Investment Method was introduced in the course to engage students and foster entrepreneurial thinking.
- Over 50% of the students indicated that this method contributed significantly to their skills, with the biggest impact being an increase in their attention during peer presentations.

- The majority's endorsement for integrating the Financial Investment Methodology in future courses (73%) underscores its perceived value in enhancing peer assessment and fostering an entrepreneurial mindset, although refining communication and addressing concerns are necessary to optimize effectiveness and ensure maximum benefit for all students.

ABSTRACT

Reflection is generally considered a key part of learning, enabling the student to clarify their understanding, embed knowledge and identify gaps in proficiency. In this regard it is also a potentially important tool to support lifelong learning. Reflective practice is however often an assumed competence, not always explicitly taught or encouraged. In this work we investigate student attitudes and experiences of reflective practice.

Two groups of students were asked to identify why they feel reflective practice should (or should not) be part of the curriculum while also identifying hurdles to implementation, together with tools and tips to support students in adopting reflection. This was achieved via debate and guided small group work.

Results showed students generally appreciated the benefits of reflective practice.

There was however concern that it might add to the student workload and that less motivated students would not engage. Debates on whether the technique should be compulsory and assessed produced mixed results.

Interestingly, the students interpreted reflection in a very wide sense and wider than might be expected in conventional academic discourse, going beyond reflecting on immediate academic content to reflecting on mindsets, well-being and learning environments. Students expressed concerns however over reflection being another topic to learn, adding load into the curriculum and one difficult to adopt among students otherwise preoccupied with technical methodologies.

1 INTRODUCTION

With an increasingly rapid evolution of the engineering profession, future engineering graduates need to be committed to continuous or lifelong learning and need to able to take responsibility for their own professional development. It is undeniable that continuous development of skills and competences is essential for fostering their employability and career perspectives (Kövesi and Csizmadia 2016). Consequently, to have a successful professional life, they are required to improve their learning effectiveness through their future career (Martinez-Mediano and Lord 2012). Despite its importance, reflective practice is often considered as an inherent or implicit competence so generally not explicitly taught and implemented in the engineering curricula. In the present work, we aim to investigate students' perception about

(1) the implementation of reflective practices into their curriculum and

(2) the possible supports for teaching and learning reflective practice in the most efficient and adapted way.

2 THEORETICAL BACKGROUND

We consider reflective practice as a central element of continuous learning allowing engineering students and graduates to transfer their current practice into different situations or to develop it into future practices. Accordingly, we define reflective practice as "practice which involves the development of learning and understanding through self-review to help determine progress against goals and future learning needs" (Thomson and Kövesi 2023.1). To ensure future engineering graduates have the ability to meet future learning needs, it is particularly important to put emphasis on the development of reflective practice.

We distinguish, based on the work of Bailie et al. (2021), four different interpretations of reflective learning by educators concerning the development of students' (1) professional practice, (2) professional identity, (3) critical consciousness and (4) critical view on the course content. These qualitatively different conceptions indicate the relevance of reflective practice both in educational and professional context in the view of a long-term perspective. According to the empirical study of Baruah et al. (2017), reflective practice is essential for engineering students' personal and professional development. On the one hand, this gives a better understanding of their career aspirations (by the development of professional practice and identity). On the other side, it is useful for identifying eventual competence gaps resulting a better engagement in their courses (by the development of critical consciousness and critical view on the course content).

As mentioned earlier, despite its widely recognised benefits (Menekse et al. 2022, Howell 2021), in most engineering schools reflective practice is not traditionally implemented in engineering curriculum (Sepp et al. 2015). We notice that even if reflective practice is usually integrated into human and social sciences disciplines' curriculum, it is increasingly being implemented in STEM curriculum (Boswell 2023) during the last decades. For Badenhorst et al. (2020, p. 12), integrating reflective learning into engineering curricula allows engineering students to enlarge their vison "to bridge the more technical aspects of their work with a more socially aware professional identity as it expanded their notions of what it is to be an engineer".

The main obstacles for the implementation of reflective practice are at the institutional level, related to the lack of space in the current curriculum or/and the lack of time for the development of new innovative programmes. In addition, it often requires reformulating the traditional curriculum and finding a new balance between the practical and theoretical training (Miranda et al. 2022). We notice also that the implementation of reflexive practice could be challenging for educators (Bailie et al. 2021), especially in STEM disciplines where educators have mainly technical and scientific background and teaching reflective thinking could cause difficulties (Nilsson 2013). For educators, it is not evident to engage and preserve (i.e. avoid their disengagement) students in the reflective activities, to help them to make a link between theoretical and practical knowledge or to find the right balance between students' guidance and autonomous work (Miranda et al. 2022).

Even with a strong technical interest and focus on their engineering studies, students have widely recognised the usefulness and various benefits of implementing reflective practice into engineering curriculum (Howell 2021) as well as they were aware of the importance of being able to reflect in their future professional life. However, the empirical results of Eshuis et al. (2022) indicate an interesting contradiction with students' perception concerning the more frequently used reflections activities (e.g.: journals, reports, essays, portfolios, logs,…) which are considered less worthwhile or meaningful in the educational context. This contradiction raises the question about the more adapted and meaningful tools or dispositives to support reflective learning. This is an interesting question in the context of an increasing digitalisation as the development of new and innovative tools (like e-learning or AI tools) and supports could be a good solution to this contradiction (Baruah et al. 2017).

3 METHODOLOGY

To elicit student views on the theme of reflection as part of the learning process a mixed approach involving small group work on key questions was supplemented by a more open debate type approach.

3.1 Participants

We recruited two sets of students for this work on based on their interest in the topic and motivation to learn more about it.

The first group was recruited in parallel with the European Students of Industrial Engineering and Management (ESTIEM) meetings held in Budapest in November 2023. This group consisted of 15 participants from ESTIEM with a background in Industrial Engineering, 6 male and 9 female. These were drawn from various European countries including Austria, Spain, Italy and Portugal.

The second set were drawn from students of the Budapest University of Technology and Economics (BME) within the framework of the Environmental Economics course. These students were drawn from a mix of engineering, business and management disciplines and consisted of 21 students, 10 male and 11 female. This group composed a mix of Hungarian, American, French, German, Turkish and Italian students.

For both workshops, participant recruitment and selection were on voluntarily basis. For the ESTIEM group, students could choose from various parallel programs including the reflective practice workshop. For the second group, the participation was encouraged by exempting them from submitting one of course requirements. All participants verbally consented for the workshop results to be used in our research.

3.2 Approach

The workshops followed a procedure initially developed to solicit views and opinions among teaching staff on reflective learning with their students (Thomson and Kövesi 2023.1). The workshop began with a 15-minute introduction to the topic of reflective practice (e.g.: definition, applied methods, evaluation, etc.) building on Bloom's cognitive taxonomy. For the guided discussion, student sets were broken down into groups of 3 to 5 students who were then asked to discuss and suggest answers to:

- Why they feel reflective practice should (or should not) be part of the curriculum
- What hurdles are there to implementation
- What tools could support the adoption of reflective practice
- What tips could they suggest to support students in reflection.

To support this, guidance sheets and post-it type notes were provided to the groups to enable free flowing collation of thoughts and ideas (Figure 1).

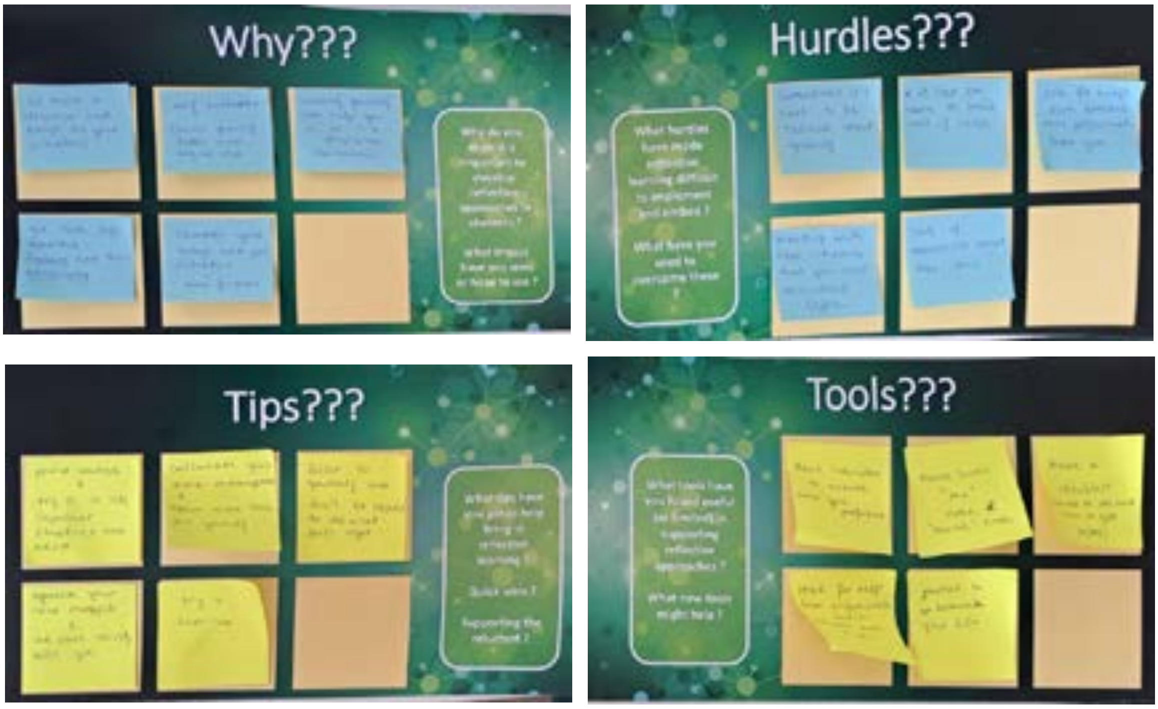

Fig. 1. Exemplar guidance sheets completed by a student group as part of this work to highlight their thoughts on reflective practice.

The student were also encouraged to debate the topic within their larger sets. These debates were set-up with the more general titles of “Should we formally evaluate (mark) reflective practice?” and the closely related “Should we make reflective practice obligatory?”. Out of the four teams, two were assigned the same question - one team to argue in favour, one to argue against it. Each team had the time to present their arguments then they could engage in a discussion with the other team. The debate was followed by a voting process using Kahoot platform where the observing teams voted who won the debate and why. The workshop concluded with feedback round for closure.

3.3 Data analysis

Data was collected through notes, photos and sound recordings taken during the workshops. The recorded discussions were transcribed, and the coding of tables was independently carried out by the authors. The results were discussed, and the differences resolved collectively at the end.

4 RESULTS

4.1 Worksheet result

Results of the work on the worksheet questions can be seen summarised in Figs. 2-4.

Within the tools section (Fig. 2) students single biggest resource in relation to self-reflection tools was to talk to others with notes recorded such as *“Ask for feedback from people close to you”, “Talk to someone (who knows you or the topic)”*. It was notable from some of the responses that the interpretation of self-reflection by the students went beyond that related to understanding of the topic at hand and into a wider and more holistic approach to the learning process. This can also be seen by the relatively high numbers of self-care notes recorded and comments such as "*be good to yourself*", "*self-compassion*". This wider interpretation was not something noted to the same extent in work on reflection with academic staff considering their engagement with students on this topic Thomson and Kövesi (2023,1 & 2).

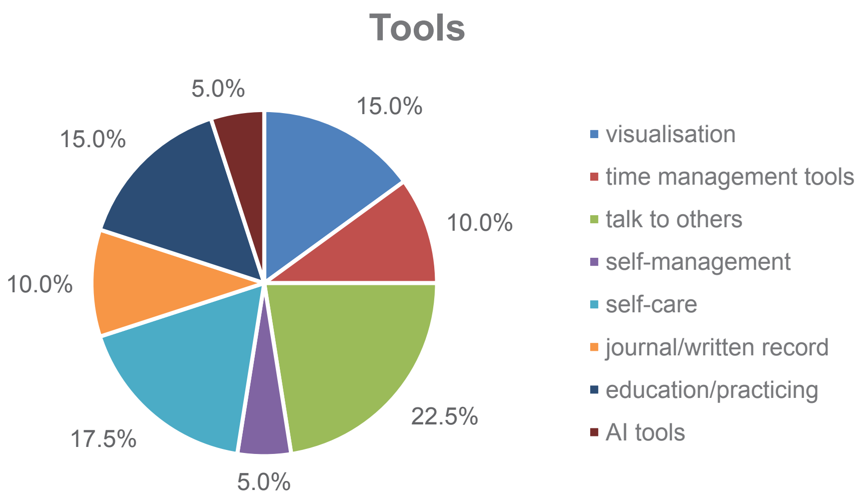

Fig. 2. Tools which students feel would aid reflective practice.

A number of issues were identified by students as hurdles inhibiting the take up of reflective practice (Fig. 3). The most common comments related to finding the time and motivation in an already dense curriculum – *"students unwilling to learn , focused in other areas, tiring routines, no interest in subject"*. The other key issue was reflection being seen as opening up personal weaknesses and worries to themselves or others – *"Afraid to face the truth", "Don't want to hear judgements of other people", "Emotions"*.

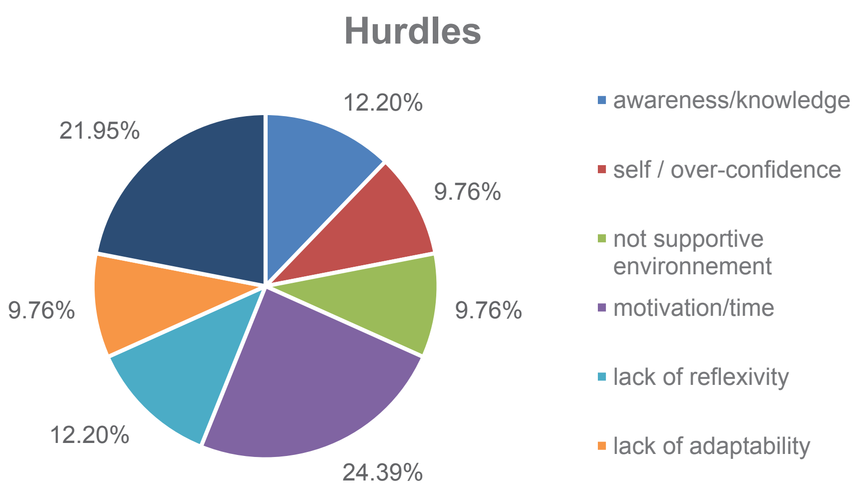

Fig. 3. Hurdles which students feel inhibit reflective practice.

Students had a number of tips to support peers in their uptake of reflective practice (Fig. 4). Again, the students raised the importance of the wider learning environment.

Comments included those related to both how physical environments support a positive approach - *"Clean the environment around you to clean your mind too"* while others addressed anxiety about reflection being associated with self-criticism *"Don't be too hard on yourself"*.

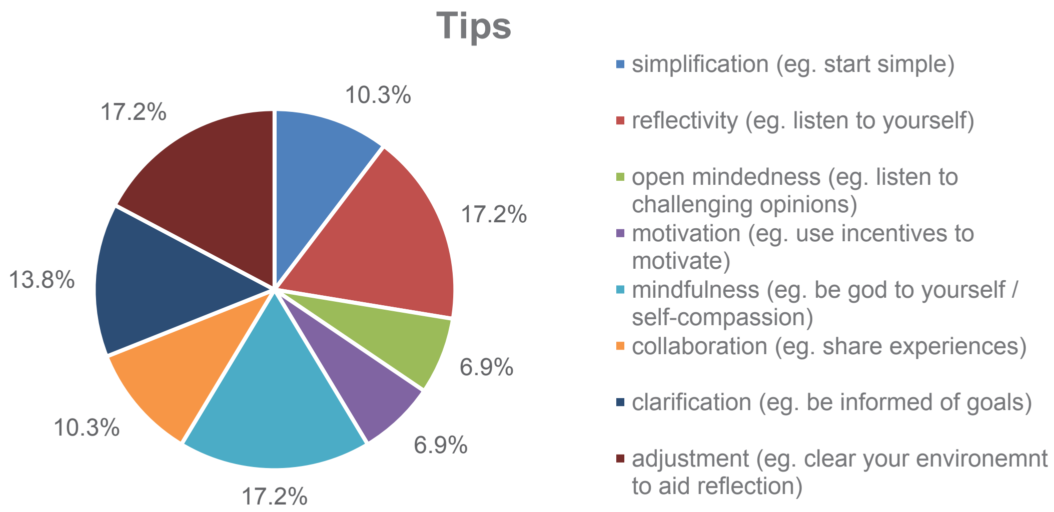

Fig. 4. Tips which students feel support reflective practice.

Students were also asked about whether they felt the need for reflective practice and there was generally a positive response to this from those taking part in the work. Comments included, *"Positive change in professional environment"*, *"Self-evaluation (know yourself better than anyone else)"* and touched on lifelong learning - *"questioning our future works for better outcomes"* and *"deep learning, lifelong knowledge"*. As noted elsewhere long term well-being was among the points raised to develop reflective competence - *"Avoid burning out and overwhelming"* and *"finding your path"*.

4.2 Student debates

Within the debates students reflected similar thoughts to those in the small group activity.

The most common arguments for making reflective practice obligatory in both workshops revolved around its impact on personal growth and professional enhancement. Students emphasized that reflective practice could enhance self-awareness and promote a deeper understanding of goals and personal identity. Those who opposed making reflective practice obligatory argued that reflective practice requires inner motivation and a positive learning environment. They discussed that voluntary engagement fosters involvement and results in better outcomes. Furthermore, the negative impact of pressure on creativity was emphasized.

Students in both workshops who supported the introduction of formal evaluation of reflective practice argued that evaluation could enhance motivation and responsibility resulting in better outcomes from reflective practice. According to them, assessment could improve giving and accepting constructive feedback, promote honest reflection, and facilitate personal growth. The most common arguments against the idea of assessing reflective practice pointed out that it cannot be easily measured, by nature it is subjective, and the evaluation may put an increased pressure on students. They argued that a teacher driven evaluation could affect the personal aspect of the reflection.

The audience assessed the debates using Kahoot platform. Most voting rounds had balanced results except for one where one team's argument was much more structured and logical as per the votes.

The students tended to agree on the importance of reflective practice being introduced in the curricula as a useful method for their self-development, but not as something the teachers should evaluate the students on due to its subjective and generally non-comparative nature.

5 SUMMARY

In summary students appeared to value and to recognise the benefits of reflective practice, in line with the work of Menekse et al. (2022) and Howell (2021), in their programmes in STEM disciplines. Despite their general recognition, they were concerned that it might be seen to carry additional workload and this may be off-putting because the lack of time as it was pointed out by Miranda et al. (2022). A continual theme among the students and one not generally present in staff views of reflective practice previously reported was that the reflection should extend beyond self-appraisal of the extent to which the specific academic material was becoming embedded but to look at reflection as a tool in a much more holistic manner. Students' extended vison of reflective practice indicates that they consider the benefice and usefulness of it in the view of a long-term perspective not only in educational and professional context but also in personnel context as outlined by Baruah et al. (2017). Consequently, this would extend to bringing in mindfulness, self-care and uncluttered physical learning environments in order to create a more caring and productive overall experience and generating an enlarged vison for students (Badenhorst et al. 2020). It therefore should be the case that when developing approaches to reflective learning that we should work together with students and develop reflective practices courses in co-construction to address their concerns and ensure a much broader approaches to reflection. This course design development in co-construction, viewed as a possible improvement of future practical implication, would be also useful for making adjustments as the student thoughts are likely to evolve with the generations and approaches to reflective learning should be continually evolved to match the needs and expectations of current students. Finally, we would like to confirm the possible adaptation of our work in other contexts with some adjustments (for example for the debating session) by taking into consideration the discipline and institutional aspects. As a future perspective, it would be interesting to compare students', educators' and other stakeholders' (ex.: industry representants, policymakers, etc.) perception about the implementation of reflective practice in engineering education at different level.

6 ACKNOWLEDGEMENTS

We would like to thank the participating students from ESTIEM and BME for their contribution.

ABSTRACT

In this paper, we aim to present the development of an innovative teaching and learning programme. The programme was designed to enhance transversal competences more particularly in conscious leadership for final year IEM (Industrial Engineering Management) engineering students – competences which are essential for effective and ethical workforce management.

---

[1] *K Kövesi*
klara.kovesi@ensta-bretagne.fr

To develop this new programme, we applied an innovative course design embracing various pedagogical practices with an active learning approach including virtual reality experiences related to sensitive topics (such as everyday sexism in male-dominated environments, discrimination at work, mental health prevention) expected to generate strong emotions. We will present the development of this new programme, his implementation and evaluation based on student feedback.

Our results indicate that the use of various pedagogical methods and virtual reality by diverting the attention of sensitive students makes this innovative module attractive and well suited to their requirements. Students reported a stimulating virtual reality experience enabling a deeper understanding of complex and sensitive topics in uncertain, conflictual, and challenging situations where conscious leadership needed.

This work provides support for educators and teachers for developing engineering students' transversal competences in conscious leadership in an innovative way via active learning applying various pedagogical approaches. In future, this programme could be adapted and used in other engineering trainings for enhancing students' emotional and social competences.

1 INTRODUCTION

In a constantly changing world, we believe that it is important to prepare engineering students by developing their transversal competences in conscious leadership for enable them to face future sustainability challenges. Future engineering graduates will work in an increasingly VUCA (volatile, uncertain, complex and ambiguous) world (Bennett and Lemoine 2014) where human capital will play a central role, more specifically in technical domains requiring effective leadership based on strong ethical and value-based attitudes and behaviour (Beagon et al. 2019). The engineering profession is widely recognised as a leader for solving the challenges of SDGs (Sustainable Development Goal). However, engineering leadership depend on engineers' self-recognition and acceptation as a leader (Rottmann et al. 2015) that requires a well-established leadership identity. For this reason, including leadership education in the engineering curriculum is an important issue in engineering education also for developing engineering students' identity as leaders (Wolfinbarger et al. 2021).

The implementation of an innovative teaching and learning programme was essential, as indicated by the results of students' satisfaction survey, because traditional practices have limited efficiency with the new generation of students who have a very different learning approach. On the one hand, they have limited interest in engaging in traditional programmes applying passive learning approaches. On the other, their engagement in active learning is promising, resulting in increasing students' involvement, motivation, engagement, and learning performance.

In the case of developing transversal competences, and especially conscious leadership, active learning is particularly relevant as it fosters students' interactions and collaborative learning (Ang et al. 2021). It is in line with the recent results of Routhe et al. (2024, p. 558) that for engineering leadership education "it is not enough to merely participate in leadership activities: more supporting actions and understandings are necessary". Consequently, to enhance the conscious leadership competence of our engineering students, we chose an active learning approach including various pedagogical methods and a 360° immersive experience (Slater and Sanchez-Vives 2016) by the creating a virtual and experiential learning space (Kolb 1984, Kolb and Kolb 2005, Bédard et al. 2020).

2 Engineering leadership development

The implementation of engineering leadership education in the engineering programmes is related to widespread acceptance and recognition of engineering as a leadership profession in society. Based on the results of Rottmann et al. (2015), there is a mismatch between the traditional notions of leadership (leaders viewed as charismatic visionaries, influence at the top of a hierarchy, agentic individuals, executive problem-solvers, delegators, or agents of change) and engineers' professional identities (engineers viewed as applied scientists, service professionals, team players, technical problem-solvers, task-oriented doers, or process-optimizers). Despite these discrepancies, professional practice for engineers involves traditionally and professionally legitimate forms of engineering leadership (technical mastery, collaborative optimization or organisational innovation). For this reason, in an engineering context, engineers' leadership identity is an important component of engineering leadership development. As highlighted by Wolfinbarger et al. (2021), leadership identity development enables engineering students to understand leadership not as a position, but as a process requiring more inclusive and collaborative behaviour. From this point of view, the ethical dimension of leadership is particularly important for practicing a 'consideration-oriented leadership' style focusing on treating employees with fairness, honesty and respect.

In the present work, we clearly distinguish between conscious and responsible leadership. We define conscious leadership as "the demonstration of normatively appropriate conduct through personal actions and interpersonal relationships and the promotion of such conduct to followers through two-way communication, reinforcement and decision-making" (Brown et al. 2005, p. 120). In line with the recent work of Kubátová and Kročil (2022), we consider conscious leadership as a larger concept embracing not only responsible leadership but also other leadership forms (like moral, ethical, or sustainable leadership). However, we underline the central role of the leader who practices fully human and social leadership, putting humanity at the center of interests.

3 Pedagogical design: five learning units with mixed pedagogy

We applied a constructivist approach when designing the new leadership teaching and learning programme, and took into consideration Richardson's (2003) critical view on student learning and effective constructivist teaching. We established a student-centred view based on discussions, interactions and collaborations between peers as well as between students and teachers or facilitators.

Our innovative course design was composed of five units with various learning and teaching content:

(1) First, students worked in groups to choose a case study on a specific topic (such as conflict management, performance interviews, or abuse of

authority in team management), developed a scenario and prepared an artefact (e.g.: improvisation, role-play, or short film). During this collaborative work, student learning is constructed by discussion of ethical, managerial and social issues. As recommended by Carl Rogers and Jerome Freiberg in "Freedom to Learn” (1994), this discussion between students and the teacher/facilitator by raising various questions is a first step for generating ideas. A second discussion was then held between peers, allowing them raise their own questions and reflect on it.

(2) Next, students had the opportunity to meet a professional Human Resources Manager with a large international company who provided constructive feedback on their case study. This professional leader presented and explained the application of the Social Responsibility Policy in his company in detail (using numerous examples) that was an important step for showing students the reality of a real work environment. This unit provided an opportunity to students to make iterative improvements on their case study resolution with the support of a professional leader in human capital management.

(3) After that, students attended tailored courses in situational leadership (Hersey-Blanchard model) and socio-dynamics providing theoretical concepts related to their case studies. We presumed that students would then be more receptive to theoretical concepts, enabling them to acquire academic knowledge that could be transferred to their cases. By directly applying the theoretical concepts presented to their case studies, a process called "concept testing" according to Jean Piaget, students can more easily assimilate and retain the knowledge gained. This application helped them to confirm their understanding.

(4) Students also participated in 360° immersive experiences using virtual reality headsets (Oculus Quest 2) and watching short films recorded using a 360° camera. The actors spoke to them, but not interactively (no response expected). The sound quality was very high and in stereo, further enhancing the sense of immersion. Students were thus immersed in virtual situations related to sensitive topics (such as everyday sexism at work, bullying, discrimination, and mental health prevention) generating intense and complex emotions. We decided to use this innovative method, with all the associated ethical considerations and students’ prior informed consent, to encourage empathy and decentring (in Piagetian theory, this is the ability to view a feeling from a third person perspective and consider multiple aspects of a situation or problem). For students, the use of virtual reality through 360° immersive technology provides an opportunity to consider diversity and integrate assertiveness by “living an experience” that is very different from their usual frame of reference. This experiential learning unit ended with a team debriefing guided by the teacher.

(5) Finally, in the last unit, after presenting their final version of their learning artefact (role-play or improvisation), students participated in debates on sensitive topics (e.g.: controversy over positive discrimination for women, controversy over the obligation of quotas to include minorities) related to their initial case study in order to help them in their decentring process and leadership development.

As this is a 16-hour compulsory module (divided into four three-hour lessons and one four-hour lesson), students assessment is required for grading. We opted for an assessment based on the presentation of a learning artefact using a criterion-based assessment with peer feedback allowing students to learn from the work of others.

4 APPLIED METHODOLOGY: MIXED QUANTITATIVE AND QUALITATIVE ANALYSIS

The programme was evaluated using mixed-methods, combining qualitative and quantitative approaches so as to make connections between our two data sets and better grasp students' perception from different perspectives. To gather quantitative data; we conducted a survey before and after the programme mainly focusing on the use 360° immersive technology for educational purposes. More specifically, we investigated students' expectations and learning experiences related to using such technology. The qualitative approach was achieved by organising a focus group discussion at the very end of the programme, prior to students learning their grades (to avoid being influenced by their feelings related to their grades). We developed a focus group guide focusing on student expectations, motivations, challenges, and perception of the applied mixed pedagogical approaches and learning outcomes. With the prior consent from participating students, the focus group was recorded and transcribed.

29 engineering students from two cohorts at Master 2 level participated in the study, and all of them were specialized in IEM (Industrial Engineering Management). This student population was composed of 8 (28%) female and 21 (72%) male students. This proportion is representative of gender distribution in our engineering school. Concerning their experiences with virtual reality headsets, 19 students (66%) reported having used it at least once before and 10 students (34%) had never used it.

We must highlight the heterogeneity of our students' population concerning their workplace and leadership experiences. On the one hand, we had 13 regular engineering students with only limited work and professional experience (in form of short internships) and no leadership experience. On the other, we had 4 military students who, prior to starting their engineering studies, completed one year of work experience in the army, including leadership training. They were required to manage senior and more experienced people in military missions allowing them to develop solid leadership competences. We also had 12 apprentice engineering students with at least two years of professional experience but generally without leadership roles.

Primary descriptive statistical data analyses were conducted on our quantitative data using SPSS. Subsequently, for the analysis of our qualitative or textual data, we conducted a thematic content analysis with the participation of three researchers. As this analysis is still in progress so we can only present our preliminary results in the following section.

5 RESULTS: STUDENTS BECOME ACTORS OF THEIR TRAINING

One of our most interesting results is that 71% of participating students believe that the new conscious leadership programme helped to prevent or decrease the risks posed by non-conscious leadership practice by making participants more aware of the dangers of discrimination, harassment, or mobbing in the workplace. In addition, half of the students confirmed changes in their perception concerning stereotypes and prejudices after their participation in the conscious leadership programme. They considered this programme an important and necessary part of their future professional development: “we're young, but we will have to manage people...and will encounter these situations which we've talked about so much”. It is interesting to note that several students underlined the importance of this programme in preparing them for sensitive and conflictual situations in a safe and secure learning environment. As they said “I think it's important to be confronted with it before being confronted with it for real” and “what was very, very good was that for once it wasn't based on consensual standards with an obvious solution, it was a real situation of conflict. I think it's very good and very important to show that sometimes there aren't obvious solutions”.

There were significant differences between students with and without leadership experience concerning their understanding and argumentation related to complex ethical, managerial and social issues. Students with leadership experience showed a deeper understanding of complex concepts and were able to deal with complexity more effectively, with a higher level of reflexivity and a more holistic view. Students without leadership experience recognized that “it's difficult to manage people when you've just come out of school. It seems completely relevant to have courses on how to manage people” in conflictual, complex, uncertain and sensitive situations.

The application of an active learning approach, which includes various pedagogical methods and virtual reality experiences, stimulated students’ expectations. As one of them said, “we came out of curiosity” and wanted to find out more of the new subject that we “really want to understand”. This mixed pedagogy was positively perceived by students for several reasons. It helped students: (1) better maintain their attention (memorial anchoring learning), (2) experience stimulating and creative interactions (e.g.: group discussions, exchange with a professional leader, improvisations) and (3) for facilitate their understanding of complex concepts through application.

In Table 1, we summarize students’ perceptions of their attention, understanding, stimulation, impact and surprise related to their participation in the new programme. We include some recommendations for improvements based on students’ feedback.

Table 1: Summary of students’ perception about the applied pedagogy and recommendations for improvements

Questions	Verbatim	Recommendations
Attention: *Was attention sustained throughout the course?*	"Better attention because you're in the action", "More captivating than a traditional course", "it doesn’t feel like taking a course"	Course planned over a period of three months. It should be over a shorter period to better maintain momentum.
Understanding: *Are the concepts more firmly anchored in your memory*?	"The range of points of view", "We get away from our usual references”, "The choice of case study is important"	Students' initiatives are constantly valued (positive education – Joseph et al. 2020) and students have the opportunity to choose a case study facilitating their learning process.
Stimulation:	“An individual experience that lets you feel strong emotions", "A course that allows you to express	Need for regular stimulation to ensure students’ involvement. It is important to keep on the autonomy of students’ teams.

Were you stimulated during the training?	yourself", "Freedom of action", "Twists and turns in the course"	
Impact: *What did you find most impactful?*	"The most impactful part of the programme was the discussion with a professional leader" (unanimous among students)	Discussion with a professional leader highlighted the usefulness of the programme for professional competences development.
Surprise: *What surprised you most?*	"Other people's views on a sensitive subject", "Debates on subjects we don't usually discuss "	Integration of socio-technical controversies makes it possible to address sensitive ethical and societal issues.

We investigated students' virtual reality experience in their programme by examining their motivation, interests and related stress (Table 2). Generally, students reported positive feedback on their immersive experience perceived as a stimulating and secure learning environment, which is important especially in the case of sensitive issues generating strong emotions. This point is in line with the findings of Bertagni et al. (2023).

Table 2: Summary of students' perception about the use of virtual reality and recommendations for improvements

Questions	Verbatim	Recommendations
Motivation	"Involvement in the story and feeling the emotions", "it's fun", "A digital tool for our generation", "Mobility and proximity of the actors who immerse us in the scene", "Hyper-realistic immersion"	Students immediately got to grips with virtual reality in a fun way with a realistic feeling but we should make sure to use virtual reality in a responsible and ethical way.
Interest	"I've already used virtual reality for instructions on board the ship and for seasickness, where the emotions were stronger", "Awareness of perceptions other than my own"	Interesting in the field of management and interpersonal relations because of the subjectivity involved. Post-stimulation debriefing is essential and reassuring.
Stress	"More curiosity than stress", "Small teams so more confidence", "Possibility of stopping if you want", "in virtual reality we experience much more shock and emotion"	There was no perceived stress. It is important to provide a safe virtual learning environment with strong ethical considerations and students' preliminary approval.

With the words of one participating student: "when we did the role-play, it was still quite light-hearted. If we start talking about sexual harassment, we can benefit from it [the use of virtual reality]". We have to highlight that the use of virtual reality was efficient for diverting the attention of sensitive students but requires strong ethical considerations for ensuring a safe and secure learning environment.

6 CONCLUSIONS

From our point of view, the main challenge of this new teaching and learning programme is shifting students' focus away from their initial values, beliefs, convictions and behaviours into a more people-centred and ethical perception of leadership. The main added value is that students have the opportunity to develop conscious leadership competences that will be essential for their future careers, through various learning experiences in a safe and secure learning environment. We underline the relevance of active and experiential learning in engaging students and encouraging them to question, reflect, share and adjust their perception of conscious leadership.

We consider that the use of virtual reality is a real asset for learning about the humanities as it supplies a safe experiential space where students can explore and manage their strong and sometimes destabilising emotions. Moreover, experiencing complex and challenging situations improves the understanding and acceptance of diversity and difference. This experience offers an interesting opportunity for participants to develop their emotional intelligence as a useful relational competence for human capital management in their future professional careers.

This new programme could be applied to contexts beyond engineering education but would require some alterations concerning the leadership identity development process (Wolfinbarger et al. 2021). Expanding the programme to other engineering schools at master level would be relatively easy with a more structured framework. However, engineering students' professional experience could be taken into consideration when designing the learning situation. As we mentioned earlier, we noticed important differences between students with or without professional leadership experience that would require some variations. The introduction of this programme at undergraduate level remains an open question as it would require significant modifications for students who have no previous experience of management or leadership education (Routhe et al. 2024).

We are currently considering developing this new programme in a more structured competency framework based on the revised Bloom's taxonomy (Bloom et al. 1956) in the affective domain. The main objective is to put more emphasis on the development of students' self-awareness, discernment capacity and emotional intelligence.

7 ACKNOWLEDGEMENTS

We would like to thank the engineering students who participated in this study and extend our warmest thank to Rebecca Clayton Bernard for her valuable help with proofreading.

ABSTRACT

The COVID-19 outbreak set in motion a ripple of changes that continue three years after the pandemic has subsided. Under pressure to provide flexible education, higher education institutions called for an increase in online and blended learning offerings. This placed a burden on educators to rapidly develop new pedagogical knowledge and skills and master online course design principles. The objective of this paper is to share the results of a pilot curriculum design process, based on the ABC Learning Design method, which has been effective in helping teachers to (re)design courses quickly and collaboratively. The process consists of a series of workshops, that encourage intense collaboration with the course team to create a visual map or storyboard of the course from the learners' perspective. To support this process in our faculty, our eLearning team modified the storyboard template and developed a course profile tool designed to enhance alignment between the course team members before they start (re)designing their course. This externalizes the vision that each team member has for the course, making it easy to have an in-depth group reflection about course goals, aiming for consensus, and helping to produce a more cohesive product.

1 INTRODUCTION

1.1 Background

In response to the post-pandemic trend towards online and blended education, our faculty determined to transition our programme to multi-modal delivery. Rather than designing one course for blended delivery and another for online delivery, a multi-modal design would mean that the same course could be delivered either fully online or face-to-face in a blended mode with only minor adjustments required. In addition to accommodating changing student expectations, the strategy is intended to offer more flexible education. A 5-phase curriculum design process was set up to enable the transformation of our programme. The process consists of Inventory, Analyse, Evaluate, Design, and Implement (Blanford and Verplanke 2023). This paper focuses on the process in Phase 4, the redesign of the courses and enabling faculty to deliver flexible education. The outputs from the first three phases were used to develop a series of workshops and resources to support educators in designing and redesigning their courses for multi-modal delivery.

The most logical first step to implement the multi-modal approach is to design fully online versions of our courses. It’s easier to adapt an online course to blended or face-to-face delivery, than working the other way around. However, we are cognizant of the challenges of transitioning to a fully online mode of delivery (Kebritchi, Lipschuetz and Santiague 2017). Rather than recommending this, we focussed on equipping teachers with practical tools and skills to support the course design process. We also wanted to provide exposure to alternative teaching approaches and best practices for online learning.

Three learning design methodologies caught our attention in terms of their practical, hands-on approach and effectiveness in supporting the design of online and blended courses: Carpe Diem Learning Design (Salmon and Wright 2014), the Creating Aligned Interactive educational Resource Opportunities workshops (Usher 2014), and ABC Learning Design (Young and Perovic 2016). All three methods are discipline-agnostic and require teachers to design courses collaboratively. However, Carpe Diem and the 7C's have a two-day workshop format. Considering the size of our programme, the workload of our academic staff, and the limited capacity of our support staff to run the workshops, these approaches were not viable for our faculty. In the case of Carpe Diem, by the end of the workshop, participants will have partly built their module in their learning management system (Salmon and Wright 2014). We didn't want any learning materials to be built until after we had aligned all courses within the programme. Courses might require a couple of iterations before the course design is finalised.

With this in mind, we developed a workshop based on the ABC Learning Design (ABC) method which was developed by Nataša Perović and Clive Young at University College London (Young and Perović 2016) and incorporates Laurillard's six learning types (Laurillard 2012). These workshops run over ninety minutes and are designed to help course teams quickly redesign their curriculum using a storyboard or visual representation of the student's journey through the course.

At the beginning of 2023, we ran several workshops and used this experience to gauge interest, determine challenges, and test and refine workshop materials so that we could start a full rollout in 2024 to support the revision of our programme. In this paper, we discuss how we adapted the ABC learning design method to meet the requirements of our programme revision process. We consider the results of the 2023 workshops and how we have further modified the course (re)design process for the upcoming workshop sessions in 2024.

1.2 The ABC Learning Design method & Laurillard's learning types

ABC Learning Design Workshops were first offered at UCL from 2015 to 2016 as a streamlined approach to curriculum (re)design (Young and Perović 2016). Since then, it has been adopted and modified by tertiary institutions in the United Kingdom and beyond. The method is built on the conversational framework developed by Prof Diana Laurillard (Laurillard 2002). Laurillard's six learning types (Laurillard 2012) are used to create a storyboard or visual overview of the course that outlines the sequence of learning activities that the student will follow. The learning types include Acquisition, Collaboration, Discussion, Investigation/Inquiry, Practice, and Production (Laurillard 2012). Five of these are active learning types, helping to prioritise active learning in the design of the course.

Overview of the original ABC workshops

The workshops were designed to encourage collaborative course creation. To do so, a series of activities are used to encourage interactive team discussions. Course teams are seated around large-format storyboards to provide opportunities to focus attention on educational strategies, gain an overview of course activities, and discuss issues raised by teachers or students.

The workshops are comprised of a series of activities that (i) start with icebreakers to encourage open discussions among course teams followed by (ii) creating a high-level map or storyboard using sequences of learning types (iii) selecting learning activities for each of the learning types in the sequence (Fig 1) (iv) and evaluate the storyboard based on several criteria e.g. learning types, online/offline mix, active learning etc. The method can be adapted to a variety of contexts by customizing the workshop introduction and the discussion and evaluation at the end.

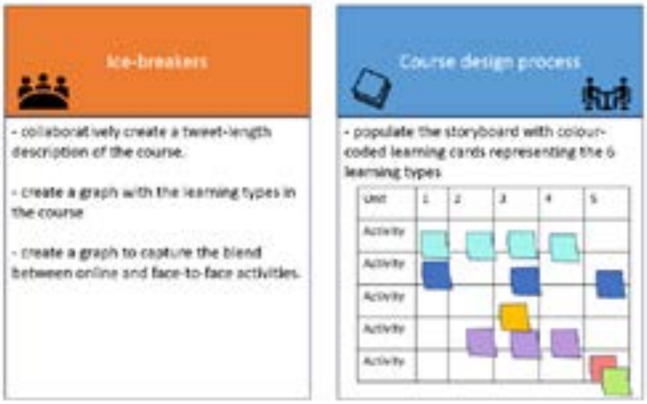

Fig 1. Overview of icebreakers and colour-coded storyboard capturing the 6 learning types used in a course.

There are many reasons that this method is a logical choice for our purposes. ABC Learning design has been particularly effective for (re)designing programmes and in transitioning courses to blended delivery. The process is activity-based, flexible, student-centered, prioritises active learning, is scalable, encourages discussion and collaboration, and is time-efficient. A map of the entire course can be created in ninety minutes to two hours (Young and Perovic 2016).

2. The Collaborative Course (Re)Design Process: Adapting the ABC method for our faculty

Localisation of the ABC method is easy to implement and was incorporated into the Collaborative Course (Re)Design (CCRD) workshop process. At UCL, most courses were verified courses, with approved learning outcomes and assessments. This was not the case for the CCRD workshops. Our programme learning outcomes have recently been revised and the course approval process in our faculty is being reconceived. As a result, we will need to support the constructive alignment of courses within the workshop.

The classic or 'Base' ABC Learning Design workshop process focuses on active learning, and diversifying learning activities. These strategies are beneficial in most educational contexts. However, in our faculty, due to the practical nature of our spatial engineering and geographic information science courses, most of our teachers already take an active approach, which means that the primary benefit for our faculty would be that it gets participants to think about diversifying their learning activities. To increase the value and impact of our Workshops, we wanted to include additional strategies and best practices for online and blended learning in the workshop process. The ABC method provides an opportunity to mention these strategies during the workshop introduction, but they are not integrated into the workshop activities. The Course Profile met this requirement in that it stimulates discussion about several course characteristics that impact online/blended learning before participants start with the design process.

Besides these adjustments, the CCRD workshop tasks and structure remain close to the original ABC method.

In 2023 we ran a pilot to test and evaluate the effectiveness of these workshops. The goal of the workshop was to enable teachers to (re)design their course within a two-hour workshop session.

2.1 Modifications to the storyboard

To make the ABC Learning Design fit for our purpose, we modified the design of the storyboard (Fig 2). One of the most important requirements was to align with a project being developed in our faculty to create a searchable catalogue of the education that we offer. The platform being developed will allow teachers and students in our Spatial Engineering and Geographic Information Science programmes to search for content by properties such as topic, software, delivery mode etc, and view elements linked to courses such as learning outcomes, European Credit and Accumulation Transfer System credits (ECTS), delivery mode, didactical approach etc. The output of our programme revision process needed to be in a format that is easy to transfer to the platform. We also needed to be able to customise the structure of the tool to our requirements.

We considered several open-source versions of the ABC Learning Design storyboard. Among these were templates created on Trello, Mural and Google Sheets and two web applications: the Learning Designer (Laurillard et al. 2018), developed at UCL and the Balanced Design Planning (BDP) tool which was developed at the University of Zagreb (Divjak et al. 2022). However, each of these presented challenges, either in terms of the General Data Protection Regulation (GDPR) requirements or adaptability. As a result, we created our own template in Microsoft Excel which is a modified version of the original ABC storyboard with some elements of the BDP tool and the Learning Design Planner (Gallenne and Jourde, 2023).

Although we modified the storyboard tool significantly, we adhered closely to ABC's storyboarding process, except for the addition of a step to write learning outcomes. Once learning outcomes and assessments have been aligned, the storyboarding process is the same as the original ABC method. First, the sequence of learning types is determined with the use of colour-coding. (See # 2 in Fig 2). Thereafter learning activities are selected for each of the cards (original ABC method) or coloured cells (CC(R)D process (see #3 in Fig2)

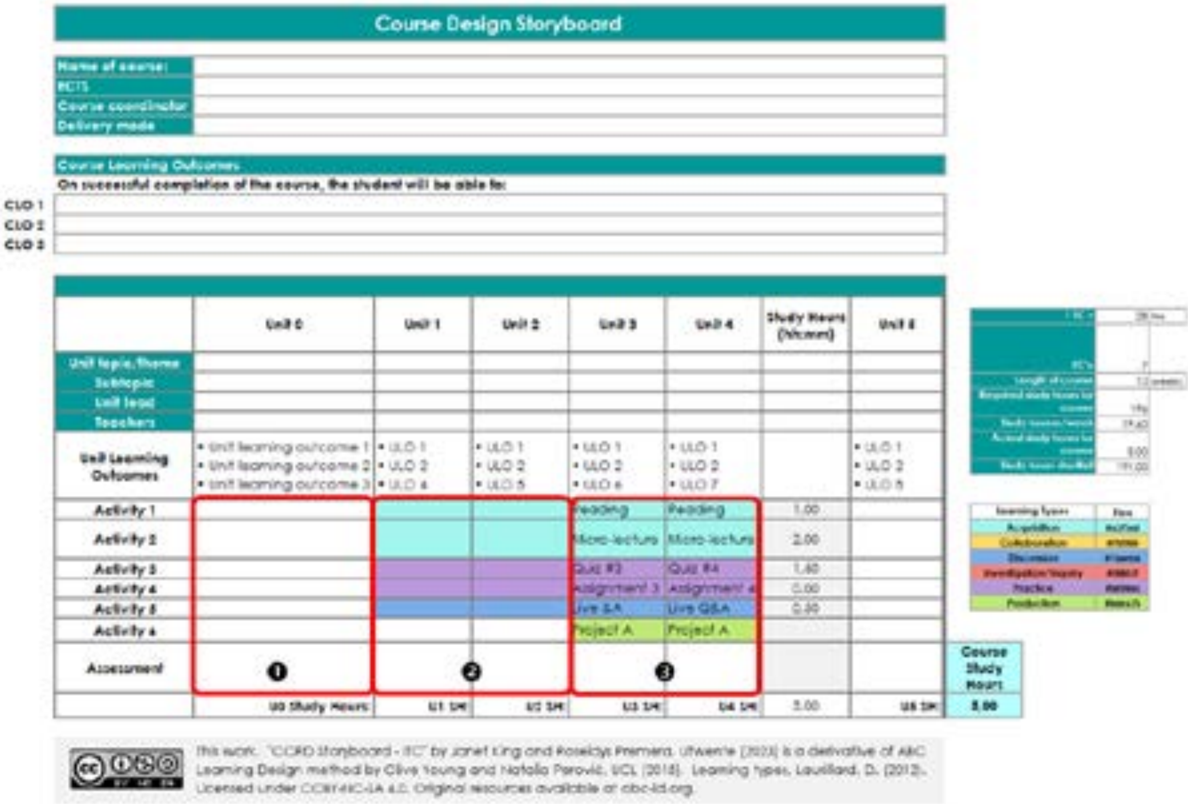

Fig. 2. Collaborative Course (Re)Design Storyboard 2023 and 2024

Adjustments included:

- **Course Learning Outcomes (CLOs).** CLOs are entered at the top of the storyboard and assessments at the bottom to support constructive alignment. There are also unit learning outcomes (ULOs) which are particularly helpful for fully online courses, if there is less interaction and feedback from teachers, because they help students monitor their own progress.
- **Storyboard layout.** The units/weeks run vertically from top to bottom rather than horizontally from left to right across the page, to make it easier to check alignment.
- **Assess workload for students.** Formulas calculate workload based on the ECTS (e.g. 1 ECTS=28 hours) and length of the course (e.g. 10 weeks). The formula captures the number of hours required to complete an activity based on the estimated times entered for each of the learning activities. The time fields are hidden by default but in Fig. 2, one of the fields has been unhidden.
- **Digital tools.** We selected MS Excel because it's easier and less time-consuming to store, share, compare and modify data. For each course team, we created an Excel workbook to capture all their workshop activities for example the course overview, the course profile, the storyboard the action plan.

2.2 Modifications to the workshop process

Our pilot workshops in 2023 followed a similar structure to the original ABC method with the addition of a couple of activities. Besides the tweet, course shape, and blend activity, we asked teams to define several other course characteristics e.g. synchronous vs asynchronous learning and group work vs individual activities, which together became the course profile.

Table 1: Overview of workshops, structure, and the activities used during the workshops.

Workshop	**ABC Learning Design**	**Workshop 2023 (Pilot)**	**Workshop 2024**
Workshop tools Format	• Physical	• Physical & Digital	• Digital only
Preworkshop tasks	N/A	• N/A Read definitions of learning types • Colour code inventory storyboard	• video on learning types
Workshop(s)	• Storyboarding workshop	• Storyboarding workshop	• Preworkshop • Prerequisite: Quality aligned CLOs • Workshop 1: Course profile, LO's & introduction • Workshop 2: Storyboarding • Workshop 3: Optimising course design
Workshop activities	• Tweet • Course shape (learning types) • Blend (online vs. face-to-face)	• Tweet • Course shape • Online vs. face-to-face blend • Synchronous vs. instructor paced • Individual vs. group work • Instructor/content centred vs. student-centred/active	• Tweet • Faculty vision on education • Course shape (learning types) • Online vs. Face-to-face • Self-study vs teacher-led activities • Synchronous vs asynchronous • Types of assessment e.g. summative, peer, self-assessment, auto-graded etc • Group vs individual • Kinds of feedback e.g. instructor to group or individual,

Based on feedback from the pilot workshops we made several adjustments and have established a set of three workshops to support the course design process (Table 1), each running between 1 hour and 2.5 hours. Workshop 1 is the introduction and includes the creation of a course profile and learning outcomes, Workshop 2 is the storyboarding workshop where teams create a first draft of their course design, and Workshop 3 introduces alternative teaching strategies and best practices and allows participants to optimise their course design by implementing some of these strategies.

The course profile activity was further extended to include among other characteristics, contact hours vs self-study, assessment types, and alignment with our faculty's vision on education (Fig.2). The discussion stimulated by this activity can help course teams to reach consensus about their goals for the course (in terms of these characteristics) before the course design process starts. This can potentially make course design quicker and easier and produce a more cohesive course.

Besides the pedagogical discussions within teams, we scheduled moments of sharing between teams to facilitate alignment and eliminate redundancies in the programme. Sharing the course profile is one of the tools that course teams can use to communicate their vision of the course with other teams.

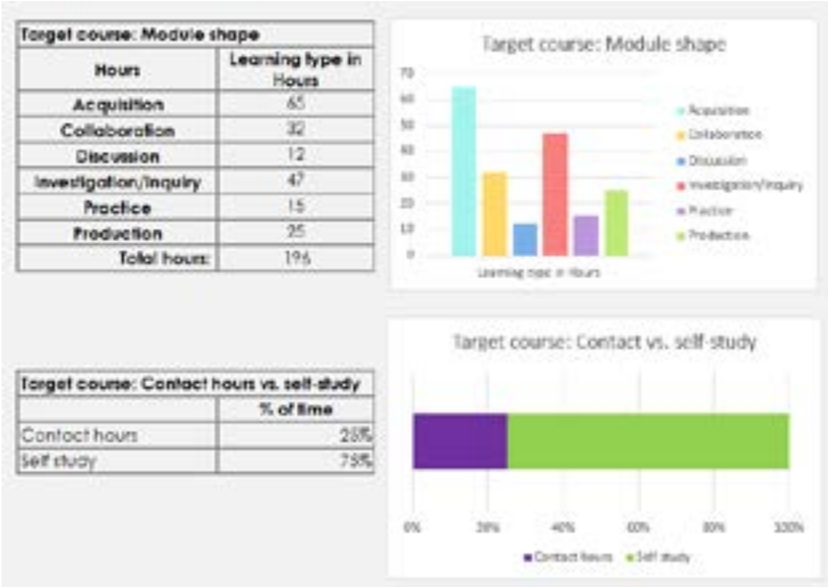

Fig. 2. Examples of some of the charts that make up the CC(R)D Course profile: Module shape chart and Contact hours vs. Self-study chart.

The course profile is easily transferable to other settings, however, the characteristics included in the tool should be selected based on the priorities of the context it's used in. For example, in our faculty we want to increase online and blended learning and reduce contact hours, therefore, it's useful to discuss the balance of self-study and teacher-led activities as well as synchronous vs. asynchronous learning. The amount of group work is significant because this can impact the sense of community online as will the quality and distribution of feedback.

3 RESULTS

In March and April 2023, seven course teams attended a CCRD workshop. Four workshops took place and 25 participants attended in total. Participants completed a Wooclap survey at the end of the workshop and we received responses from 17 of the 25 participants.

We are currently running the CCRD with the 3 workshops for the complete development of a new course for one-course team (N=7 participants).

Table 2: Workshops conducted, duration of workshops and number of participants.

Year	Workshop	N	Duration
2023	CCRD Pilot workshop	25	2 hours
2024	CCRD Workshop 1: Introduction to CC(R)D process & creating a course profile	+/-7	1 hour
	CCRD Workshop 2: Storyboarding	+/-7	2.5 hours
	CCRD Workshop 3: Optimise your course for online/blended delivery	+/-7	2.5 hours

3.1 2023 Workshops Results

Participants found the workshop process and tools valuable and most said that they would continue to use the tools after the workshop. Although the course storyboards differed in the level of detail, all but one team achieved the workshop objective which was to complete a first draft of their storyboard. Five of the course teams revised an existing course and one designed a new course. The team that didn’t complete their storyboard spent time discussing learning outcomes and ran out of time as a result.

Once the storyboards had been completed, teams were asked to evaluate them. Evaluating the extent of active learning in the storyboard was easy because of the colour-coded learning types. Evaluating other elements of the storyboard was not as successful. We had not provided an effective way to connect the best practices and strategies that we discussed to the evaluation step. Nor was there a way to reflect and record the additional detail. Further extending the course profile is one of the ways that we will tackle this challenge. Course teams define their target course characteristics (e.g. a ratio of 25% contact hours to 75% self-study) using the course profile tool, before designing the course. Ater their storyboard is completed they create a second course profile that reflects the actual course design. A comparison can be made between the two versions and discussed within the team.

Table 3: Survey results for 2023 pilot

question	response
Most useful aspects of the workshop	• having the opportunity to think about, discuss, and brainstorm their course design • usefulness of applying Dianna Laurillard’s learning types to their course design (N=6) • storyboard was useful (N=4) • A hands-on approach, • allocated time with the course team to talk about the course, • checking the boxes regarding the synchronous/asynchronous and online/face-to-face blend, • having to argue about the validity of activity types for the various LOs, • discussing the organization in the storyboard, • brainstorming in a structured manner, • colourful storytelling, • ideas and models for practical redesign online
What will staff continue to use	• use the process/tools that were shared with them in the workshop (N=13), one said that they already use it, and another gave an unclear answer
Improvements	• more time to complete the activities (N=4) • more examples would be helpful (N=2) • clearer instructions on how to use the workshop tools and complete the tasks (N=2)

3.2 2024 Trial Observations/Results

The team completed their storyboard design for a fully online course. The course profile activity proved to be a highly effective method to stimulate discussion within the group, particularly if the team is not yet fully aligned. As a result of our experiences with this trial, we will eliminate all pre-workshop tasks, except for an optional video about the learning types. Teachers are already overburdened so we have designed future workshops to ensure all tasks can be completed within the time they have set aside to attend a workshop.

Future goals

We will continue to develop and evolve the CCRD process, by adding and upgrading resources and providing examples of storyboard designs that have proved to be effective for online environments. What we ultimately hope for is to develop the process and tools to a point where teachers want to use these independently, outside of the workshop process. We are looking for suitable alternatives to the MS Excel storyboard. If we want it to include all of the features that we need, we will have to build this ourselves. The ABC learning design method was the right choice for our faculty because it didn't put an unnecessary time burden on our teachers or support staff and we were able to adapt it to our goals, priorities, and vision without affecting the consistency and effectiveness of the outcomes.

ABSTRACT

With robots becoming an increasingly constant feature in daily life, we must prepare and educate current and future generations. Although robotics outreach and robotics education are not new in engineering education, many educators and outreach providers face the same hurdles when using educational robots: Educational robots are expensive to buy, can become obsolete quickly and are time-consuming to maintain. In addition, many people feel unequipped to select the right robot for their purpose. This paper describes the development and implementation of a family of modular, affordable, open educational resource, mobile robots called MIRTE, that can be implemented across the entire educational spectrum and how continuity of the robots is ensured by following the principles of Open Education and Open Science. In the paper, current educational implementations are highlighted and plans for future developments and future research are discussed.

1 Introduction

Robots are becoming a common occurrence in our society, with the use of robots no longer limited to industrial and medical applications but also as everyday appliances ranging from self-driving cars to robot vacuum cleaners. This will affect how we live and work in the not-so-distant future. Therefore, we must prepare and educate current and future generations for a life in which interacting with robots is commonplace. Using robots in education is not new. These days, courses in robotics at various levels of complexity, are common practice in most bachelor programmes in engineering. There is also an increasing trend towards dedicated bachelor, master and PhD programmes in robotics worldwide (Tilbury and Xiao 2023). In addition, many secondary schools have been using educational robots as a focal point for years as part of their science and technology curriculum (Evripidrou et al. 2020) as do many STEM outreach programmes aimed at the K-12 audience, such as First Lego League and RoboCup Junior (Eguchi 2016). All these programmes and initiatives face the same hurdles when using robots in their education and outreach: buying and maintaining robots in education is expensive and time-consuming and teachers often feel unequipped to select the right robot for their purpose.

In this paper, we will present an innovative, open-source, open-hardware, open-education mobile robot platform family for implementation in all levels of education which also can serve as an innovation and research platform for industry and research institutes.

1.1 Challenges of current robots used in education

Typically, three types of robots can be identified: fixed-base manipulators, as often seen in medical and industrial applications and two types of mobile robots: the legged robots, such as Boston Dynamics Spot and the rolling mobile robots, such as a robot vacuum cleaner, using tracks or wheels to move around with various levels of autonomy and self-learning capabilities. For education purposes, rolling mobile robots are used most frequently. Generally, educators across the entire education spectrum face several challenges when using robots in education:

1. Educational robots are not cheap, ranging from €100 - €600 per unit, with typically one robot needed per 2 – 8 students for meaningful engagement.
2. Robots become obsolete quickly, either because the manufacturer ceases to exist or because they cease support for the robot or its operating system. The latter is the case with the LEGO Mindstorms robots.
3. Robots are often only used a few hours per week during a few weeks per year, making robots an expensive investment for education (Arvin et al. 2019).
4. Many robot platforms are only aimed at one education level, for instance, only primary education. Few platforms offer flexibility across the educational spectrum and making the step to a more complex robot is an (unsurmountable) big step.
5. The educational focus of many robots is only on programming the robot. The robot itself comes as a finished product with LEGO Mindstorms and mBot being the most well-known exceptions.
6. Many robots are incompatible with standard components or other platforms, limiting possibilities and leading to educators being locked into one supplier (See Table 1).

It is therefore not surprising that many schools have outdated robots or are less keen to invest in yet another new robot, aside from the sustainability issues of schools having to keep purchasing new equipment.

Table 1. Comparison of a selection of low-cost mobile robot platforms for education (HW =Hardware, SW = Software, ★ = Supports ROS 1 and 2)

Robot	Cost (€)	Open Source (HW/SW)	Last OEM update	Easily available	Intended for use in			3rd party compatible (HW/ SW)	Visual Program.	ROS compatible

1.2 Introducing MIRTE

Frustrated with these challenges, in 2019, the first author, a lecturer in Mechanical Engineering at TU Delft set out to develop an affordable mobile robot platform, inspired by the One-Laptop-Per-Child initiative (Ames 2019) so that all children should have access to a robot, that like them, evolves in its capabilities as children become older. The aim of creating such a robot was to enable all levels of students to practice robotics making optimal use of the principles of Open Science to reduce cost and avoid the threat of obsoletion. This resulted in the development of MIRTE, which stands for: "*MIRTE, an Inspiring Robot for Technology Education".* In the remainder of this paper, we will present MIRTE, its features and capabilities and share our experiences in using MIRTE in education and its non-anticipated use for research and development purposes.

2 DESIGN PRINCIPLES BEHIND MIRTE

The first author's primary goal was to create an affordable robot that would last during the entire time any child anywhere spends in their formal education and that the robot itself would always be able to work, developing on par with the developments in the field of robotics and not be hindered by proprietary limitations. This gave rise to two main frameworks guiding the design:

Educational Framework: the robot must fit within the existing educational frameworks. Hence, in line with TU Delft's vision of education, the framework of Biesta (2021) was chosen which is based on the principles of *qualification* (foundational STEM knowledge at the appropriate level), *socialisation* (being able to think critically across cultural and societal contexts by working together in diverse classrooms) and *subjectification* (teaching students to take responsibility for their choices). The Biesta framework is designed for primary, secondary, and higher education and allows for continuous challenging of learners at their level.

Open Science Framework: To keep the cost of the robot to a minimum and to ensure the robot and its operating software would never become obsolete or that users run into limitations due to proprietary issues an Open Source approach was chosen. All software used in the robot is open source and will be made available through GitHub allowing others to contribute and continue development even if the initial creators are no longer involved. In line with that, all educational resources developed for the robot should be free and shared as much as possible as Open Educational Resources (OER). An Open Hardware approach must be used for hardware: no proprietary hardware was to be used and as few custom parts as possible. All components should be generic off-the-shelf components and any custom parts should be producible locally by a user. Using these principles, the cost can be kept at an absolute minimum and the robot will be as accessible, modular, and as inclusive as possible.

3 MIRTE ROBOT FAMILY

Following these principles, a family of affordable robots was created using an onion analogy, which allows the consumer of the onion to peel away a layer at a time (Fig.1). With each layer being removed, the next, more complex layer of technology is revealed underneath, allowing the learner to be challenged in deepening levels of education, delving deeper into the robot with increasing levels of hardware, the operating software and its complexity. This has resulted in an initial MIRTE family of three. In increasing order of hardware complexity and educational and software challenges, they are the MIRTE Light (Fig. 2a), the MIRTE Basic (Fig. 2b), and the MIRTE Pioneer (Fig. 2c).

Fig. 1. MIRTE's Onion Approach (blue = software, red = electronics, yellow = mechanical/design)

3.1 Design Features

All MIRTEs (https://www.mirte.org) share a common hardware basis consisting of a (wooden) chassis, wheels, motors, battery pack, and light sensor which allows users to add more hardware depending on their needs (modularity) and are powered by a standard 5V power bank. The base is not an off-the-shelf product, instead, we provide the DXF, STL, and FreeCAD files for people to make their own. Alternatively, they can use an existing or custom base. For the MIRTE Pioneer, we developed a dedicated PCB as an alternative to the Open Hardware solution of a breadboard combined with an MB102 Micro USB Interface Breadboard Power Supply Module and a splitter cable. More details on MIRTE's hardware options can be found in the MIRTE Docs (https://docs.mirte.org). In addition, a variety of sensors can be added to the robot, depending on needs and budget. The MIRTE chassis is partially compatible with LEGO Technics to allow for more modularity. In terms of software, the core of the onion is based on the open-source Robot Operating System (ROS: www.ros.org). All source code can be found in our GitHub repository (https://github.com/mirte-robot).

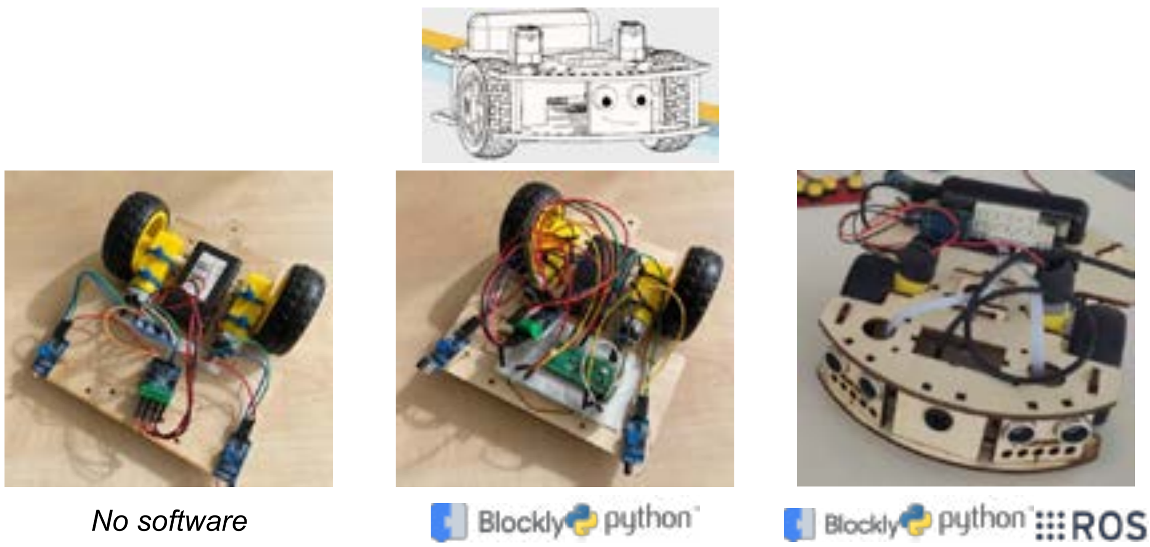

Fig. 2a. MIRTE Light (€15)Primary Education | *Fig. 2b. MIRTE Basic (€25)Primary and lower Secondary Education* | *Fig. 2c. MIRTE Pioneer (€100 – kit: €150) Secondary and Higher Education*

(prizes shown based on sourcing components and self-assembly)

From an educational viewpoint, ROS is suitable for use in Higher Education but likely too complex for primary and secondary education, hence two layers of software to reduce complexity have been added. A Python shell was added, for use in secondary education allowing students to code their robot. As this may still be too complex for most primary school students, an additional layer was created using Blockly. By varying the complexity of the hardware on the MIRTE Basic and MIRTE Pioneer and whether or not students are given a built robot or are assembling the robot themselves, students can also be introduced to different levels of complexity in electronics. You can use an off-the-shelf PCB or allow students to delve deeper into the electronics of the robot by using the breadboard alternative instead. You can also vary the types of sensors and actuators to enable students to learn more about signals and sensors.

Within the development process, the MIRTE Pioneer was developed first and is currently furthest in its development and implementation. At the core of this onion is a small, but complex, versatile, mobile, semi-autonomous robot, the MIRTE Pioneer, (Fig. 2c) primarily intended for use in secondary and higher education. The MIRTE Pioneer is fully programmable using ROS, with the ability to use many different sensors varying in complexity including a LIDAR which allows the robot to have simultaneous location and mapping (SLAM) to aid its navigational capabilities. MIRTE Basic and MIRTE Pioneer are currently being developed further, with emphasis on creating additional educational resources and teacher training modules as teachers in primary and secondary education need more support in teaching robotics and computer science.

3.2 Under Development

The MIRTE family is growing. The current MIRTE family can more than cover the domains of primary, secondary, and bachelor education. Recently, a larger, more powerful MIRTE, the MIRTE Master, was developed, (see Fig. 3) with a mobile robot arm, a LIDAR, a depth camera, omnidirectional wheels and a dedicated PCB. It was developed based on a design by 4 BSc students in Mechanical Engineering, showcasing the software modularity of MIRTE. The MIRTE Master is intended for use in BSc final year projects and MSc education as well as research and development projects that require a heavier base and the use of a robot arm. Whilst working under the same principles using the same software, all hardware components of the MIRTE Master have been upgraded and extended compared to the MIRTE Pioneer. It is currently being tested in a BSc final project and an MSc course at our university. Design iterations are being made to further modularity. As soon as the testing phase is finished we will make its open resources available. As

Fig. 3. MIRTE Master (€560)

ROS2 is rapidly becoming mainstream, we are also in the final testing stages of the ROS2 support for the MIRTEs which will be used in our education from next academic year and will be added to our GitHub later this year.

4 MIRTE DEPLOYMENT

Since their creation MIRTEs have been used across the educational spectrum.

4.1 Primary and Secondary Education and Outreach

MIRTE is currently being used regularly at four local primary schools to introduce young students to the foundational concepts of robotics, and computational thinking. In addition, through outreach programmes, many primary schools source workshops on Robotics using MIRTE (Fig. 4a). MIRTE fits seamlessly into our national STEM curricula, providing a hands-on approach to learning that complements theoretical studies in STEM fields. Currently, MIRTEs are used as an integrated part of the STEM curriculum in three local secondary schools. In addition, students and staff regularly give 2-hour workshops at secondary schools.

Due to their affordability and diversity MIRTEs are an excellent tool to promote STEM with young people. Through workshops, facilitated by dedicated educators and robotics enthusiasts, young people are provided with hands-on experiences that not only teach the fundamentals of robotics but also encourage creative problem-solving and collaborative learning. These workshops take place both on campus and on location on an almost weekly basis. Within this initiative, there is also a strong emphasis on instructor training to equip more educators and STEM volunteers with the knowledge and tools needed.

There is a clear need for resources and support for primary and secondary teachers and workshop facilitators. We are therefore developing dedicated (open) education resources. For primary schools, we are in the process of creating open resources based on our workshops. For secondary education, we have developed open educational resources (https://workshops.mirte.org/nl/) in workshop format. We also provide workshops for primary and secondary school teachers to gain first-hand experience with MIRTE. We are currently in the process of developing a full MIRTE-based robotics learning line for the subject Nature, Life, and Technology, which is an elective in Dutch upper secondary schools.

4.2 Higher Education

MIRTEs are already used intensively in the BSc and MSc Mechanical Engineering (ME) and the BSc of Computer Science and Engineering (CSE) at TU Delft:

1. In the second year BSc Robotics project (6 EC) at ME students are taught about robotics, electronics and sensors. 600 Students build their own MIRTE pioneer in pairs and design and manufacture parts of their base and a small robot arm to perform a specific task, such as trash sorting (Fig. 4b).
2. MIRTE pioneers are also used in the 20 EC, interdisciplinary robotics honours programme for excellent BSc students.
3. In the Introduction to ROS course (2 EC) of the interdisciplinary minor Robotics (30 EC) in the 3rd year of the BSc.
4. MIRTE pioneers have also been used in our MSc Robotics - Fig. 4c (Saunders-Smits et al. 2023, van der Niet et al. 2023) having been replaced by MIRTE Masters this year (Fig. 3).
5. Within the 2nd year BSc course Embedded Software some 100 CSE students make different use of the MIRTE Pioneer, programming the microcontroller but do not change the design of the base.

The affordability of MIRTE allows students to not have to settle for programming simulations, they can test their programmes on a real robot. MIRTE allows lecturers flexibility to select which feature of MIRTE can aid them in achieving the desired learning objectives.

4.3 Commercial and Research and Development Use

An unexpected, but much-valued, user area of MIRTEs also emerged from this project. Due to their affordability combined with their versatility and ROS capabilities, startups and the R&D departments of companies such as Lely and Alliander have started to use MIRTE as a research and development platform which led to demand for us to produce MIRTES for others. However, in line with the non-profit status of our university and our Open Hardware philosophy of build-you-own, we decided not to produce and sell MIRTEs commercially ourselves. To meet this demand and to make it easier for 'non-makers' to get started with MIRTE, the "I am MIRTE Foundation" (https://iammirte.org) was created which produces and sells MIRTE kits to aid those unable or unwilling to source MIRTE materials with all proceeds being used to fund MIRTE workshops in underprivileged areas.

5 REFLECTION AND FUTURE DEVELOPMENTS

With MIRTE approaching its 5th birthday, most of the initial objectives of the first author to make an affordable, open mobile platform have been reached. Although the exact number of robots produced is hard to estimate, as MIRTE is open hardware, more than 1600 MIRTEs have been produced for use within TU Delft and our outreach workshops. To our knowledge, MIRTEs are currently owned and used by 8 schools and universities, with many more schools choosing not to own robots but buy in MIRTE workshops. Starting this summer, we are increasing our promotion activities, for instance through workshops at the RoboCup Junior Symposium in Eindhoven, and presenting this paper at this year's SEFI conference. Using this snowballing approach, we hope to add more users and developers to the MIRTE community, which can be found at: https://www.mirte.org/.

MIRTE Pioneer has matured well, but we foresee the following future developments:

1. Make the MIRTE Basic and MIRTE Light more accessible for primary schools and STEM outreach for that age range by developing open educational resources to aid primary school teachers and STEM volunteers.
2. Facilitate and expedite the use of MIRTE Pioneers in secondary education by developing educational frameworks and modules together with the Science Education and Teacher Training Specialists of both TU Delft and TU Eindhoven to fit within government-set STEM learning outcomes.
3. Expand the use of MIRTE to more universities: a project with the Mechatronics programme of The Hague University of Applied Sciences is awaiting a funding decision and further (inter)national collaboration is high on our wish list.
4. Continue development of the MIRTE Master and its outdoor sibling to add them to the Open Family of MIRTEs.
5. Continue to Grow an Open Science Community of MIRTE users and developers beyond the doors of our university and its immediate surroundings.
6. Scientifically evaluate MIRTE's educational and outreach contributions and carry out long-term studies on its impact, allowing evidence-based improvements to the educational qualities and potential of our MIRTEs across all levels of education
7. Arrange more funding to realise our ambitions

We believe these developments are needed to allow MIRTE to become the affordable (and hence more inclusive) open platform of choice in robotics.

ACKNOWLEDGEMENTS

We would like to acknowledge the hard work of our colleagues, teaching assistants, teachers, and STEM volunteers who contributed to the MIRTE project. In particular, we would like to thank Martijn Wisse, Cilia Claij, Arend-Jan van Hilten, Ditske Kranenburg-de Lange, the TU Delft Robotics Institute, and the TU Delft Science Centre for their help. It takes a village to raise a child or in this case MIRTEs.

ABSTRACT

In Sweden various laws and regulations related to Sustainable Development (SD) has been implemented, and Swedish companies must adhere to such laws and regulations and declare how those are met. Moreover, directives from the European Union point out obligations that even further increases the sustainability demands on the companies. Thus, alumni's' competences and skills regarding SD should be valuable to fit well into their employers' SD strategies, and possibly be contributing to such. This contribution aims to study how well alumni from the Computer Science dept. of Kristianstad University, Sweden, contribute to their profession and working place with respect to SD, *seen from an employer perspective*. A survey was sent to representatives of companies collaborating with the university to provide a preliminary view on how well the alumni contribute to the companies' SD context. From the responses, which came only 25% of the survey participants, we observe an awareness of SD knowledge and an approach of integrating SD into their organisations. Furthermore, it could be valuable to equip students with additional knowledge of the companies' situation regarding SD regulations.

kamilla.klonowska@hkr.se

1 INTRODUCTION

1.1 Background

Since early 2017, Swedish companies have been required to report on their sustainability efforts, including environmental, social, and anti-corruption measures, as well as their organizational strategies for improvement (QBase 2024). Additionally, the European Union's (EU) Corporate Sustainability Reporting Directive (CSRD) aims to standardize sustainability reporting for companies within the EU (PERSEFONI 2024).

Given these regulations, educating students in SD is crucial for enhancing their employability and benefiting employers. Swedish universities are also mandated to integrate SD into various organizational levels, incorporating relevant knowledge and experience into programs and courses (UHR, Act 2023).

1.2 Educational Frameworks

From a historical perspective, it may be interesting to see Aristotle's three forms of knowledge, Episteme (scientific knowledge), Techne (skill and crafts) and Phronesis (often translated as practical wisdom) (Järnerot, Veelo and Lund 2019). Here, Phronesis in particular stands for competencies regarding ethics and relation to politics and society (Einarson and Melén Fäldt , HKR 2017), and (Steyn and Sewchurran 2021) argue that this virtue as a form of practical wisdom should be an integral part of management development.

Moreover, the Swedish Higher Education Ordinance (UHR, Ordinance 2023) specifies the general forms for the learning outcomes that must apply to the various education programs. The learning outcomes are mainly divided into three sections, that is, 1) Knowledge and understanding, 2) Competence and skills, and 3) Judgment and approach. For each of these sections, it is then specified what these contain. For example, for a Degree of Bachelor (DA399E 2024), the third section for instance includes:

- demonstrate the ability to make assessments with regard to relevant scientific, societal and ethical aspects in the field of computer science (learning outcome 3.6)
- demonstrate insight into the role of computer science in society and the responsibility of the individual for how it is used (learning outcome 3.7).

It can be interpreted as that this corresponds to a future-oriented approach, where the students will be prepared for insights into how their knowledge and skills should be implemented in a societal perspective, and in responsible and ethical ways.

In the above contexts (Einarson and Fäldt, 2017) discusses the striking similarity between the Higher Education Ordinance's sections on knowledge and Aristotle's forms of knowledge and points out the following relationships:

1) Knowledge and understanding - Episteme.
2) Competence and skills - Techne
3) Judgment and approach – Phronesis

Here, sustainability is not mentioned explicitly, but it is of particular interest in this paper to see the conditions regarding point 3) above. When it comes to social impact and ethical aspects, we here see SD as a way to correspond to such issues. With the knowledge the students have acquired, how are these used in appropriate ways in the working contexts in which they in the future will operate? Einarson discusses how point 3) is implemented in one of the courses in computer science program (Einarson, HKR 2017).

Computer Science at Kristianstad University (CS@HKR) has been a member of an international network and educational framework CDIO (CDIO n.d.), for several years. CDIO proposes a set of learning outcomes (CDIO Syllabus 3.0 n.d.) for engineering courses to prepare students to face the complexities faced by business. It is interesting to see here that this is not only a question of elucidating the mentioned points 1) and 2) above, but also essentially point 3). For instance, examples that illuminate on this and moreover address SD, include:

- Visions for a sustainable future for society and for one's profession,
- The impact of engineering on the environmental, social, knowledge and economic systems in modern culture,
- Considering one's contributions to the local community and (global) society.

1.3 The CS@HKR Case

The Bachelor Program in Software Development at Kristianstad University in Sweden is a three-year program provided to both national (Swedish) and international students. Following multiple revisions, the program now offers a well-defined progression through its courses. It also emphasizes the development of academic skills and integrates sustainable development principles throughout the curriculum. Already at the beginning of the first semester, the students take part in the concepts within SD and especially with a starting point in Agenda 2030 and the 17 Sustainability Goals (SDGs). With this as inspiration, students then write a report focusing on an imagined system with SD contributions, enabling them to make simpler assessments with regard to relevant social and ethical aspects (learning outcome 3.10). In the second year, students take a further step by implementing their systems and reporting on how these contribute to SD. During the third year, the students participate in a larger project, in the direction of smart home technologies for quality-of-life values for disabled young people. This approach is further detailed in reports by (Klonowska, Teljega and Einarson, SEFI 2023). In addition, reflecting on SD-aspects is mandatory in the degree thesis, aligning with the assessments outlined in the "Judgment and approach" learning outcomes described above.

A survey showed that the students predominantly thought it was important that software developers consider ethical and sustainable issues in their work

(Klonowska, Teljega and Einarson, SEFI 2023). Furthermore, it also emerged that the students considered that they had acquired good knowledge within SD and how they can contribute to SD.

Another component in this context concerns how well the students are prepared in the education for professional life through contacts with the surrounding society, such as with companies. (Einarson, Frisk and Klonowska, CDIO 2022) reports on concepts regarding Work-Integrated Learning (WIL) and Work-Based Learning (WBL) and addresses the good values that such educational elements have. Although (Einarson, Frisk and Klonowska, CDIO 2022) also sees challenges in finding good forms for this within the highly specialized IT industry, the meetings between student and company are seen as valuable for several reasons.

One form adopted at HKR is the Imagine project (Imagine 2023), (Klonowska, Teljega and Frisk, SEFI 2023). Imagine is applied with the aim of preparing the students in their professional role, to be able to actively contribute to their workplace and work to identify and find innovative solutions to societal challenges. Imagine is offered several times a year with different main themes, such as, City and Society of the Future, Sustainable Food Production, and Food of the Future / Healthy Life / Purchasing Behaviour. Several external actors participate as clients, such as from business and municipalities. The concept has generally been seen as very successful from the perspective of all involved parties.

From the above presented discussions, it is motivated to believe that students are fairly well prepared to meet the demands on companies regarding SD and the impact they may have on SD. Still, while the universities are in control during the study programs, it is not always clear what the effect is at the students' transform into alumni. This contribution aims to investigate the awareness of SD in society seen from a perspective of their professions, and of their employers.

1.4 Related work

To the best of our knowledge, there is no specific research that examines companies' perspectives on education related to sustainable development (SD) in a broad sense. However, numerous articles document the outcomes of various projects that involve collaborations between universities and companies with a focus on SD, e.g. (Swacha, et al. 2021), or from students' perspective, e.g. (Fourati-Jamoussi, et al. 2021).

2 METHODOLOGY

2.1 Context and Participants

During the spring of 2024, the authors of this contribution designed a survey that was sent to representatives of companies collaborating with CS@HKR. The first question focused on the companies understanding of SD. Further questions were assessed of alumni perceptions and experiences regarding the integration of SD principles within their professional contexts and the effectiveness of their education in preparing them for roles related to SD within their companies. Since we did not find similar study, all questions were prepared from scratch.

The survey of this study has addressed the following questions:

1. What role do you believe knowledge in sustainable development plays in promoting innovation and competitiveness within the company?
2. Is sustainable development a topic discussed within the company with alumni as part of their professional framework?
3. Can you perceive how well-prepared alumni are to take responsibility for sustainable development within their profession?
4. Can you observe how effectively alumni contribute to sustainable development at various levels of the company's operations?
5. Do you feel that there is anything additional that alumni should have learned from their education in sustainable development to carry out their work responsibly?

2.2 Data collection and Analysis

The questionary has been sent to 32 individuals from 22 companies collaborating with the university. There were 8 responses, equivalent to a 25% response rate.

Since the questionary was anonymous, it is not possible to determine whether the responses came from the same company or different companies. This survey was based on qualitative data.

3 RESULTS AND ANALYSIS

Questions (1 to 5) and their corresponding answers were grouped into incremental agreement categories represented by a scale, including "not relevant/not applicable" (denoted as **N**), "potentially meaningful" (denoted as **P**), and "meaningful" (denoted as **M**). The distribution of the answers is presented in Table 1 below.

Table 1. Distribution of answers

	N	P	M
1	0	1	7
2	0	3	5
3	2	4	2
4	2	1	5
5	3	4	1

Below are exemplified some of the responses, where example answers are indexed according to **[Row,Column]**.

1. What role do you believe knowledge in sustainable development plays in promoting innovation and competitiveness within the company?
   - **[1,P]**: Generally speaking, quite a small role. For some narrower areas, it can be of great importance, but the majority of companies are largely governed by the limitations "sustainable development" creates. Knowledge of future policies and directives is of course directly valuable, but is again often a limitation, even if innovation and competitiveness are affected by knowledge of the area.
   - **[1,M]**: In view of the CSRD reporting that will soon become a legal requirement, this is a requirement. The companies that succeed in embracing CSRD as a tool in their efficiency work will do better than their competitors who see CSRD as a burden and cost.
2. Is sustainable development a topic discussed within the company with alumni as part of their professional framework?
   - **[2,P]**: Yes and no. My experience is that it is discussed, but too little.
   - **[2,M]**: Within XXX, we have an organization that works with sustainability issues related to Agenda 2030.
3. Can you perceive how well-prepared alumni are to take responsibility for sustainable development within their profession?
   - **[3,N]**: The employees we have who are trained in computer systems are reasonably well prepared technically but not commercially. Use cases and their possible sustainability aspects often require several years of concrete commercial activity to create relevant creative competence.
   - **[3,P]**: It largely depends on the role and area of responsibility. It will be a huge waste of resources if everyone in a company focuses their energy on that

issue. Of course, it can have an impact on many areas, but it is usually not the primary area.
- **[3,M]**: Sustainable development is a need that we recognize is needed in these new times. This means new solutions that require new knowledge from various educational programmes. However, this also requires constant learning after school. Something that alumni definitely need to bring with them in their jobs.

4. Can you observe how effectively alumni contribute to sustainable development at various levels of the company's operations?
   - **[4,P]**: I am sure they can contribute with academic and research-based knowledge
   - **[4,M]**: Take, for example, AI, which is a new field (well, the mathematics is from the 40s) where development is happening at breakneck speed. It is a good example of how courses that both make students more attractive, but also alumni quickly become senior. There aren't that many people who have worked on this subject.
   - **[4,M]**: Having a broader perspective usually accompanies people with higher education.
5. Do you feel that there is anything additional that alumni should have learned from their education in sustainable development to carry out their work responsibly?
   - **[5,P]**: According to the reply to 3 "genuine" internships if they are possible to get. The company is an odd bird in this context, a small privately owned development company (about 20 developers) but with global customers and technical expertise.
   - **[5,P]**: You have to put everything in perspective so you don't sub-optimize and because this is a "tool" that everyone works with in some respect, you can waste a lot of resource time. Much like with the fact that everyone in the EU approves Cookie settings still to really very little use. An incredible amount of resources are put into it, both to build and to manage.
   - **[5,P]**: My education is too far back in time, so it's hard for me to determine how much is being done today. Nor can I tell from today's alumni how much they know or have learned. The short answer is therefore: I would have liked to have seen more knowledge on the subject.
   - **[5,M]**: ESG/CSRD, how will it affect companies and their role in the future. Many companies today are looking for expertise in ESG/CSRD. Issues of traceability will be of great importance both in terms of the physical flow but also in terms of data.

The respondents´ positive responses on two first questions confirm the awareness of knowledge in SD and indicate an approach of integrating SD into the organisation. In questions 3 – 5, the respondents classified in **N** column usually put the answers of type ‘No’ or ‘Not concrete’. One respondent claims that several years of experience are required to take responsibility for sustainable development. Another respondent considers sustainable development as a broad perspective subject where the responsibility lies with people with higher education (question 4). Question 5 was mostly qualified as a recommendation to the university.

What can possibly be sensed on the part of the entrepreneurs is a certain frustration at having to be pressured by regulations that are difficult to understand and deal with. Their primary priorities are of course mainly on doing business. What can be mentioned in this context is that the UN's Agenda 2030 for SD is based on three dimensions, the environmental, social and economic (Sweden 2024). CSRD does not actually mention the third dimension, i.e. economy, but where this seems to be seen more as a trade-off. The Agenda 2030's 17 SD Goals are interrelated and where both synergies and balances are discussed in, for example, (Wong 2021). Trade-offs and possible negative consequences may itself justify regulations to avoid bad impact from the part of companies. This, in turn, entails a need for greater knowledge of such regulations on the part of the companies.

4 SUMMARY AND ACKNOWLEDGEMENTS

Educational frameworks address student adaption towards their future work through pointing out learning outcomes regarding social and ethical aspects. While SD may not always explicitly be pointed out, it can be understood that such aspects also regard SD. Alumni’s’ competences and skills regarding SD should be valuable to fit well into their employers’ SD strategies, and possibly be contributing to such.

This study, even with the limited number of responses (8) confirms that the companies (included in the study) generally seem to have good knowledge of SD. What emerges, however, is that it is more challenging to work with SD-based assignments than to give such assignments to newly graduated students, especially computer science students. Employees with such responsibilities usually have more experience than recent graduates. Our students obtain fairly good competences in concepts regarding SD. However, it is recommended to contribute to the students with additional knowledge of the companies' situation regarding SD regulations such as CSRD. This could benefit companies as well as students' future career opportunities. What one can ask, however, is how reasonable it is to provide such themes within a Computer Science education. One possibility, which will be investigated further, is to use WIL, as previously described in this contribution, to look further into the IT companies' SD activities and the regulations regarding them.

The authors of this contribution would like to give a thanks to Marijana Teljega at HKR for her assistance concerning the survey. Furthermore, a special big thank you goes to the companies collaborating with the university who have taken the time to respond to the survey behind these studies. Also, thanks to the anonymous peer reviewers for valuable comments on a previous version of this contribution.

Conference Key Areas: Educating the whole engineer: teaching through knowing, thinking, feeling and doing; Engineering skills, professional skills, and transversal skills
Keywords: institutional strategy, holistic engineering education, stakeholder engagement, transversal skills

ABSTRACT

Educating responsible engineers is the challenge engineering schools are tackling today to address the needs of society, today and in the future. Instead of thinking of how to redesign courses and curricula to include relevant topics on ethics, sustainability and more generally social science and humanities subjects, in this paper we propose an institutional strategy that engages diverse stakeholders in creating a holistic engineering education. Focusing on our approach to enrich the learning journey with transversal skills opportunities for all students at our institution, we promote the integrated view of curricular and extracurricular activities to bring a responsible mindset in focus, while acknowledging the importance that self-directed learning has on the motivation to become a responsible professional able to solve complex challenges of the future.

1 THE BRICK ROAD: STUDENT LEARNING JOURNEY

Fig. 1. Illustration of a student learning journey through higher education

Caption: A vast network of brick roads through diverse landscapes, each brick represents a curricular element on the student's learning journey and the landscape represents everything else the student engages with during this journey, all of it contributing to various extents to the student's learning

1.1 Education ecosystem: responsible consideration of levels, dimensions and stakeholders

Higher education encompasses a multifaceted ecosystem that operates on several levels and dimensions and with a diverse set of stakeholders, each playing a crucial role in the functioning of the institution, and more importantly, each also plays a role in how students are educated. In this ecosystem, holistic student development is increasingly recognised as paramount (Grasso and Burkings 2010), bringing forth learning beyond what we traditionally conceive as knowledge, i.e. learning to do and learning to be. The attention to competences, attitudes and values highlights how teachers teach the content of their courses, but also significantly emphasizes the influence of the hidden curriculum and the extracurricular activities in developing of a responsible professional.

While curricular planning, content, outcomes and impact have been studied extensively, the significance of extracurricular activities and their impact on shaping a more comprehensive image of student learning has been gaining attention from engineering education scholars and educators alike only in the last decade (Figure 2).

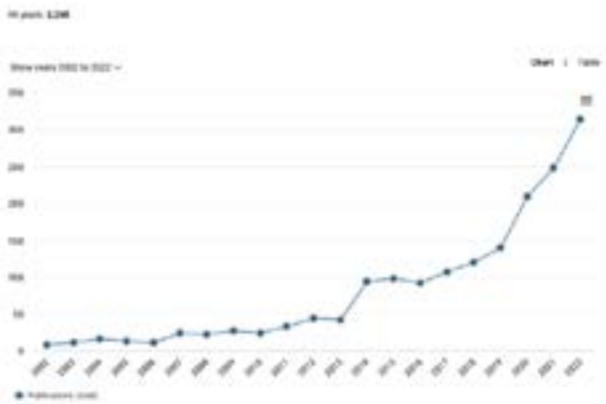

Fig. 2. Number of articles including “engineering education” and “extracurricular activity” in the last 20 years (graph generated in April 2024 using https://dimensions.ai)

Research indicates that student participation in extracurricular activities at universities correlates positively with academic performance and it is beneficial for skills development (Buckley and Lee 2018) as well as contributing positively to the feeling of belonging and well-being (Sisto, Huq, and Dickinson 2021). These studies include a wide range of stakeholders, such as students, alumni, recruiters and industry members, some of them showing that extracurricular activities are especially important for students from underrepresented backgrounds, helping them develop skills and improve their academic life (King, McQuarrie, and Brigham 2021). Furthermore, concluding a narrative synthesis of 39 articles from 2010-2021 about the impact of extracurricular activities on employability, Ribeiro et al. (2023) recommend a stronger promotion of activities outside of the classrooms to foster holistic student development.

In engineering education, Dalrymple and Evangelou (2006) connect the benefits of extracurricular activities to gaining social capital and developing social networks important for graduates' professional lives. Positive outcomes seem to be seen in terms of gender, particularly for strengthening confidence and leadership skills (Dalrymple and Evangelou 2006). Communication, leadership skills, problem-solving and “people skills” are also prominently mentioned in most studies in engineering education (Dalrymple and Evangelou 2006; Fakhretdinova, Osipov, and Dulalaeva 2021; Fisher, Bagiati, and Sarma 2014).

Moreover, the interconnection of curricular and extracurricular content within the academic framework promotes a holistic understanding of disciplinary knowledge and enhances student’s involvement in their own learning (Astin 1999). The benefits for the students go beyond the obvious and they are well known in the current state-of-the-art; coherent education and learning opportunities help students build resilience, learn time management and enhance their abilities to navigate the complexities of professional environments.

Beyond this, hidden curriculum has a multifaceted and significant impact on students’ character and development of identity. Since it refers to the unspoken lessons, norms, values and expectations that are absorbed within the environment and through educational experience, it is exceptionally important to be aware of the existence of hidden curriculum and its impact on students’ personal and professional formation (Villanueva et al. 2018). Rea et al. (2021) note that hidden curriculum has a subtle but powerful contribution to students’ overall learning experience. Examples of hidden curriculum thus include, but are not limited to (Cotton, Winter, and Bailey 2013):

- Course content: what to include and exclude from teaching, what and how to assess learning,
- Pedagogy: ways in which teachers' views form lessons, ways teachers act as models for certain behaviours and which behaviours are deemed unsuitable,
- Institution at large: messages that are passed in the physical environment, values that are communicated, and narratives present or missing from the public discourse.

Uncovering the values passed through the hidden curriculum has its significance in discovering how and why certain competences and identities are strongly present and persistent (Villanueva et al. 2018), but furthermore, it helps us understand how to coherently and comprehensively drive change in higher education institutions (Koutsouris, Mountford-Zimdars, and Dingwall 2021).

1.2 Co-creation, ownership and coherent framework to educate responsible engineers

Moving the academic discussion forward into what it means to have a responsible and responsive education system, especially considering the holistic development of students through their learning journeys, requires us to address the responsible approaches and the role of each stakeholder. Thus, we postulate that responsible education cannot be reduced to classrooms and auditoriums alone, but rather needs to be co-created and owned by everyone at a university.

Co-creation and ownership in a broad sense, but also in the educational sphere, emphasise the importance of collaborative efforts between diverse members of a community with the objective of more sustainable and impactful outcomes. Yet, literature and evidence on creating a coherent, co-constructed engineering education ecosystem that draws on multiple stakeholder engagement and considers diverse curricular aspects of the learning journey is scarce. Responsible engineering education often refers to embedding ethics and/or sustainability in the curricular offer, or at best referring to social responsibility as a learning outcome (Lathem, Neumann, and Hayden 2011). Even though Anderson (2000) rightfully questions who is responsible for student character development, the teacher seems to be the central figure in most of these studies, thus the quest for comprehensive co-construction is again diluted.

In their systematic literature review on strategic policy creation and implementation, Viennet and Pont (2017) note that one of the critical elements of effective policy implementation is stakeholder engagement. Sometimes referred to as "educational change", bottom-up theories of policy implementation suggest that it does not matter whether the change makes sense to those who initiate it, but rather what is the generated reaction of those who carry the work. Yet, as with anything in a complex system, awareness-raising and negotiation between those who need to be engaged is paramount (Viennet and Pont 2017). Nonetheless, there is a lack of literature on strategy development and leadership in higher education through the engagement of a complete ecosystem and here we wish to describe our practice.

1.3 Our role in co-creation of a responsible education ecosystems

We both work at the Transversal Skills and Career Centre at EPFL, and our mission in the last year has been to propose a strategic direction for transversal skills across the entire spectrum of curricular and extra-curricular learning and teaching activities. We have complementary backgrounds in STEM and social sciences, years of teaching and research in various educational contexts, and strong experience in transversal skills and institutional change.

2 BRICKS AND LANDSCAPES: BUILDING A COMPREHENSIVE AND TRANSPARENT METHODOLOGY

Building onwards, we look into what it means to develop an education system that integrates all learning opportunities and promotes the responsibility of all stakeholders, focusing on the transversal skills framework. Based on our understanding of educational change, the interaction and influence of different aspects of the curriculum and the importance of engagement of all stakeholders, we approached our transversal skills strategic direction in a co-constructive way.

To create a comprehensive and coherent approach, we devised a strategic direction based on two main missions, curricular and extracurricular, with proactive transparent information sessions for all the stakeholders in our institution. These two main missions run along our efforts to develop a coherent research and impact assessment initiative and are supported by awareness raising at all levels and with all stakeholders.

2.1 Responsibly involving stakeholders in the curricular strategic direction

Even though we advocate that learning at the university is complex, we nonetheless start with the obvious “brick road” – curricular content embedded in the courses and educational programs as the most visible and prominent activity, receiving high value from both teachers and students.

With a mandate to develop a new transversal skills framework, and with a thorough understanding of skills frameworks evidenced in the literature and by the engineering education community, we engaged in the bottom-up approach to help with the emergence of local context and hidden institutional and disciplinary values and attitudes. In collaboration with the EPFL Teaching support centre, we created 90-minute workshops and invited teachers from each department to discuss the future skills within their respective disciplines. To avoid disengagement of certain teachers, we avoided mentioning “transversal skills” at the beginning but rather embraced the open discussion on the important technical and non-technical skills future-oriented engineers would require to be considered competent in their field.

The teacher workshops serve two distinct aims:

1. Providing space for teachers to express in their own words what they feel are the skills that future graduates should have,
2. Providing an opportunity to discuss the place of teaching and learning skills, and particularly transversal skills, in the core curriculum, and outside of it.

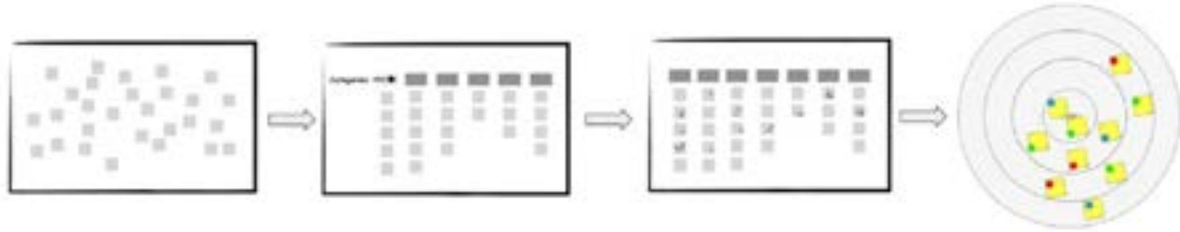

Fig. 3. Workshop with teachers to determine relevant skills for the future-ready engineers

Caption: Phase 1 consists of freely listing all the technical and transversal skills each teacher finds relevant, expressed in their own words. Phase 2 is a collaborative unguided categorisation that supports discussing similarities and subtle differences while the teaching team connects skills into relevant skills groups. In Phase 3 each teacher votes for the most relevant skills across different groups, supporting the final phase where the most voted skills are placed in "circular curriculum map2, to indicate where they should be taught and learnt, with the core disciplinary curriculum at the centre, and the extracurricular learning at the outer edge of the circle.

All steps described in Figure 3 have been carefully chosen to emphasise awareness raising and support co-creation:

1. We ask teachers to specify the skills in their own words, rather than providing a pre-set list; we use this (a) to gain an understanding of the vocabulary in specific disciplines, and (b) as an input for definitions grounded in first-hand evidence,
2. We ask teachers to classify and categorise the skills themselves, rather than suggesting a well-designed framework; in this step, teachers who usually might not ever speak about skills have the opportunity to discuss and exchange their viewpoints,
3. While we stress that all of their input is important, we offer teachers only 10 votes to allocate to a few skills they find most important; in this way, we raise awareness that it is not possible to teach all of the relevant skills and that there is a limited amount of time and resources, thus supporting a more responsible selection of key skills for future graduates,
4. Finally, by seeing the circular model where they can place certain skills in the core curriculum and others elsewhere in the wide scope of educational activities at our institution, we raise the point that while some skills might need to be taught in their own courses, others could be learnt elsewhere, i.e. in educational activities offered by service centres or through the student engagement in student associations. This raises awareness that students' learning happens across the rich institutional offer.

We use the data collected from each department to create a red thread through the core curriculum and extracurricular offer, in an attempt to understand the commonalities, and to identify disciplinary differences in skills relevant for each profession.

The data gathered from teachers is then triangulated with a similar process of collection from student representatives, grouped to create interdisciplinary groups to examine the student perspective on their learning journey independently of their field of study, and a slightly different model of data collection from industrial and civil/governmental institution representatives. Contrary to the data collection for students, we use a simplified Q method when working with external industrial and nonindustrial stakeholders do not work within the context of (extra)curricular activities. The Q method allows us to collect rich qualitative and quantitative data, comparable to the approach we use with teachers and students, thus allowing us to complete the picture of what relevant stakeholders hold important to teach future graduates.

2.2 A coherent extracurricular offer that gives ownership to students and valorises learning outside the classroom

While the core curricular content is complex and slow to change, the extracurricular offer makes part of the learning journey that does not follow strict institutional procedures and accreditation guidelines, and where experimentation can be done more frequently and freely. Student engagement in extracurricular activities is more self-driven and is not tightly dependent on the transactional nature of credits and grades. However, the nature of the extracurricular offer at our, and most other, institutions is that it is dispersed and incoherent and the skills development from extracurricular activities is seldom assessed for quality or depth.

To provide a clearer picture of how students can develop transversal skills through extracurricular activities, we have started by organising information sessions for different services and centres that provide extracurricular skills development on campus. Our focus is on transparent communication of our mission to consolidate the transversal skills offer, and seeking opportunities for engagement and co-construction.

Additionally, we reach out to each service to discuss their educational offer and the ways this offer can be valorised in terms of student skills development, offering coaching and co-creating extracurricular activities when needed. Specifically, our work consists of discussing the educational offer and exploring ways to valorise student development with the aim of increasing the visibility of skills development pathways.

To streamline the existing training offer, we use a single platform (https://epflcareer.ch/en/skills/overview/) as a one-stop shop for all the extracurricular activities related to the development of transversal skills. The benefit of processing the available transversal skills offer through a single platform is access to data on (a) which specific topics students are interested in working on outside regular courses, and (b) what times and periods are most effective for learning besides the regular courses. Beyond this, the extracurricular offer is usually shorter and more modular than regular course content and thus can be quickly developed, tested and evaluated. Being completely voluntary, it offers students a chance to shape their own learning journey, adding crucial experiential learning and mindset development outside of the classroom. Finally, in the long-term, the single platform can serve as a collection of extra-curricular learning, and help students understand better their current skills development level, and how their intended objectives could be satisfied with the existing extra-curricular learning opportunities.

3 WHAT LIES ON THE HORIZON OF THE COMPREHENSIVE STUDENT LEARNING JOURNEY

We presented above a student-centred institutional strategy for developing transversal skills through a diversity of interlinked learning opportunities. Our approach requires that all education providers agree on the same direction, while also allowing student engagement to be at the foundation of their learning journey. Working in such a direction takes time, patience and effort, yet by creating a mutually accepted education strategy, we address not only the alignment of the curricular and extracurricular activities but also nourish the hidden curriculum that supports the transversal skills development.

3.1 Responsibilizing each student to construct their learning journey: e-portfolio

Synchronising curricular and extracurricular offers, aligning stakeholders, and having transparent and active communication around transversal skills, are all relevant elements that support students' holistic development. Nevertheless, we return to the illustration of the bricks and landscapes of the student learning journey (Fig 1). By acknowledging that the most important element there is the student, we move forward with a proposal that mobilises student engagement in the journey and their ownership of their learning.

Part of the purpose of aligning teaching, learning and assessment of transversal skills is to bring all of it together in a student e-portfolio. We know from prior evidence that portfolios support student active learning and engagement (Hernández de Menéndez et al. 2019; Kovacs, Milosevic, and Niculescu 2023). We also acknowledge that engaged students feel more ownership over their learning; Besterfield-Sacre et al. (Besterfield-Sacre, Atman, and Shuman 1998) note that engaged students are more likely to participate in extracurricular activities which provide opportunities for hands-on learning and real-life application of engineering principles. This supports their holistic development and cultivates a growth mindset.

Thus, an e-portfolio comes as a self-directed roadmap of the student learning journey with three objectives:

1. Enables students to reflect on which skills they want to learn at which level (where and how far do I want to go?)
2. Integrates all learning related to transversal skills and maps it across the full ecosystem (what are all the options and different pathways I have available on my journey?)
3. Offers procedures for validation of skills, through self-assessment, peer-assessment and assessment by experts (how do I know where I am now and how far do I still have to go to reach my destination?).

Skills listed in the e-portfolio will be those resulting from a co-constructive work on a framework through curricular and extracurricular data collection, focus groups, and workshops. The proposed skills framework will integrate the linguistic nuances and discipline-specific content, interlinked with more interdisciplinary and transdisciplinary perspectives of students, external stakeholders and educators in services. In addition to this, a gradual progression of each skill which will make the assessment and evaluation more accurate for students and those in charge of assessment. Finally, the e-portfolio system will tie into a map of learning opportunities for transversal skills, and connect the key learning outcomes from both curricular and extracurricular learning opportunities, making it possible to valorise the whole learning journey in the diploma supplement as the ultimate outcome.

4 RESPONSIBLE EDUCATION FOR RESPONSIBLE ENGINEERS OF THE FUTURE

In the landscape of higher (engineering) education, the holistic development of students is increasingly recognised as crucial to providing relevant professional development. While academic curriculum lays the foundation for disciplinary knowledge and skills acquisition, extracurricular activities serve as indispensable complements, enriching the learning journey by fostering personal growth, leadership and decision-making abilities, and a sense of community engagement. The impact of this integrated approach to education is not only to prepare students for the complexities of professional life but also to nurture well-rounded individuals capable of contributing meaningfully to society. Furthermore, appreciating the complexity of the learning journey sends a message that learning is valued in all forms, and different ways of skills assessment are nurtured, which builds into a coherent hidden curriculum.

> “In order to improve the quality of education that university students receive, universities need to take a close look at the way they promote and assess learning and development, bridging the gap between academic and non-academic education experiences. Higher education institutions should create conditions to promote activities with an educational purpose outside the strictly curricular objectives and beyond the classrooms, promoting more holistic development of students” (Ribeiro et al. 2023, 14).

This holistic perspective on engineering education underscores the collective and individual responsibility of all actors within the university ecosystem – faculty, administrators, service staff, leadership, and students themselves. In this paper, we exposed our practice in developing and implementing systemic institutional change towards responsible education, the value of which is to promote co-creation, ownership and coherence, and pave the way towards ever-evolving responsible and responsive education systems of the future.

ABSTRACT

Service-Learning (SL) has emerged as an important high-impact practice in contemporary higher education. Rooted in experiential learning, SL constructs alliances between faculty-led academic courses and community-based organizations and institutions aiming to enhance several students' competencies. In this context, second-year Mechanical Engineering students, enrolled in a Statistical Methods course, were tasked with conceptualizing and executing Service-Learning initiatives in collaboration with an institution. Possible Service-Learning projects were proposed to address the specific needs of the institution while aligning with the diverse students' interests. Moreover, students participated in pre- and post-questionnaires to quantify the development of competencies associated with the service-learning experience they undertook. This paper presents the experience of integrating Service-Learning principles within the curriculum, specifically within the Statistical Methods course for second-year Mechanical Engineering students, to cultivate practical problem-solving skills, foster meaningful community engagement, and evaluate the impact on student competencies through rigorous assessment measures. Service-Learning steps performed, and the fruit of this experience are also discussed.

1 INTRODUCTION

Service-Learning (SL) has emerged as an important high-impact practice in contemporary higher education. Rooted in experiential learning, SL constructs alliances between faculty-led academic courses and community-based organizations aiming to enhance several students' competencies (Hadlock 2005).

Community service, as many of us know, has been a part of educational systems for years. Nevertheless, what takes Service-Learning to the next level is that it combines serving the community with the rich academic frontloading, assessment, and reflection typically seen in project-based learning. In a service-learning unit, goals are clearly defined, and there are many kinds of projects that classrooms can adopt. Classes or students can be involved in direct issues that are more personal and face-to-face, like working with the homeless or performing a data analysis survey for an institution or company. Involvement can be indirect when the students work on broader issues, perhaps a local environmental problem. It can include advocacy to educate others about pertinent issues, it can be research-based where the students act to curate and present information based on public needs. Different types of projects can be developed. A possible classification is as follows:

- Direct or external projects: these are those that are carried out on-site, in the

association itself or in the community, outside of classrooms or university spaces.

- Indirect or internal projects: take place mainly on campuses or university facilities. Research projects or research for information that the community needs can be included here.

A description of SL pedagogical methodology and the effects of SL quality on self-efficacy and engagement may be found in Joseph A. Allen, et al (2021) paper. A widespread of SL applications in engineering courses may be found at (Queiruga-Dios, et al. 2021).

In all SL projects it is necessary to consider and overcome the following phases (Queiruga-Dios, et al. 2024):

Fig. 1. Service-Learning process

1.1 Service-Learning and Mathematics

Engineering students often encounter mathematical difficulties during their academic journey. The need for abstract thinking of some complex nature of mathematical concepts and their applications in engineering fields can pose challenges for students, especially those in the early stages of their education (Lawson et al. 2020). Recognizing this problem, the authors have increasingly turned to innovative approaches, including SL, to engage students in addressing societal problems while gaining competencies, both scientific and personal (Caridade, et al. 2018; Queiruga-Dios, et al. 2020; Rasteiro, D.M.L.D., et al. 2024). Service-Learning, as an active methodology, integrates classroom learning with hands-on experience in community-based projects. By immersing themselves in real-world challenges, such as analysing environmental data for local organizations as was done in the curricular unit of Statistical Methods, students not only apply mathematical principles but also gain a deeper understanding of their relevance and impact. Engaging students with societal problems through SL enhances their educational experience by providing a sense of purpose and relevance. By addressing pressing issues related to local societal problems students see firsthand the potential their skills must make a positive impact on society. This experiential learning approach encourages critical thinking, creativity, and ethical decision-making as students navigate complex engineering challenges. Moreover, SL promotes the development of competencies beyond scientific knowledge. Through collaborative projects and interactions with community members, students refine their communication, teamwork, and leadership skills. They learn to effectively communicate technical concepts to diverse audiences, collaborate with stakeholders, and adapt to changing circumstances - a crucial skill set for success in both academia and the professional world. In addition to gaining scientific competencies, students also experience personal growth through their engagement with societal problems. They develop a deeper sense of empathy, cultural awareness, and social responsibility as they grasp the ethical implications of their work. This holistic approach to education nurtures well-rounded engineers who excel in their technical field and positively contribute to society. As a result, by integrating SL as well as other active methodologies, educators empower engineering students to become innovative problem solvers and responsible global citizens. Thus, students are not only better equipped to overcome mathematical difficulties but also inspired to make meaningful contributions to the world around them. It is worth mentioning that the skills gained by students with SL pedagogical methodology are transversal skills, therefore this pedagogical methodology is applicable within all education fields.

2 METHODOLOGY

2.1 Statistical Methods course

The Statistical Methods curricular unit is one of the mandatory units of the 1st year of Engineering graduation courses at the Coimbra Engineering Institute, Polytechnic University of Coimbra. It is designed to equip students with a comprehensive understanding of fundamental statistical concepts and their applications in engineering and other fields. The course is structured around mandatory content areas, ensuring a systematic and thorough exploration of key topics. The course begins with an introduction to probabilities, laying the groundwork for understanding random experiences, spaces for results, and events. Students delve into probability definitions, conditional probability, independent events, as well as foundational theorems such as the Total Probability Theorem and Bayes' Theorem. Moving forward, the course progresses to the study of random variables and discrete probability distributions. Students learn about discrete random variables, including their probability functions, distribution functions, and key parameters such as location and dispersion. Special discrete distributions such as the Bernoulli, Binomial, Hypergeometric, and Poisson distributions are explored in detail. Additionally, students examine discrete bidimensional random variables, joint and marginal probability functions, conditioned probability functions, and concepts of independence and correlation. Continuing the exploration, students delve into continuous probability distributions, understanding probability density functions, distribution functions, and parameters of location and dispersion. Special attention is given to prominent continuous distributions such as the Normal, Chi-square, and T-Student distributions, with brief references to Uniform and Exponential distributions. The course then transitions to sampling and sampling distributions, where students learn about the principles of random sampling, statistics, and the distribution of sample averages and variances. Building upon this foundation, students explore estimation techniques, including point and interval estimation, with a focus on constructing confidence intervals for both population means and variances. Finally, the course concludes with a study of parametric hypothesis tests, providing students with fundamental notions and methodologies for testing hypotheses about population means and variances. Through rigorous examination and practical applications, students develop a solid understanding of statistical methods and their relevance in scientific research, engineering analysis, and decision-making processes. To enhance student learning and achievement of key competencies (Alpers et al. 2013; Niss 2003; Niss and Højgaard 2019), active methodologies are integrated into the course design. Community study using Padlet allows students to collaborate and engage in problem-solving activities beyond the classroom (Rasteiro, D.M.L.D., et al. 2024). Additionally, office hours are dedicated to real problem-solving activities, providing students with opportunities for one-on-one guidance and application of statistical methods to real-world scenarios. These methodologies foster the development of competencies such as thinking mathematically, reasoning mathematically, posing and solving mathematical problems, modelling mathematically, representing mathematical identities, handling mathematical symbols and formalism, communicating in, with, and about mathematics, and making use of aids and tools (Alpers et al. 2013; Niss and Højgaard 2019). By linking active methodologies with the course content, students not only master statistical methods but also cultivate essential skills for success in their academic and professional endeavours.

To achieve mastery of the course content and competencies, students are encouraged to utilize software tools such as IBM SPSS Statistics (Version 27) and R software (RStudio Team 2020), as well as any model of calculator that supports probability distributions. Attending to this course the authors had 115 students (4 female and 111 male).

2.2 Service-Learning methodology followed

At the beginning of the semester, students were introduced to the concept of Service-Learning, explaining the distinction between volunteer work within organizations. Emphasis was placed on the integration of content learning with service-oriented activities, which would subsequently be evaluated. The procedural framework comprising seven steps- observation, preparation, action, reflection, data registration, evaluation, and recognition (Figure 1. above)- was clarified to the students. Subsequently, students were encouraged to enrol for participation. Upon conclusion of the registration period, a total of 16 students (all male) had submitted applications and from those, 10 students engaged in this learning experience. A meeting with the chosen non-profit organization (NPO) was promoted where besides presenting the organization and its projects, its President also presented the needs where students' knowledge of Statistical Methods could be of service. The NPO chosen was CASPAE. CASPAE, Social Support Center for Parents and Friends of the School, is an IPSS that develops Free Time Activities in several primary schools in the municipality of Coimbra, in partnership with the respective Parents' Associations and School Groups. With the mission of promoting responses of a social nature, personal development and well-being of individuals, with a view to their inclusion in society, there is the CASPAE Sports Academy, which promotes sport for all ages and also provides the Take care of yourself with a Home Support Service specialized in responding to the needs of elderly people.

Currently, CASPAE makes a strong investment in projects that cover several areas, from education to nature, to technological education for all, including projects that aim at social inclusion, as well as valuing the elderly, among others. It is also the entity that coordinates support programs for the most needy people, also developing several initiatives to collect and distribute essential goods. For further details on this NPO the reader is invited to access https://caspae.pt/PT/ . Some students who were not able to be present in person were present online. Students were invited to brainstorm from all they watched and heard and identify what major topics could be addressed (Observation and Preparation phases). At the same time, students were divided into groups of 2. The themes chosen to be worked were:

- Characterize the population that uses the CASPAE. That is, understanding the factors that lead parents to enrol their children in the various services/activities provided and analyse other information collected in the registration forms;
- Study the projects (areas) that beneficiaries seek to complete the CASPAE offer. Understand why there is no interest in other projects already created and with little support;

- Study secondary and higher education students to assist the CASPAE in detecting gaps in the use of technology to support learning, as well as detecting differences in this understanding between genders;
- Analyse the activities carried out by the CASPAE from its beginnings to the present, with emphasis on the evolution of the number of children served, the expansion of training offered over time, and the increase in the number of activities over the years;
- Study current CASPAE projects that cover a large number of beneficiaries and understand their success to help other less successful projects.

Throughout the semester, while in the action phase, regular meetings with students were held, mostly online to clarify questions, reinforce their motivation, and explain mathematical concepts related to Statistical Methods.

While in the action phase some of the groups needed to develop questionnaires and collect data with all the knowledge gathered on how to correctly do it, and all groups had to perform data analysis. The data analysis was performed using Excel and/or SPSS with professor guidance and help.

Reports were performed and presented orally to the CASPAE President. After, and sometimes during, reports presentation discussion periods were held about the results and the reality of CASPAE, which gave students a sense of involvement that would not be possible if this learning activity was not performed.

The evaluation phase consisted of taking stock of the entire project development process, analysing the results obtained, and the fulfilment of the proposed objectives. A self-assessment was also necessary, evaluating possible improvements and future projects. Students answered pre- and post-questionnaires to quantify the development of competencies associated with the service-learning experience they undertook.

A SL rubric adapted from Coverdell's World Wise Schools publication Looking at Ourselves and Others (Washington, DC: Peace Corps, 1998, p. 6) was used to evaluate students. In the next section, the experience we will present the results obtained.

3 RESULTS

3.1 Pre- and post-questionnaire analysis

Pre- and post-questionnaires had 21 questions, see Table 1 below, graded from 1- *Not at all important* to 7- *Very much important* as Likert scale. As said previously, students answered the questionnaires before starting the SL activity and after concluding it.

Table 1. Pre- and post-questionnaire questions

Q1 - Experience personal growth	Q11 - Apply problem-solving techniques
Q2 - Ability to work with others	Q12 - Build my self-confidence
Q3 - Improve my leadership skills	Q13 - Conflict resolution

Q4 - Improve my communication skills	Q14 - Ability to take personal responsibilities
Q5 - Gaining a greater understanding of cultural and racial differences	Q15 - Learn practical skills in the workplace
Q6 - Improve my social responsibility and citizenship skills	Q16 - Ability to learn from experience
Q7 - Community involvement	Q17 - Develop organizational skills
Q8 - Ability to have influence in the community	Q18 - Connect theory with practice
Q9 - Apply information learnt in the classroom to real-life scenarios	Q19 - Establish affectionate relationships
Q10 - Problem analysis and critical thinking	Q20 – Empathy and sensitivity to the situation of others
Q21 - Demonstrate that I am someone who can be trusted	

The results obtained from the pre- and post-questionnaire analysis reveal significant improvements in various competencies among the students. According to their answers, there is a notable enhancement in the following areas: (Q2.) Ability to work well with others, (Q3.) Improving leadership skills, (Q5.) Gaining a greater understanding of cultural and racial differences, (Q6.) Improving social responsibility and citizenship skills, (Q10.) Problem analysis and critical thinking, (Q11.) Applying problem-solving techniques, (Q18.) Connecting theory with practice.

Data collected indicates, see Figure 2, that students perceive a marked improvement in their collaborative skills, leadership abilities, appreciation and understanding of cultural and racial diversity, sense of social responsibility, and citizenship. It is also notable the enhancement in students' ability to analyse problems and think critically, and their proficiency in applying problem-solving techniques. Questionnaires' answers also suggest that students have successfully bridged the gap between theoretical knowledge and practical application. This suggests that the Service-Learning experience has facilitated effective teamwork and cooperation among peers. These results indicate to us, as professors, that SL is a learning and teaching methodology that allows students to accomplish their learning path regarding curricular unit's contents curriculum, but also allows students to improve other social competencies as well. These findings validate the effectiveness of integrating SL initiatives into the curriculum to enhance students' holistic growth and learning outcomes.

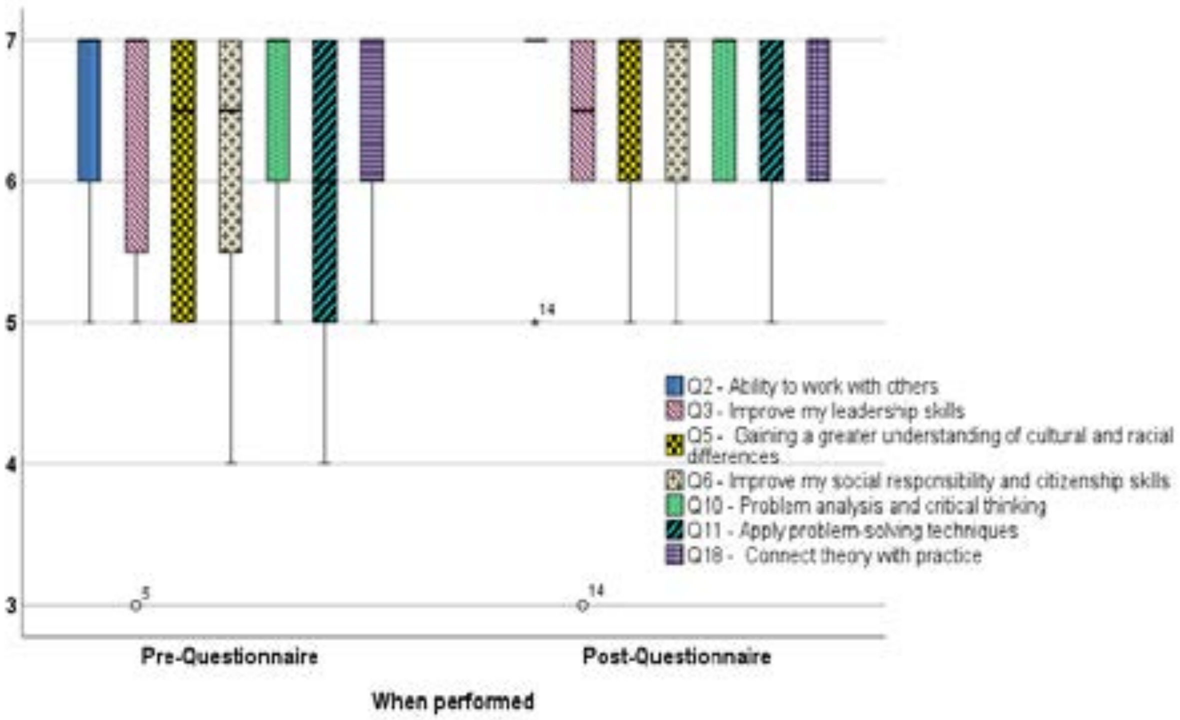

Fig. 2. Pre- and post-questionnaire results comparison

For questions not depicted in Figure 2 above, students' answers indicate that either their proficiency remained unchanged from the beginning of the activity, or the Service-Learning (SL) projects followed did not align with the referred competencies they anticipated, as illustrated in Figure 3,

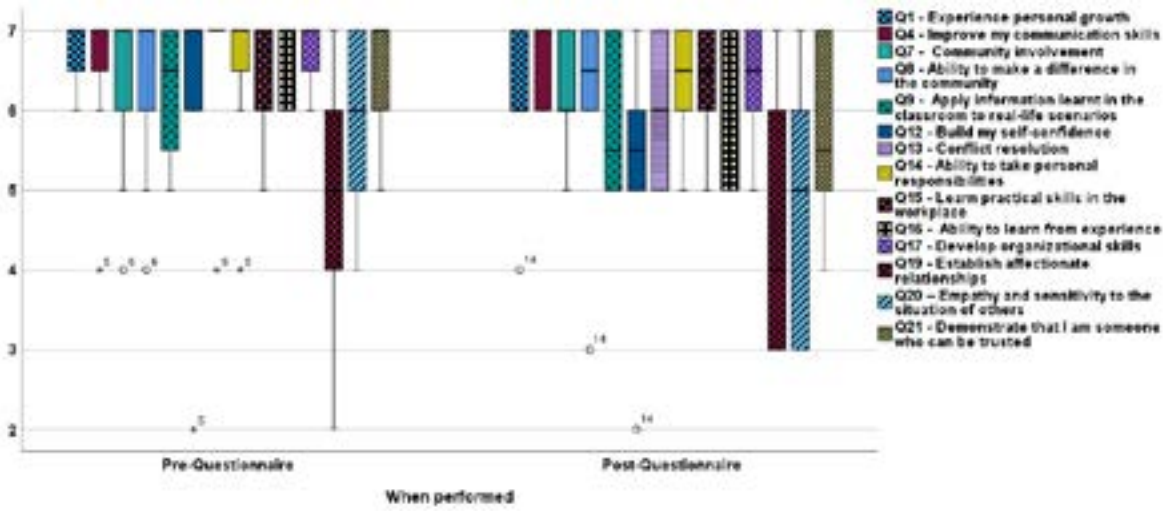

Fig. 3. Pre- and post-questionnaire questions where there were no competencies improvement

4 SUMMARY

With the proposed SL activity, competence improvements were observed in students' ability to work well with others, improve leadership skills, gain a greater understanding of cultural and racial differences, enhance social responsibility and citizenship skills, engage in problem analysis and critical thinking, apply problem-solving techniques, and connect theory with practice. Data analysis indicates that students perceived notable developments in collaborative skills, leadership abilities, cultural understanding, social responsibility, problem-solving proficiency, and theoretical application. These findings underscore the efficacy of SL in fostering teamwork, enhancing social competencies, and bridging theoretical and practical knowledge. Furthermore, the results confirm that SL is a valuable pedagogical approach for facilitating comprehensive student development within the curriculum. However, for some of the competencies covered by the questionnaires, students' responses suggested either unchanged proficiency or a misalignment between SL projects and anticipated competencies. It must be noticed that at the beginning students did not know which were the needs of the NPO institution and neither the service they were going to do. Still, these findings encourage authors to continue promoting the integration of SL initiatives into the curriculum to promote holistic student growth and learning outcomes.

ABSTRACT

In contemporary engineering education, project-based learning (PBL) has emerged as a prominent pedagogical approach to foster transversal skills like collaboration and communication. However, effective supervision and guidance of student groups in PBL present challenges. This paper introduces an innovative approach to support student groups and teaching assistants (TAs) in PBL, utilizing a digital experience platform. The presented pedagogical scenario features a digital collaboration journal used by students to document their progress. Through the implementation of this scenario in an interdisciplinary course, data was collected via surveys and interviews. Results indicate that students perceived the collaboration journal as supportive for poster preparation and discussions with the TAs. While the scenario was well received, challenges persist in fostering online communication. Future iterations aim to enhance the platform's role in facilitating group-TA interactions and providing a comprehensive collaborative environment. This research contributes to the advancement of PBL methodologies by offering practical insights into leveraging

jeremy.lascala@epfl.ch

digital platforms to enhance collaboration, communication, and feedback processes, ultimately enriching the learning experience for students and TAs alike.

1 INTRODUCTION

Engineering education of the last few decades has recognized the development of transversal skills as essential to the development of responsible and skilled engineers (Jalali et al. 2022). Among these transversal skills, collaboration and communication is of particular importance for future engineers to be able to tackle the large and ill-defined problems of the 21st century through collaboration and coordination (Ercan and Khan 2017). One of the most prominent pedagogical approaches to combine the development of collaboration and communication skills with discipline learning is project-based learning (PBL) (Granado-Alcón et al. 2020; Hussein 2021; Saldo and Walag 2020).

In spite of its benefits, PBL is hindered by the flexibility and amount of facilitation it requires (Shpeizer 2019; Vasiliene-Vasiliauskiene, Vasiliauskas, and Sabaityte 2020). Indeed, supervising and guiding small groups of students in PBL is a common challenge in engineering education. In projects that develop over multiple weeks, teachers must implement strategies to assess the progress of the groups and deliver timely feedback (Meng et al. 2023) which can represent a considerable challenge for teachers.

This challenge is exacerbated in courses with a large number of students. In such settings, teachers may rely on Teaching Assistants (TAs) to supervise and guide the groups of students. At our institution TAs are most often Ph.D or undergraduate students. Thus, they are not trained teachers and they don't have expert knowledge of the course material, nor complete mastery of the skills that are trained in the course. Because of that TAs must coordinate with the main teacher(s) and often report to them. Coordinating the work between multiple TAs can be a challenging task that requires time, energy, and method. Additional difficulties may arise when the pedagogical scenarios involve blended or online modalities. Strategies to develop and prepare TAs to teach and support these scenarios appears to have received little attention in the literature (Wadams and Schick-Makaroff 2022).

Finally, it is important to consider the challenge posed by the creation and management of assignments to the groups of students. The collaborative redaction of a small report can be a daunting task if the group does not follow a proper procedure backed by relevant technologies (Hussein 2021). In this case, the scenario deceives its purpose and the progress of the groups may be limited by collaboration issues and conflicts (Chan and Chen 2010).

In this paper, we present an innovative approach to the supervision and guidance of groups in PBL, leveraging a digital experience platform and real-time collaborative documents to structure and enhance the collaboration between all stakeholders. While the use of digital platforms to foster collaboration in PBL has already been explored (Balderas-Díaz, Guerrero-Contreras, and De Castro-Cabrera 2022; Ørngreen *et al.* 2021), our approach contributes to the understanding of this practice by exploring the participation of TAs. We present the evaluation of this scenario through a survey of the students and semi-structured interviews with the TAs.

2 PEDAGOGICAL DESIGN FOR SUPPORTING GROUPS OF STUDENTS AND TEACHING ASSISTANTS IN PROJECTS

Our design is the continuation of an ongoing work aiming to improve the scenario of the Communication course at our university. This course is part of an interdisciplinary program which was introduced in 2013 as a compulsory course for all first-year students, to develop transversal skills as early as possible in their curriculum (Gillet and Vonèche-Cardia 2021; Holzer *et al.* 2016). Teachers are assisted by TAs from our academic institution. The course is divided in two parts: the first one is a series of lectures, and the second one is dedicated to a collaborative project. In this second part, students form groups of five teammates and choose a topic related to communication. Groups have to prepare a poster which tackles a global issue related to communication. It has to include the definition of the selected issue, its technical and societal dimensions, as well as the current and potential future solutions to tackle it, with the relevant scientific references (Gillet and Vonèche-Cardia 2021). In the original scenario of the course, groups were required to submit short reports every week on one particular aspect of their global issue. These reports were read by the TAs who provided oral feedback to each group.

In previous iterations of the course, we attempted to improve this scenario by providing a simple digital task management application to the students and access to a collaborative platform to share files and create documents (La Scala *et al.* 2022). We hypothesized that the students would use the provided tools considering their potential added value. Nevertheless, we found that those tools were not perceived as helpful by most students. We also realized that we had overlooked the burden of integrating tools within the pedagogical scenario.

Building on these findings and observations, and considering the challenges mentioned in the introduction, we elicited some core design principles (DPs) to guide the design of our new pedagogical scenario that should provide support to all stakeholders (students, TAs, and teachers).

DP1: Centralization

All digital tools, artifacts, communication and collaboration tools should be available on a single platform. One should mention that the Moodle LMS used to detail the syllabus and distribute slides in the first part of the course is not suitable to support effective collaborative learning in its second part.

We assume that the multiplication of online services and applications constitute an additional barrier to the effective adoption by the students. Therefore, we postulate that a centralized environment removes the burden and the cognitive load due to the management of multiple independent services.

DP2: Integration of activities and technology

Learning activities and learning technologies should be integrated to each other. Activities should be adapted to draw from the full potential offered by the selected technologies.

This was motivated by the observation that tasks and processes irrelevant for learning may be removed or simplified. For example, we removed the need to submit a report by using collaborative document accessible to the teachers and TAs.

DP3: Feedback delivering process

TAs should have a well defined and easy process to deliver their feedback to the students.

The potential benefits of feedback systems in higher education (Figas, Bartel, and Hagel 2017) motivates this DP.

DP4: Logs of the progress of the groups

All feedback delivered to the groups should be consigned in a document on the central platform. TAs should be able to use this document to assess the progress of the groups.

This is motivated by the current lack of visibility on the progress of the group. We assume that those logs will provide a clear overview on the advancement of each project and facilitate the delivery of useful and accurate feedback.

DP5: Promote connection and coherence between assignments

The different assignments of the project should build on each other. Moreover, this building process should be flexible and allow students to revise previous assignments to align them with the development of their project and allow for their reuse in the final deliverables.

We consider the project as an iterative design process. Thus, and for the feedback to benefit future assignments, those must be coherent.

Following these DPs, we designed and implemented a new approach relying on Graasp[2], a learning experience platform used to create collaborative online spaces. Graasp aims at building rich and interactive learning experiences in blended learning scenarios which integrate face-to-face and online activities (Gillet *et al.* 2022). The platform provides collaborative spaces that are built with **folders**, similarly to a conventional file system. Each folder can be shared with other users and access rights can be fine-tuned to control who can read or edit the content.

Graasp is a collaborative platform where users can exchange files, use built-in collaborative tools and elaborate documents. This collection of features was instrumental to the implementation of structured collaborative activities. It allowed us to centralize all the required features in one platform (*DP1*). In our scenario, we created a folder for each group. Each group was provided with a space where they could exchange files and collect references for their poster. In this space, we provided a **Collaboration Journal** (CJ) based on Etherpad[3], a real-time collaborative text editor integrated to Graasp (“Etherpad: A Real-Time Collaborative Editor for the Web” [2011] 2023). This application can be used in teamwork activities to jointly elaborate documents or share notes. The CJ was a template document in Etherpad to support the collaboration and the elaboration of the poster. In the CJ, the text written by each student is highlighted in a different color, allowing users to distinguish individual contributions as shown in Fig 1.

The template of the CJ contains three sections, each dedicated to one part of the poster, matching a dimension of a global issue. Every week, groups must fill a

[2] https://graasp.org
[3] https://etherpad.org/

section to complete the assignments summarized in Table 1. TAs will provide feedback to the groups after reviewing their assignment. The feedback is provided directly in the CJ, following *DP3*, and additional comments can be sent to the whole group with the help of a chat integrated in Graasp.

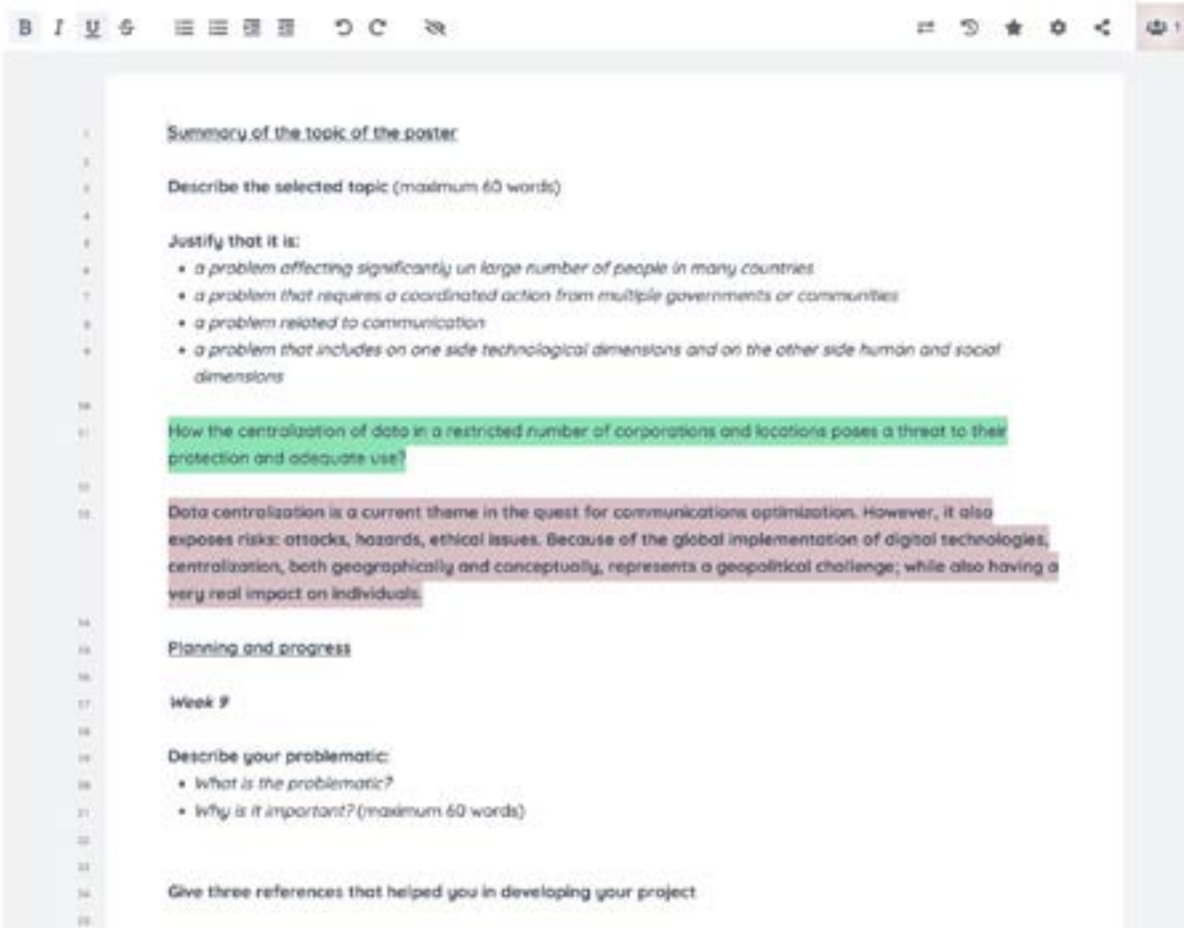

Fig. 1 A sample collaboration journal. The contributions of two students are highlighted with two different colors.

Table 1. Sections of the collaboration journal and corresponding assignments.

	Section	Assignment
1	Problem statement	Describe the problematic and justify its importance.
2	Technical and human dimensions	Describe the technical and social/human challenges.
3	Context and interest	Describe the context and show the interest of the selected topic.

After reviewing the assignments and having provided a written feedback to the groups, the TAs will also put their feedback in the **progress journal**. The latter is also an Etherpad that is provided to TAs to help them track the progress of the groups, implementing *DP4*. These journals are located at a level of the hierarchy in Graasp that is not accessible to the students but can be read by all TAs and teachers. Thus, teachers can get a quick overview of the work of all groups without having to read each CJ.

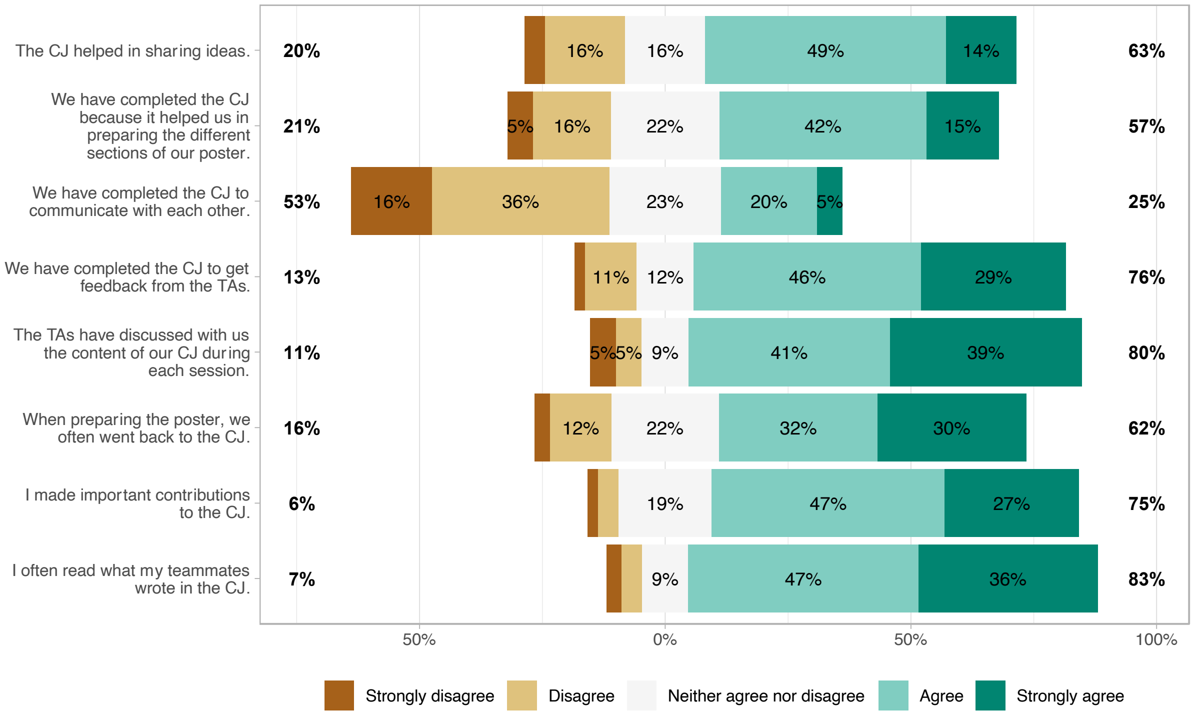

Fig. 2. Answers of the students to the survey items on the Collaboration Journal.

Overall, this process leads to the elaboration by each group of a complete document containing the essence of the poster that the students have to co-design and submit at the end of the project. By uniting all these sections in a single document, we aim at bringing the attention of the students on incoherence and discrepancies in the elaboration of their poster as early as possible, following *DP5*.

3 EVALUATION OF THE EDUCATIONAL SCENARIO

After implementing our redesigned scenario, we collected anonymous qualitative and quantitative data to build a first evaluation of our approach.

3.1 Data collection

At the end of the semester, we conducted an anonymous survey with the students and semi-structured interviews with the TAs. The survey was made of a unique paper questionnaire distributed to all the students after they presented their poster. The questionnaire was fully anonymous and did not require the students to provide any personal information. It contained 17 items to rate on a 5-point Likert scale and three open questions. The first ten items were related to the CJ. The survey was administered by the first author who briefly explained its purpose to the students. It was also clearly stated in the introduction to the questionnaire that all answers are anonymous and that participation to this survey is optional and not part of the course. This was also explained again during the administration of the survey. Overall, we transcribed **98** answers to the survey (n=98) selected randomly for analysis. More answers were collected but not transcribed as we had reached data saturation (Fusch and Ness 2015). The paper questionnaire was transcribed to an anonymous dataset and analyzed with R (R Core Team 2024).

To grasp the perception of the TAs, semi-structured interviews were conducted with all the TAs in the two weeks following the end of the course. Each interview was audio recorded. The TAs were informed that they would be recorded and that their participation to the interviews was optional. After the interviews, the audio files were transcribed automatically using Whisper ("Whisper" [2022] 2024; Radford *et al.* 2022). The transcripts were manually edited to correct transcriptions mistakes. Finally, the transcripts were imported in Taguette (Rampin and Rampin 2021) for coding and analysis.

3.2 Perception of the Students

As shown in Fig. 2, most students perceived the purpose of the CJ in supporting the preparation of the poster (57%) and getting feedback from the TAs (76%). The majority of the students agreed on having contributed to the CJ (75%) and having participated in the group work by reading the contributions of others (83%). These positive results highlight a good understanding of the scenario. Conversely, it appears that the CJ was not perceived as a communication tool.

3.3 Perception of the Teaching Assistants

With the objective to elaborate a comprehensive picture of the perception of the TAs, we followed an emergent coding strategy to identify the main themes of the interviews and the opinions of the TAs on those themes. The coding process was conducted by the first author and focused on identifying mentions of the behavior of the students, the communication between the students and the TAs, the interactions among the TAs, and the use of the CJ.

The analysis was done in two phases. First, a definition the main codes based on the guiding questions used during the interview. Second, the transcripts were coded by one researcher. During this process, new codes were created to encompass new themes and subthemes that were not foreseen in the preparation of the interview.

This analysis allowed for the identification of the main themes regarding the previously mentioned points. In the following subsections, we will focus on two themes that were extensively discussed by the TAs.

Delivering Feedback on the Collaboration Journal

Five TAs described how they delivered the feedback to the students using the CJ. All of them explained that they did not write their feedback directly in the CJ but mostly using the chat integrated to Graasp. They sent their comments using the chat but most of the time did not receive an answer from the students. They mentioned, however, discussing the feedback with the students during the course session and one TA explained he provided more detailed feedback when meeting the groups.

Following the Progress of the Groups

All TAs made positive comments on the use of the CJ to assess the progress of the students. They explained that it was convenient and one TA said he could not imagine how they would have followed the progress of the groups without such a tool. Nevertheless, two limitations were mentioned:

1. The instructions given in the CJ were not clear for all students. They asked many clarification questions on the length of the text they should produce and the style they should adopt.

2. The feature of Etherpad that highlights each piece of text with a color corresponding to its author impaired the readability of the CJ. Some students complained to the TAs about this feature and had created another collaborative document to elaborate their text before copying and pasting it in the CJ, despite the fact that the color highlighting feature can be disactivated in Etherpad (a fact that was probably not known by the TAs).

Nevertheless, one TA reported having observed the flexible and evolutive possibilities offered by the CJ. She described a group who did modify the previous section of their work to maintain the coherence of the whole journal after receiving the feedback from the TAs.

4 CONCLUSIONS

In this paper, we have presented our design principles to support the interaction and the work of TAs and students. We have then shown how we followed these design principles to enhance the pedagogical scenario of an interdisciplinary course. Finally, we evaluated this scenario after having implemented it in the course given in spring 2023, based on insights drawn from an anonymous survey of the students and interviews conducted with the TAs.

The communication between students and with TAs is always a challenge due to the channels they are using and their integration in their personal digital ecosystem. Chats in LMS are not used, discussions associated to documents (like in Google Drive or Graasp) are only used when they actually access these resources. Apps, like WhatsApp (used daily by 84% of the students of the course), are always preferred, but the associated discussions are invisible for assessing the actual interactions.

Our evaluation leads us to conclude that our pedagogical scenario was well received by the students and the TAs. The CJ was considered as helpful by the TAs in following the work of the groups. However, they preferred to use the chat or other channels, such as instant messaging apps, to deliver their feedback to the students. In addition, communications on the platform appear to have been limited in general, most discussions having happened face-to-face during the course sessions. This is also shown in the feedback from the students, most of them having not considered the CJ for communicating among group members.

The choice of Graasp was motivated by the flexibility and openness of the platform which was very much aligned with the need for the course. Moreover, we are involved in its development and had previous experience in using it for similar collaborative scenarios (La Scala *et al.* 2022; La Scala, Vonèche-Cardia, and Gillet 2023).

In 2024, we will continue to improve this pedagogical scenario, focusing on the CJ as a guiding tool to foster exchange between the groups and the TAs. We will strengthen the structure of the scenario to ensure that feedback is always delivered in a timely fashion. Finally, we dedicate more time to showing the possibilities of Graasp for communication among the students (chat, shared files, and collaborative documents) with the objective of providing them with a complete and easy-to-use collaborative environment.

ABSTRACT

First-year engineering subjects play an important role in setting up a solid foundation for the ongoing development of technical and professional engineering skills. However, these subjects are not easy to design, as they must tackle the challenge of introducing students to the world of engineering while helping them navigate the difficult transition from high school to university. This paper presents a case study of one such first-year engineering subject: "Engineering Technology and Society". The subject's structure and delivery is discussed with reference to social constructivist and constructionist learning theories, as well as a framework of four dimensions identified as being critical in the design of first-year subjects. The most recent round of student feedback on the subject is also presented, identifying the development of time management, organisational, and teamwork skills as a key area of focus for future improvements to the subject. This case study provides a specific example of how an engaging first-year engineering experience can be designed for both small

[1] *L. Lam,*
lionel.lam@unimelb.edu.au.

and large student cohorts, providing elements that can potentially be adapted by other tertiary institutions seeking to improve their first-year engineering offerings.

1 INTRODUCTION

Engineers are characterised by their ability to harness scientific principles in creative ways to design effective solutions for the benefit of society. Engineers therefore play a crucial role in working towards – and even beyond – the Sustainable Development Goals adopted by the United Nations in 2015. It is therefore essential that our future engineers be equipped with robust technical and professional skills, and also a keen awareness of the importance of sustainability. This foundation should be laid down early, through the effective design of first-year engineering subjects that can simultaneously teach new concepts, inspire and motivate students to push boundaries, and facilitate the transition from secondary to tertiary education (Burton 2007). In this paper, we present a case study of one such first-year engineering subject offered at the University of Melbourne: “Engineering Technology and Society” (ETS).

2 CHALLENGES, CONSTRAINTS, AND FRAMEWORKS

At the University of Melbourne, engineering qualifications are awarded at the postgraduate level. To qualify as professional engineers, students must first complete a three-year undergraduate degree (typically the Bachelor of Science) before commencing a two-year Master’s degree in their chosen engineering discipline. While this provides undergraduates with more flexibility in subject choice and thus the opportunity to develop a greater breadth of knowledge, it imposes constraints on the undergraduate engineering experience. More specifically, it does not allow as large a footprint for engineering representation in the first year, differing from a traditional Bachelor of Engineering. In fact, ETS is one of only first-year engineering subjects offered at the University. As such, it has had to take an integrated approach to curriculum design: its content spans multiple engineering disciplines, and incorporates basic programming and collaborative project work. In contrast, other institutions typically offer multiple first-year subjects that each focus on foundational concepts aligned with specific engineering disciplines. As ETS is offered in Semester 1, when most students start out their university journey, it also faces the challenge of helping first-years navigate the challenging transition from high school to university.

In this context, Trautwein and Bosse (2017) have presented a framework of four critical dimensions that should be considered when designing first-year subjects:

1. **Personal Dimension.** First-years should begin to identify learning styles and specific study skills that they find effective. The hands-off nature of university relative to secondary education means that students should be assisted in developing time management and organisational skills that will aid them in balancing their academic and non-academic commitments.
2. **Organisational Dimension.** First-years should begin familiarising themselves with university regulations, policies, and expectations. These encompass how teaching and learning is organised (e.g. lectures/tutorials/workshops, learning management systems, etc.), different approaches to teaching, rules around

assessment submissions, as well as the various university facilities and support services available to them.

3. **Content-related Dimension.** The rapid pace of university learning, along with the generally low learner maturity of first-years (Tomas et al. 2019), means that content should be appropriately chunked and scaffolded. Students should be introduced to conventions and rules-of-thumb common in their chosen field of study. They should also start developing assessment literacy: this includes familiarity with various assessment types, as well as the ability to use constructive feedback for improvement.
4. **Social Dimension.** First-years should be assisted in building peer relationships and networks, as well as navigating the social climate in class and on campus. This dimension aligns closely with Vygotsky's (2012) social constructivist views on learning, whereby the knowledge is best internalised by working together with peers or with "more knowledgeable others". These social interactions provide first-years with the scaffolding and confidence to push the boundaries of their knowledge and explore their zones of proximal development (Amani and Asl 2015), and to develop effective communication and teamwork skills.

First-year subjects should also be designed to maximise student engagement, as this has been shown to correlate positively with learning, satisfaction, and retention. The incorporation of active learning approaches is one way of doing this. These promote conceptual understanding by involving students in interactive "heads-on" and "hands-on" activities that generate closed feedback loops with their peers or instructors (Hake 1998). As with Trautwein and Bosse's Social Dimension, active learning is closely aligned with social constructivism, as it stresses the importance of peer-to-peer and peer-to-teacher interactions in the learning process. Project-based learning is a specific active learning approach that additionally draws on Papert's constructionist theory, whereby knowledge development is facilitated by the hands-on manipulation and construction of physical, shareable artefacts (Harel and Papert 1991).

ETS has been offered at the University of Melbourne since 2021, inheriting much of the philosophy of its spiritual predecessor "Engineering Systems Design 1", which ran from 2018 to 2020. Its current structure, which involves weekly lectures and workshops, a strongly-scaffolded assessment structure, and a heavy emphasis on collaborative project-based learning, is the culmination of years of iterative improvements informed by student feedback and best practice in teaching. It is worth noting that this structure has proven scalable from 100 to 700 students per semester, with similar experiences and outcomes for both small and large student cohorts. The authors, who make up the current ETS teaching team, continue to make adjustments to the subject in line with a design-based research methodology (McKenney and Reeves 2020). In this paper, we discuss ETS's current curriculum and how its design addresses the previously described challenges, constraints, and frameworks.

3 CURRICULUM DESIGN

Only two first-year engineering subjects are offered at the University of Melbourne, running in separate semesters. This small footprint has meant that between them, both subjects have to represent the breadth of engineering disciplines offered at the

University. ETS does this by embracing the growing transdisciplinarity of engineering. The subject revolves around a semester-long real-world design project: students collaborate in teams of four to design a water pumping, disinfection, monitoring, and distribution system to supply potable water sourced from an underground well to a remote village. Key concepts required for the design project are delivered via lectures, with the core content divided into four modules: professional engineering skills, fluid mechanics, water disinfection, and image processing. Here, a just-in-time learning approach is taken, where ideas developed in lectures one week are applied by students in hands-on workshop-based activities the following week. This general structure is visualised in Figure 1, and is elaborated upon in the following sub-sections.

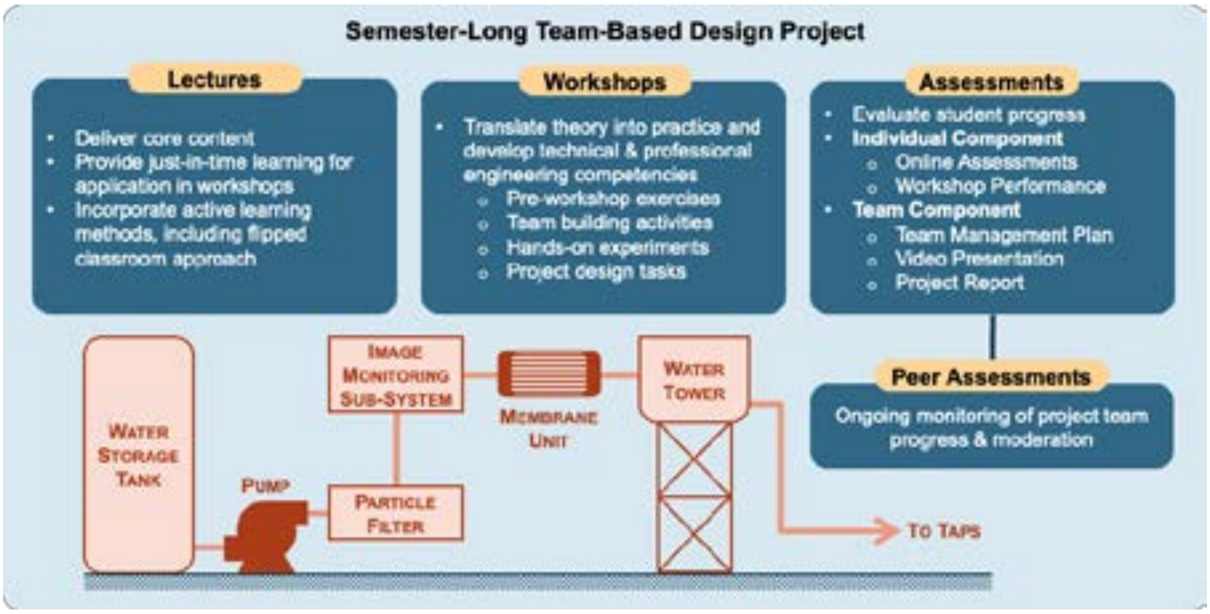

Figure 1: General structure of Engineering Technology and Society.

3.1 Lectures

Lectures run three times per week with each lasting an hour. These provide just-in-time learning of key concepts, which are applied by students in their workshops the following week. This staggered arrangement means that lectures only run from Weeks 1 to 11 in a regular 12-week semester. The lecture content by week and its relevance to the design project are summarised in Table 1.

Table 1: Summary of lecture content in Engineering Technology and Society.

Weeks	Module	Topics	Relevance to Design Project
1	**Professional Engineering Skills**	Subject structure, diversity of engineering disciplines, contributions of engineers to society, teamwork & communication skills, project & time management skills	Appreciation for the importance of interdisciplinary collaboration, communication, and project management skills in engineering projects
2 to 4	**Fluid Mechanics**	Pipe flow, the mechanical energy balance, pump design & scale-up, CAD & 3D printing of pump impellers, pipe networks,	Design of pumping & water distribution sub-systems

		introductory MATLAB programming skills	
5 to 6	Water Disinfection	Membranes, diffusive mass transfer, mass balances, log inactivation credits, the Chick-Watson Law, further development of MATLAB programming skills	Design of water disinfection sub-system (ozone infusion via membranes)
7 to 10	Image Processing	Digital images as matrices, image filters, convolution, for & while loops, if-else statements (programming flow control in MATLAB), video processing	Design of image monitoring sub-system (particle detection algorithm)
11		Subject summary	

Active learning methods are incorporated into lecture delivery to boost student engagement and learning. In fact, the entire Image Processing module is delivered using a flipped classroom approach. Here, students are assigned about 15 minutes of pre-lecture video content which cover key technical concepts. This frees up lecture time for more hands-on collaborative problem-solving and instructor-facilitated live coding sessions (Lam and Chan 2023). It also has the advantage of providing early exposure to our first-years of alternative teaching modalities that they might encounter at university, in line with Trautwein and Bosse's Organisational Dimension.

The subject also features three guest lectures delivered by industry-linked experts. These expand on the core content with topics that align closely with one of the four modules: product development and start-ups (Professional Engineering Skills module), industrial applications of membrane technology (Water Disinfection module), and medical imaging (Image Processing module). The Content-related Dimension is addressed here, as these provide first-years with some exposure to the norms and expectations of the engineering profession. In addition, an "Engineering Student Club Showcase" is held in Week 1, during which various engineering student clubs and societies are invited to talk about their activities and initiatives, and how first-years can get involved. This aligns with the Social Dimension, as it introduces first-years to existing on-campus networks that they can tap into to start building connections early.

3.2 Workshops

Weekly workshop sessions are an integral part of ETS, as these allow students to apply the theoretical concepts covered in lectures in practice. They also address Trautwein and Bosse's Social Dimension by providing students with an environment to engage in cooperative learning, and to actively collaborate with their teammates on a series of progressive tasks leading up to their final project outcome. Each three-hour workshop session consists of at most 56 students and is facilitated by two demonstrators. Demonstrators are typically more senior students who have previously completed ETS, and are selected to represent the breadth of engineering disciplines offered at the University. This allows them to act as "more knowledgeable others" in accordance with a social constructivist learning framework.

Prior to attending each workshop session, students must complete pre-workshop exercises deployed as online H5P-based interactives. In line with the Content-related Dimension, these scaffold relevant concepts and ensure that students are familiar with the operational procedures for each week's workshop. The workshops themselves consist of three categories of activities that collectively develop students' technical and professional engineering skills, and reinforce and supplement lecture content:

1. **Team Building Activities.** These short activities are conducted at the beginning of workshop sessions and focus on professional skills. Student teams are presented with a variety of activities over the semester, including physical Lego construction activities, virtual "Escape Room" scenarios, as well as reflective and discussion-based activities. These are all designed to promote engagement and encourage team bonding in a relaxed setting, allowing for the development of teamwork and communication skills (Chan and Lam 2023).
2. **Hands-on Experiments.** Drawing on constructionism, students work in teams to conduct hands-on experiments on scaled-down versions of the design project's sub-systems. This process of collaborative hands-on experimentation allows students to develop their teamwork and verbal communication skills.
3. **Project Design Tasks.** Towards the end of each workshop session, students are given time to work on their project-related tasks and deliverables such as the Team Management Plan, Video Presentation, and Project Report. Any collected experimental data is also analysed in MATLAB, providing students with a basis on which to scale-up and design the real-world version of their project. Through this process, students improve their programming skills and gain an appreciation for computational tools in technical engineering design and problem-solving applications. They also develop professional engineering skills around planning and project management by working together as a team.

3.3 Assessments

ETS has an assessment structure consisting of two equally-weighted components:

- The **Individual Component** includes numerous assessments spread over the semester that recognise students' individual progress and achievements. These assessments are largely low-stakes and function to scaffold student learning while providing exposure to a range of assessment types, in line with the Content-related Dimension.
- The **Team Component** consists of three major deliverables that are core to the progress of the semester-long design project. These are spaced out strategically over the semester, building up towards the final project outcome. The scale of these assessments means that collaborative teamwork is necessary, in line with the Social Dimension.

Both components also address the Personal and Organisational Dimensions of Trautwein and Bosse's framework by promoting the development of time management and organisational skills in the context of expectations around assessment quality and submission processes. The assessment structure in ETS is summarised in Table 2, with finer details on the assessments that make up each component.

3.4 Student Support

ETS is also designed to provide students with support beyond its regularly scheduled lectures, workshops, and assessments. As with all other subjects offered at the University, all subject content is accessible via the Canvas Learning Management System. As one of the first subjects students will encounter during their time at university, the Canvas page for ETS has been optimised for ease of navigation, and time is spent in Week 1 to demonstrate to students how Canvas works. The Discussion Boards on Canvas are a key feature of the subject, and are constantly monitored by the teaching team and demonstrators. Students are strongly encouraged to post questions about the subject content and to engage in discussions, drawing on social constructivism and addressing Trautwein and Bosse's Social Dimension.

In line with the Organisational Dimension, students are also introduced to various on-campus facilities, services, and networks that they will likely make use of as they progress through their degrees. These include the Telstra Creator Space, the University's makerspace that students use to 3D print custom-designed pump impellers for experimental testing. Various technical workshops and events (both academic and social) organised by the Faculty and student clubs are also advertised to students over the course of the semester.

Table 2: Assessment structure in Engineering Technology and Society.

Component	Assessments	Descriptions
Individual (50%)	**Online Assessments (25%)**	**Weekly Homework (5%)** • 9 problem sets deployed as Canvas Quizzes or with the MATLAB Grader platform • Low-stakes formative assessment: best 5 of 9 scores considered, unlimited attempts with automated marking and immediate feedback allows students to build confidence (Chan et al. 2022)
		Mid-Semester Quiz (10%) • Mid-semester summative assessment deployed as Canvas Quiz • More challenging with imposed time limits to assess students' technical knowledge
		End-of-Semester Quiz (10%) • End-of-semester summative deployed with the MATLAB Grader platform • More challenging with imposed time limits to assess students' technical knowledge
	Workshop Performance (25%)	**Health & Safety Training Modules (1%)** • Required for participation in workshop activities • Promote culture of safety in engineering
		Pre-Workshop Exercises (8%)

		• Provide scaffolding & relevant knowledge around hands-on workshop activities
		In-Workshop Tasks (14%) • Test competencies in engineering practice e.g. following experimental procedures, MATLAB-based data analysis, and reporting of outcomes
		Peer Assessments (2%) • Provide feedback on team health & contributions of team members • Used to moderate marks for the Video Presentation & Project Report (Team Component)
Team (50%)	**Team Management Plan (5%)**	• Helps establish project goals, expectations, and member responsibilities, as well as to distribute tasks and assess risks (Chan and Lam 2023)
	Video Presentation (10%)	• Motivates students to reflect on & summarise their project progress to date • Students develop skills around video production & presentation e.g. scripting, storyboarding, recording, video editing, and verbal communication • Marks moderated using peer assessment
	Project Report (35%)	**Draft Report (5%)** • Motivates students to start their report early • Critically assessed by markers to provide feedback students can use to improve their final report
		Final Report (30%) • 40-page technical report summarising the team's final design & project outcomes • Students develop written communication skills & experience with formal language & referencing

4 FEEDBACK & REFLECTIONS

Anchoring content to a semester-long team-based design project has proven to be an effective means of introducing engineering fundamentals to first-years, and this has been a constant feature of ETS since its inception. However, its structure has undergone numerous rounds of improvements to keep abreast of evolving student expectations, pedagogies, and learning technologies. These have previously been described in detail (Chan et al. 2022, Chan and Lam 2023, Lam and Chan 2023), and so here we present instead our high-level reflections on the ETS's current structure.

The most recent round of feedback involved discussions with student representatives to identify aspects of the subject that were working well versus those that could be improved. In general, students found the subject well-structured and well-taught, with the majority in agreement that the real-world design project provided an effective introduction to engineering. Students particularly appreciated the integration of MATLAB and other software-based tools with engineering design, as well as the opportunity to bridge theoretical knowledge and practice via collaborative hands-on workshop activities. Despite this, some students found the sheer volume of subject content and the fast pace of content delivery quite challenging. This was particularly evident in the workshop sessions, where a significant amount of tasks must be completed within a three-hour duration. Future adjustments to ETS will focus on identifying the right balance between pacing and subject content, and providing more support around developing time management and organisational skills in line the Content-related and Personal Dimensions, respectively.

In terms of assessments, the consensus was that regular low-stakes assessments spread over the semester (i.e. weekly homework, pre-workshop exercises, and in-workshop tasks) were helpful in ensuring students keep on track with the subject content. Students also expressed relief that the subject does not have a final examination, as this meant that they could focus on developing technical and professional engineering skills instead of rote-learning and regurgitating knowledge. There was, however, some level of discontent with the high weighting associated with team-based assessments, predominantly from students in teams with uncooperative member(s) and/or with mismatched achievement goals. In past runs of the subject, measures such as peer assessments and manual interventions have been enacted to ensure the fair moderation of marks for such teams. Building strong teamwork and collaboration skills – including effective conflict management strategies – continues to be a primary focus in ETS, in line with social constructivism and the Social Dimension.

5 SUMMARY

In this paper, we have discussed the current structure of ETS in the context of social constructivist and constructionist learning theories, as well as the Personal, Organisational, Content-related, and Social Dimensions identified as being critical in the design of first-year subjects. The authors will continue to review the curriculum of the subject based on feedback gathered via surveys, informal discussions with student representatives, and general class observations, in line with an iterative design-based research methodology. All feedback will be considered in the context of the subject’s objective of introducing first-years to the world of engineering while helping them successfully transition from secondary to tertiary education.

ABSTRACT

During the past two decades, educating students about sustainability issues has been a concern when designing engineering schools' curricula. One could think that nowadays students are trained to take into account the multiple dimensions of sustainability when addressing a project-based design challenge. Is this really the case? This paper presents an explorative qualitative study on the understanding and perspectives of engineering students regarding sustainability in the framework of such a course. The dataset consists of more than 200 reflexive notes gathered over a period of 3 years. The preliminary results of the study indicate that despite their previous knowledge and training about sustainability, engineering students still have an initial tendency to limit their perspectives and understanding to their own field of study. This points to the need to address the potential bias towards techno-centric perspectives and understanding of sustainability in engineering education by integrating or strengthening additional dimensions, including but not limited to social desirability or economic viability.

1 INTRODUCTION

Our societies are facing increasingly pressing sustainability issues encompassing many different environmental and human dimensions, as reflected through the six planetary boundaries crossed (Richardson et al. 2023), and the many societal challenges to face (United Nations 2015). Educating responsible engineers implies transferring knowledge about these issues, but also transferring competences on how to appropriately act on such complex problems (Beagon et al. 2023).

'Design for sustainability', as defined by Ceschin and Gaziulusoy (2016), proposes to design systemic interventions, aiming at addressing sustainability issues in adequation with their inherent complexity. Design for sustainability takes roots in the observation that usual approaches to sustainable (engineering) design are "not sustainable" (Egenhoefer 2024). In sustainable design, the framing of the design problem as well as the design interventions towards sustainability are regularly limited to the technical dimension of the product (e.g., materials, processes), which fails to address the sustainability issues in their complexity.

Design for sustainability invites to address sustainability-related issues with design tools in a systemic way and at different scales. It includes the usual sustainable design interventions (e.g., on materials, components or products), but also invites to consider larger scales, regarding both design problem framing (ranging from product-service systems to local communities or even to socio-technical systems) and scope of design interventions (consumption habits, community practices, or even socio-technical systems dynamics). This opens the floor to a variety of additional design intervention types, such as design for sustainable behavior, design for social innovation, or design for sustainability transition, which act beyond the product scale and therefore offer a better grasp on sustainability dimensions which cannot be addressed at this scale only.

The 'Design for sustainability' course we present in this study, echoing other similar initiatives (Ceschin 2024), was created with the intention to train our students to act effectively on complex sustainability issues. This course brings together engineering and industrial design students from two separate institutions. It aims at training them to work in interdisciplinary teams and to define and execute a practical design project. This project should propose an economically viable design intervention while effectively addressing a sustainability issue. The class is taught by an industrial designer, a design strategist, an economist and an engineer specialized in sustainability. One third of the course[2] is dedicated to introductory classes covering theory and practical tools useful for the project work, as well as introductory exercises related to the three dimensions of the course (design, sustainability and economic viability). The remaining of the course is dedicated to the definition and execution of a practical design project in teams of 4 students (1-2 industrial design students and 2-3 engineering students from various disciplines). During this phase, regular consultations with all four teachers take place, to ensure project follow-up on the three dimensions covered by the course. The assessment is performed through multiple deliverables over the two semesters (see Table 1).

[2] The course runs over 2 semesters and is credited overall with 6 ECTS.

Table 1. Course assessment

Semester	Assessment elements	Sub-elements
Fall	Design process (40%)	Design (50%), Viability (50%)
	Project proposal (40%)	Design (33%), Sustainability (33%), Viability (33%)
	Reflexivity (20%)	Reflexive note (100%)
Spring	Project (80%)	Design (50%), Sustainability (30%), Viability (20%)
	Reflexivity (20%)	Reflexive note (100%)

As part of the assessment, students have to hand in a reflexive note (around 1000 words) at the end of the first semester (i.e., after having completed an introductory part of 60 hours and about 30 hours of actual project work). In the note, students are asked to reflect on cross-boundary collaboration in their team, as well as "[their] journey from sustainable design to design for sustainability"[3]. Prior to this reflexive note, students are asked to think about the issue of design for sustainability through a number of in-class and out-of-class activities. These include the re-design of an everyday object to make it more sustainable, as well as the integration of sustainability into a company's business model. Moreover, a guideline inspired from Hatton and Smith (1995) is provided to help students structure their reflexive practice.

In this framework, the question we set out to answer is: how do students understand and integrate the multiple dimensions of sustainability provided in the course? The purpose is to assess whether the proposed pedagogical setup, including many different dimensions (project-based learning, teamwork, cross-boundary collaboration beyond engineering, integration of social desirability and economic viability, etc.), manages, unlike other 'sustainable design'-centered initiatives, to equip our students with a complex multi-dimensional vision of sustainability, and would therefore be a relevant contribution to the improvement of the sustainability education in engineering.

To do so, the study explores the semantic content of the reflexive notes to gain insights as to the kind of sustainability understanding and perspectives students display. The content of reflexive notes on sustainability produced within design studio classes has already been analyzed in the literature, but from a reflexivity standpoint, rather than the sustainability understanding students are displaying (Gulwadi 2009). In parallel, several systematic frameworks have been established to assess the sustainability perspectives of students (e.g., Birdsall 2014) in different kinds of deliverables, but generally with a manual coding methodology and not directly based on reflexive notes. The exploration is conducted with MAXQDA, a qualitative lexical analysis software.

[3] The analysis presented hereafter only covers the "design for sustainability" part.

2 METHODOLOGY

2.1 Overview

The study involves students from two Swiss academic institutions (an engineering school and a design school) over a period of 3 years (2021-2023). The data gathered is based on the production of reflexive notes by the students at the end of the semester. As part of their reflexive note, students have to write about the following sub-theme: “My journey from sustainable design to design for sustainability”. While the course is taught in English, students can write their note either in French or in English. The sample is (n=223).

Table 2. Summary of dataset

	Design school		Engineering school		Total by language		Total
Year	French	English	French	English	French	English	
2021-2022	23	6	2	27	25	33	**58**
2022-2023	19	7	19	40	38	47	**85**
2023-2024	20	6	10	44	30	50	**80**
Total	**62**	**19**	**31**	**111**	**93**	**130**	**223**
as a %	**36.32%**		**63.68%**		**41.70%**	**58.30%**	

Note: enrollment was capped at 60 for 2021-2022 and 90 for the following 2 years.

2.2 Data analysis and coding process

For the preliminary study we applied an inductive thematic analysis approach to the dataset. The following coding process was used. In the first phase, both authors read the totality of the reflexive notes (n=223) and created separate lists of words related to the perspectives and understanding of sustainability (e.g., environment, complexity, etc.). These lists were then compared and discussed to flesh out frequent and salient keywords. Once merged, the list was then matched with a word frequency analysis on the entire dataset using MAXQDA. The rationale behind this was that we made the hypothesis that some words may appear less frequently than others but « weigh » more for the coders. Put differently, the word frequency analysis would potentially reduce our subjectivity and/or bias towards certain words while the subjective listing of words would prevent « salient » words from falling through the frequency trap. This led to a first list of 10 codes (see Table 3).

In the second phase, the dataset was auto-coded using MAXQDA on the basis of the ensuing list[4]. One author then identified a second set of words pertaining to the understanding and perspectives on sustainability based on the sentences surrounding the words from the first list. This led to a second list of 9 codes (see Table 4).

[4] Since the reflexive notes in the dataset are both in French and in English, the dataset was coded in both languages. Only the codes in English are presented here.

Table 3. Frequency of codes from first list (single, percentage and multiple counts)

	Single counts	**as % of notes**	**Multiple counts**
impact	138	61.88%	297
viable / viability	117	52.47%	212
need / needs	116	52.02%	194
question / questions	101	45.29%	208
environment	95	42.60%	168
economic / economy	92	41.26%	137
social	92	41.26%	164
value	62	27.80%	96
complex / complexity	61	27.35%	89
responsible / responsibility	52	23.32%	81
SUM	926		1646
N = Reflexive notes	**223**	**100.00%**	**223**

Table 4. Frequency of codes from second list (single, percentage and multiple counts)

	Single counts	**as % of notes**	**Multiple counts**
understanding / understand	171	76.68%	427
important importance	168	75.34%	394
aspect / aspects	147	65.92%	328
future	84	37.67%	141
change	77	34.53%	116
role	50	22.42%	61
conscious / consciousness	33	14.80%	53
justice	15	6.73%	17
coherent / coherence	12	5.38%	14
SUM	757		1551
N = Reflexive notes	**223**	**100.00%**	**223**

3 RESULTS AND DISCUSSION

Figure 1 shows how the 19 codes are distributed among the reflexive notes. More than 50% of the notes contain between 6 and 10 codes (this increases to 80% when one extends this to 4 and 11 codes). Going back to some of the earlier studies

(Azapagic, Perdan, and Shallcross 2005), one can wonder to what extent the knowledge and understanding of engineering students has deepened. On the one hand, the content analysis indicates that some high-level concepts (e.g., SDGs) are well integrated in students' perspectives and understanding on sustainability. Whereas Lozano et al. (2019) find that the social dimension of sustainability was the least addressed in European higher education institutions (below 20%), our dataset shows that more than 40% of the notes explicitly address this dimension. The same can be said for the economic and environmental dimensions. At this stage, it is hard to attribute this increase to any given factor. Several hypotheses can be put forward including an overall awareness increase in the student population, the fact that a course on sustainability attracts students already aware of such dimensions and/or that the content of the course helps raising such awareness.

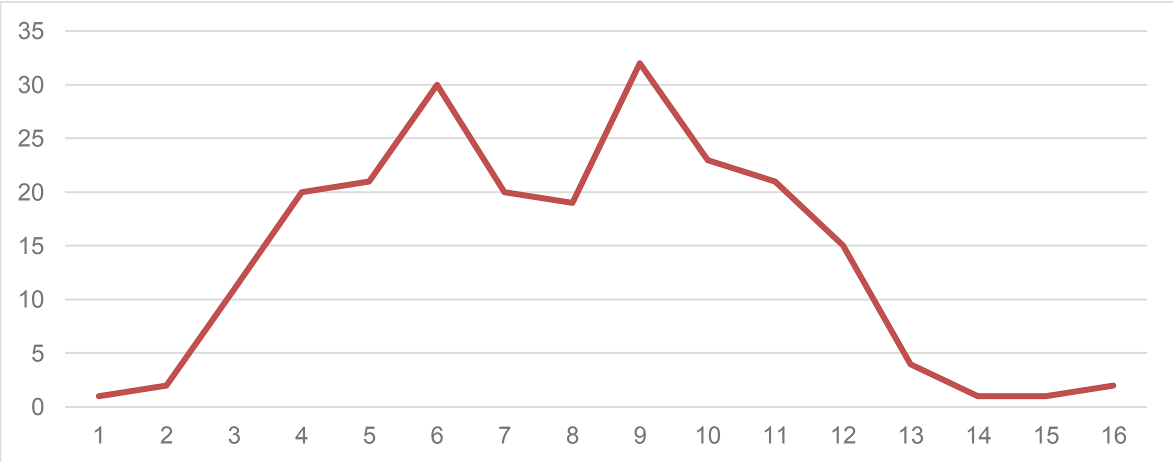

Fig. 1. Distribution of codes among reflexive notes (max=19)

On the other hand, the analysis shows that concepts related to inclusivity or justice feature much less prominently in students' reflections. The same can be said for concepts related to responsibility, as they are featured in less than 25% of the notes.

Given the interdisciplinary nature of the course, we also ran a frequency analysis comparing keywords found in the reflexive notes from engineering and design students (see Table 5).

Table 5. Comparison between engineering and design students (first list of codes)

	Design students	**Engineering students**	**Total**
impact	45.70%	71.10%	61.90%
viable / viability	55.60%	50.70%	52.50%
need / needs	38.30%	59.90%	52.00%
question / questions	58.00%	38.00%	45.30%
environment	37.00%	45.80%	42.60%
economic / economy	45.70%	38.70%	41.30%
social	37.00%	43.70%	41.30%
value	22.20%	31.00%	27.80%
complex / complexity	23.50%	29.60%	27.40%

responsible / responsibility	33.30%	17.60%	23.30%
N = Reflexive notes	81	142	100.00%

One cannot fail to notice some large discrepancies between engineers and designers in the use of certain words (e.g., impact, responsibility), something that we will need to further investigate by conducting a number of interviews with students both from the dataset and outside of the dataset to control for a selection bias.

The analysis of the reflexive notes has also fed our reflexivity as teachers. For instance, it helped us to identify if the students' understanding and perspectives of sustainability match the learning outcomes that we defined, and to what extent the teaching and learning strategies we developed actually help students reach these outcomes. Additional teaching material focusing on some of the "forgotten" dimensions (e.g., inclusivity) will be included in the course. Last but not least, the study also prompted us to initiate a discussion on how to refine the rubric used to assess the reflexive notes.

3.1 Limitations

The current study suffers from a number of limitations. A first one relates to the open-ended nature of the reflexive note. Elements of the reflexive process aside, no specific structure was imposed, which may have led students to comment only on a selected number of aspects rather than cover the whole span of their learning journey. Asking students to comment on their *journey* could also push them to express something they may not have experienced. This could even have been reinforced by the fact that the reflexive note is graded. To our knowledge, this has not been the case. For instance, some students clearly indicated that their journey had not taken them very far since they were already very much aware of sustainability-related questions. Other students provided substantial evidence on how their understanding regarding sustainability had broadened and the questions this raised (e.g., integration of multiple constraints, personal responsibility or professional identity). The following quote from an engineering student illustrates this point: "*Before taking this course, my understanding of sustainability was very techno-centric, which means that as a material engineer, I only thought of sustainable design and how to find a solution for questions like 'How to reduce the energy consumption for producing a specific material'*". Similar quotes can be attributed to designers: "*In the past, I approached the question of the sustainable object with the gaze of a designer who took care of its characteristics using the tools at my disposal, but my approach was limited to this. I now understand that the object is intrinsically linked to a larger network of relationships and impacts*".

A second limitation relates to the fact that at the time of the writing of the reflexive note, students have only spent 4 weeks working on their final project. To overcome this problem, we have added an element to the second reflexive note (due at the end of the second semester) pertaining to the practical work. This will hopefully shed additional light on the students' journey throughout the entire course.

A third and growing concern relates to the potential use of generative AI (GAI) for producing the individual reflexive note. This issue regards both the actual grading of the assignment and the core of this study. While it is for now impossible to check with high levels of reliability whether or not the note has been produced or 'enhanced' by ChatGPT or another GAI, we have checked the notes that appeared too ‘polished’ and believe that less than a handful fall in this category. To limit the use of GAI, students were asked to provide concrete examples from their actual project and experience with group work.

A final limitation relates not to the study itself but to the transferability of the set-up. Since the course is built around the bringing together of engineering and design students and instructors, not all academic institutions are in a position to propose such an interdisciplinary learning environment. We believe that a project-based approach around designing for sustainability can nonetheless be achieved in an “engineers-only” environment, provided that students are trained and challenged on issues beyond engineering issues (e.g., social and economic dimensions) and that the projects are assessed equally on their technical and non-technical merits. In our experience with project-based courses, students tend to “overinvest” in the artefact (the “hardware”), which often comes at the expense of other dimensions (e.g., theoretical content or transversal skills).

4 FUTURE WORK AND CONCLUSION

Future work needs to be carried out on at least two fronts. First and foremost, we need to refine and enhance the current analytical approach. This can be achieved by looking at the co-occurrence of codes and supplementing the quantitative analysis with more qualitative insights (e.g., conducting in-depth interviews). Second, we plan to compare our results with existing theoretical frameworks (Birdsall 2014; Brundiers et al. 2021; Lönngren et al. 2016; Wiek, Withycombe, and Redman 2011) and/or by applying a SOLO analysis (Carew and Mitchell 2002), thus moving from an inductive approach to a deductive one. Further comparisons could be run between our sample and students not enrolled in the course. This would provide some insights as to the general understanding and perspectives on sustainability among engineering students. Given some of the inherent limitations encountered with the frequency analysis, one could also imagine borrowing tools from sentiment analysis (Liu 2020) to gain further insights.

The preliminary analysis has allowed us to get a glimpse of engineering and design students’ journey towards design for sustainability. So far, we can conclude that in comparison with recent studies their perspectives and understanding of sustainability integrates slightly more social, economic and environmental dimensions. At the same time, more indirect concepts like justice or inclusivity feature less prominently in students’ reflections. In our view, this calls for strengthening the non-engineering component of the course while finding an equilibrium between the expectations of engineering students in a project-based course and the opportunity such a course provides to explore the responsibilities that come with design and engineering. Following the study, the teaching team will need to reflect on how to bring early on the non-technological elements pertaining to the broad understanding of sustainability we aim to foster. This would need to be reflected in the course content (knowledge, skills and attitudes), the learning activities and the assessment modalities.

ABSTRACT

This practice paper presents a novel way of designing a work experience program for lower secondary school pupils, combining university and company activities. The program aims to broaden pupils' understanding of engineering jobs and the educational pathways that lead to them. To highlight and illustrate the need for a diverse engineering workforce, the program was specifically targeted at young women and students from immigrant backgrounds. The experience of the first pilot was positive for both the students and the university and company personnel. However, it was also found that communicating the expert nature of the engineering work can be a challenging task.

1 INTRODUCTION

In Finland, like in many other countries, occupational gender segregation persists despite efforts to promote gender equality. The fields of technology, engineering, and construction are still strongly male-dominated (Statistics Finland 2022). Segregation begins in childhood and continues throughout individuals' education and into their careers (Keski-Petäjä and Witting 2018). In addition to gender segregation, the Finnish education system is experiencing a continuously strengthening segregation according to social background (Bernelius and Huilla 2021). Family background more strongly guides some young people into higher education and some away from it. Young people with immigrant backgrounds, for example, seek higher education far less often than the general Finnish population (Nori et al. 2021).

Periods of work experience (a.k.a. TET) refer to the opportunities offered to lower secondary school pupils in Finland to familiarize themselves with various fields and professions, as well as to learn workplace practices. This may include short internship periods in companies or organizations, visits to workplaces, and tasks simulating real work situations. The collaboration between schools and working life is designed to offer pupils opportunities to discover their areas of interest, enhance their work-seeking skills, develop an understanding of entrepreneurship, and gain insights into working life in general (OPH 2014). TET is a compulsory part of the lower secondary school curriculum, but the format of execution may vary according to the municipality and school (Mayer et al. 2022).

LUT University’s project *TechnoTET South Karelia* establishes pathways for lower and higher secondary school students to familiarize themselves with the technology sector education and labor market. The project utilizes different concepts of working life cooperation, which are included in the lower and upper secondary education curriculum in Finland. The project aims to reach especially young females and young people with immigrant backgrounds in order to broaden their educational opportunity horizons and interests. The goal is to attract more young people to pursue studies in technology while simultaneously alleviating the segregation between different fields of education and professions. This practice paper describes and analyzes the first *TechnoTET* pilot from the fall of 2023.

2 PERIODS OF WORK EXPERIENCE AS A MEANS TO ATTRACT MINORITIES TO TECHNOLOGY

Periods of work experience are typically conducted during the upper grades of lower secondary school when the pupils are 14-16 years old. The most typical way to offer the experience to pupils is to do it in 1–2-week periods, during which they visit companies or other organizations and familiarize themselves with working life practices, various professions, and tasks. Even though this concept has existed in the Finnish lower secondary schools for several decades it is, unfortunately, an underutilized opportunity for several reasons.

Firstly, organizations’ shortage of resources can limit the opportunities to offer diverse and high-quality workplace orientation experiences (Mayer et al. 2022). In many cases, employers recognize the value, but cannot offer a wide enough range of tasks or guidance for the trainees. Another significant challenge is a regional imbalance (Mayer et al. 2022). Some areas in Finland have limited availability of companies and organizations, making it difficult for pupils to gain diverse workplace experiences. Furthermore, in some schools, there is very little collaboration with any employer organizations, which leads to an unbalanced situation where some pupils have a wide selection of companies and other organizations to choose from while others have significantly less (Mayer et al. 2022).

Additionally, in certain fields such as the technology industry, arranging work experience periods is difficult due to reasons such as occupational safety and lack of time resources. Minors cannot be allowed to familiarize themselves with production tasks, as legislation alone prohibits it (Occupational Safety and Health Act 2002). On the other hand, it would be possible to introduce them to expert tasks without significant occupational safety risks, but simulating expert tasks is challenging without proper preparation, which in turn would require time and commitment from employees.

All the aforementioned reasons have led pupils to typically gravitate towards places that are easily accessible and where simple tasks such as cleaning, stocking shelves, dishwashing, etc., are available to them. While these work experiences are valuable and important, they may not necessarily broaden pupils' horizons regarding further studies or career opportunities. Companies and professions in the field of technology, especially, are such that pupils typically haven't had the opportunity to familiarize themselves with. The young people’s lack of familiarity and knowledge of vocations, activities, and opportunities of STEM fields was identified by van Tuijl and van der Molen (2016) as one of the three factors driving young people away from STEM careers.

Various reach-out activities have shown that technology-related hands-on activities are an effective way to evoke adolescents' interest in technology and engineering regardless of their age or gender (Naukkarinen and Ikonen 2018; Naukkarinen et al. 2019; Naukkarinen et al. 2021). Their effectiveness is further enhanced by connecting the experiences to youngsters’ world spheres (Naukkarinen and Ikonen 2018). Vennix et al. (2018) discovered that a positive attitude toward STEM careers was positively associated especially with activities that enhanced the autonomous-motivation. This was best achieved with workshop-format out-of-school activities suggesting that *“the out-of-school component is important to get a more complete picture of the implications of STEM and of possible career opportunities”* (Vennix et al. 2018, 1280).

Linking the activities to the demonstrations of the positive effects that technology can have on society can be beneficial, especially in evoking girls’ interest in technology (Naukkarinen et al. 2021). As girls are less likely to have technology-related hobbies and are less often encouraged to act with technology at school and home (Naukkarinen et al. 2021), a period of work experience in a technology company can provide the much-needed opportunities to gain technology-related concrete experiences with real-life connections that girls easily otherwise lack. These experiences also increase the adolescents’ science capital, by conveying knowledge about STEM-related jobs and the transferability of science in working life, as well as giving the opportunity to get to know people in science-related roles (Moote et al. 2019). As science capital is known to positively correlate with engineering aspirations (Moote et al. 2019), period of work experience in a technology company can be expected to increase pupils’ interest in engineering careers.

Secondary schoolers with immigration backgrounds are generally not identified as a distinct group (Airas et al. 2019) hence little is known about their experiences in choosing educational paths. An evaluation of students with an immigrant background in Finnish higher education recognized marketing cooperation between companies, higher education institutions, and the public sector as a good practice that can both advance the employment of graduates with immigration backgrounds and make higher education opportunities better known to those with no prior experience of it (Airas et al. 2019). A period of work experience in a technology company coupled with information about the educational paths leading to respective professions serves these objectives well.

The spectrum of STEM outreach activities is vast yet work placement does not seem to be common among them (see e.g. Tillinghast et al. 2020). Hence little is also known about its effectiveness in attracting young people to engineering.

3 TECHNOTET SOUTH KARELIA PROJECT

LUT University has long been aware of the segregation of different fields of education based on gender, as well as the significant influence of young people's social background on whether they choose to pursue higher education or not. For years, LUT has also been an organization offering periods of work experience (a.k.a. TET) to lower secondary school pupils, like many other employer organizations. However, LUT's TET periods have not been conceptualized. Thus, their full potential has not been utilized. A solution to these challenges arose in the form of the *TechnoTET South Karelia* project.

In the early stages of the project, various options were considered for constructing a TechnoTET period for lower secondary school pupils. The first decision was that TechnoTET would be aimed at 9th graders because they are the ones most actively considering their further education options. In local lower secondary schools, 9th graders have a two-week work experience period, so the TechnoTET period also had to be designed as a two-week package.

The project also aimed to involve companies from the technology sectors because the goal was to show young people what kinds of tasks are carried out in technical expert roles and what opportunities the technology sectors offer in general. It was decided that during the two-week TechnoTET period, pupils would spend the first week at LUT getting acquainted with the different education opportunities, academic work environment, and researcher's work. During the second week, pupils would familiarize themselves with expert tasks in companies for the first four days. On the final day, all pupils would gather again at LUT, where experiences would be shared and feedback collected.

Since this is a local project and pupils need to be able to easily access the companies, it made sense to invite tech companies that operate in Lappeenranta region and are located close enough to the pilot school. Another selection criterion was that the companies had to have technical expert positions that the young people could observe. Approximately 25 companies were contacted, and it was found that it was generally very difficult to reach company representatives. Once contact was established, the companies liked the idea of the project but were not willing to take in TET trainees due to workload and the lack of meaningful tasks for the trainees. The project schedule was also very tight, which made it difficult to engage the companies. However, negotiations were successful with a few, and the first pilot involved four partner companies: Metso, Roxia, UPM and Yaskawa. Each company was able to offer 2-4 internship positions.

The selection process also included a visit from a LUT representative to each company at least once. Internship contracts were signed with all partner companies to make sure that the young people would have meaningful tasks and a supervisor during the company days, too. Based on the discussions, it was clear that the companies selected for the pilot were suitable because they were genuinely motivated to participate in the project and recognized its value in terms of social responsibility. Additionally, the company representatives were willing to put effort into planning the program and wanted to leave the young people with a positive impression of the company, its operations, and employees.

Sammonlahti School, a comprehensive school with approximately 900 students served as a partner school in the first TechnoTET pilot. During the 2023-2024 academic year, there were around 100 ninth graders at Sammonlahti School. TechnoTET was promoted to them during student counseling classes in September 2023, with each 9th-grade class having a TechnoTET-themed lesson where the concept was introduced, and pupils were encouraged to consider the significance and opportunities of technology education and careers. During the lesson, pupils rotated in small groups to stations where they discussed, among other things, gender segregation in various professions, read career stories from the field of technology, and familiarized themselves with the partner companies.

After the lessons, pupils were invited to apply for the TechnoTET period. A total of 27 applications were received but there were only 15 positions available. The selections were made in collaboration with Sammonlahti school student counselors. In line with the project's objectives, priority was given to females and pupils with immigrant backgrounds. Following these principles, a group of 15 pupils was formed, consisting of a total of 8 females and 7 males. Two out of 15 were pupils with an immigrant background.

3.1 The program

The two-week pilot was carried out between October 9th and 20th, 2023. During the first week, pupils were introduced to educational opportunities in technology fields and the academic work at the university. The aim was to create a program that was as varied as possible to keep the pupils' interest alive throughout the entire week. The week included, among other things, an escape room game related to environmental technology, an introduction to researcher's work, making sorbet in the chemical engineering laboratory, and delving into electrolysis under the guidance of an electrical engineering student. The theme of gender segregation was also addressed. Additionally, the pupils familiarized themselves with partner companies and pondered what kind of skills are required in the workplaces. The program for the first week is illustrated in Figure 1.

Time	Monday 9.10.	Tuesday 10.10.	Wednesday 11.10.	Thursday 12.10.	Friday 13.10.
09.00-10.00	Getting to know each other, Team-building activities	ABB classroom: electrolysis	Introduction to the work of a researcher	Introduction to gender segregation	TEK: science and technology education
10.00-11.00	Familiarization with partner companies	*Draw an Engineer* assignment	Introduction to the academic library	*Shaking up Tech Stream*	
11.00-12.00	Lunch	Lunch	Lunch	Lunch	Lunch
12.00-13.00	Creating a written or video presentation about oneself and sending it to company	Campus orienteering: study programmes	Chemical engineering Making sorbet: heat transfer and phase change Thin-layer chromatography Analytical balances, SEM	Preparing for the following week: TET report, working life skills, strengths	TEK: science and technology education
13.00-14.00	Guild room tour	13.00-13.30 Orienteering: right answers			
14.00-15.00	Introduction to Jamie Hyneman Center	13.30-15.00 Environmental engineering escape room game		Gender segregation: addressing the topic interactively	xxxxxxx

Fig. 1. TechnoTET schedule, 1st week

During the second week, the pupils were at partner companies from Monday to Thursday. The aim was to provide them with insights into expert tasks in technology fields by simulating real expert work. At UPM, for example, pupils manufactured laboratory sheets, tested them, and wrote a report on the entire process. At Metso, interns engaged in tasks such as equipment engineering using SolidWorks and identifying different types of rock. At Roxia, interns had their own small project during which they interviewed employees, wrote career stories, and updated them on the company's website. At Yaskawa, students were introduced to different departments of the company through various tasks. They became familiar with areas such as occupational safety, quality, design, project management scheduling and management of production facility instructions.

On the Friday of the second week, all pupils gathered once again at the university to share experiences and to give feedback. As the pupils had spent four days in different companies, it was important to bring the group together one more time. The morning was mainly spent exchanging experiences and giving feedback. Additionally, the pupils recorded short videos describing their experiences and created a thank-you message to the company they had been in. After lunch, the pupils familiarized themselves with LUTES, which is a student-driven entrepreneurship society based at the university. In the afternoon, they played with VR glasses and consoles before it was time to bid farewell to the TechnoTET experience.

4 EXPERIENCES AND FEEDBACK

The pupils' experiences from the TechnoTET period were generally very positive and they liked the training. Discussions with the participants revealed that pupils who wouldn't have otherwise pursued a technical field for work experience participated in the internship. It also became apparent that before TET, most of the pupils had had limited knowledge about the possibilities in technology-related fields and the various tasks that can be undertaken in expert roles. Additionally, the partner companies had not been familiar to everyone, especially regarding what is done in the companies and why. Furthermore, the pupils' perceptions of engineers as a professional group had been somewhat incomplete and, in some cases, biased. However, all of this changed somewhat during the internship, as the pupils' understanding of the technology sector and the people working in it increased.

For example, at the beginning of the TechnoTET period, pupils were asked to draw an engineer and describe them along with their working conditions. Only one drawing depicted a female, while the rest were of males. Many figures had helmets on their heads and tools in their hands, implying a perception of work as primarily hands-on installation and repair tasks. Many pupils also described engineers as working alone and being introverted. In the discussions on the final day, however, the pupils mentioned a better understanding of the diverse working field of engineers and the variety of people involved in engineering tasks.

At the end of the period pupils were administered a short survey about their TechnoTET encounters. The survey aimed at gauging different aspects of student experience: attractivity, perspicuity, efficiency, dependability, stimulation, and novelty (Laugwitz et al. 2008). The feedback was altogether very positive but foremost the pupils evaluated the experience as pleasant (as opposed to unpleasant), modern (as opposed to old-fashioned), innovative (as opposed to conventional), and organized (as opposed to chaotic). One out of thirteen respondents stated to be slightly disappointed with the experience, whereas all the rest regarded it as meeting their expectations on positive terms.

When asked about potential changes to the TechnoTET concept, the pupils unanimously expressed a desire for more hands-on experiences both at the university and in the companies. The company representatives also noticed the same preference. They mentioned that although the pupils had the opportunity to try out real expert tasks, they did not perceive them as actual work. For example, at Yaskawa, students had worked on project scheduling but, according to their own words, did not consider it real work but more like playing with Excel.

However, the companies were generally very pleased with the experience and praised the behavior and actions of the young participants. A common improvement point highlighted by both the university and the companies was the need to simulate expert tasks at an even more concrete level. Despite this, all four partner companies were so satisfied with the experience that they expressed their willingness to continue participating in the project and host TechnoTET interns in the future as well.

The university was also very satisfied with the first TechnoTET experience. Thirteen university employees participated in implementing the program, and their experiences with the internship were very positive. Interns are welcomed as long as the responsibility is distributed enough among different units and as long as the coordination of the program functions well. Employees are happy to participate when they know what is required of them in their respective roles and as long as it is closely related to their own work and expertise. The coordination responsibility is gladly given to a coordinator who is responsible for organizing the whole program and ensuring that the youth are in the right place at the right time.

Additionally, it was observed that organizing a TechnoTET period is more efficient than receiving individual TET interns. Since the university has now done both, it was easy to compare the two alternatives. Through the conceptualized internship, a broader group of young people can be reached, and it is easier to build 1-2 high-quality programs per academic year than constantly tailor individual programs for a few interns.

5 CONCLUSIONS AND CONTINUATION

Overall, the first TechnoTET pilot was a very positive experience that encouraged continuing the work and expanding the TechnoTET concept to high school and vocational school students in the spring semester of 2024. In autumn 2024 the lower secondary school TechnoTET internship will be repeated, but this time it will be expanded to include a total of three schools and twelve partner companies.

Although collecting longitudinal data to assess the effectiveness of the program is not possible due to data protection regulations, we will collect research data on the effects of the TechnoTET program next academic year. For example, pupils' perceptions of engineering, their understanding of engineer's work and their aspirations toward engineering will be examined.

So far, the narrow data from the project has not allowed us to evaluate the attractiveness and effectiveness of the activities from the viewpoint of the targeted minorities. However, a new round of pilots coupled with a growing number of participants allows us to examine the concept and its impact on a deeper level and hopefully enables us to evaluate the possible differences related to participants' gender and ethnic background, too.

While awaiting research evidence, we base our current thoughts on discussions and feedback from the different stakeholders. As expected, they seem to confirm the value of out-of-school activities (Vennix et al. 2018) and of first-hand experience and knowledge in increasing the pupils' science capital (Moote et al. 2019) and in increasing the attractiveness of engineering as a possible career (van Tuijl and van der Molen 2016).

6 ACKNOWLEDGEMENTS

The authors wish to thank the European Social Fund equality project TechnoTET South Carelia (S30069) for the resources of this project.

ABSTRACT

Engineering and technology are necessary for handling global challenges that encompass technological, environmental, economic and social dimensions. However, there can be unintended consequences if technological solutions are not aligned with societal needs or ethical considerations. This paper emphasizes the need for engineering students to understand social, economic and environmental responsibilities associated with their profession. The paper highlights the importance of fostering the concept of Responsible Research and Innovation (RRI) within higher education institutions and positioning universities as stakeholders in promoting socially responsible innovation. At RWTH Aachen University, the institutionalization of a RRI Hub underscores the commitment to embedding RRI principles in research, teaching, and collaboration efforts.

By introducing the concept of RRI, engineering students can develop an understanding of socially responsible technological development. The article outlines the conception and implementation of a seminar at RWTH Aachen University that aims to awaken students' sense of responsibility towards societal challenges. The

[1] *C Lemke*
clara.lemke@gdi.rwth-aachen.de

seminar integrates different dimensions of RRI, including multi-stakeholder involvement, reflective approaches, and responsiveness and adaptability. Through a structured course design, students explore topics such as ethics, gender equality and public engagement while developing solutions to local sustainability problems. Reflecting on the seminar's outcomes, the paper identifies areas for further development, including interdisciplinary collaboration and the integration of external expertise.

1 INTRODUCTION

Engineering and technology can offer sustainable and responsible solutions for global challenges, which includes technological, ecological, economic and social effects. However, technical and engineering solutions can also cause social and environmental problems if, technological innovations are used for unintended purposes or if unexpected and undesirable impacts occur. With their technical expertise, future engineers contribute essentially to achieving the sustainable development goals (Steuer-Dankert et al. 2019; UNESCO 2021; Tabas et al. 2019). Engineering students have to recognize this social and environmental responsibility of their profession und have to know what responsibility means and how they can deal with itself in their engineering practice (Rulifson und Bielefeldt 2019). This contrasts with a trend towards depoliticization within engineering (Cech und Sherick 2019; Cech und Sherick 2015; Henderson 2022; Hughes und Kothari 2021). Depoliticization in engineering reinforces the attitude that political, social and ethical aspects can be separated from technical aspects and are not part of the scope of engineering (Cech und Sherick 2015). Studies show that awareness of social responsibility decreases with the duration of engineering education and that the consideration of social values and needs is not considered by students as a relevant part of professional identity (Cech 2014).

The concept of Responsible Research and Innovation (RRI) provides engineering students an opportunity to develop an understanding of the need for socially responsible research and innovation and to receive orientation for their work as engineers in the development of technical solutions to cope with societal challenges. Technical universities and institutions involved in engineering education have thereby an important role in the implementation of RRI in research and innovation processes, particularly through the training of students. Prospective engineering students must be prepared for their role as developers of responsible technological innovations and equipped with the relevant competencies (Tassone et al. 2018). For this purpose, this paper presents the concept of the seminar “Selected Aspects of Responsible Research and Innovation” and discusses how the various dimensions of the RRI concept can be integrated into the conceptual design of a seminar for engineering students. In the sense of responsiveness and adaptability, we analyze the feedback of the students at the end of the course and reflect how engineering students perceive the discussion of the RRI concept as well as outline possibilities for the further development based on the reflection and evaluation of the seminar.

2 BACKGROUND

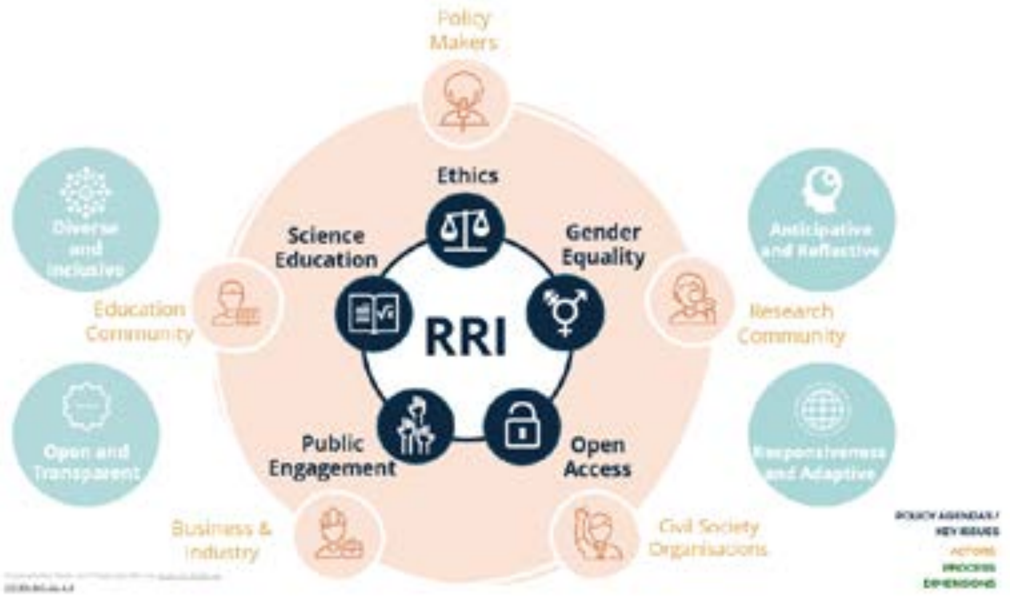
2.1 Responsible Research and Innovation

Schomberg´s (2013) often cited definition of RRI explains responsible innovation as

> a transparent, interactive process by which societal actors and innovators become mutually responsive to each other regarding the ethical acceptability, sustainability and social desirability of the innovation process and its marketable products. (von Schomberg 2013, S. 63).

The ethical acceptance of innovations (products) and the innovation process means compatibility with fundamental values and rights of society as well as the alignment of these processes with the social needs and perspectives of diverse societal groups (Sutcliffe 2011; Burget et al. 2017). In addition to technical or economic aspects, current and future social, ethical and ecological effects, risks and opportunities are anticipated and a response is made to changing knowledge and circumstances (Sutcliffe 2011).

Figure 1. Dimensions of the RRI concept (illustration in Berg-Postweiler et al. in press based on RRItools)



“Multistakeholder involvement” (von Schomberg 2013, S. 67) refers to the shared responsibility for an ethically acceptable, sustainable and socially desirable orientation of research and innovation by different actors from academia, industry, government and society. The EU commission named different dimensions of RRI (Figure 1, dark blue): All stakeholders assume responsibility for research and innovation processes and their results (engagement), which also includes science education and open access to research findings, as well as consideration of gender equality and ethical issues. The EU-funded program “RRItools” formulates four process dimensions (Figure 1, light green) for the collaboration of society, research and education sector, politics as well as industry and business. Diversity and inclusiveness - as a process dimension - is related to the involvement of a broad spectrum of stakeholders and society in research and innovation. The requirement to be open and transparent includes communicating the findings of methods, results, conclusions and effects openly and transparently. Third, research and innovation must be viewed in an anticipatory and reflexive manner in order to predict important implications and consider appropriate opportunities for action. The last dimension, responsive and adaptive, aims to be able to adapt research processes and the necessary structural requirements to changing conditions, needs or new scientific findings (RRI Tools 2016).

3.1 Fostering RRI at RWTH Aachen University

Universities and other higher education institutions are relevant stakeholders in the implementation of the RRI concept (Nulli und Stahl 2018). On the one hand, the fostering of science education is one dimension of the RRI framework and, on the other hand, it is necessary for the implementation of RRI in research and innovation processes that the involved persons are familiar with the concept and acquire competencies to implement RRI in the sense of the four process dimensions described.

With around 45,000 students 550 professors and 6500 scientific employees RWTH Aachen University is one of the largest technical universities in Germany. And one of Germany´s Universities of Excellence. In the excellence strategy of the German state and federal governments RWTH formulates 2019 under the title “The Integrated Interdisciplinary University of Science and Technology. Knowledge. Impact. Networks” the goal “to further grow beyond a unique integrated, interdisciplinary university by embracing the convergence of knowledge, approaches and insights from the humanities, economics, engineering, natural and life sciences, i.e. biology and medicine” (RWTH Aachen University o.J., S. 11). The RRI concept serves as a “guiding principle” (RWTH Aachen University o.J., S. 47) for shaping the process described in the Excellence Strategy. The Responsible Research and Innovation Hub (RRI Hub) has been institutionalized for the implementation and fostering of RRI at RWTH Aachen University. The aim of the RRI Hub is to “anchor responsible research and innovation as one of the central guiding ideas in research, teaching, and transfer, and become a nucleus for a socially responsible orientation of the university” (Berg-Postweiler et al. 2024). The RRI Hub operates in the three areas of research, teaching and transfer. It promotes cooperation and the joint action of various stakeholders from science, industry, politics and civil society. The assumption of social responsibility is seen as the basis and objective of an excellent university. In addition to responsibly oriented research and cooperation with civil society, this also includes the training of responsible future engineers (Berg-Postweiler et al. 2024).

3 COURSE DESIGN

Within the teaching area of the RRI Hub, the seminar “Selected Aspects of Responsible Research and Innovation (RRI)” is offered annually in the winter semester for master students of the study programs, Civil Engineering, Environmental Engineering and Business Administration and Engineering specializing in Civil Engineering at RWTH Aachen University. The seminar was conceptualized and implemented for the first time in the winter semester 2023/2024. Because the course is offered in German, we translated all material into English.

3.1 Learning Outcomes

The aim of the seminar is for students to reflect on the relevance of a responsible orientation of research and innovation and their own responsibility in the concept of science and research and to apply the RRI concept to current societal challenges.

Following the concept of constructive alignment (Biggs und Tang 2011), there a several learning outcomes, which students should attain after completing the course. Students should first of all **describe** the position of the RRI concept in the European context, **characterize** the RRI concept as well as **explain** its various dimensions and content areas. Furthermore, after the course students are able to **explain** the relevance of a responsible orientation of research and innovation and to **discuss** current challenges in selected subject areas of the RRI context. Through the analysis of selected examples of technical or engineering examples, students are able to **reflect** on the consideration of different dimensions of responsible research and innovation. Students should **reflect** on their own responsibility in a scientific or research context, particularly within their own discipline. Through the knowledge and competencies they acquire, students **develop** a concept for an activity that deals with a current societal challenge and integrates various aspects of RRI.

3.2 Course Structure

The presented policy agendas, actors and process dimensions of RRI (section 1) are taken into account in the conceptualization of the course.

The course structure (Table 1) attempts to address the various policy agendas. After the introductory session explains the course and examination concept, presents the RRI Hub and introduces the SDGs as a context for responsible technical developments and innovations, the following session introduces the approaches of RRI. Initially, the development of the RRI concept in the European research context is presented and then the principles of responsible research and innovation are elaborated on the basis of different administrative and scientific definitions. Students develop the process dimensions of RRI and reflect on relevant actors in research and innovation processes. The exploration of the RRI framework is the basis for the subsequent seminar sessions. In individual sessions, the policy agendas Ethics, Gender Equality, Open Access and Public Engagement are examined from the perspective of the various stakeholders and connections to the four process dimensions are established. Table 1 shows the content covered in each session. In the "RRI and Gender Equality" session, for example, students discuss the gender balance in research and innovation teams as well as the relevance of gender aspects in research and innovation. Based on the question “How must the mobility infrastructure in Aachen be designed to consider the needs of women and men”, students discuss the impact of the needs and requirements of different genders on the development and design of infrastructure. To promote the students' ability to adopt perspectives, this is done with the help of the Disney method, in which ideas are generated by the participants adopting the roles of dreamer, realist and critic in turn (Schawel und Billing 2014).

The content sessions are complemented by an interactive seminar session on public engagement methods, in which students have the opportunity to practice selected methods (i.e. fishbowl discussion or World Café) with the seminar group and reflect on the opportunities and challenges of these methods. In preparation for this session, students deal with the Action Catalogue (http://actioncatalogue.eu/) and briefly present a method of their choice. In the session they reflect together on the purposes for which the methods are suitable, which stakeholders are addressed, and what strengths and weaknesses the methods have. In a workshop session, students get to know Living Labs and discuss their significance for the implementation of RRI. In the conclusion session, students reflect on their own expectations and learning progress. Together with their fellow students and the course supervisor, they discuss on which topics have addressed, which challenges have arisen and which possibilities for improvement would be appropriate.

Table 1. Course Structure

	Topic	Content	Individual Reflection
1	Introduction	Course concept and examination Introduction RRI Hub SDGs, Societal challenges	x
2	RRI as a Framework	Definitions RRI policy agendas, actors and process dimensions	x
3	RRI and Gender Equality	Gender Equality in the world Gender Balance in Research, Leaky Pipeline Gender aspects in research and innovation Gender Mainstreaming & Planning	x
4	RRI and Ethics	Ethics in Research, Scientific Integrity Science communication Open Access, Open Science	x
5	RRI and Public Engagement	Participation, Civic Engagement Citizen Science Methods of Public Engagement	x
6	Methods of Public Engagement	Interactive session, Methods of Public Engagement in Practice	x
7	Living Labs	Definition, Types of Living Labs Living Labs and RRI	
8	Pitch-Session	Short Presentations of the elaborated concepts	
9	Conclusion & Reflection	Reflection seminar concept, own expectations	

After each seminar session, students could reflect on one aspect of the session in writing and discuss their thoughts on this aspect. For example, after the session on RRI and public engagement, students reflect on structural and individual barriers or ethical challenges, such as distribution of power and the use of influence. The individual written reflection papers serve to deepen the discussion of the RRI concept.

3.3 Examination

The examination consists of the task to develop a concept for a sustainability week organized by the RRI Hub, where students work together with various stakeholders from research, business and industry, politics and civil society to elaborate solutions for the challenges to mastered by the city of Aachen to achieve the SDGs. Table 2 shows how the four process dimensions of RRI are taken into account in the design of the examination.

Table 2. Addressing RRI process dimensions in the examination

Diverse & Inclusive	- Sustainability week for students and different stakeholders/actors - Impact and effects of the challenge for different actors and social groups
Open & Transparent	- Presentations/Pitchs - Documentation of the Concept
Anticipative & Reflective	- Analyse of the challenge in term of positive and negative developments - Effects of the challenge for different actors and social groups
Responsiveness & Adaptive	- Feedback from fellow students and the course supervisor during the pitch session - Reflection on the group work - Peer feedback and self-assessment of social competencies in group work

The task is divided into two parts that build on each other. The students are given guiding questions for both parts to provide orientation. In the first part, the students identify a challenge that Aachen has to master to achieve sustainable development by 2030. This challenge should address an SDG. The students decide independently in their groups how to identify the challenge. In doing so, the students should also speak with different stakeholders in the city. They analyse the challenge in terms of positive and negative development opportunities, connections with other challenges as well as the extent to which the challenge affect different actors and social groups. Based on the challenge they have identified, they develop a concept for a sustainability week, which will work out and discuss possible solutions to this challenge. As part of the concept, students work out how the various policy agendas, actors and process dimensions of RRI (s. section 1) can be integrated into their concept.

The students present their concept for a sustainability week in the pitch session in the format of a five-minute pitch. The pitch should be created in such a way that potential organizers of the sustainability week are convinced of the concept. In the pitch session, the students receive feedback on the concepts from their fellow students and the course supervisor. In the subsequent written documentation, students explain certain aspects in more detail and incorporate feedback from their fellow students and the course supervisor. The aim is not to revise the concept, but to explain how to respond to the feedback.

In addition to reflecting on the concept as part of the documentation, the documentation should also include a joint reflection of the group on the work processes. This is supported by the following key questions: What worked well? What worked less well - and why? In the winter semester 2023/2024, students identified open communication, clear objectives and coordination as elements of successful group work. Each group member should take responsibility, while at the same time tasks need to be distributed and regular coordination is necessary. In addition to jointly reflecting on the group work, the students give each group member anonymous feedback on their communication and teamwork skills as well as their commitment within the group. The students receive an evaluation of this feedback, including a comparison with their own personal rating.

4 REFLECTION AND FURTHER DEVELOPMENT

In terms of the RRI process dimensions “anticipative and reflective” and “responsive and adaptive”, the last seminar session "Conclusion and Reflection" (Table 1) serves to evaluate the seminar and review the students' expectations. In preparation for the session, students can note down their thoughts on a digital Miro board with the help of six key questions on the seminar topics, acquired competencies, challenges and suggestions for improvement. In the session, the students discuss these first in small groups and then in plenary. In general, the students indicated their satisfaction with the seminar concept and underlined the relevance of the RRI concept for future engineers during the discussion and reflection. In addition to the positive feedback, the students criticized only a few aspects. The students were missing more seminar participants.

The students emphasize the need to make research and innovation processes more transparent. This is an elementary component of the RRI concept through the described process dimension "open and transparent" as well as the topics of public engagement and open access. They mention the reflection on their responsibility as engineers and a member of the civil society as a learning gain from the seminar. Reflection is an important part of the RRI concept and therefore also plays a relevant part in the seminar. Reflection is considered holistically in the seminar, by critically examining the RRI concept and its elements, by students writing individual reflections on individual aspects of the sessions, by fellow students and course supervisors giving feedback on the concepts and pitches, by the groups reflecting on the feedback in their documentation, by students thinking about their group work, by giving each other feedback on the social skills within the group work (peer feedback) and by receiving detailed feedback from the course supervisor during the assessment.

In line with the RRI process dimension "Responsiveness and Adaptive", research and innovation have to react to changing needs and conditions as well as new knowledge. This also applies to the seminar concept and therefore some changes, adaptations and improvements are already planned for the next cycle of the seminar.

As we did only have a small amount of students, we are expecting more students in the next round of the seminar. For example, the structures of the RRI Hub could be used to attract students. In addition to the university's course evaluation, a pre-post survey on student motivation and satisfaction as well as the development of RRI-related competencies is planned for the next semester. This quantitative data will allow further insights about the effectiveness of the teaching and learning approach presented.

In the winter semester 2023/2024, the students independently selected a challenge of sustainable development in the city of Aachen and developed a concept for an event (Sustainability Week) based on this. The next time the seminar is conducted, the cooperation between different stakeholders that is necessary in terms of the RRI concept will also be practically implemented, in that students will work together with stakeholders from the city of Aachen and the surrounding region to develop challenges for sustainable development in Aachen. This can then be followed by the planning of a living lab or a citizen science project in the form of group work. The stakeholders will be recruited through the network structures of the RRI Hub (e.g. contacts to the city administration, civil organizations or entrepreneurs).

The diverse involvement of a broad spectrum of stakeholders (diverse & inclusive) is to be achieved through various components. The intention of the seminar is to strengthen the exploration of inter- and transdisciplinary perspectives on RRI. For this purpose, students of political science will participate in the next cycle of the seminar alongside students of the engineering study programs. For the group work interdisciplinary groups will then be arranged. In a further step, the seminar can be supplemented by additional input from experts from the partner universities of the ENHANCE Alliance. With the Massive Open Online Course "Responsible Innovators of Tomorrow", the RRI Hub already has a teaching and learning offer that is available to the students at the ten ENHANCE universities. The integration of this content into the seminar, a subsequent discussion and reflection of this content and the processing of a case study are possibilities for expanding the concept.

This practice paper shows that the institutionalization of a structure such as the RRI Hub at RWTH Aachen University enables the implementation of RRI as a guiding principle of a technical university by practically integrating the RRI concept into engineering education and the interaction of science, business and industry, politics and civil actors. Dealing with RRI allows the trend towards depoliticization within engineering (Cech und Sherick 2015; Cech und Sherick 2019) to be countered and encourages students to reflect on their social responsibility as future engineers.

Keywords: *AI, Large Language Model, Project Based Learning, Design, Feedback*

ABSTRACT

This practice paper report the use of by Inflection AI's Pi chatbot and Azure OpenAI GPT-3.5-Turbo and GPT-4 APIs to provide insightful and timely feedback across written, oral, project-based and team-based assessment tasks in a level 2 capstone engineering design course. The Large Language Model (LLM) driven AIs can text and audio based artefacts submitted by students, including short written tasks, draft reports, pitch presentations and meeting transcripts. This in turn allows course instructors to address students' learning needs more efficiently and effectively. The present work further demonstrated there are still limitations and barrier to full implementation of AI-assisted feedback in the classroom. Unless trained on specific content, LLM-driven AI lacks nuanced contextual understanding. For some students, the AI generated feedback did not appear to develop or improve the student's metacognitive abilities or their self-regulation of learning. At the time, use of LLM-driven AI for feedback was hindered by an absent of toolchain for data capture and processing, as well as the lack of an institutional level AI strategy and roadmap, partnerships to bridge capability and capacity gaps, robust guiderail and policies around the use of AI in the classroom. The final section of this paper outlines strategies that can be used to address these limitations and how the needs of academics who intent to apply LLM-driven AI in feedback practice should be supported.

1 INTRODUCTION

Design is generally considered a core competency in undergraduate engineering education and a main component in value creation. The modern engineer is also expected to possess the necessary technical, project management, communication, and teamwork skills needed to deliver the best design solution. As such, many engineering schools have introduced project-based design courses into their curriculum to better align engineering theory with practice. Students are given opportunities to work on authentic problems, and some recent developments include the teaching of user-centred approach such as design thinking (Charosky et al. 2022).

While authentic, real-world based design courses have been reported to engage and motivate students more effectively, their implementation in large class remains a challenge (Heller et al. 2010). Engineering students often have difficulty conceptualising and contextualising user-centred problems solving, particularly if it is their first exposure to the approach. Some students also had the tendency to switch immediately to solution mode, skipping or rushing through the user research stage of the design. Teaching strategies that are based on project and collaborative learning are also vulnerable to the students' lack of project management and teamwork skills. The issues that can hampered a student progress in a design course are also difficult to detect and address, particularly in large classes with high student to staff ratio.

A way to overcome the abovementioned issues and improve the learner experience in project-based design courses is to provide timely feedback that is aligned with the course learning outcomes and learner needs (Gülbahar and Tinmaz 2006). In recognition of this fact, engineering educators have embraced various feedback tools and strategies to improve student's feedback literacy in their practice (Coppens et al. 2023, Gilbuena et al. 2015). Peer feedback, for instance, have been shown to foster a culture of constructive criticism and continuous improvement among students, while enhancing their ability to provide and receive feedback effectively (Dong et al. 2023, Tai et al. 2018).

Another important development is the increase affordance of digital platforms. Learning analytics and educational data mining offer promises in enhancing students' learning in design courses through early intervention, individualized feedback mechanisms and improved workflow (Xing et al. 2023). Recent development in LLM-driven AI, as exemplified by ChatGPT, Open AI's widely accessible web based chatbot, further reshaped the landscape (Bauer et al. 2022).

Several investigators have reported the use of LLM-driven AI to generate feedback for written and programming tasks (Dong 2024; Escalante 2023; Mahapatra 2024; Husain 2024; Sun et al. 2024; Wilson et al. 2024; Xiao and Zhi 2023). Banihashem et al. (2024) found a statistically significant difference between the feedback generated by an AI and student peers for a written task. Using statistical methods, they showed the former was more descriptive while the latter was better at identifying deficiencies in the written task. Nonetheless, the quality of both types of feedback did not affect the quality of the written task. Instead, a positive correlation was found between the former and the affective features present in the AI-generated feedback.

So far, the consensus in the literature was that LLM-driven AI has the potential to alleviate the challenge of providing feedback to large classes and to promote self-regulating skills such as feedback seeking, goal-setting, and progress monitoring (Guo 2023; Hopfenbeck et al. 2023; Li and Kim 2024). Subtle variations remain in how students and teachers perceive the trustworthiness of AI-generated feedback. Barrett and Pack (2023) noted a disagreement between students and teachers concerning the acceptable use of LLM-driven AI tools for generating feedback for written tasks. Ding et al (2023) found physics students held misconceptions about the capability of LLM-driven AI, with nearly half of the students trusting LLM-driven AI generated answers even though the AI only has 85% accuracy. Contrarily, Tossell et al (2024) found students were not confident in the feedback generated by LLM-driven AI and did not trust its' use as an independent evaluation and feedback tool. Darvishi et al. (2024) found students tended to rely on, rather than learn from, AI. Moreover, supplementing AI assistance with self-regulated strategies did not yield significant advantages over relying solely on AI assistance.

Taken together, these findings suggest a complex dynamics between the use of LLM-driven AI to generate feedback, attainment of learning outcomes, and student's perception of the tool which requires further exploration and elucidation, and for learning tasks other than writing or programming. The present study examine how LLM-driven AI can be employed to monitor or evaluate the quality of formative written and oral assessment tasks, as well as team interactions and contributions in a 10-week long project based design course. The course was taught to level 2 chemical engineering students with the aims of developing the students' design thinking and professional skills. Outputs from the LLM-driven AI were also used to provide tailored and immediate feedback to individual students (class size = 54 students). The use of AI generated feedback as a complement to instructor and peer feedback was also explored.

2 METHODOLOGY

Due to the rapidly evolving nature of LLM-driven AI technologies in 2023, a design-based research methodology was applied in this study (Holland et al. 2019). Instead of pre-defining and controlling all variables in the study, a variety of LLM-driven feedback mechanisms were introduced to support students in different formative tasks at various stage of the course delivery (see Figure 1). The outcome of each intervention which were then used to guide subsequent feedback mechanisms design.

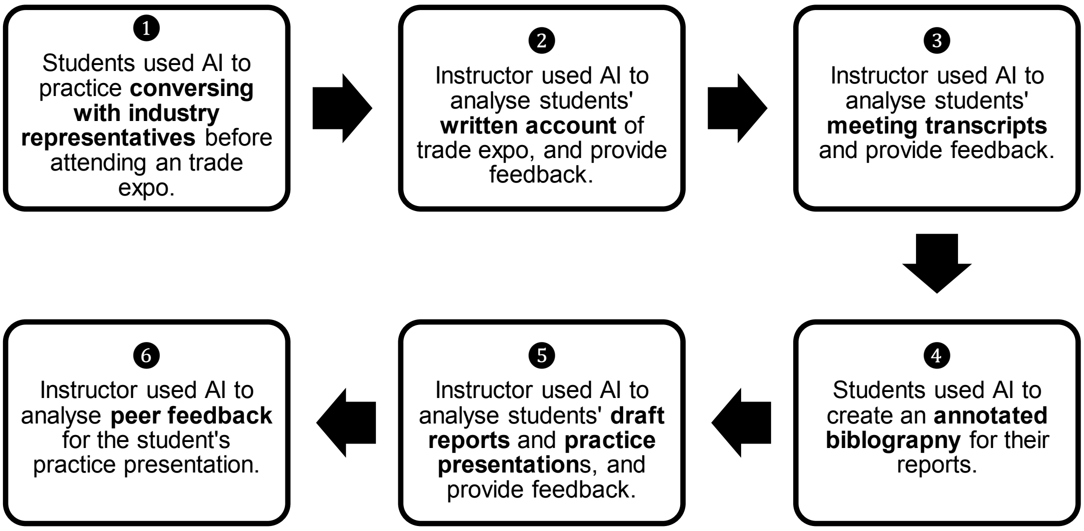

Fig. 1. Schematic of the design-based approach.

At the start of the course, students role-play conversation with industry representative at a trade show with Pi, a chatbot by Inflection AI's, via a web interface (see text box marked '1' in Figure 1). Based on Inflection's proprietary LLM Inflection-1, Pi was designed to maintain an interactive text or voice-based dialogue with a human user in personable manner. It was for this reason which Pi was selected over other chatbot at the time.

The students then attend a trade show that is related to the course. The students were assigned the task of sharing their experience, observations and conversations with industry representative at the trade show on Padlet, a virtual bulletin board. The instructor downloaded the student's accounts of their interactions at the trade show as a CSV file and summarised the submission using Azure Open AI's gpt-35-turbo model via the API (see text box marked '2' in Figure 1).

Throughout the course, the students who were assigned to teams of six students. The student teams held regular online meetings on Microsoft Teams outside of class time. In these meetings, collective sensemaking, brainstorming, planning and decision making about the design solution occurred. The meetings were setup to automatically record and generate a transcript at the end. The transcripts were analysed periodically using Azure Open AI's gpt-4 model via the API (see marked '3' in Figure 1).

Mid-way through the term, the students had to submit draft of their reports and practice pitching their design solution individually as formative tasks for end-of-term summative assessments that are worth 60% and 20% of the total mark, respectively. As part of the report writing process, the students were instructed on how to use elicit.org, an AI research tool which can create annotated bibliography from articles the students have found (see text box marked '4' in Figure 1). It should be noted here that the use of elicit.org is not mandatory, but students were evaluated based whether they can accurately gauge the quality and relevancy of the articles they have selected for their report. The draft reports were all written 'from scratch' on Microsoft Word documents that were saved to a SharePoint library.

The practice pitches were recorded during class time in the same way as the students' meeting. Both type of submissions were summarised by the instructor using Azure Open AI's gpt-35-turbo model via the API (see text box marked '5' in Figure 1). When a student was practicing their pitch in class, other students who were in the audience were required to provide peer feedback on the quality and content of the pitch on Padlet. The instructor downloaded the students' feedback as a CSV file and summarised them using Azure Open AI's gpt-4 model via the API (see text box marked '6' in Figure 1).

A survey with two sets of questions was developed for this study. The first set of questions, derived from the work of Brookhart (2017), Haughney et al. (2020), and Carless and Boud (2018) surveyed students' feedback literacy and experiences of feedback practice. The second set of questions explored students' experiences and perceptions of AI-assisted feedback. This includes comparing the perceived quality of feedback generated by or with the assistance of AI, to that of their instructor, and peers. A total of 17 students' responses were received (32% of cohort). This is typical in an academic setting, and is due to the fact that the students were only invited twice to complete the survey in order to reduce the number of inauthentic responses.

The survey data was complemented by autoethnographic account of the instructor's experiences of implementing the LLM-drive AI interventions in their course. Here, 'auto' relates to a focus on personal experience; 'ethno' relates to the study of a culture; and 'graphy', refers to a systematic process for describing and analysing both personal and cultural experience arising from the study (Ellis et al. 2011). The act of self-enquiry by an author-instructor who had designed the present design course from scratch and has good insight into the support needs of their students can lead t0 a deeper and more nuanced understanding of LLM-driven AI use in teaching practice (Mao et al. 2023).

3 RESULTS

3.1 Instructor's Account of Developing AI Feedback Tools for a Design Course

In an essay on constructionism, Harel and Papert (1991) described two styles of solving problems. One is the methodical and analytical method of problem solving that is familiar to many engineers. The other is 'bricolage', which is a way to learn and solve problems by tinkering, that is, trying, testing, learning, and iterating. More recently, the term bricolage was used when referring to an innovation practice that is based on using the least amount of immediately available resources, usually in a resource-constrained context (Bouvier-Patron, 2021).

The instructor was first exposed to LLM-driven AI in early December of 2022, immediately after ChatGPT was launched. The disruptive and somewhat unpredictable nature of LLM tools has generated excitement and academic integrity concerns among the education community on social media. The ensuring Christmas break afforded time for the author-instructor to tinker with ChatGPT and Open AI's APIs. At this stage, the instructor found their prior expertise in the subject matter, experience in learning design, and intuition on what will or will not work in the classroom is critical. For instance, the instructor soon realise some of the response generated by the LLM-driven AI is superficial and unreliable. The instructor experience at this stage is akin to traditional bricolage as defined by Papert.

It later became clear that the toolchain needed to deploy AI tools and apps in a manner that met the institution’s data, privacy, cybersecurity policies are not immediately unavailable to teaching staff. The cost of Open AI’s premium subscription and APIs needed to process large volume of input is also prohibitive. Through their professional network, the instructor was able to secure access to non-production Azure Open AI GPT-3.5-Turbo and GPT-4 APIs via their institution’s Microsoft O365 tenancy. Using a citizen development approach, i.e. simple Python scripts and in-built speech-to-text (STT) function of the Office suite applications (e.g. meeting transcript in Teams), the instructor deployed basic LLM-driven feedback tool in their course (McHugh et al. 2023). Here, the instructor felt their experience aligns more with contemporary bricolage where resource constrain necessitate the use of resource that are already available.

Towards the end of the development cycle, it became clear to the author-instructor that any LLM-driven AI tools developed in-house for education purposes or otherwise will not scale easily. For innovation around LLM-driven AI to thrive, the institution will have to develop the following: (1) Short and long term AI strategy and roadmap; (2) internal or external partnerships that bridges the institution’s capability and capacity gaps; (3) robust guiderail and policies around the use of AI in the classroom; (4) program to identify and upskill teaching staff wanting to upskill; and (5) process for scaling and translating successful implementations.

3.2 Student Experience and Perception of AI Assisted Feedback

Figure 2 shows students’ responses on a Likert scale to questions on receiving (top-left) and giving feedback (bottom-left). Both chart shows in general, students are comfortable with giving and receiving feedback. The more negative response appeared to be related to managing affect.

The responses to the open question “**Can you describe your experiences with giving feedback?**” contained a mixture of positive and challenging experiences. Most individuals expressed difficulty and anxiety over the process, highlighting concerns about the time required, difficulty in evaluating tasks against guidelines, and potential negative outcome for the reviewee due to incorrect feedback. Only one individual was appreciative of peer feedback, noting the mutual learning aspect as an inherent benefit.

The open question “**Can you describe your experiences with receiving feedback?**” resulted in a range of responses. Some individuals reported the feedback they received was beneficial, aiding in improvement and learning. There are also instances where feedback is seen as non-constructive or substandard. Complaints include feedback being vague, shallow, too brief, not enough justification for marks given, or that it didn't align with the student’s expectations.

The responses to the open questions “**What guidance have you received to date on giving feedback?**” indicate students have received inconsistent levels of guidance on how to give feedback. The response ranging from “none” to needing to several individuals noting that they were instructed to adhere to a rubric, and to provide feedback that were actionable, specific, and constructive.

Taken together, these response suggested the negative affect maybe due to quality of feedback received by the students. Carless and Boud (2018) reported that feedback can have varied affective effects depending on the student's self-confidence, motivation, and emotional management skills. The feedback's tone and feedback provider expressed care for students also significantly influences student reaction. Here, the student may have perceived a lack of care after receiving poor quality feedback, i.e. feedback that are generic or unconstructive. This in turn maybe due to poor instruction received by students and graders on how to give constructive feedback.

Figure 2 further shows student’s responses on a Likert scale to questions around receiving AI assisted feedback (top-right), and perception of the feedback quality relative to feedback provided by course instructor and peers (bottom-right).

It is interesting to note in that while the responses to AI generated feedback is generally positive, the students did not perceive the feedback to be better (or worst) than feedback provided by their instructor or peers. This response can be explained by the fact that most of the feedback produced by the LLM-driven AI will lack nuanced contextual understanding is unless it is trained on specific content (which it is not in this study). Hence, the utility of the feedback is similar to that produced by a human.

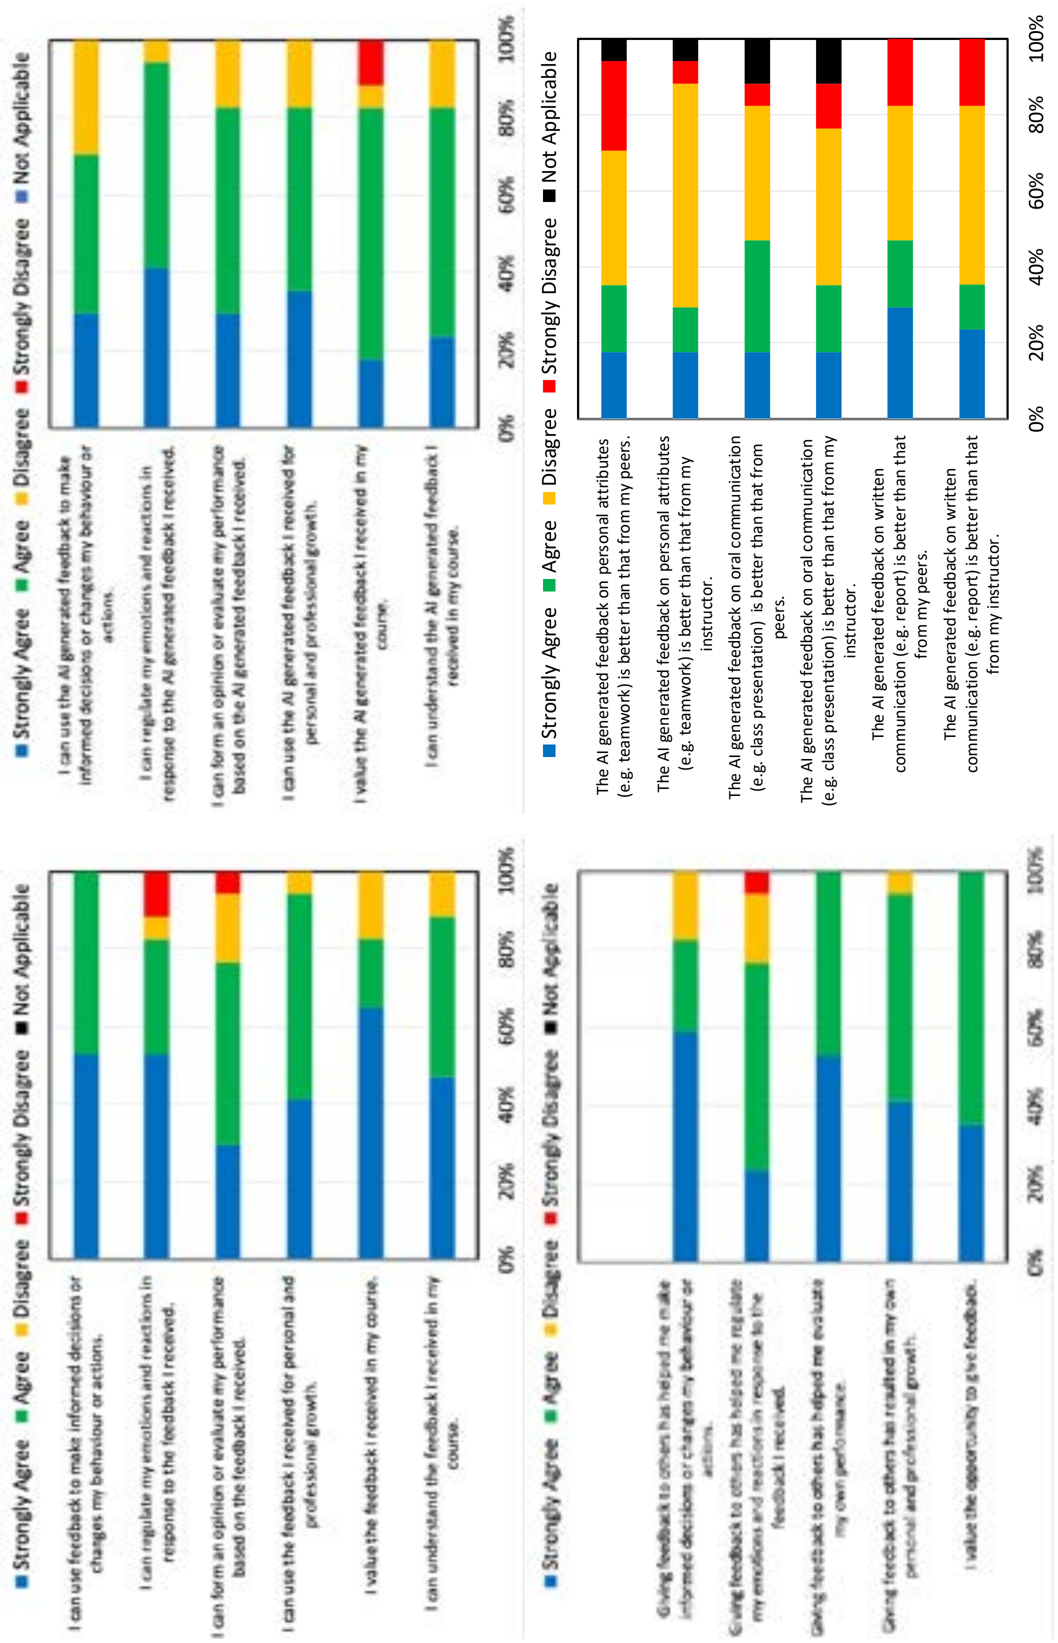

Fig 2. Students' responses on a Likert scale to questions around receiving feedback (top-left), giving feedback (bottom-left), receiving AI assisted feedback for different formative task (top-right), and their perception of the feedback quality relative to feedback provided by course instructor and peers (bottom-right).

The responses to the open question "**What guidance have you received to date on AI generated feedback?**" was peculiar in the sense that there was huge variability in experiences with guidance on AI-generated feedback. Some student indicated that they have received no direction at all. Other student noted that they have been advised by the instructor to view AI feedback critically, not to take the AI generated feedback too seriously, which suggest the student was aware of the limitations of AI and the need for human judgment.

Finally, the responses to the open question "**Can you describe your experiences with AI generated feedback?**" provide insights into the student's varied experiences involving AI-generated feedback. Some students found AI feedback valuable, helping them enhance their work through recommendations. Others, however, reported negative experiences where the AI failed to accurately assess their work, as discussed previously. There appeared to be a recurring theme in the response regarding how the AI had failed to recognise some sections of reports, or failed to capture certain aspects of team contribution.

4 SUMMARY AND ACKNOWLEDGEMENTS

LLM-driven AI can improve student learning in design courses by offering tailored and immediate feedback on written, oral, and team-based formative tasks. However, integrating AI-generated feedback into courses presents some challenges. It involves an ongoing process of tinkering, iterating and adapting, often within a resource-constrained context. Expertise in the subject matter and experience in learning design are important factors for successful implementation. Moreover, scaling the use of AI in feedback practices would require an institution-wide strategic approach. This includes developing an AI strategy and roadmap, forming partnerships and innovation pathways to bridge capability gaps, establishing robust policies and guardrails for AI use in classrooms, identifying and upskilling teaching staff, and creating processes for scaling and translating successful implementations.

Students' experiences with AI-generated feedback further reveal a complex interplay of factors influencing their perceptions and reactions. While students generally have good feedback literacy, and are comfortable receiving AI-generated feedback, the quality of the AI-generated feedback can significantly impact their experiences. Future development should include fine-tuning the LLM-based AI to produce more nuanced feedback.

The author would like to acknowledge the assistance of Martina Pham in the design of the survey questions, and the assistance of Alexander Wangsanata in accessing the Azure Open AI resources needed to undertake this work.

ABSTRACT

This paper discusses how peer review evaluations can simplify the assessment process and ensure quality in a 3D modelling course. The method was implemented in the second year of a bachelor's degree course in 3D modelling. Compared with other massive courses such as mathematics and physics, the evaluation of this 3D

[1] *C. Li*
li.changyang@lut.fi

modelling course can only be done manually. Teachers provide an evaluation matrix, which students use to grade their peers' work. The average points from different reviews are then used as the final grade for the submission. During the evaluations, students can identify their own mistakes in their drawings and assess the quality of their peers' work. This peer review system saves teachers time on evaluations so that teachers can focus on answering questions during exercise sessions and giving more instructions. The statistics of students' grades in individual exercises over the past three academic years were collected and analysed. The results indicate that peer-review assessments can decrease teachers' workload without sacrificing course's quality. In addition, this peer review system can be also used in other course, especially when the exercise submission is fully online.

1. INTRODUCTION

A large body of research literature suggests that peer assessment is an effective way of promoting learning and optimising teaching resources (Double et al. 2020). As an assessment method, peer assessment has been shown to be reliable and to correlate well with teacher assessment (Chang et al. 2021, Power and Tanner 2023). In addition to improved learning outcomes, peer assessment has been found to improve students' critical thinking and tendencies towards collaboration, problem solving and meta-cognition (Chang et al. 2021), as well as their ability to make informed judgements and articulate those judgements (Nicol et al. 2014).

The benefits of peer assessment often focus on its ability to provide feedback to students in circumstances where this would not otherwise be possible, e.g. large class sizes. As a result, more attention has been paid to the learning support provided by feedback than to the benefits of assessing and providing feedback on the work of others. However, some studies suggest that students taking an active role in assessment by evaluating the work of peers can have a significant effect on evaluating and improving their own work (Nicol et al. 2014), even if they do not receive feedback in return (Culver 2023). Indeed, Culver's (2023) work found that assessing the work of others was more influential than receiving feedback, even though students did not perceive it to be of similar value.

Peer-review tasks have gained more attention in large university courses in the past decade. In the paper (Luckner and Purgathofer 2015), a peer review system was used in a course with up to 800 students. The objective was to provide students with personal feedback and support them in self-directed studies. Online courses have been adopted by many universities during the Covid-19 pandemic, and even before that. In paper (Knight and Steinbach 2011), a course was offered both on campus and online. The online course utilised a peer review system, which was found to be challenging without appropriate software. Peer-review tasks are adopted in the education system as well, for example, such system is used in the initial stage of the Covid-19 pandemic and approved to be robust (Pick. 2022). Oral peer review exercises in postgraduate students is presented in (Dickson et al. 2019), the results reveal that students' confidence increase and anxiety decrease in the whole process, and get good results in course.

This paper describes a course designed mainly for the second year bachelor's students in university level. Upon completion of the course, students will be proficient in using 3D modelling software, specifically SolidWorks, for 3D modelling and 2D drawing. Additionally, they will gain knowledge related to technical documentation, including general tolerance, geometry tolerance, surface roughness, standards, and welding symbols. This course runs from September to April each year and has approximately 600 students every year. The teaching method is hybrid and exercises are conducted in the classroom only. Due to the large number of students, exercise sessions are conducted in a question-and-answer format. Teachers provide guidance only when students have questions.

As 3D modelling exercises cannot be evaluated automatically, unlike mathematics or physics, this 3D modelling course always require human evaluation. Therefore, a peer-review system was considered as a tool. The course includes both individual and group exercises, but the peer-review system is only adopted for individual exercises, making the evaluation half-supervised. The evaluation of group exercises is always checked by teachers. Literature reviews (Mulder et al. 2014, Hew and Wing 2014) suggest that the peer-review system at the university level may be challenging and may not always meet the teacher's goals. However, the purpose of individual exercises in this course is to familiarise students with the software and enable them to design different models within the scope of the exercise requirements. As teachers, we provide students with a detailed evaluation matrix, and students should evaluate other's work based on the given criteria. The peer-review system in Moodle is actively used. Additionally, teachers randomly check exercises to ensure fair evaluation. This approach is a good choice for reducing teacher workload while maintaining the quality of students' work.

2. DESCRIPTION OF THE METHOD

2.1 Course setting

The course is a second-year bachelor level course in Technical Documentation and 3D Modelling that takes place in the autumn semester. However, it is noticed that some first-year students also take this course because there is no prerequisite. Before 2021 the course was organized in Finnish only. During 2021-2022, the course was organized as two separate course modules in Finnish and English. In 2023, the Finnish and English modules were merged, and the general instructions were in both Finnish and English, but all students were in the same classroom. Lectures are given online, but exercises are held on campus to ensure the quality of the course. The students in this course are divided between two campuses, so sometimes the teachers have to travel between the campuses, but there are permanent teaching assistants at both campuses who can give some general instructions to the students. In total there are about 600 students each year. All the exercises are held on campus because it is not efficient to instruct students on how to use software online. The course extends over the whole academic year with periods 1 and 2 in the autumn and periods 3 and 4 in the spring term. The course schedule is shown in the Fig. 1.

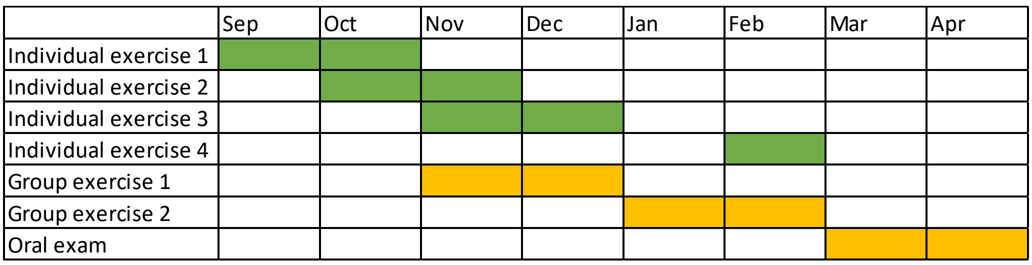

Fig. 1. Schedule of different exercises.

The learning tasks in the course consist of individual exercises, group exercises, and oral exam. In this paper, only the individual exercises will be introduced in detail since the peer review system is adopted only in individual exercises. There are altogether four individual exercises. Each individual exercise is worth 10% of the final course grade. The full grading scheme of the course is presented in Table 1.

Table 1. The grading scheme of the course

Assessment task	Description	Share of the final grade
Individual exercise	Four individual tasks (10% each) completed with SolidWorks.	40%
Group exercise	1st part: make 3D modelling using SolidWorks 2nd part: make technical drawings based on the model from 1st part	35%
Oral examination	Individual oral discussion with the teacher on the 2nd part of group exercise	25%

A step-by-step tutorial on how to use SolidWorks is provided to the students, and the students need to follow those steps, and complete the exercises, the aim is to motivate the students and activate their interest in this course, so the focus is on how to maximize their ability to use SolidWorks. The individual exercises are arranged in Periods 1 and 2. Over the years, there are minor changes on the instructions.

2.2 Improved method

When the course was organized for the third time in 2023-2024, there were some minor changes to the exercise, but major changes to the management based on the experience and feedback from the previous two years.

Firstly, the peer review system has been adopted in the Individual Exercise 1-3, the tasks require student to use SolidWorks software to create some 3D modelling, and the evaluation of this exercise can only be done by teachers. The aim is to motivate students to create a model based on their daily life and interests. In the peer review system, after the submission is closed, each student receives three submissions from three other students, and they have to evaluate each submission based on the provided evaluation matrix. By using this peer review system, the workload of teachers is dramatically reduced. Firstly, the peer review system follows the strict deadline, so there is no way that students can submit the exercise late. In the past, there have been some cases where students had various excuses and wanted to submit the exercise late. Secondly, when students are evaluating other people's work, they have to check the evaluation matrix so that they know what good work is, what is bad work and how their own work is. This will reduce the number of emails asking why they get certain grades. In addition, if students are not satisfied with the grades of the exercises, they will come to the exercise sessions and the responsible teachers will check the work and change the grades if necessary. This approach encourages students to come to class, discuss with teachers, learn more about the course, and drastically reduces the time spent answering emails, as these types of questions cannot usually be resolved by email.

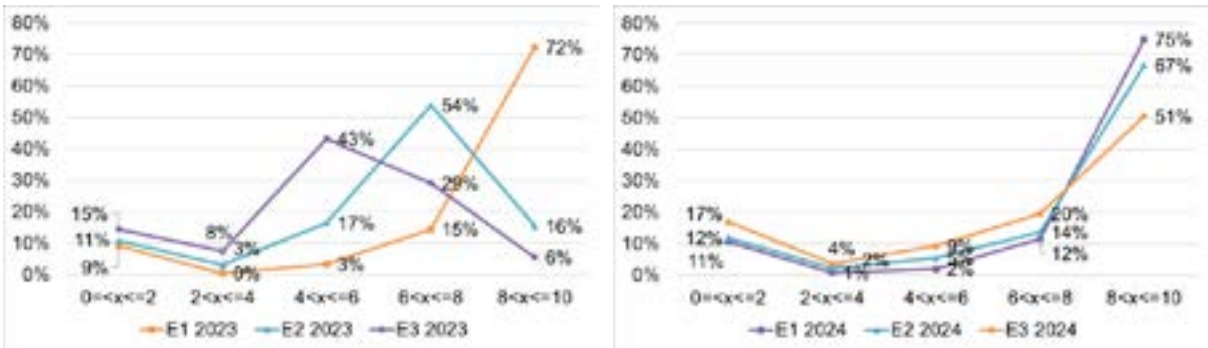
The duties of responsible teachers remain the same, but the duties of teaching assistants are only giving instruction during the exercise session, since we notice different teaching assistant has different level of knowledge, sometimes, it caused some confusion among students. To better control the teaching quality, the teaching assistants can only provide help, not give advice related to the grades.

In the next sections we compare the individual exercises in two consecutive academic years. In the academic year 2022-2023, the Individual Exercise 1/2/3 were evaluated by the teaching staff. In the academic year 2023-2024, the Individual Exercise 1/2/3 were evaluated using a peer review system. First, the grades of the exercises between two years are compared, which represents the quality of the students' work. Second, the estimated time for evaluation between two years is compared, which is considered as teacher workload. Finally, we elaborate the student experience of the peer feedback with excerpts from the course feedback.

3. RESULTS

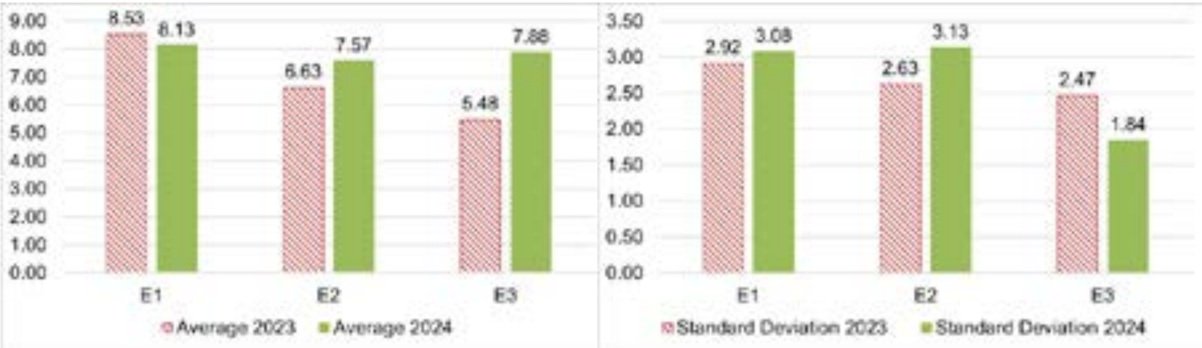
3.1 Student learning

The points of each exercise 1/2/3 are exported and then analysed. Firstly, the scale of the points of each exercise is from 0 to 10. The x-axis represents the grades, then these points are divided into five intervals: 1) 0⩽point⩽2; 2) 2<point⩽4; 3) 4<point ⩽6; 4) 6<point⩽8; 5) 8<point⩽10. The y-axis represents the percentage of students who received this score out of the total number of students. Different colours/markers represent different exercises in different years, details can be seen in the labels. Fig. 2 illustrates line charts showing the distribution of students' scores in individual exercises 1/2/3 in academic years (a) 2022-2023, and (b) 2023-2024. And Fig.3 illustrates students’ points statistics in individual exercise 1/2/3 in different academic years. Table 2 summarizes the frequencise of scores, average values, and standard devision in academic years 2022-2023 and 2023-2024.



(a) (b)

Fig. 2. Students’ points distributions in individual exercise 1/2/3 in academic year (a) 2022-2023 and (b) 2023-2024 (comparison between different exercise in the same academic year).



(a) (b)

Fig. 3. Students' points statistics in individual exercise 1/2/3 in academic years (a) average value x̄, and (b) standard deviation σ.

Table 2. Course grades' frequencies in different intervals, average value x̄, and standard deviation σ.

	2023							2024						
	0-2	2-4	4-6	6-8	8-10	x̄	σ	0-2	2-4	4-6	6-8	8-10	x̄	σ
E1	9%	0%	3%	15%	72%	8.53	2.92	11%	1%	2%	12%	75%	8.13	3.08
E2	11%	3%	17%	54%	16%	6.63	2.63	12%	2%	5%	14%	67%	7.57	3.13
E3	15%	8%	43%	29%	6%	5.48	2.47	17%	4%	9%	20%	51%	7.88	1.84

From the Fig. 2 (a), it seems that most of the students have a grade in the scale of 8<point≤10 in individual exercise 1. The distribution of individual exercise 2/3 are close to the normal distribution. From Fig. 2 (b), the trends of individual exercises 1/2/3 are similar. These trends follow the teachers' expectations, this year most of the students have higher scores, it may be that the tutorials are well developed, and more instructions are given in the exercises, in addition, teaching assistants were hired to assist students in the tutorial sessions. However, it could also be that students prefer to give relatively very low and very high scores to their peers, which could lead to unfair assessment.

In addition, from Fig. 2, there are 9%-24% students who got points on the scale of 0<point≤2. There might be different reasons, it might be military service that students have to leave the course for a while, or some students realise that the current workload is too much, they have to drop out this course, or some students forgot to submit previous exercises and they realise that they cannot reach high grades in this course no matter how hard they try.

Fig.3 and Table 2 show that the difference between the average scores between different years are not large when the total score of the course is 100. The aim of the individual exercises 1/2/3 is to motivate the students to be more creative in 3D modelling, instead of giving up at the beginning of the course, since the beginning of any software is always difficult.

3.2 Teacher workload

As mentioned previously, the goal of adopting peer review system in the course is to decrease teachers' workload without sacrificing the course quality. Considering the workload, in academic year 2022-2023, the evaluation of each individual exercise for each student is about 3 minutes, in total 90 hours for all individual exercises in each year. In academic year 2023-2024, all evaluations will be done by peer review system, if students have any questions about their scores, teachers will check with students during the exercise session. This saves time and encourages interaction between teachers and students. All the teachers in the course have the same feeling that workload is decreased. In additional, similar idea will be extended to MOOC course in the future. When talking about course quality, it can be reflected on the grades, in a course with total points of 100, the differences in all the individual exercises are not huge. And the goal of the individual exercises is to motivate students to use the 3D modelling software, so the evaluation is not very strict.

From students' perspective, the peer review systems allow students to check how other students are working on the exercise, they can see the error in their own work, and they do not need to send emails to teachers asking what is wrong. There are students who appreciate this approach very much because they take advantages of it, such as recognizing the mistake and learning new things by checking other's work. In traditional way, students cannot see their classmates' work, and do not know how well themselves have done. In some countries, there is ranking system, so students want to compete with each other somehow. In addition, they can recognize hard-working students, and choose them as potential group member in the future, since getting higher grade is their common goal.

3.3 Student experience

The course feedback contained one open question about the best features of the course and one open question about the aspects of the course needing most improvement. 219 out of 486 answered the survey.

Individual exercises were named as the best feature of the course by many students. Peer assessment of the individual exercises was mentioned by six students, with three students questioning the fairness or reliability of the peer assessment, two students calling for clearer criteria for assessment, and one student mentioning technical difficulties with peer assessment (problems with opening files). Relating the number of comments to the number of respondents shows that student have very few complaints or concerns regarding peer assessment, but a high appreciation for the individual exercises which are in part enabled by the use of peer assessment instead of grading by teachers. However, just like Culver (2023) noticed, students do not recognize that assessing the work of others can in fact also support their own learning process.

4. SUMMARY

The results from the statistics show that peer review assessment supports this course well, it reduces the workload of teachers without sacrificing the quality of the course. From exercise sessions, feedbacks are collected orally and in paper, both teachers and most of students are satisfied with the peer review systems. Some random exercises samples were taken after the assessment to check on the reliability of the peer-assessment, and teachers found the given grades to be mostly aligned with their expert opinions, just as expected from the literature (Chang et al. 2021, Power and Tanner 2023). It is true that some students do not give a fair mark, but it does not affect the final points much because average points from three students will be used as the final points. In addition, if students are not satisfied with the results, teacher will evaluate together with the students. The aim of the individual exercise is not to select the best students, but to motivate the students in this course because the group exercise will be more difficult. However, if peer review system will be used in other courses, the weight of this evaluation method must be considered carefully, as students may tend to give very high or very low results. Teachers must find a way to make this process fair.

A detailed evaluation matrix was given to the students and further guidance was given during the exercise so that students take responsibility and evaluate each other's work. The students were not, however, informed about the motives of the use or peer assessment and its potential benefits for student learning. In the future also these aspects should be communicated better, to enhance the motivation and increase the student effort put into peer assessment.

Some unexpected and interesting phenomenon was noticed during the statistical analysis, such as many students dropped out of the course at the very beginning before the individual exercise 1. The reasons behind this situation will be investigated in the future. If the reason is related to the teaching quality, the course should be improved. If the reason is related to enrolment system error, then the course selection tool should be developed.

ABSTRACT

Understanding the semantic connections between the increasingly online-based offered educational content is becoming more relevant for educational institutions. The fast adoption of AI-based techniques and their application in semantic search offers new possibilities and challenges when working in an educational context.

In this paper, we explore the usage of broadly used text embedding models in Retrieval-Augmented Generation (RAG) systems for semantic retrieval when searching multilingual educational content from Massive Open Online Courses (MOOCs), a significant part of which belongs to engineering studies. More specifically, we analyse the performance of text embedding models when searching multilingual content and the impact of mathematical notation on the retrieval results. Furthermore, we introduce a series of developed prototypes and applications that

[1] *J. Lloret Pardo*
javier.lloretpardo@epfl.ch

inspect embedding models and utilise them to find semantically relevant lectures and courses.

1 INTRODUCTION

The last decade has seen an explosion of online courses being published by higher education institutions. These courses harbour a wealth of different learning materials that could serve multiple purposes beyond the entire course to which they belong: revising before an exam, pre-requisite check before starting a course, re-use in other courses or modules, etc. Offering elements of these courses individually allows learners to have more individualised experiences and increases the flexibility of an institution's educational offer. However, defining what constitutes an element and how to make those elements searchable and available is not trivial: what is the size of a meaningful course element? One quiz question or several? A chapter including text, video and assignments? And how can we 're-package' individual elements together to create meaningful elements? For example, students who revise before an exam may want to search for interactive quizzes to test themselves, receive meaningful feedback after answering and maybe watch an exploratory video, whereas, for re-use in another course, teachers need interoperable or "technically agnostic" files that contain questions, answers, explanatory texts and (links to) video files.

This paper presents the work done to make existing online quizzes from a collection (64) of open edX Massive Open Online Courses (MOOCs) available for learners. In particular, we focus on how we can enrich the individual quiz question with references to short video content to serve as feedback so that it can be presented together as a meaningful learning experience.

We study the potential of Retrieval-Augmented Generation (RAG) systems and embeddings-based semantic retrieval, using the transcriptions of video lectures and the quiz questions from the MOOCs as the educational resources indexed. We foresee two unique challenges in our indexing and enriching the MOOC elements, stemming from 1) the mathematical notations used in our STEM MOOCs (49) that may negatively impact retrieval rates (Gangwar et al. 2022) and 2) the multilingual content with courses in English (24) and in French (40) that may affect the performance of semantic retrieval.

After this introduction, section 2 introduces RAG systems and their components, how they are used in education, and the challenges we faced in our use case. We then discuss how we generated our dataset (section 3), and we introduce the metric used in the analysis of existing embedding models for our RAG (section 4). In section 5, we describe the prototypes and tools we developed with the goals of, on the one hand, inspecting further the semantic embedding space to understand better the semantic similarities between the different educational content and, on the other hand, to use these methods to conduct semantic search for finding relevant educational content, including lectures and courses. At last, we present our conclusions.

2 TEXT EMBEDDINGS AND RETRIEVAL-AUGMENTED GENERATION

Our aim is to index individual quiz questions, make them searchable, and enrich them with a video that provides an explanation. Text embedding models are efficient in indexing text and searching for related information (Jurafski and Martin 2024). These are machine learning models that have been trained with a large corpus of text. The underlying assumption is that words that occur in similar contexts tend to have similar meanings, the so-called distributional hypothesis (Harris 1954). Text embedding models receive a text fragment as an input and output a multidimensional vector with semantic properties.

When conducting a semantic search with embedding models, different text fragments (such as transcripts of video lectures in our case) are encoded into vectors stored in a database (vector store). Then, this database can be queried to retrieve the text fragments (transcripts from lectures in our case) closest to an input text (a quiz in our case). This similarity is based on the distance between the vectors (Fig. 1, Step 1). Text embedding models and vector stores are often used in RAG systems.

RAG systems have emerged (Lewis et al. 2020) as a paradigm that combines information retrieval from a provided knowledge source with large language models (LLMs). RAGs, by making use of verified external content (in our case a vector store), have the potential to mitigate one of the risks posed by LLMs: the presence of wrong facts in their answers, also known as hallucinations (Ji et al. 2023). In an educational setting, RAGs are being utilised for multiple tasks, such as Question Answering (Levonian et al. 2023; Abdulrahman et al. 2024; Liu et al. 2024), tutoring evaluation (Han et al. 2024) and exam generation (Guinet et al. 2024).

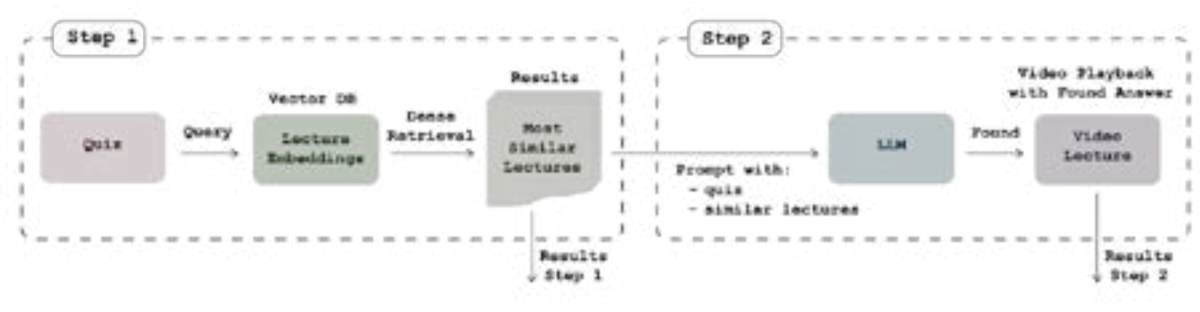

Fig. 1. Diagram of the components of our RAG system.

2.1 Challenges

2.1.1 Multilingual Content

As stated previously, the multilingual capabilities of our semantic search system are essential. Although information about the multilingual capabilities of certain text embedding models is available in the form of model cards (Mitchell et al. 2019), these are often incomplete, and it is not straightforward to find sources that evaluate embedding models under conditions similar to our use case. Therefore, evaluating the retrieval capabilities of widely adopted embedding models with our multilingual content was fundamental to increasing the retrieval performance of our system.

2.1.2 Mathematical Notation

Given that our dataset is constituted by a large part of courses in the realm of engineering, it was important for us to evaluate the impact (Gangwar et al. 2022) that mathematical formulas would have on the retrieval success rate.

An additional challenge in our study is the different representations of our mathematical content: many quizzes use LaTeX notation, whereas our transcripts contain natural language, as they are transcripts of spoken language. Therefore, we evaluate the impact of several options: 1) inclusion vs exclusion of mathematical content, 2) translating mathematical notation into natural language.

3 METHODOLOGY

3.1 Initial Dataset

First, we generated a dataset from the quizzes and transcribed video lectures. To evaluate the capability of the embeddings from different available models to retrieve meaningful lectures, we needed our dataset to have a ground truth. Determining the ground truth of every quiz manually would be unrealistic due to time constraints.

The majority of our MOOCs have an internal structure in which, in the same learning unit, a quiz, or a series of quizzes, comes right after a video lecture. Therefore, we discarded the MOOC content that does not follow this pattern, and we made the assumption that we could use a lecture as “ground truth” for the quiz (or quizzes) that come right after it (Fig. 2). This helped us to generate a dataset to evaluate the retrieval capabilities of text embedding models.

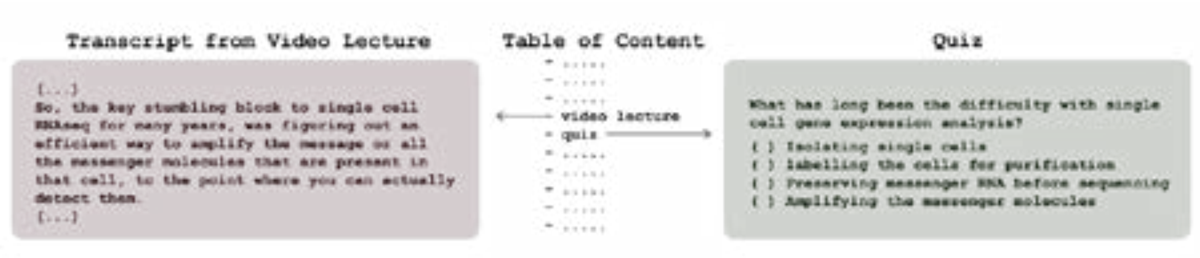

Fig. 2. Diagram that depicts the ground truth assumption followed to generate our dataset.

3.2 Languages

We initially created variants of our dataset for English and French content. For the base version, we randomly selected 300 pairs of quizzes with their “ground truth” lecture in French (“FR Base”) and the other three hundred in English (“EN Base”).

3.3 Mathematical notation

To evaluate the impact on the retrieval performance of different models with content including LaTeX notation, we generated French and English versions of our dataset with 300 randomly selected quizzes that contained LaTeX (“FR LaTeX”, “EN LaTeX”), 300 that did not (“FR No LaTeX”, “EN No LaTeX”).

We also created a fourth variant of our dataset (in English and French) in which we used an LLM to replace the LaTeX notation present in the dataset variants “FR LaTeX” and “EN LaTeX” with natural language (“EN Nat. Lg.”, “FR Nat. Lg.”). For example, \frac{5}{3} becomes ”5 divided by 3”.

3.4 Embeddings and Retrieval

Text embedding models used in RAG systems generate a maximum text length that can be encoded. When text is input into a model that is larger than its maximum input length, the rest of the input text will not influence the generated embedding. Multiple chunking strategies can be used to address this problem (Gao et al. 2023). When processing the transcripts from the lectures, we decided to use the longer chunk (fragment) of text containing complete sentences that do not exceed the model's maximum input length. For encoding the quizzes, due to their shorter length, we decided not to chunk them and to generate an embedding per quiz.

For retrieval, we employ a dense retriever (Karpukhin et al. 2020) and cosine distance as a metric to compute similarity. In our use case, the cosine distance between the input quiz embedding and all the embeddings from the lecture transcripts in the vector store will determine which lectures are the most similar to the input quiz.

3.5 Task and Performance Metric

The task consisted of finding a text fragment (chunk) from the "ground truth" lecture from a given quiz in the different variants of our dataset. We used Average Precision (AP), a widely used metric in ranking problems, as our metric for the analysis of how different text embedding models perform at this given task. The final performance for each text embedding model is measured by the mean of the AP of all quizzes in the variants of our dataset.

$$AP = \frac{1}{m}\sum_{k=1}^{n} P_k \ rel_k$$

(1).

Where:

n is the total number of video lectures.

m is the number of relevant items (in our case, it is always 1).

k iterates over all video lectures.

P_k is the precision at position k.

rel_k is the relevance at position k, a binary value indicating whether the video lecture at position k is relevant (1) or not (0), i.e. is part of the "ground truth" described in section 3.1.

4 RESULTS

For this evaluation (Table 1), we made a selection of openly available text embedding models. We chose models for English content (the four first rows of the table), French content (the last two rows of the table), and models that claimed to have been trained on multilingual content that includes English and French languages (the rest of rows).

As we could expect, the models for English content suffered a more accentuated drop in performance when used on French content than the top-performing model considered multilingual: "Multilingual-e5-large" (Wang et al. 2024).

In the French variants of our dataset, "Solon-embeddings-large-0.1" ("Solon") outperformed the other models for French content by a wide margin, with the multilingual model, "Multilingual-e5-large", the second top performer. Unexpectedly, “Solon” was not only very close in performance to the top English embedding models in three of the four variants of our dataset but outperformed them in the “EN Base” variant by a slight margin. Although the model claims to have some English capabilities, it is not advertised to be fully multilingual. These results made “Solon” and “Multilingual-e5-large” our top options for working with our English-French bilingual content.

We also observe in the table that across all models, unsurprisingly according to the literature (Gangwar et al. 2022), there are significant drops in performance when using the dataset variants that contained mathematical notation in the form of LaTeX (columns “EN LaTeX” and “FR LaTeX”) compared to the dataset variants that do not (columns “EN No LaTeX” and “FR No LaTeX”). However, the French model, “Sentence-camembert-large” (Martin et al. 2019), was the only model that had significantly improved results when replacing LaTeX with natural language in the “FR Nat. Lg.” dataset variant. Some models decreased in performance, with “Solon” and “Multilingual-e5-large” being the most affected ones (column “FR Nat. Lg.”). In the English variant of our dataset, the results were barely affected by replacing LaTeX with natural language. This disparity in performance across models in the natural language variants of our dataset stresses the need for further exploration before we can reach conclusions.

Table 1. Mean of the Average Precision scores for finding a text fragment (chunk) from the “ground truth” lecture (in English and French) for quizzes without restriction (“EN Base”, “FR Base”), quizzes that contain LaTeX (“EN LaTeX”, “FR LaTeX”), quizzes that do not contain LaTeX (“EN No LaTeX”, “FR No LaTeX”) and quizzes that contained LaTeX translated into natural language (“EN Nat. Lg.”, “FR Nat. Lg.”). Scores range from 0.0 to 1.0 (higher is better).

5 APPLICATIONS

We have developed a series of tools and prototypes that make use of the introduced RAG system and model embeddings. While the “Embeddings Explorer” and “Course

Retriever" target education administrators, curriculum designers, educators and researchers, the "Lecture Finder" is primarily oriented to students.

5.1 Embeddings Explorer for MOOCs

This web-based application[2] was developed as an internal tool to visualise the semantic connections between quizzes and lectures from MOOC courses when encoded with text embedding models. To reduce the dimensionality of the embeddings to a plottable two-dimensional space, we used the method for dimensionality reduction UMAP (McInnes et al. 2018).

The application has two main functionalities. Firstly, it allows the user to visualise the embedding space as an Interactive Scatter Plot (Fig. 3, Panel C) containing the quizzes (outline of a circle) and transcript from the video lectures (full circle) from all courses at once, providing a general overview of the semantic connections between the content from the different MOOC courses.

Secondly, the user can select a specific course and analyse its embeddings in more detail. The Course Structure Panel (Fig. 3, Panel B) visualises the hierarchical structure of the selected course. The user can expand and collapse the nodes from the different chapters and units. When a quiz or video lecture is selected (via the Course Structure Panel or the Interactive Scatter Plot), it is highlighted, its information is shown in the Metadata Panel (Fig. 3, Panel E), and its textual content, used to generate its embedding, is displayed in the Content Panel (Fig. 3, Panel F).

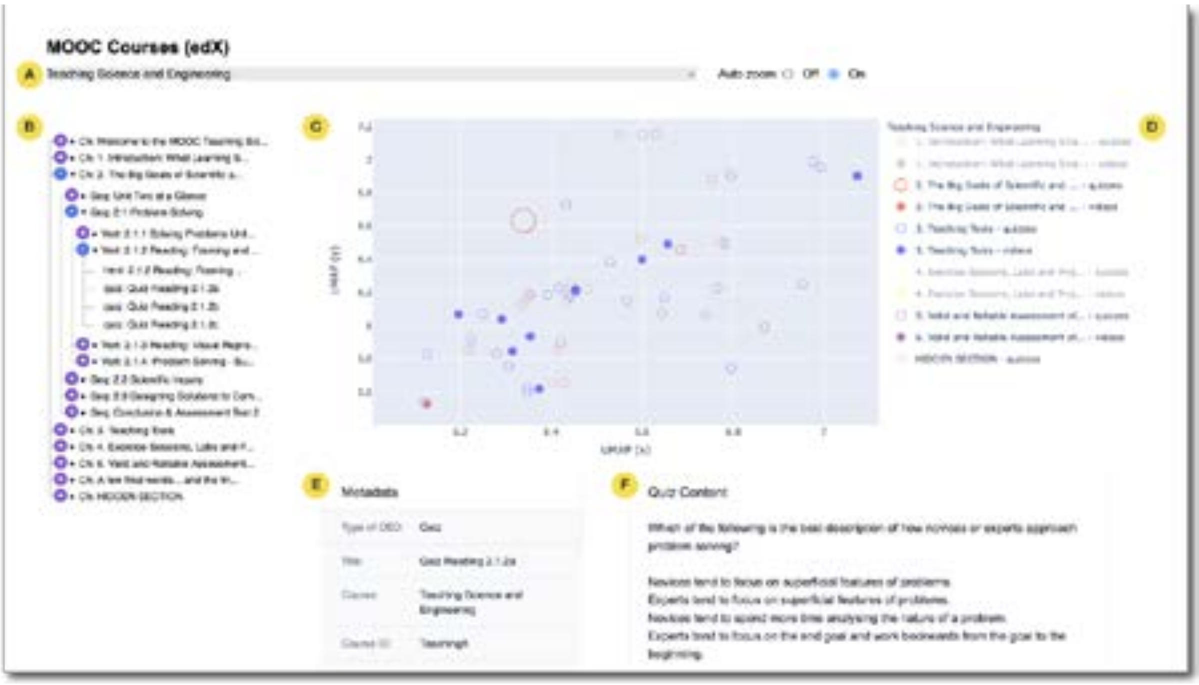

Fig. 3. Embeddings Explorer: Course Selector (A), Course Structure Panel (B), Interactive Scatter Plot (C), Interactive Legend (D), Metadata Panel (E) and Content Panel (F).

5.2 Lecture Finder Prototype for MOOCs

This prototype aims to allow users to find relevant indexed video lectures starting from a quiz. We used the RAG system described in section 2, splitting the process

[2] https://github.com/jllp-epfl/mooc-embeddings-visualizer

into two steps. In the first step (Fig. 1, Step 1), the system retrieves the closest semantically found lectures in order of similarity.

In the second step (Fig. 1, Step 2), the user can search for the specific fragment of these lectures containing the answer to the quiz. An LLM (GPT 3.5) receives the content of the given quiz and the transcript of the top-ranked video lectures and is asked to find the fragment of text that contains the knowledge to solve the quiz in the given transcripts. If the LLM finds the answer, the LLM is asked to quote the found answer and to playback the segment of the video lecture that contains it.

By asking the LLM to quote the lecture instead of rephrasing or summarising the answer, we take a safer approach, preventing the model from hallucinating.

5.3 Embeddings-based Course Retriever

To semantically compare courses, we developed a web-based application[3] in which we generated embeddings from course descriptions (Fig. 4, right side). When the user selects a MOOC course from a list, the top 20 semantically most similar non-MOOC courses available on our online platforms, based on the embeddings of their description, are shown in an interactive bar plot. The user can then select one of these top most similar courses, which will display additional information and both course descriptions side by side.

Fig. 4. Lecture Finder on the left side and Course Retriever on the right side.

6 SUMMARY AND CONCLUSIONS

In this study, we generated a dataset from MOOC courses' content to compare the retrieval capabilities of embedding models for text similarity. To evaluate the impact of several aspects of our educational setting, such as its multilingualism and the abundance of STEM content that contains mathematical notation, we created variants of our dataset to evaluate the influence of these factors in the retrieval.

Regarding the multilingual capabilities of text embedding models, we learned that, although in 7 out of 8 variants of our dataset, the best-performing model was one recommended for the language (English or French), a high-performing model conceived for French content, "Solon-embeddings-large-0.1", can outperform models recommended for English content when searching lectures in English. From the evaluated models described as multilingual, "Multilingual-e5-large" was the top

[3] https://github.com/jllp-epfl/mooc-embeddings-sim-other-courses

performer, being this one and “Solon-embeddings-large-0.1” our top choices for our use cases.

The results of our analysis on the capabilities of text embeddings to retrieve LaTeX representation of mathematical notation were inconclusive. This underscores the need for further research to identify other factors that may influence the retrieval performance of such models when searching for relevant lectures from quizzes from STEM courses.

Lastly, we applied the knowledge we gained to develop web-based applications and work-in-progress prototypes for finding lectures and courses based on the similarity of their embeddings.

ABSTRACT

Challenge-based learning is a teaching approach where the learning takes place through the identification, analysis and design of a solution to a sociotechnical challenge (problem). In this paper we present how we use challenge-based learning in a 2nd year course with focus on entrepreneurship. We especially focus on the cases and on how the students value working with real-life cases and what information is important. Based on a survey, we found that the students enjoyed working with real-life cases, which they found both motivating and as a good frame for the course. They did however stress the importance of having a good contact with the case-owner. The students also mentioned that the case should be relevant and realistic in addition to being well-framed and open. Furthermore, the students also highlighted the importance of having access to case-owners, data and to other stakeholders. Based on these reflections – and our own observations during this course over the past four years, we offer a list of recommendations for choosing and framing cases - and for aligning expectations with case-owners with regards to results and availability; especially when it comes to the use of cases as a tool for learning in more introductory courses, such as ours.

1 INTRODUCTION

1.1 Background: Challenge-based learning

Engineering students are increasingly expected to be able to handle complex global 21st century challenges and to develop innovative technological and sustainable solutions (Hadgraft and& Kolmos, 2020). In order to ensure these competences, more and more engineering programs focus on active learning methods including group work, by offering courses based on challenge-based learning, problem-based learning etc.

Challenge-based learning (CBL) focuses on student-centered learning and has become increasingly popular in engineering programs and courses. CBL offers a frame for inter-disciplinary group work where teams of students address real-life, open-ended challenges. CBL aims to stimulate students to take the lead in their own learning, by acquiring and applying relevant knowledge to cases and challenges in order to both suggest solutions and develop interdisciplinary skills (Helker et al., 2024). In CBL, the teacher acts as a facilitator (Doulougeri et al., 2024).

CBL normally starts with an open-ended, real-life challenge, ideally addressed by interdisciplinary teams, as the students should integrate knowledge and skills from multiple areas. The students propose solutions to the challenges after a process of problem identification, investigation, ideation and implementation, applying entrepreneurial tools and design thinking (Doulougeri et al., 2024)

Cases used for CBL are normally societally relevant and connected to sustainable development goals. The cases are often presented by external partners and the student teams collaborate with both the case-owners, and internal and external stakeholders to develop a solution (Doulougeri et al., 2024). The use of real-life challenges allows students to link new and prior knowledge, while applying it to new challenges (Hadcraft and Kolmos, 2020); and by also addressing sociotechnical issues, the cases address pressing current challenges such as climate change; thus requiring that the students apply a combination of technological innovation, policy development and societal engagement (Malmqvist et al., 2015).

Challenges and cases in CBL are often characterized by being open-ended and real-world, with external industry partners and societal stakeholders (Doulougeri et al., 2024). The cases can be created by a group of teachers; it has however been reported to be difficult to create the cases both with and without industry partners (Doulougeri et al., 2024) and it is also time consuming (Bombaerts et al. (2021). There are many examples of literature in which external (extra-academic actors) are used in CBL projects, but only little information about what their input was, their perceptions of the CBL approach, and whether their participation was evaluated (Gallagher and Savage, 2020).

1.2 Case study description

In this study, we present how we work with challenge-based learning (CBL) in a 2nd year introductory entrepreneurship course. The goal of the course is that students develop an entrepreneurial mindset while at the same time developing an innovative solution to a case challenge. The students come from different BEng programs and bring a range of skills and competences to the course. The students are grouped in mixed, interdisciplinary groups.

The course consists of common sessions where students are introduced to various methods (e.g. Business Model Canvas, Effectuation, Value Proposition etc), and sessions where students pitch for their peers and receive feedback (from both peers and teachers). In addition, the students work independently on their own group projects and plan how to collect data and meet with stakeholders and case-owner. The students (in groups) can choose which challenge to work with. In the beginning of the course the cases are presented, and at the end of the course there is a poster session where the students pitch their solutions to the other groups, teachers and case-owners and receive feedback before handing in their final reports. The cases are connected to the local environment with a focus on real-life, open-ended challenges from local companies, start-ups or organisations. The students are asked to develop a solution with societal values in addition to sustainability focus. The case-owners are contacted some months before the course starts and we have a meeting with them to discuss the case and alignment expectations with regards to how the students can contact them, data available for the students etc.

An example of a case description

Case description – Food scraps for sled dog food

A large part of Sisimiut's waste is food. This resource is mostly thrown away and burned, but can it possibly be used differently? Sisimiut has about 2000 sled dogs, and as it is now, all their food is imported from outside.

Investigate, among other things, the Fish Factory, the Board, the Supermarkets, institutions and possibly catchers' residual waste.
Case questions:

o Can the discarded food resource be used as dog food?

o What is thrown away in the various production companies, institutions and eateries?

o What is the total food resource from waste? Give an estimated value in terms of protein, carbohydrate and fat.

o How should the leftovers be processed in order for it to be used as dog food?

o Can production possibly be run circularly?

Throughout the course the students have the opportunity to meet with the case-owner and other stakeholders to ask questions relating to the case.

The learning activities consist of both activating learning elements such as design thinking, ideation - and self-regulated learning in form of group work, self-study and reflection on the student’s own learning process. Furthermore, the students are encouraged to venture outside campus to meet the users, customers and stakeholders with relevance for the project.

In the first week of the course various definitions of entrepreneurship and innovation are introduced and the students are introduced to design thinking and effectuation. Theory is tested in practice by exercises. An individual portfolio is written based on the use of the methods and tools (individual report).
The groups develop a business opportunity and write a business plan and in the

process use entrepreneurial methods. The students should contact potential users/customers for ideating, having their feedback and use the feedback for further development of their concept/solution.
The groups present their result at a poster presentation during the the last week of the course. Subsequently, each group prepares a final report (group report) and submit it on the last day of the course – while each student also individually update and submit a revised portfolio of methods and tools, also reflection on the feedback they have received during the course.
During the course, the students work with peer feedback, thereby training them to give and receive feedback. More information about the course *'Entrepreneurship in Greenland'* and the learning objectives can be found in the course description at https://kurser.dtu.dk/course/62054

As is normally the case in CBL, the teachers increasingly act as facilitators in order to provide scaffolding and support the students while they work on the challenges. The teachers are available every day during the course. The first week of the course is more teacher directed with joint teaching sessions, while the last two weeks primarily consist of group work; with both planned group feedback sessions on specific topics (e.g. business model canvas for the case solution) - and both individual and group sparring sessions with the teachers when needed.

The course is a three-week course taking place at DTU's campus in Sisimiut, Greenland. The students primarily come from the two Bachelor of Engineering programs in Fisheries Technology and Arctic Civil Engineering - and for these students the course is mandatory and placed between their 2^{nd} and 3^{rd} semester. Furthermore, the course is open for other students to take as an elective course, and in 2023 five students from the Bachelor of Engineering program in Global Business Engineering participated (travelling to Greenland for the course). A total of 16 students were enrolled in the course in August 2023. And four groups were formed to include students from the different disciplines.

The course is an intensive 5 ECTS course where the students work every day for three weeks. The outcome after the course is a concept for how to solve the challenge – while using the methods learned during the course. It is not expected that the students in the relatively short period of time the course runs, produce prototypes or set their solution into actual production.

The course has been running since 2020 and each year we have used (new) real-life open-ended cases provided by local companies and start-ups. This time we asked the students about the cases, and what is important for them when working with cases in their courses.

2 METHODOLOGY

2.1 Background

The data was collected during the course held in August 2023.

The cases were all from Sisimiut/Greenland and included cases from start-up's and from more established companies. All cases focused on actual challenges observed by the case owner. The cases were chosen to be relevant for engineers and to have a technical aspect and a socio/sustainable focus.

In 2023 the student groups could choose between three different cases: One on using rest products for food for Greenlandic sled dogs; one on a design of a local knowledge walking-trail in Sisimiut for tourists; and one on the use of local rock and stone in production/construction. Two groups chose the sled dog-case, and one group each chose the remaining two cases.

2.2 Survey

A survey was conducted during the course. The survey consisted of 5 questions related to the use of real-life cases. There were 16 students enrolled in the course and of those 11 students handed in the survey.

Q1: Do you think it is relevant to work with cases in teaching? Please explain why/why not?

Q2: What do you think is important when working with a case in class?

Q3: What is important in relation to the case-maker/company?

Q4: What should a good case description contain (feel free to write keywords) of information?

Q5: Good advice for using cases in teaching.

The survey was handed out to the students in class, and they had time to fill it out and hand it in during class.

3 Results

Overall, the students enjoyed working with real-life cases, which they found motivating and as a good frame for the course. They did however stress the importance of having a good contact with the case-owner. The students also mentioned that the case should be relevant and realistic. Furthermore, the students highlighted the importance of having access to data and to stakeholders.

The feedback from the students fell in three categories:

- The cases provided a good and motivational frame for learning
- The importance of contact with the case-owner
- The importance of a well selected, well-framed, relevant and open case

The case as motivational frame for learning

Most respondents found the case to be a very relevant, motivational frame for the course and theory – and stated that it supported both learning and transfer of new knowledge. They stated that the case made it easier to relate theory to the real world, and that the real-life challenges made the theory much more relatable.

Statements (translated from Danish):

- “I think it is very relevant working with real life cases gives a better understanding of the goals and methods we read about. Also it makes it easier to remember the methods when I can connect it to an example”
- “It helps to connect the theory we learn in the classroom with the world outside”
- “it gives a deeper understanding”
- “it is easier to think of when it is a real-life problem”
- “It provides a good frame”

The importance of contact with the case-owner

The respondents generally stated that it is important that the case-owners have time to talk with the students about the case; that they are available – and willing to be “disturbed” by the students. Also important that they (and their case) have a relevant technical and educational background.

Statements (translated from Danish):

- ”They must be contactable and not too ‘big’”
- “[Important] that they have time for some questions / time to meet”
- “important that the case-owner knows or has an education within the case-industry”
- “Availability [is important]”
- “It is important that they are willing to cooperate and be disturbed by the students”

The importance of a well-selected, well-framed, relevant and open case:

The respondents emphasized throughout the questions the importance of a well-selected case, and they stated that the cases must be both relevant, open-ended – and well-framed. And at the right level and relatable for the students with regards to both their own background - and the topic of the specific course.

Statements (translated from Danish):

- ”The case must seem approachable”
- “it is important that the cases you can choose are realistic”
- “Also [important] that the case is relevant for where you are”
- “important that the case is well investigated by those who pose it”
- “must contain a topic that can be viewed from different perspectives”
- “[the case must be] inspiring (idea generating) … open question”
- “[the challenge must be] open but not too open and a frame that is not too narrow”
- “[the case must be] relatable”

Overall observations and reflections

We have been working with (different) real-life cases in this course every year since its launch in 2020. In 2023, we found that the set-up was working particularly well – and that it supported the group work process and the scaffolding and application of both new and existing tools and knowledge in the mixed student groups. One important difference this year was, that the case owners were much more available throughout the course, and it seemed to be easier for the students to form a working relationship with their case owners. This was further emphasized by the fact that all case owners participated in the final poster presentation session; also asking further questions to the groups regarding their solutions and thoughts, which has not been the case to that extend in earlier courses.

All in all, this has confirmed what both we – and the CBL-model stresses: that it is important to work with real-life – and open-ended challenges; and that it enforces both the motivation and co-creation in the teams – especially when they are able to have a continuous dialogue with the case owners. This also further supported the development of a team-identity in the groups, emphasising the use of the group's interdisciplinary skills and knowledge.

When working with open-ended real-life cases in challenge-based learning we recommend the following reflections when designing the course and choosing cases – especially in an introductory course like ours:

1) The use of real-life – and open ended – case-challenges is central
2) The cases must be framed to fit the learning objectives for the specific course, i.e. in this course, the cases must function as a supporting learning tool for the entrepreneurial content of the course
   - and not primarily be a 'wish-list' from the case-owner.
3) It is important that the case-owners are available during the course and willing to meet with the students and discuss the case and possible solutions
   - this stipulates that importance of the case-owner keeping an open mind with regards to possible solutions (rather than having a fixed solution in mind).
4) Based on the case-owners we have worked with over the years, we find that it may be more important that the (albeit still a real-life) case is framed to fit the course – rather than an actual company's specific demands and wishes. This also stipulates the importance of the case-owner understanding the learning objectives and/or setting of the specific course in order to engage in dialogue with the students – and having an open mind with regards to possible solutions. Especially in an introductory course like the one described.
5) In more advanced courses it may be more relevant to have more non-prepared case-owners (with regards to the specific course), as the dialogue with them will be a larger part of finding innovative solutions for the benefit of both the specific company – and globally.

It is overall our impression that the success of this year's cases as frames for the course to a large extend was based on the case-owners' understanding of the purpose and frame of the course (and thus their cases' role as tools for student learning) – and their willingness to enter into an open dialogue with the students, rather than having a preset mind with regards to a concrete and specific solution.

This paper thus introduces a novel and innovative approach to the development of challenges and cases for CBL where the case-owner not only develop the case but also is closely involved in the students' learning process throughout the course.

4 SUMMARY AND ACKNOWLEDGEMENTS

In this paper we present how we work with challenge-based learning in a course with the purpose of introducing entrepreneurship to the students. This time we asked the students what is important for them when working with cases in their courses. And based on their responses – and our own observations, we offer suggestions regarding the kind of cases and the frame around them in a challenge-based learning setting.

ABSTRACT

Motivation to include sociotechnical content in engineering courses comes from students, the workplace, and accreditation bodies. However, incorporating explorations of engineering's social impacts is challenging for most engineering professors who have been educated with a deep technical focus. In this work, we offer one option for addressing social implications in a required course for many engineering students (i.e., Introduction to Circuits). We developed a one-hour class module focused on electric vehicle (EV) batteries and circular economies that can be integrated into the basic Circuits course. The module includes pre-class, in-class, and post-class materials contained in a comprehensive teaching guide. We piloted the module with a few students and then deployed it in a small undergraduate-focused institution. In this paper, we outline the module development process, which leverages the principles of backward design, and present examples of the module materials. Students did well on the related homework problems and were enthusiastic about the discussions, calculations, and focus on the circular economy. Interviews revealed that students valued the connection of technical and social aspects and enhanced their interest in electrical engineering. We hope that this module will help engineering instructors interested in teaching about social implications in their own Circuits courses.

1 INTRODUCTION

Motivation to include sociotechnical content in engineering courses comes from students, the workplace, and accreditation bodies. Many undergraduate students enter engineering wanting to help people through their profession (Bairaktarova and Pilotte, 2020; National Academy of Engineering, 2008). They want to see how their engineering knowledge can make a difference in people's lives. Real problems provide this opportunity - they are multidimensional and interdisciplinary, and they encompass complex sociotechnical issues (Baillie, Pawley, and Riley, 2012; Leydens and Lucena, 2017; Riley, 2020).

To prepare graduates for the workforce, instructors must help students learn about technical and social dimensions of engineering. Engineering accreditation criteria (e.g., ABET, n.d.; the European Network for Accreditation of Engineering Education, n.d.) emphasize the importance of such sociotechnical knowledge by expecting engineering undergraduate programs to address ethical, global, cultural, social, environmental, and economic considerations in student outcomes.

However, many engineering instructors, educated with in-depth technical knowledge, are not sure how to incorporate explorations of technology's social impacts. Instructors may also feel that they do not have time to develop instructional material that connects the social and the technical. As a result, many students learn core engineering concepts with a focus on calculations and modelling but no critical evaluation of their major's impact on sociotechnical areas such as public welfare, ethics, climate change, and policy (Bielefeldt, 2018; Børsen et al., 2021; Jesiek et al., 2019; Williams and Trevelyan, 2013).

In our current research project, we offer one approach for addressing social implications in a required foundational course for engineering students. We aim to help engineering instructors to provide sociotechnical content for their students by making it as easy as possible. We are developing short, one-hour modules for use in the Introduction to Electric Circuits course that connect social and technical considerations. The Circuits course is typically the first course for students studying electrical engineering (EE) and is a common course for students in other disciplines of engineering. Thus, this course reaches many students. It is a course that students often find very abstract and struggle to find the relevance of (Bell and Horowitz, 2018). Our modules are designed to be used in this foundational course where we hope they will help students see the relevance of the technical content and instructors be empowered to conduct discussions of the sociotechnical nature of the course content (Lord, Przestrzelski, and Reddy, 2019; Finelli and Lord, 2023; Lord and Finelli 2023).

In this paper, we report on the development and implementation of a one class period (about one hour) module focused on electric vehicle (EV) batteries and circular economies that includes pre-class, in-class, and post-class materials contained in a comprehensive teaching guide. In May 2023, we piloted the module with a small group of students and then deployed this module in a small undergraduate-focused institution with twenty students. After the session, we conducted interviews with two student participants. In this paper, we present examples of the module materials and student feedback. We hope that this module will help engineering instructors interested in integrating social implications in their own Circuits courses.

2 DEVELOPMENT OF MODULE

The goal of this module, “Electric Vehicle Batteries and the Circular Economy” is to introduce students to issues related to recycling the rapidly growing number of electric vehicles (EVs) reaching end-of-life. This topic serves as a case study for applying principles of a circular economy. For the instructor, we supply the learning objectives; assignments for before, during, and after class; the in-class slides; and an accompanying instructor’s guide to the slides. Instructors may choose any combination of problems and/or slides and can choose when in the semester to insert the content.

The module was developed by a graduate student in EE along with two EE professors with decades of experience teaching the Introduction to Circuits course (preliminarily described previously Judge, Lord, and Finelli, 2022). We used the principles of backward design (Wiggins and McTighe, 2005) and constructive alignment (Biggs, 1996) to connect learning objectives with activities and assessments. We also followed guidelines developed by Gelles and Lord (2021) for integrating sociotechnical content into engineering courses.

1. Identify a salient course topic that has broader social and environmental implications.
2. Identify, add, or update existing course learning objectives and/or ABET student outcome that this sociotechnical course topic aligns with.
3. Create learning objectives for specific sociotechnical modules.
4. Create modules by designing activities for homework before and/or after class session(s) as well as class session(s) that integrate technical content and calculations students are familiar with and social and environmental context.
5. Include low stakes assessment for module (e.g., homework) and consider including sociotechnical questions on exams.
6. Conduct formative assessment and/or engineering education research on sociotechnical modules to get student input and improve module offerings in the future.
7. Refine modules and identify possible sociotechnical collaborators for the next course offering.

To accomplish Step 1, we began by relating the concept of voltage dividers to repurposing of electric vehicle (EV) batteries. The manufacturing and use of EVs has increased dramatically recently (Breiter et al., 2022; IEA, 2022). Many students are familiar with EVs; thus this topic is relevant to current undergraduate students’ lives and connects to EE. Once EV batteries have degraded to about 70% of their initial charge storage capability, they are no longer useful for EVs since they could leave a driver stranded. Recycling has many challenges (Kul, 2022; Morse, 2021). However, they may be very useful for other applications. (Ali, Khan and Pecht, 2021; Haram et al, 2021; Song et al., 2022). Thus, the repurposing of EV batteries is an excellent topic for introducing students to the circular economy. The circular economy is “a system where materials never become waste and nature is regenerated. In a circular economy, products and materials are kept in circulation through processes like maintenance, reuse, refurbishment, remanufacture, recycling, and composting" (Ellen MacArthur Foundation, n.d.). In addition, because repurposing EV batteries likely involves changing a DC voltage, the topic can be connected to voltage dividers, a concept addressed in most circuits courses that can be used for both analysis and design. Voltage dividers are typically covered early in the Circuits course, and the EV module could be done any time after voltage dividers have been introduced. We acknowledge that voltage dividers are not the best way to provide a desired output from an EV battery and mention this to the students. However, we felt that it was important for them to see an application of something in the class that could be connected to a larger topic.

For Step 2, we identified a series of course learning objectives related to the EV module. The learning objectives include:

- Be able to write, derive, and apply the voltage-divider relationship for circuits containing two or more resistors.
- State when it is appropriate to use the voltage divider equation.
- Explain what a voltage divider is and why it is useful.
- Analyze batteries as DC electrical devices

Next, for Step 3, we identified specific learning objectives for the sociotechnical module. These module learning objectives include:

- Design a voltage divider for a DC source to illustrate repurposing EV battery packs
- Estimate energy available in end-of-life EV batteries and explain how they could be used for other purposes
- Describe societal risks introduced by recycling EV batteries that could be alleviated by applying circular economy principles

Steps 4 and 5 involved developing materials which will be summarized in the next section. This paper is part of Step 6 and we are in the process of Step 7 as we refine the module.

3 SAMPLE MATERIALS

3.1 Pre-class Problems

Before the class session with the integrated module, instructors could ask students to complete some pre-class activities. One possible pre-class activity is that students could listen to one or more podcasts that introduce concepts related to EV Batteries and the Circular Economy (e.g., Loveless and Sanderson, 2022; Whalen, 2020) and answer multiple choice questions. Another possible activity is a numerical calculation (Fig. 1, note that estimates of numbers of EVs may need to be updated as this is a rapidly changing field) which sets the stage for the need for EV battery repurposing. Instructors also have the option of not assigning pre-class activities and doing the initial calculations as an in-class activity.

End-of-life battery capacity and the circular economy: In the year 2021, there were about 16.5 million electric cars on the road, and the numbers continue to increase. Annual sales of electric cars are predicted to reach approximately 30 million in the year 2030. Assume that each EV battery pack has an initial 500-volt charge at time of sale and that approximately 70% of EV battery packs from 2021 will reach their end of life by the year 2030 (still having 75% of their initial capacity). Then, answer the following questions:

a. When the EVs from 2021 reach their end of life, how many total volts will remain on the battery packs?
b. What percentage of future battery demand (in Volts) could be supplied using repurposed batteries from 2021?
c. What does this imply about the feasibility of using repurposed EV batteries?

Note: The initial charge on EV batteries currently ranges from 300 – 900V, which connects to either a 400 or 800 V system. There is an industry movement to standardize the 800V system level design for faster charging.

Fig 1. Sample pre-class assignment

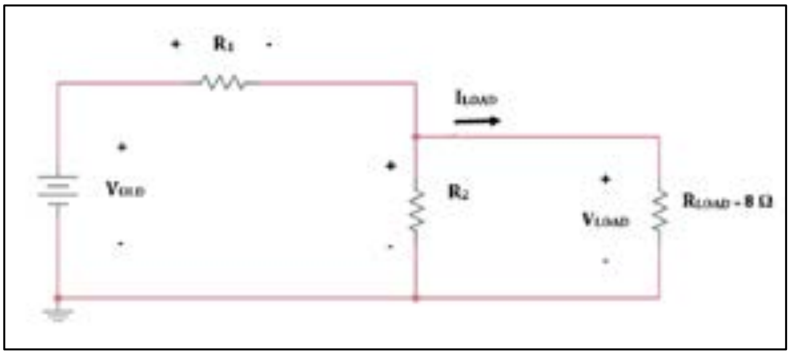
3.2 In-class Presentation

To support instructors using the EV module, we developed a slide presentation and accompanying script with suggested timings. The presentation includes descriptions of EVs and EV batteries, an overview of the circular economy, prompts for student discussions, and example voltage divider problems in the context of EV battery repurposing.

The instructor presentation begins by describing that, when they reach their end of life, the growing number of EV batteries are no longer suitable for use in EVs. The numerical example (done either as a pre-class activity or inserted in class at this point) illustrates that recycling can only meet about 30% of the demand for future EV batteries and that this complex problem requires engineers. The instructor then outlines assumptions that were part of the calculations and introduces benefits and challenges of recycling EV batteries, leading to a discussion of the circular economy and its implications for engineering design. Next, students are encouraged to think of applications of the circular economy for EE and then to focus on EV batteries. The instructor illustrates that an EV battery with an initial range of 150 miles has a reduced range of only 105 miles, potentially insufficient for the owner, when its capacity if diminished to 70%. Then, as a fun way to see this idea in action students check the health of their phone batteries.

Next, the instructor describes what the circular economy might look like throughout the life cycle of the battery. The instructor highlights some industry areas where repurposed EV batteries could be used, including microgrids, and then presents students with the challenge of powering a microgrid that requires a specific voltage (e.g., 350 Volts) with an EV battery having 493 Volts. Students are guided to use the voltage divider, and they design a circuit to provide the appropriate scaling. The instructor confirms their answers and discuss how the voltage divider is not the ideal circuit for this giving them a glimpse of more complex circuits. The instructor then transitions into preparing for the homework and summarizing main takeaways from the module.

1. (a) Provide an example of a challenge or solution for each of the following sociotechnical factors in the manufacturing and repurposing of EV batteries: Technical, Environmental, Health and safety, Economic. (b) Please provide a few sentence description of **one** of these.
2. In your own words, describe the purpose and benefits of a circular economy.
3. A repurposed battery (represented by V_{OLD} in the schematic diagram below) is used to power a mobile home. The load requires 240 V and 30 A to charge, and the load resistance (represented as R_{LOAD}) is included to draw current from the battery – this is a common rating in microgrid applications. In this problem, R_{LOAD} is 8 Ω and R_2 is 100kΩ.
   a. Assuming that the repurposed battery is a 600 V pack at 76% capacity, enter the following values in the table below.
      i. The effective voltage of the entire second-life battery pack, V_{OLD}. (You may assume that all the current can be supplied by the battery
      ii. The value of R1 required to set the output voltage and current to 240 V & 30 A.
      iii. The total power supplied by the repurposed EV battery to the load.
   b. Repeat the calculations for (i) – (iii) if the battery degrades over 2 years to 65%.
   c. Describe what concerns you might have about your results.



Battery Capacity	V_{OLD}(V)_	R_1 (Ω)	Power Supplied to Load (W)
76%			
65%			

Fig. 2 Example problems for after the module

3.3 Post-class Problems

We provide several options for post-class activities (Fig. 2, note that these problems could be used for homework and/or exams). We also provide a list of related references on EV manufacturing and the circular economy.

4 STUDENT RESPONSES

In May 2023, the graduate student who developed the EV module presented it in an "integrated approach to EE" course taught by a member of the research team. The course is for second year students and is a broad introduction to EE, including many circuits topics. The day before the module was presented in class, we piloted it with a small group of volunteer students who had taken the course the previous year. Overall, the volunteers found the module interesting and informative, and their feedback was incorporated into the module before it was presented to a class of 20 students on the following day.

4.1 Pre-class Problems

For the Spring 2023 offering, we did not do the pre-class problems. Rather, we incorporated the activity (Fig. 1) into the beginning of the class period. Students successfully completed the calculations for the activity during class.

As an extra credit assignment, students in the class were asked to listen to the two podcasts and explain which one they thought would be more beneficial as a future pre-class assignment. Of the 20 students, ten did not complete the extra credit assignment, six students preferred the longer podcast, which was about 40 minutes, (Loveless and Sanderson, 2022) for its comprehensive technical details, three preferred the shorter podcast, which was about 18 min, (Whalen, 2020) for its clear organization and relatable host, and one did not make a recommendation. Instructors can decide which, if either, is more appropriate for their class.

4.2 In-class Feedback

The student volunteers who participated in the first offering in Spring 2023 were very enthusiastic about the module and the topic. In fact, one of the students was so inspired that she proposed the topic of repurposing EV batteries for her engineering senior design course for Fall 2023-Spring 2024 and is currently working on this with an interdisciplinary team and considering starting her own business.

Students who participated in the class module recorded their impressions about it at the end of the session by listing one thing they liked about the module and one suggestion for improvement. Students liked the discussions, the calculations, consideration of the circular economy as a current issue, and thought the presenter did a good job. For example,

> *"Enjoyed calculations and real applications so we could see it wasn't as theoretical."*

> *"The discussions and activities went really well."*

Students also provided several suggestions for improving the module including considering the pacing as "s*ome points went too fast, but others took too long.*" Several students suggested topics to add such as more detail on manufacturing process for batteries, overview of how EV batteries work, where parts go, different types of batteries, and changes to infrastructure needed.

4.3 Homework Problems

Students completed the three assigned homework problems in cooperative learning groups of four (Lord, 2001) as part of the final assignment of the semester, and overall they did well on the problems. Of the five groups, three got full credit for

Problem 1, the fourth group earned 1.75/2 (88%) for not substantiating statements about costs, and the fifth group earned 2.25/2 for an outstanding job. For Problem 2, four groups earned full credit and one earned 0.75/1 for a grammatical error and not providing a citation for “biodiversity loss” as an integral part of the circular economy. For Problem 3, three groups received full credit, one earned 2.5/3 (83%) and one got 2.25/3 (75%). Common student errors included insufficiently explaining why numbers were chosen, using wrong numbers, and calculating power supplied by the battery rather than to the load. Students were encouraged to use Multisim simulation to check their work.

4.4 Interviews

Students responded enthusiastically to the implementation of EV module. Two students from the class, both of whom were female Integrated Engineering majors, participated in semi-structured interviews after the module. One was pursuing a concentration in biomedical engineering and the other in sustainability. Both students described the module as interesting, relevant, and helpful.

> *“I think if more people knew about [topics like this EV module] and it was brought to the attention of more people, especially like our generation of engineers, it would be really helpful towards the future.”*

> *“… [the EV module] definitely made me consider going into something that does more with like sustainability and stuff like that.”*

One student expressed an honest opinion about not being excited about EE at the beginning of the semester, stating that this module helped improve that outlook.

> *“... I came in hating electrical engineering, like it was just not for me. So I think like actually doing the voltage divider and using that for like sustainability purposes and the circular economy was really cool to like actually be like, okay, the stuff we're learning is like being used for something …. I liked that part of it.”*

One student emphasized the importance of this topic to them personally.

> *“… we are a part of the issue if we don't decide to fix it.”*

5.SUMMARY AND FUTURE WORK

We successfully designed and implemented a sociotechnical module about EV batteries and the circular economy in a small undergraduate engineering course. The module ties the technical topic of voltage dividers, typically included in an Introduction to Circuits course, to the circular economy using the idea of repurposing EV batteries. Students responded enthusiastically and liked seeing the connection between the social and technical concepts.

Next, we aim to scale up our implementation by integrating the module into a significantly taught by a member of the research team a different institution. We will also conduct surveys, interviews, and focus groups to gauge student feedback on the module and evaluate students’ homework solutions to assess their technical proficiency. Then we intend to collaborate with engineering educators to introduce this module into circuits courses at universities beyond our research team’s institutions.

We are currently partnering with eight graduate students from across the USA to develop more sociotechnical modules for the Introduction to Circuits class. Once these are successfully implemented in our own small and large courses, we will share them with other educators, thus impacting students at many universities.

Conference Key Areas*: Diversity, equity and inclusion in our universities and in our teaching; Engineering skills, professional skills, and transversal skills*
Keywords*: Mentorship, women engineering students, early career female engineers, mentorship programme*

ABSTRACT

Women are underrepresented in STEM fields internationally and in South Africa, with engineering being the most male-dominated. Statistics show high attrition rates for women in engineering careers and education. Universities have implemented mentorship programmes to enhance learning experiences and increase the retention of female engineering students. Literature suggests mentorship positively contributes to undergraduate experiences, retention, performance, motivation, career outcomes, and health for mentees. This research explores the design and execution of mentorship programmes for female engineering students at national and international universities, considering the unique socio-economic environment in developing countries like South Africa. It also investigates the involvement of business and industry members in mentoring female engineering students and early career engineers. Using a descriptive and interpretative case study design with a mixed-

[1] *A S Lourens*
ann.lourens@mandela.ac.za

method approach, this study identifies complexities surrounding mentorship for women in engineering. Quantitative and qualitative data inform the development of a robust mentorship framework by identifying key components for retaining female engineering students. The study aims to use the proposed framework to develop a mentorship programme for female engineering students and early career engineers. While focused on developing countries, the findings and proposed framework are anticipated to benefit STEM faculties and organisations worldwide in retaining females in STEM-related employment fields.

1 INTRODUCTION AND BACKGROUND

Addressing the underrepresentation of women in STEM fields, particularly in engineering, remains a critical challenge in South Africa and globally. Despite the high demand for qualified engineers, a significant gap persists in the enrollment and retention of female graduates in this sector. In response, the School of Engineering at a South African University, supported by the Manufacturing, Engineering and Related Services Sector (merSETA), established the Women Engineering Leadership Association (WELA) in 2011. WELA's comprehensive programme supports the entire life cycle of women engineers' education and early career, characterised by a structured mentorship and leadership development programme.

WELA's mentorship life cycle unfolds in phases designed to support Women Engineering Students (WES) during their academic journey through to their professional integration. In Phase 1, WES are invited to join WELA, where they are enrolled in a Leadership Development Programme (LDP). In Phase 2, they are assigned a peer mentor to guide their academic and early career development. In Phase 3, WES participants have the opportunity to become mentors themselves, passing on their knowledge and experience to the next generation of WES. Finally, in Phase 4, they transition into supportive roles, such as early career engineers, contributing back to the community and the engineering field at large.

Central to our study is the evaluation and potential expansion of WELA's mentorship initiatives, with a particular focus on leveraging e-mentoring (online mentoring) to overcome geographical barriers and enhance accessibility. This approach underscores the importance of e-mentoring within our proposed mentorship model, aiming to enrich the mentorship experience with global perspectives and digital connectivity.

This study presents an empirical investigation into the effectiveness of the existing WELA mentorship strategies and explores the potential of e-mentoring to augment the programme. By analysing quantitative data from new WELA members and qualitative insights from Early Career Women Engineers (ECWE), alongside a review of international mentorship programmes, we aim to propose a refined mentorship model. This model seeks to address the educational and professional development needs of WES and ECWE within the socio-economic context of a developing country, contributing to narrowing the gender gap in the engineering sector. Our goal is to provide a scalable, adaptable mentorship framework that incorporates both traditional and e-mentoring strategies, ensuring comprehensive support for female engineers at various stages of their career development.

South African Context and Women in Stem Challenges

The context of women in engineering and STEM fields in South Africa is deeply influenced by persistent societal and organisational challenges. As noted by Fajardo and Erasmus (2017), the traditional and stereotypical roles of male and female employees within organisations and society often place women aiming for senior roles in positions as "going against the grain". This sentiment is further compounded by familial contexts in South Africa, which play a significant role in perpetuating gender stereotypical roles, indicating a pressing need for a reimagined approach to conventional roles at home and in the workplace.

Moreover, the longitudinal study by Glass, Sassler, Levitte and Michelmore (2013) underscores a concerning trend that women in STEM-related occupations are more likely to exit their careers than their counterparts in other professions. This attrition rate is echoed by Hewlett and Luce's (2005) findings, who observed that despite the intellectual satisfaction and societal contribution reported by women in Science, Engineering, and Technology (SET) fields, they face considerable obstacles. These obstacles include extreme job pressures, limited career advancement opportunities and, often, a workplace culture that ranges from being unsupportive to outright hostile. Such environments severely hinder women's ability to thrive in the SET industry.

Adding to these challenges, Fouad, Chang, Wan and Singh (2017) highlighted the pervasive "old boys club" culture within organisations. This culture not only affects women's sense of belonging but also influences their job satisfaction levels owing to perceived inequalities in compensation and recognition. Women report having to work significantly harder than their male counterparts for equivalent acknowledgement and advancement, illustrating the systemic barriers that contribute to the high attrition rates of women engineers in South Africa.

The societal and organisational context in South Africa, characterised by entrenched gender norms and an often-unwelcoming industry atmosphere, which plays a crucial role in the career trajectories of women in engineering. This backdrop necessitates targeted interventions, such as the mentorship programmes, to support and retain women in SET fields. By addressing these systemic challenges, the barriers that women face can begin to be dismantled, paving the way for more inclusive and supportive professional environments.

2 CURRENT WELA MENTORSHIP PROGRAMME

The current WELA mentorship process consists of asking senior WELA members (these are students who are in their second year of the WELA LDP but are senior engineering students) to volunteer to be trained as mentors. Training consists of a one-day training programme. Mentees (other WELA members) are allocated to mentors (senior WELA members). They are encouraged to meet regularly, and, in their training, mentors are educated about certain topics, which they will need to discuss with mentees. Mentors are also encouraged to become involved in social and community activities. Since 2020, a former WELA member was contracted as the "lead mentor". The student had also been a mentee and a mentor, whilst being a former engineering student and graduate. Her tasks and duties included managing the mentors, obtaining feedback and guiding mentors in their duties.

The current mentorship programme allows mentors to teach or expose mentees to skills such as budgeting, flexibility, leadership, teamwork and assertiveness

(Lourens, Connelly and Plaatjes, 2019). This is in addition to supporting mentees in their academic activities. Feedback from mentors indicated that through the mentor-mentee relationship, WELA had created a learning community, supporting the notion that each WES is an "architect of her own learning" (Lourens et al, 2019).

Establishing learning communities is important in the current higher education context. This is especially so, as the academic community recovers from the impact of the 2016 #FeesMustFall campaign and, a few years later, the COVID-19 pandemic. As a result of these occurrences, it has become pertinent for the engineering curriculum to entrench a humanised pedagogy as well as digitalisation to meet these WELA goals. According to Salazar (2013:121), a humanising pedagogy is "crucial for both teacher and student success and critical for the academic and social resiliency of students". One effort that universities can make towards a humanised pedagogy is to encourage and actively pursue the establishment of learning communities and a collaborative pedagogy (Tinto, 2003). These are goals which WELA strives to achieve by providing mentorship.

3 Impact of Mentorship: Retention and Benefits

Wu, Thiem and Dasgupta (2022) refer to interventions to train people to cognitively reappraise their experiences, which often influence those who are underrepresented to mentally adapt to their environment. This includes strategies for re-affirmation, a growth mindset and emotional regulations. Wu et al (2022) further state that these strategies have been successful in reducing sex, race and class disparities in academic performance. However, Wu et al (2022) found that often the responsibility was placed on students to change their mindset rather than placing the responsibility on academic institutions to change the learning environment to meet the needs of diverse student populations. Furthermore, students' subjective experiences in academic spaces such as their feelings of belonging, confidence, anxiety and motivation are often not considered when developing interventions and support programmes. This confirms the importance of a mentorship programme to create a sense of belonging, improve feelings of self-efficacy and increase motivation.

In their study, Wu et al (2022) found that:

- Assigning female participants, a male mentor or no mentor significantly decreased their confidence in overall engineering skills and their motivation. However, another study (Nelson, 2023) found that male mentors in the workplace could have a significant impact in terms of coaching, support, allyship and being a champion. In addition, male mentors could build positive relationships with women in the organisation, and this could lead to male mentors improving interpersonal skills and broadening their outlook.
- Being assigned a female peer mentor was consistently associated with a reduced decline in confidence and motivation.
- Being assigned a female peer mentor was associated with an increased rate of participation in engineering internships during college, increased graduation rates and maintenance of higher aspirations to pursue post-graduate degrees.

- Offering female mentorship resulted in greater reported mentee emotional wellness.
- Having male mentorship or no mentee was associated with a decline in emotional well-being throughout college and one-year post college.

In addition, having a *stable confidence* in engineering ability best explained why female peer mentorship promoted success in engineering internships, completion of STEM degrees and pursuit of graduate training in engineering. Based on these abilities, it becomes evident that having both a male mentor, who can act as an ally and champion for change in the work environment, as well as a female industry mentor and a peer mentor can be beneficial to the mentee.

There is vast research and discussion on the benefits of mentoring, personally as well as professionally. There seems to be a clear cycle in the mentoring process and it has been found that 89% of those who are mentored go on further to mentor others, and 84% reported that the mentor and mentee relationship acted as dual inspiration for both parties (Winstanely, 2023). More statistics from the research conducted by Winstanely (2023) revealed that 87% of both mentors and mentees developed greater confidence and felt more empowered, while 84% felt that there was inspiration for both mentors and mentees in a mentoring relationship. However, no extensive research has been conducted on the benefits that a mentor has when mentoring a mentee. However, Lin, Cai and Yin (2021) indicated that learning-orientated members who acted as mentors found psychological meaningfulness in their work, which, in turn, enhanced their work engagement. In addition, retention rates were also higher for mentees and mentors as opposed to those who did not wish to participate in mentoring programmes (Winstanely, 2023). Behesti (2022) suggests that there is a positive link between mentoring programmes and diversity as well as inclusion within an organisation. Similarly, statistics provided by Cornell University School of Industrial and Labour Relations (2020) showed that there was a vast improvement in promotion and retention rates for minorities and women who participated in mentoring initiatives as opposed to those who did not.

In the rapidly evolving landscape of engineering education and professional development, the significance of mentorship, especially for female students and early career engineers in developing countries, is paramount. Faced with challenges such as geographical dispersion and limited access to experienced mentors, innovative mentorship approaches have become essential. E-mentoring, leveraging digital platforms to bridge physical distances, has emerged as a compelling solution to these challenges. The inclusion of e-mentoring in our study underscores our commitment to exploring comprehensive, adaptable mentorship strategies that resonate with the unique socio-economic environments of developing countries. E-mentoring, a critical component of our proposed mentorship programme, offers flexibility and broadens access to a diverse mentorship resource pool, effectively catering to the specific needs of female engineering students and early career engineers. This adaptability and accessibility align with our objective to create an impactful mentorship programme. Empirical evidence supports the efficacy of e-mentoring. For example, Single and Single (2005) highlight that it preserves the benefits of traditional face-to-face mentoring, including fostering honesty between mentors and mentees, thereby enhancing self-esteem, building confidence, and supporting risk-taking. Furthermore, e-mentoring’s global reach not only facilitates knowledge transfer and the exchange of field expertise (Rowland, 2011) but also broadens access to a more diverse pool of mentors (Hamilton and Scandura, 2002). E-mentoring, thus, presents a viable option for overcoming the logistical challenges inherent in mentorship in developing contexts.

Based on previous research, it becomes evident that mentorship is beneficial for the mentor, mentee and society as a whole. This can be especially advantageous in the South African context where deep-seated male and female traditional roles are still prevalent. In Section 5, a summary is provided based on key mentorship programme developments of well-known international universities that the researchers extracted based on the proposed concepts for the redesign of the WELA mentorship programme.

4 INTERNATIONAL PRACTICES

Table 1 provides a summary of selected higher education mentorship programmes and information regarded as important for the development of a mentorship programme for WELA members**.**

Table 1. Summary of international practices

INSTITUTION	DETAILS
Imperial College London UK Resource Centre for Women in Science, Engineering and Technology (2008) (www.ukrc4setwomen.org)	The programme at this university is run by the students and most activities are self-financed. There appears to be a large number of student clubs and societies and, hence, there is a good chance the issues of women will be noticed by students who form part of the student union. This type of student-run organisation is of great interest to the researchers as there is a drive to encourage more student ownership of the WELA mentoring programme.

University College Dublin (UCD) (2014) (UCD, 2014)	For this institution, students were provided with networking opportunities with experienced members of the industry to gain a better understanding of the expectations within a corporate environment. These networking opportunities could be extended into the mentoring process. UCD highlighted that networking opportunities of this nature could be beneficial to potential WES. As a result, the researchers noted that a meet and greet event should be included in the revised mentoring programme. Social media was also mentioned as a very effective marketing tool and UCD's future social media endeavours are similar to those of the proposed revised mentorship programme being investigated. These campaigns will include links to webpages, including biographies of potential role models and mentors. UCD's TV advertisements also made extensive use of women engineers, and, in the South African context, similar advertisements could be marketed across all social media platforms. As in South Africa, UCD noted that there is low visibility of role models for female learners. As a result, social media platforms could be a useful marketing tool to combat the low visibility of WES.
Brunel University London (nd) (brunel.ac.uk/wibec)	Brunel University London seems to have an extensive and successful mentoring programme. Their programme is structured, requiring mentors and mentees to commit to at least two mentoring events along with signing a mentoring contract. WELA currently asks members to complete a commitment form when joining WELA but can explore the possibility of a stand-alone mentorship commitment form. Students also complete the CliftonStrengths test

	(https://www.gallup.com/cliftonstrengths), which has proven to be a very useful tool to build self-awareness, and will be used in the revised WELA mentorship programme. There are ten stages to the mentorship programme at Brunel University, beginning with the completion of online profiles, which is an aspect that the revised WELA mentorship programme will consider. Students are then placed on a waiting list and matching is done considering career interests and studies. Students attend pre-programmed training, which is another consideration for the WELA mentorship programme to create self-ownership. A mentoring manager can be appointed to manage the programme. In the current WELA programme, a mentoring team leader was appointed, and this has been a valuable addition. As with UCD, Brunel hosts a mentor induction as well as a meet and greet, which is a component that the WELA mentoring programme will further explore.
University of Leicester UK Resource Centre for Women in Science, Engineering and Technology. (2008) (www.ukrc4setwomen.org)	This institution runs an online mentoring programme as its members and students are spread across the country. Online mentoring will allow the WELA programme to include a wider range of mentors as location will not be an issue. The University of Leicester's website includes women at various stages of their careers, which is another consideration for the revised WELA programme.

Although Stemazing's (2023) programme is traditionally geared toward learners and not higher education students, there were still concepts that the researchers felt were important to include in the redesign of the WELA mentorship programme. An important extract from this university is that they have highlighted the diversity and inclusion benefits of both young boys and young girls who have female role models. As a result, consideration into opening the WELA mentoring programme to male engineering students will be considered. It also appears to be an important aspect of any programme to provide extensive online training, in particular, for the new WELA mentorship programme. In addition, students often do not understand the reasons for mentoring and the long-term benefits associated with it, which should be made explicit.

Based on an overview of the selected mentorship programmes, it is important that the mentorship is run and managed by students, and it is clear that being a mentor and/or a mentee is a self-directed and self-managed activity. In addition, it is also important that students completely understand what mentorship is, the benefits as well as the long-term benefits thereof and that it is a developmental and networking opportunity. Training for both mentors and mentees appears to be a vital component of a successful mentoring programme. An important component would also be an assessment such as the CliftonStrengths test as used by Brunel University London (nd) not only to be used as a self-development instrument but also to serve as a tool to match mentors and mentees. From a technology point of view, mentorship can be offered online, and a mentorship platform can be designed where prospective mentors and mentees can meet and interact.

Social media is very important in marketing engineering as a desirable career, in addition to marketing the institution and the services it provides to students by offering a mentorship programme to WES. In addition, it would also be important that social media marketing is geared to primary and high school learners. Mentors can include both men and women in various stages of their careers working in industry, in addition to WELA peer mentors. This research has led to the development of a proposed framework, which is discussed in Section 6.

5 PROPOSED FRAMEWORK

The proposed framework in Figure 1 is explained below. Prior to the mentorship website's launch, a robust social media marketing campaign is planned to highlight the mentorship programme's benefits and the advantages of attending a university with a successful mentoring culture. The overarching aims of a successful mentorship programme, capturing the full life cycle of mentoring across all career stages of WES, are visually summarised in Figure 1 below.

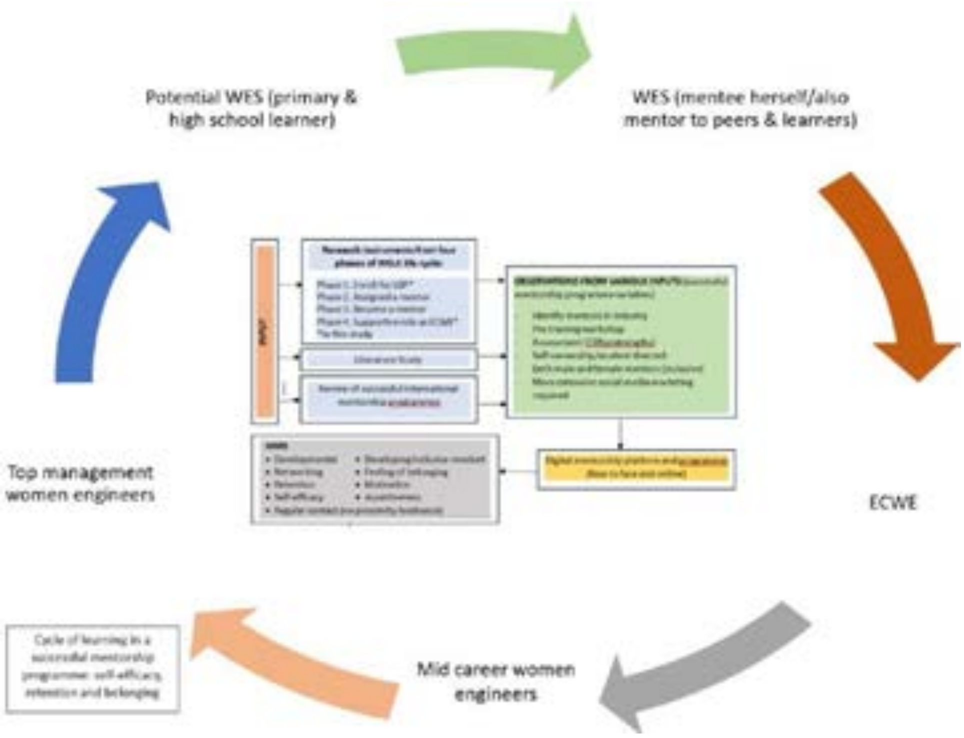

Fig. 1. Proposed framework

The proposed framework outlines the inputs reviewed for the redesign of the WELA mentoring programme, detailing the phases of the WELA LDP mentorship programme and the aims or goals necessary for successful execution. It also introduces a proposed cycle of learning that spans potential students, women engineering students, ECWE, mid-career women engineers, and top management. Central to the framework's effectiveness is ensuring a comprehensive understanding of the mentorship programme's benefits among WES and fostering their ownership of the process. An extensive training workshop is anticipated to bridge any gaps in understanding, thereby promoting self-ownership and active participation.

In developing the proposed mentorship framework, it is crucial to recognise that while certain practices have shown widespread success, the concept of *best practice* in mentorship must be viewed through a lens of adaptability and contextual sensitivity.

6 ACKNOWLEDGING

the diversity of socio-economic and cultural environments in which women engineers operate, our framework rather advocates for a *best fit* approach. This methodology emphasises the customisation of mentorship practices to meet the specific needs and conditions of different countries and communities, thus, ensuring greater effectiveness and inclusivity. The adoption of a paradox approach may also be beneficial, where acknowledging and leveraging the inherent complexities and contradictions within diverse contexts can lead to innovative solutions. Therefore, the framework is designed to be dynamic and flexible, allowing for the integration of successful elements of mentorship while adapting to local nuances, thereby more accurately reflecting the multifaceted nature of global engineering fields (see Figure 1).

Section 7 explains the methodology followed that aimed to confirm the findings of the literature review depicted in Figure 1.

7 METHODOLOGY

This research followed a descriptive and interpretative case study design to describe interventions and the real-life context in which they occurred (Maree, 2016). A mixed-method of quantitative and qualitative data was used to describe and understand WES's reasons for joining WELA, their fears and expectations, and their experiences of being a mentee and a mentor in addition to being an early career female engineer. The findings from the mixed-method study will inform the development of a mentorship framework for WES and ECWE. Table 2 summarises the instruments used in each phase of the WELA member life cycle, the number of respondents, the aim of the research instrument and the type of data collected. Finally, Table 2 illustrates the value of the data obtained as input for the revised mentorship programme.

Table 2. Data analysis

Phase	WELA LIFE CYCLE	INSTRUMENT	n	AIM OF INSTRUMENT	INPUT FOR MENTORSHIP PROGRAMME
1	First-year commitment form (new members)	Questionnaire	183	● Fears and challenges ● Expectations for joining WELA	● Address fears & challenges

2	Mentee feedback (year-end questionnaire)	Questionnaire	38	● Impact of mentorship	● Implement suggestions ● Address challenges & shortcomings
3	Mentor feedback (application form, training form, portfolio leader feedback form)	Questionnaire	9	● Suggested improvements ● Self-reflection	● Implement suggestions ● Address challenges & shortcomings
4	ECWE feedback (former WELA members, mentees and mentors)	Questionnaire and Interview	5	● Challenges in the work place	● Address challenges & shortcomings

This paper reports on the quantitative data from Phase 1 (new members) as well as the quantitative and qualitative findings from five ECWE (Phase 4) who are former WELA members, student mentees and mentors.

8 PHASE 1 AND PHASE 4 RESULTS AND DISCUSSION

Section 8.1 provides a summary of the findings of the first-year questionnaire where prospective WELA members were asked to list their perceived fears and concerns as women entering the field of engineering. It would be important in a mentorship programme to recognise and address these fears and concerns.

8.1 Phase 1: First-year commitment questionnaire

Over a six-year period (2016-2022), first-year WES and aspiring WELA members have consistently rated “being intimidated”, “made to feel inferior”, “undermined and discriminated against” as their greatest concerns upon entering a traditionally male-dominated field of study and work. These concerns are followed by “not being seen as an equal”, “not being taken seriously” and “not being heard”. One of the goals of the revised mentorship programme will be to provide WELA members with the self-knowledge and tools to create a sense of belonging and improve their feelings of self-efficacy. Having support from a mentor would greatly assist them in overcoming their perceived fears and concerns.

8.2 Phase 4: Experience of being an ECWE

Interviews and a short questionnaire were given to five WELA alumni who had graduated and were employed in various industries for at least five years. The respondents indicated that their experiences as female engineers in the workplace were challenging. One respondent indicated that, at times, she felt as if her suggestions were looked down upon “*just because I am regarded as young and* *female*", while two others stated that they felt as though they constantly had to prove themselves. One respondent indicated that even if she was "*looked down upon and undermined*", she was still expected to be "*assertive and respectful*". Although all the respondents reported experiencing challenges such as "*proving myself capable*" and being "*assertive, heard and respected*" as female engineers, they also mentioned how it had increased their self-reflection. One respondent stated she felt "*inspired [by] the fact that I am smart enough and I am capable to do work that my male colleague can do*". One respondent stated that the challenges "*pushes me to do better every day and I love being a female engineer and changing how it is seen by the world*".

Four of the respondents stated that they had never experienced sexual harassment, yet remarks had often been made about their appearance in the workplace. They further indicated that, at times, they were told they were "*over sensitive*" and felt as though their male colleagues did not fully understand gender equality and how to treat women as equals in the workplace. Four respondents also indicated that the workplace often felt like a "*boys club*" of which they would never be a part.

9 SUMMARY AND ACKNOWLEDGMENTS

The feedback from respondents underscores the significant challenges and experiences women face in traditionally male-dominated engineering environments. Despite these obstacles, the WELA programme played a pivotal role in preparing them for such environments, contributing not only to their professional readiness but also to their personal development and assertiveness in the workplace. Participants highlighted their undeterred motivation and determination to succeed as women engineers and serve as role models, underscoring the programme's importance at both the tertiary education level and within the workplace.

Acknowledging the limitations of our study, particularly the small sample size, we contend that the experiences of our participants reflect broader trends affecting many women in engineering. The need for further development of self-efficacy through additional workshops, like CliftonStrength assessments, and the creation of a supportive community through mentorship were identified as critical areas for programme enhancement. Such initiatives, coupled with training on addressing bias, micro-aggressions, and sexual harassment, are essential for fostering a more inclusive and equitable professional environment.

The proposed enhancements to the WELA mentorship programme, informed by both the initial feedback and subsequent phases of our study, aim to address these identified needs more effectively. Our proposed framework, emphasising both traditional and digital e-mentoring approaches, offers a scalable, adaptable solution to the unique challenges faced by female engineering students and early career professionals. This comprehensive framework is designed to be responsive to the evolving landscape of mentorship in engineering, particularly in the context of developing countries like South Africa.

Specifically, our study contributes novel insights into the mentorship field by empirically demonstrating how structured mentorship, integrated with leadership development initiatives, can profoundly impact the retention and success of women in engineering fields. The inclusion of e-mentoring significantly broadens access to mentorship opportunities, addressing key challenges such as geographical dispersion and the scarcity of female role models in engineering. These findings not only enrich the academic discourse on STEM mentorship but also offer actionable guidance for the design and implementation of more effective mentorship programmes that support women in overcoming the barriers to success in male-dominated industries.

Looking ahead, further research is warranted to examine the long-term impacts of such mentorship programmes on women's career trajectories in STEM fields. Exploring these longitudinal effects will be crucial in validating and potentially expanding the applicability and effectiveness of our proposed mentorship framework, ensuring it can adapt to and meet the needs of women engineers in various contexts and stages of their careers.

ABSTRACT

This paper offers a policy analysis of UN document on how to address sustainability in engineering education. It argues that integrating sustainability into engineering education is not only a technical matter of course curricula and teaching methods but also a matter of fostering the awareness and attitudes.

The paper first describe how engineering education has sought to integrate sustainability in terms of curricular and programmatic building-blocks that acknowledge the complexity of most sustainability challenges and the contested nature of the concept of sustainability, which is illustrated through a policy analysis of UNESCO´s two reports on engineering education (UNESCO, 2010, 2021). Second, the chapter presents the Cynefin framework in relation to sustainable development in order to acknowledge complexity and to act accordingly. Finally, the paper exemplifies some practical didactical implications of this approach to sustainability in engineering education through a discussion of three general conceptions of sustainability and the horizons they open and invite change agents to investigate.

1 INTRODUCTION

Sustainability is one of the most pressing challenges of the 21st century. It is pressing and challenging both because it has important, sometimes fatal consequences for many people and because it involves a broad and complex spectrum of interrelated economic, social and environmental issues, such as poverty alleviation, infrastructure enhancement, water availability, healthcare accessibility, and much more. The UNs Agenda 2023 (UN, 2015) has had a large impact on the global society in providing a vision of 17 sustainable development goals (SDG) that pinpoint the necessity to re-align the functioning of many institutions of society towards a sustainable development. Worldwide, private and public organizations are addressing the 17 SDGs, however the complex and interwoven nature of the SDGs and sustainability in general requires unforeseen creativity and collaboration.

Engineering education is instrumental for fostering the necessary skills for graduates to address sustainability challenges and be change agents for sustainable development. According to the UN´s Educational, Scientific and Cultural Organization (UNESCO, 2009, 2010, 2017, 2021), and the UN´s Principles of Responsible Management Education (UNPRME, 2009, 2016, 2018), higher education in general and engineering education in particular stands as a cornerstone supporting sustainable development and the 17 SDGs, however these organizations also argue that education needs change in order to enable the necessary "*transformation of how we think and act*" (UNESCO, 2017, p. 7). This is also stressed by higher education research that shows that higher education is instrumental but also that traditional course curricula and programs need to change be in order to foster the necessary knowledge, skills and attitudes (e.g. Amaeshi, Muthuri, & Ogbechie, 2019; Barth, 2015; Flynn, Tan, & Gudic´, 2018).

We have witnessed a growing effort to integrate sustainability into engineering education. In a recent bibliometric review of the literature on research how engineering education has approached sustainability since the 1990s, Narong & Hallinger (2024) identify an evolution in research trends through three periods or waves, from a first wave of research that focused mainly on curriculum development in terms of the professional competencies required by engineers to effectively address sustainability challenges, both `hard´ scientific and technical skills as well as `soft´ social skills related to creative thinking and interdisciplinary collaboration, through a second wave that focused on broader issues of program and teaching development, such as problem-based, project-based and team-based learning, to a recent wave, driven by increasing government rules and regulations, that focus on compliance to standards and certification procedures as well as how Industry 4.0 technologies can be instrumental in these processes.

Similar trends have been identified in previous reviews, for instance by Gutierrez-Bucheli et al. (2022) and Thürer et al. (2018), who identify an increasing effort to integrate sustainability into engineering education curricula, programs and teaching methods. These reviews, however, also identify difficulties and tensions. For instance, they note that many engineering educators and education programs struggle to change the senses and connotations of being and becoming and engineer. These reviews, thus, yield valuable insights into the trends and tensions involved in the integration of sustainability into engineering education in order to empower students as active and responsible change agents.

In this chapter, we argue that the integration of sustainability in engineering education is not only a matter of the technical building-blocks of engineering education curricula, programs and teaching methods, but also a matter of acknowledging complexity and this is not achieved through the application of a fixed yardstick, i.e. it is not a purely technical matter, but is a matter of awareness and attention to unforeseen elements and developments.

The remining part of the chapter is structured as follows: Firstly, we describe in more detail the difficulties involved in the integration of sustainability into engineering and illustrate this through a document analysis of UNESCO´s two reports on engineering education (UNESCO, 2010, 2021). Then, secondly, we argue that the Cynefin framework offers a conceptual foundation to sustainability and the complexities this encompasses. Thirdly and finally, we exemplify some practical didactical implications of this framework through a discussion of three general approaches to and ways of understanding sustainability and the challenges they raise for attempts to address sustainability issues in a responsible way.

2 NARRATIVE REVIEW: BUILDING BLOCKS IN ENGINEERING EDUCATION

As one of the oldest professions in the world, engineering has played a vital role in shaping the world as we know it. Engineering has helped to solve both daily problems and production needs with regards to food and water supplies, health care services as well as transportation and communication. Traditionally, engineering education has been characterized by a strong scientific and mathematical foundation for technical problem-solving. This can be illustrated with the first UNESCO report on engineering education from 2010, which defines engineering as:

"*Engineering is the field or discipline, practice, profession and art that relates to the development, acquisition and application of technical, scientific and mathematical knowledge about the understanding, design, development, invention, innovation and use of materials, machines, structures, systems and processes for specific purposes*." (UNESCO, 2010, p. 24)

As the quote states, engineering has usually been related to scientific and mathematical knowledge about materials, machines, systems and processes. Some of these solutions that engineering has contributed to, however, have turned out to create new problems, for instance regarding social and environmental sustainability. Thus, in as much as engineering have been instrumental in creating the technical underpinnings of modern society, it is also a symptom of the compartmentalization of knowledge into distinct building-blocks and the firm belief in technical problem-solving. Hence, engineering has not only caused various economic, social and environmental problems, but has contributed to the creation of economically, socially and environmentally unsustainable institutions and systems (Leifler & Dahlin, 2020).

As mentioned above, reviews of research on the integration of sustainability into engineering education shows that the early efforts often consisted of add-on sustainability courses with a very technical focus and the role of an add-on to existing programs, for instance as electives, while more recent attempts to integrate sustainability into engineering education has thus focused on more thorough integration of sustainability awareness and attitudes into programs and teaching methods (Gutierrez-Bucheli et al., 2022; Narong & Hallinger, 2024; Thürer et al., 2018). This can be illustrated with the second, more recent UNESCO report on engineering education from 2021, which is entitled *Engineering for Sustainable Development*, that stresses that:

"*Engineering is experiencing a moment of profound transformation and is facing immense challenges. As a discipline, it is expanding rapidly beyond the creation of artefact-based solutions to permeate economic, ecological and social systems. This evolution is taking place within a broader context in which the timeframe for new discoveries, new technologies, new materials and new products is becoming increasingly short. Meanwhile, the challenges facing engineering, including those encapsulated in the SDGs, are becoming ever more complex and often require multi-disciplinary, cross-country and inter-cultural solutions*." (UNESCO, 2021, p. 7)

As the quote states, engineering is facing still more complex challenges that require broad multi-disciplinary and inter-cultural competencies. The report thus suggests that engineering education must transcend traditional disciplinary boundaries and shift focus from optimizing current institutions and systems to facilitating system changes. In as much as engineering is to play a role in the transformation towards sustainable institutions and systems, it not only will have to find new technical solutions, but it will also need to adopt a broader view on how technical solutions affect economic, social and environmental systems in order to counter negative consequences such as inequality, oppression, environmental degradation and destructive climate change.

Thus the second UNESCO report goes on to argue that this requires a shift in engineering education away from a narrow technical focus towards a broader interdisciplinary and complex problem-solving approach that combines technical knowledge and solutions with societal and sustainable problem analyses (UNESCO, 2021:122). It introduces the so-called "cynefin framework" (Snowden & Boone, 2007) in order to stress that engineering education must address sustainability issues that are complex, if not chaotic. More specifically, the cynefin framework distinguishes between five different contexts one can be in regarding a problem: the context of simple problems, complicated problems, complex problems, chaotic problems and disordered problems.

"Cynefin" is a Welsh term referring to a condition of "multiple belongings", i.e. the condition of being rooted in several different places or cultures that influence how one thinks and acts, but of which one can only be partially aware, and a key point in the framework is that we usually find ourselves in the context of a disordered problem when we approach a problematic situation, and the first task, then, is to "order" or, in Schöns terms, "frame" the problematic situation at hand into either a simple problem, a complicated problem, a complex problem or a chaotic problems.

Simple problems are well-defined and characterized by clear cause and-effect relationships that are easily discernible by everyone. According to Snowden & Boone, simple problems are in the realm of "known knowns" (Snowden & Boone, 2007, p. 70), where the right answer is self-evident and undisputed. Som technical engineering problems are in this category, i.e. are simple problems that require straightforward management and monitoring in terms of command-and-control project management where directives are straightforward, decisions are easily delegated, and functions can be automated, while exhaustive communication is not usually required because disagreement about what needs to be done is rare.

Complicated problems, on the other hand, may contain multiple right answers, however although they are based upon cause-and-effect relationship, they require expertise to identify and handle. According to Snowden & Boone, complicated problems are in the realm of “known unknowns” (Snowden & Boone, 2007, p. 71), where appropriate action requires expertise within a particular field. Much engineering design is in this domain in terms of there being different acceptable solutions to a given problem. Although complicated problems require expertise, if suggestions by nonexperts are overlooked or dismissed, this may result in lost opportunities. Hence, complicated problems requires listening to experts while simultaneously welcoming novel thoughts and solutions from others, which in itself is complicated and involves a trade-off between finding the right answer and simply making a decision.

With complex problems right answers cannot be ferreted out. According to Snowden & Boone, complex problems are in the realm of “unknown unknowns” (Snowden & Boone, 2007, p. 74), where we can understand why things happen only in retrospect. Snowden & Boone stress that many business issues today appear complex because change – a shift in management, products, suppliers or customers – introduces unpredictability and flux. Instructive patterns, however, can emerge if one conducts experiments that are safe to fail. Thus, instead of attempting to impose a course of action, one must allow the path forward to reveal itself. Many sustainability problems require not only engagement with stakeholders to understand what which solutions could be acceptable but also require an experimental probe-response approach. If one does not recognize that a complex problem requires an experimental mode of management but try to over-control the situation, one will pre-empt the opportunity for informative patterns to emerge. Trying to impose order in a complex context is doomed to fail, but those who step back a bit and allow patterns to emerge will succeed in discerning opportunities for innovation and new business models.

With chaotic problems, searching for right answers is pointless. According to Snowden & Boone, complicated problems are in the realm of “unknowables” (Snowden & Boone, 2007, p. 74), where cause-and-effect relationship are impossible to determine. There are no manageable patterns, only turbulence. When facing a chaotic problem, one´s job is not to look for patterns but to stanch the bleeding. Top-down communication is imperative, since crisis demand decisive action with little or no time to ask for input. However, a danger for business developers who successfully handle a crisis is that they can develop an overinflated self-image and become legends in their own minds, and, hence, become less successful when they are not able to switch management styles to match other problems.

While we acknowledge the distinction between four kinds of problems, we do not recognize the argument made by Snowden & Boone (2007, p. 75) that chaotic problems always provide an opportunity for innovation, since people are open to novelty. This is not our experience, neither is it backed up by innovation research that suggest that innovation requires more involvement, dialogue and probing than the directive leadership that Snowden & Boone suggest. It is, however, beyond the scope of this chapter to address this issue further. Rather, we want to stress that UNESCO (2021, p. 123) makes an inspiring and instructive use of the cynefin framework to argue that most engineering disciplines are taught as simple problem solving, whereas this approach is inadequate regarding many challenges of sustainable development, since such challenges often involve not only simple or even complicated problems, but also complex and sometimes chaotic problems.

The report goes on to argue that problem-based learning (PBL), where students work in project-teams to identify problems and responsible approaches to them, is more appropriate. However, PBL is often limited to single subjects and single courses, and should, rather, be organized across subjects and disciplines, and, further, not only formulated within an academic context, i.e. ”course-based BPL”, but (also) together with stakeholders outside the academic context, which allows for even more complex and sometimes chaotic problems and learning processes (UNESCO, 2021, p. 124).

Table 1 sums up the characteristics of different kinds of problems and how they can be addressed in engineering education in terms of the key curricular elements and the learning methods that best support them.

Table 1. Different types of problems and their implications for education

Type of problem	Key characterictics	Curricular elements	Learning methods
Simple	Known solutions to known problems	Single discipline courses and subjects	Lectures and flipped classroom
Complicated	Unknown solutions to known problems	Multi-disciplinary collaboration	Academic PBL across disciplines
Complex	Unknown solutions to unknown problems	Inter-disciplinary projects	PBL involving stakeholders
Chaotic	Unknowable solutions to unknown problems	Crisis management	Training in immediate action

The UNESCO report (2021) thus makes a strong argument for a variation in problem and project types in order to allow students to work on different kinds of real-world engineering challenges and the different kinds of problems encompassed in real-world business development projects. Course-based PBL is useful in establishing an understanding of simple and complicated issues, but such academic-initiated projects may prove limited in terms of the complex and even chaotic problems involved in some business development projects.

On the other hand, collaboration with companies and other stakeholders allows students to understand the more complex and chaotic types of problems they may encounter in work settings, however such projects are often very hard to control as part of an academic curriculum as problems can lead in directions not anticipated at the outset. Hence, while Snowden & Boone suggest that students can learn to handle only simple and complicated problems and not complex and chaotic problems, which rely on “natural capabilities” (Snowden & Boone, 2007, p. 76), the UNESCO report suggest that the Cynefin framework is instrumental for organizing projects of various sizes and types of problems and learning outcomes. Projects can range from being course-related and academically initiated projects to those initiated by different societal actors, e.g. in the form of a student project in collaboration with a company, or a project identified and formulated by a group of students developing a business idea and business model themselves.

In the following section we will argue that this framework provides a didactic framework for addressing complexity regarding sustainable development in general and the 17 UN sustainable development goals in particular.

3 ENGINEERING AND SUSTAINABLE BUSINESS DEVELOPMENT

In this section we will exemplify some practical didactical implications of the Cynefin framework through a document analysis of reports and policies UNESCO and UNPRME. The document analysis identifies three general conceptions of sustainable development: a narrow, economic conception of sustainable development, a broader, balanced conceptions of sustainable development and a deeper, systemic conceptions of sustainable development. We use the metaphors of a "narrow", "broader" and "deeper" conception to illustrate the point made above that a conception like a horizon indicate what can be seen from a particular vantage point and, as such, it is at the same time enabling and limiting. It can be narrow, but at the same time also be opening up, and *Bildung* is exactly the ability to keep oneself open and, thus, being able to open up a limited horizon in the search for a better, more holistic understanding of sustainable business development.

A narrow understanding of sustainable business development

Traditionally, sustainable business development has predominantly been conceived of in economic terms and by reference to economic indicators such as revenue and profit. This understanding of sustainable business development thus represents "business as usual", i.e. a narrow understanding of business development that only stresses economic concerns. Both UNESCO reports (UNESCO, 2010, 2021) and UNPRME reports (UNPRME, 2016, 2018) stress that the narrow, economic understanding of sustainable business development has been dominant in engineering business education. For instance, one UNPRME report states that "*business school students are exposed to economics and finance courses based on a Homo economicus view of human nature*" (UNPRME, 2016, p. 9), e.g. by giving primacy to self-interest and shareholder value. As the quote indicate, the narrow, economic understanding of sustainable development is grounded in business and management traditions of taking the environment for granted. People and the natural environment are viewed as available resources which are separate and susceptible to control, and consequently they are not accounted for but are, rather, taken for granted and treated as externalities. Underpinning this understanding is an assumption of unlimited growth via increasing consumption of products and services.

The practical implication of this narrow, economic understanding of sustainable development is that economic concerns are understood as the main focus of business and business research. The didactical implication is that business education (and research) should relate to the economic content of traditional business dimensions finance, accounting, marketing, organization behavior, strategy, etc. Social and environmental issues are addressed as add-on concerns as if such issues are not relevant for running a successful business (Sharma & Hart, 2014).

Although the last decades have seen increasing recognition of environmental problems, the narrow, economic understanding of sustainable development is still widespread in engineering educations, and is a huge obstacle to real change in curricula and education programs. In the sustainability literature, this mindset is made explicit in hierarchical pyramid models (e.g. Carroll, 1991), which rank management concerns in order of relative importance, with economic concerns depicted as primary followed by legal, ethical and finally philanthropic concerns. Thus, the one-dimensional economic concern that if a business does not make a profit then it will not survive, and other concerns become a moot point (Masoud, 2017).

The profit-first mindset is implicit if not explicit in many models of management and creates strong norms for business behavior that can easily become self-fulfilling (Ghoshal, 2005), and efforts to integrate sustainability into engineering and management education risk being cosmetic green washing, predominantly due to the reluctance of textbooks, teaching staff and program directors to change their basic mindset (Baden & Higgs, 2015).

However, the Cynefin framework suggests that sustainability issues are more complex than this. For instance, even when the economic concern is taken as a starting point, one can justify a broader understanding of sustainable development in economic terms by investigating whether social and environmental responsibility can be profitable, for instance if they cut energy and material costs or offer good marketing opportunities (Brooks, 2010). With routine references to “efficiency” and “the bottom line” this might remain a feasible stance. However, the Cynefin framework would still consider this conception one-sided and limited and would seek towards other, more complex understandings of sustainable development.

A broad understanding of sustainable development

As mentioned, the second UNESCO report on engineering refers to the United Nations 2030 Agenda and the 17 SDGs and stress that enterprises today must integrate in a balanced manner the economic, social and environmental dimensions of sustainable development (UNESCO, 2021, p. 13). This broad understanding of sustainable development also dominates the UNPRME documents (UNPRME, 2016, 2018). For instance, they argue that the United Nations sustainable development goals are fundamental to the contemporary corporation need to balance environmental, social and economic considerations.

The broad understanding of sustainable development dates back to, at least, 1987 and the Brundtland Commission report, a report of the UNs World Commission on Environment and Development (WCED), which defined sustainable development as the ability to “*meet the needs of the present generation without compromising the ability of future generations to meet their own needs*” (WCED, 1987, p. 8). This report thus argued for a broad understanding of sustainable development that balance different needs, costs and benefits. Using scientific evidence to mobilize public awareness of the toxic side effects of industrial progress, the Brundtland Commission showed the risk of unproblematic commitment to economic growth and challenged business schools and business developers to incorporate a broad understanding of sustainable development into their curricula that balance economic, social and environmental concerns. Underpinning the broad, balanced understanding of sustainable development is the idea business developers face complementary concerns

The implication of the broad understanding of sustainable development is that business developers should understand both economic, social and environmental concerns and relate to the balances and trade-offs between them. Social and environmental concerns, then, should not just be an add-on, but should be built into existing functional areas and activities of management. For instance, these functional areas should address issues related to multiple bottom lines and thus integrate sustainable development goals into corporate strategies and operations (Chen, Wu, & Tsai, 2018).

Often, this mindset is illustrated in a Venn diagram that place sustainability at the intersection of environmental, social and economic concerns, which is also called the 3 P´s: profit, people and planet. Thus, business developers have several concerns and should seek a balance between concerns related to profit, people and the planet. The ideal overlap resides at the center of the diagram where economic, social and environmental concerns are simultaneously fulfilled, but other pure and partly overlapping segments create situations which also represents situations that one may face in the business world. A company may develop products or services for new markets or strategize to position itself as an environmental leader in an established market. The integration of environmental concerns into corporate strategies has become increasingly meaningful as customers in some markets want to see corporate environmental performance. As social and environmental problems have pervaded all areas of daily life, including business life, many corporations seek the business opportunities in them. Business developers, then, should not only relate to social and environmental content, but should counter the profit-first mindset.

The Cynefin framework would, however, invite us to seek even more complex relationships between economic, social and environmental systems.

A deep understanding of sustainable development

The broad understanding of sustainable development that promotes a balance between economic, social and environmental development dominates the recent UNESCO report (UNESCO, 2021) and UNPRME report (UNPRME, 2018), however these reports also entails elements that reflects a genuine systemic understanding of sustainable development that involves deep and thorough changes. Thus, it is emphasized that sustainable development entails both sustainable production and consumption with a view to decoupling economic growth from environmental degradation and enabling the transition to a circular economy, which involves building capacity to ensure environmental sustainability in the pursuit of the green growth.

For instance, the recent UNESCO report states "*megatrends, such as green and digital transitions, are also re-shaping the engineering landscape and educational requirements. The engineering education system needs to be reassessed and fully shift to technological problem-solving with an holistic approach that considers the impacts of engineering innovations and activities on the environment and on society more generally.*" (UNESCO, 2021, p. 154) Similarly, referring explicitly to the 17 sustainable development goals, UNPRME documents argue that sustainability involves new ways of organizing, such as shared value creation, social innovation, social entrepreneurship, diversity and gender equality issues, sustainable cities, circular and sharing economies, etc. (UNPRME, 2016, p. 4)

Underpinning the deep, systemic understanding of sustainable development is the assumption of the inherent value of ecosystems, which has deep historical and philosophical origins in ideas that emphasize the complex, interrelated, non-linear and therefore unpredictable nature of the world (Keulartz, 1998). The concept of “circular economy” has been developed by, among others, Stehal (2006, 2019), and is today promoted by several NGOs, such as the Ellen MacArthur Foundation, that have become influential in putting the circular economy concept on the agenda of policy-makers around the world. Criticizing the linear take-make-waste model of production and consumption, the concept of “circular economy” aims to redefine growth by decoupling economic activity from the consumption of finite resources, and designing waste out of the system. The transition to a circular economy, then, does not only amount to adjustments aimed at reducing the negative impacts of the linear economy but requires a systemic shift (EllenMacArthurFoundation, 2019).

The implication of this understanding of sustainable development is that business developers should understand corporations as part of a natural eco-system, i.e. a network that sees nature as the primary stakeholder, and establish closed-loop, cradle-to-cradle production systems in order not only to reduce the use of natural resources but renew them. Production and consumption should be conceived of as a circular borrow-use-return process, which if often energy and resource intensive (Stahel, 2019). As part of a systemic business environment and network, corporations should cooperate to minimize environmental degradation, for instance by building and sharing infrastructure to support recycling and renewable energy. By aiming for zero waste, corporations take responsibility for the complete life-cycle of its solutions. End-of-life products are recycled to produce new products in an industrial eco-system, recognizing that earth´s resources are finite (EllenMacArthurFoundation, 2019). A prosperous economy depends on social and ecological health and integrity and vice versa. Systemic thinking, then, involves seeing corporations as part of an interdependent ecological system where they may be facilitating the health of the whole population and of the long run. Systemic thinking draws attention to the networks in which the corporations partakes and without which they could not exist. According to a systemic view, corporations are embedded within valuable social and environmental systems that are internally linked to one another and thus inseparably intertwined.

The above analyses shows that UNESCO and UNPRME reports present different conceptions of sustainable development. We argue that it requires more than technical competence to recognize the distinct understandings and the different types of problems they encompass and to respond appropriately. The narrow, economic conceptions of sustainable development value economic concerns first and views social and environmental concerns as possible attachments, i.e. as add-ons, “bolted-on” to existing program curricula, for instance as electives that serves to satisfy a demand among students or policy makers. This understanding of sustainable development, then, only entails a very small commitment to reform business development in response to United Nations SDGs. The broader, balanced conceptions of sustainable development on the other hand entails a greater level of commitment to such change in business and management and research interests. This conception of sustainable development ascribes equal value to economic, social and environmental concerns and thus suggest that social and environmental content is integrated into the curricula, i.e. built-into the core courses on different functional areas and disciplines. The systemic conception of sustainable development entails an even stronger commitment to fundamental changes in response to United Nations SDGs. This conception of sustainable development views corporate systems as interdependent to social and environmental systems and thus suggest that business practices are re-imagined and re-designed with social and environmental content constituting core elements, i.e. with management courses being build-up around social and environmental concerns.

4 CONCLUDING SUMMARY

Sustainability is generally acknowledged as the most pressing challenge of the 21st century. We have argued that engineering education is instrumental for fostering the necessary skills for graduates to become change agents for sustainable development, however most efforts have focused on changing the building-blocks of engineering education in terms of the curricula, programs, and teaching methods, whereas we argue that integration of sustainability into engineering education require a focus on complexity.

We find the Cynefin framework particularly relevant to engineering education in order to address how many sustainability problems require not only technical competencies, but also an open awareness and attitude in terms of a continuous effort to understand more. Not in order to look away from what we currently focus on and tries to achieve, but in order to understand it better, within a larger whole. Such an awareness and attitude can be designed into engineering education through by allowing students to work on different kinds of engineering challenges in real-world development projects. Collaboration with companies and other stakeholders allows students to understand the complex and chaotic problems of real-world development projects.

Approaches to business development have been dominated by a narrow economic conception. The Cynefin framework invites us to seek to open up to other, more complex conceptions of economic, social and environmental systems and the relationships between them. Sustainable development is rarely simple, but rather often complex or even chaotic, involving competing and conflicting elements and perspectives. Sustainability never comes to an end. Understandings are produced and reproduced as traditions move. This need to be acknowledged in order to recognize the limits attached to any understanding of sustainable development that aspires to be sufficient.

Rather than focusing on one understanding of sustainable development, engaging with different understandings helps to understand sustainable development from different perspectives and to respond appropriately, i.e. to act responsibly. The strengths and weaknesses of specific conceptions of sustainable development need to be recognized in order to address their opportunities and limits. Sustainable development, then, is both indispensable and problematic, and business developers need to develop the ability to be open to new and better ways of understanding, while acknowledging that understanding is a continuous process. Hence, we cannot wait to act but must act responsibly as we go along, continuously trying to understand and act in better ways.

ABSTRACT

This practice paper introduces the project-based approach of the Center for Project-Based Learning within the Department of Information Technology and Electrical Engineering of ETH Zürich. This center's approach to education is built around a three-stage education model that includes projects early on in the students' educational journeys, gradually increasing their complexity in alignment with their growing level of experience. This approach ensures students develop both technical expertise and essential professional skills necessary for their engineering careers, scaffolding course work, small scale group projects and interdisciplinary flagship projects. The center is further enhanced by an evidence-based approach to

[2] *Victoria Abou-Khalil*
victoria.aboukhalil@epfl.ch

continued improvement, using regular surveys, reflective journals, and research findings to refine course design and supervision. Students have reported high satisfaction levels with the courses, expressing that the projects aided their understanding of future aspirations and helped develop crucial soft skills, notably in collaboration, communication, and presentation. Projects focus on real-world applicability, ensuring students are well-prepared to tackle real-world challenges, with many focusing on contemporary problems in areas such as sustainability.

1 INTRODUCTION

The rapidly evolving technological landscape, accompanied by the rise of automation, has transformed the skills demanded by industries ("The Future of Jobs Report 2020 | World Economic Forum," 2020). In the field of engineering, professionals are now required to serve as effective intermediaries between human workers and automated systems. Recognizing these changing demands, prominent engineering accreditation bodies, such as ABET and the European Network for the Accreditation of Engineering Education (ENAEE), have incorporated professional skills into their criteria for accrediting engineering programs. Consequently, engineering programs have increasingly embraced inquiry-based learning approaches like Project-Based Learning (PBL) over the past five decades to enhance learning outcomes and foster the development of essential professional competencies (Bielefeldt, Paterson, and Swan 2009; Chen and Yang 2019; Jamison et al. 2022).

Numerous studies have shown that project-based learning equips students with a wide range of skills (Habbal et al. 2024). By engaging in projects, students develop problem-solving abilities as they tackle complex problems, break them down into manageable parts, evaluate multiple solutions, and make informed decisions (Finkelstein et al. 2011). Moreover, PBL cultivates positive attitudes toward learning (Holmes and Hwang 2016) and fosters collaboration, as teamwork often plays a vital role in project-based settings (Kaldi, Filippatou, and Govaris 2011). However, a notable gap remains between the competencies of graduates and the expectations of employers (Markes 2006; Nair, Patil, and Mertova 2009; Ramadi, Ramadi, and Nasr 2016). Frequently, students encounter projects only during their capstone projects, limiting their opportunities for competency development (Dutson et al. 1997). Delaying the practical application of professional skills until late in the curriculum can leave students ill-prepared for their future careers. Therefore, it is crucial to provide early exposure to projects, enabling students to face challenges repeatedly and better prepare them to address complex societal problems.

The Center for Project Based Learning at ETH Zürich was set up to provide project-based education to all the students of the Department of Information Technology and Electrical Engineering, regardless of their backgrounds and past academic achievements. The center aims to promote activities that involve projects early on in students' educational journeys, gradually increasing their complexity in alignment with their level of experience. Furthermore, interdisciplinary projects are emphasized, allowing students to collaborate and tackle real-world problems throughout their courses, theses, and interdisciplinary team projects. As a final culminating step in their project-based learning journey, they may participate in a so-called flagship project, where students from diverse backgrounds combine their unique skills and perspectives to tackle complex real-world problems in larger teams and in collaboration with external stakeholders. Our approach, which is built upon interdisciplinarity and collaborative problem-solving, promotes innovation by encouraging new forms of knowledge transfer, interaction, and independent learning. The center's approach is built on evidence-based practices from the ground up, with a focus on the development of essential skills. Additionally, the center conducts regular assessment of its courses and projects. The use of comprehensive evaluation methods, such as pre-and post-project surveys and weekly reflective journals, enables the center to effectively assess and monitor student progress. Through this feedback, the center continuously refines its course design and pedagogical approaches to enhance student engagement and optimize learning outcomes.

2 THE STRUCTURAL MODEL OF THE CENTER FOR PROJECT-BASED LEARNING

In this section, we will discuss how our curriculum is structured. Specifically, the center as adopted a three-stage education model that emphasizes a scaffolded progression of project-based learning and skill development, as shown in Figure 1.

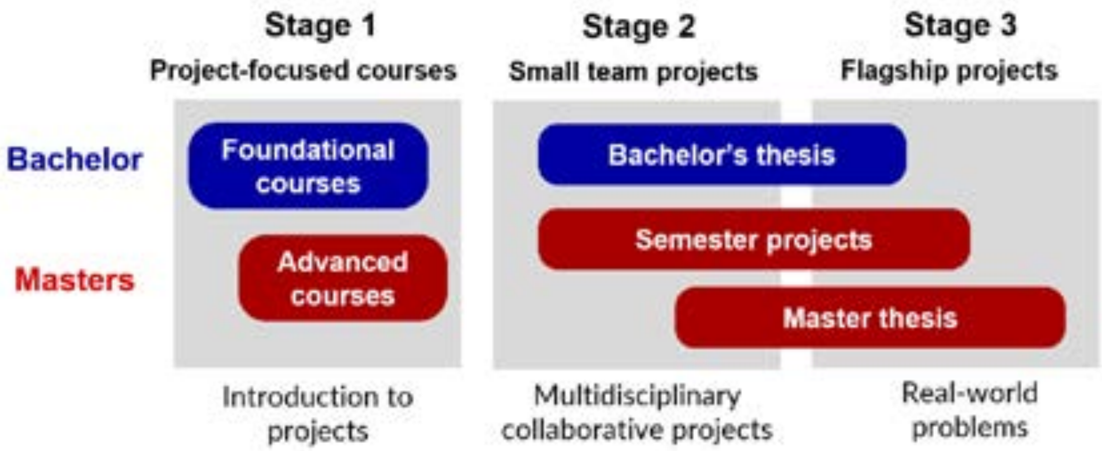

Fig. 1. Overview of the 3 stages and the feedback for constant monitoring

This model is built upon the realization that in the realm of engineering education, it is important to go beyond lectures and theoretical concepts, and instead create an environment that fosters practical application and hands-on experience. First, at both the Bachelor and Masters level, students participate in course work. These courses not only teach the theoretical foundations, but already incorporate significant project-focussed elements. Next, both groups of students have the opportunity to then participate in standalone projects, as part of their Bachelor's thesis, their Masters thesis or one or more semester projects (for Masters students).

As students move from project-focussed course work to projects, they progress through the three stages of our PBL model structure. This three-stage model captures the scaffolded nature of the student learning experience, where they progress from guided problem solving (stage 1) to small team projects (stage 2) to large complex multidisciplinary flagship projects (stage 3).

This three-stage model can also be understood in how it maps directly to three stages of problem solving. An important strength of project-based learning is that it has been recognized as a premier approach to teach students practical problem solving. This is extremely valuable, as the ability of be an effective problem solver is one the key skills that engineers need to possess [NACE 2023]. Our three-stage model can be viewed through the lens of progressively building students' problem-solving skills, which follow a similar progressing ("Problem-solve like an Expert", 2024). This is illustrated in Figure 2. Starting at the bottom, in their course work, students are doing projects and labs that relate directly to the technical core of these courses. Here, they need to apply debugging techniques, or more generally troubleshooting, where the challenge is to find why something that should be working is not. Progressing to small team projects, students are challenged with domain problem solving, which focuses on solution development: exploring how can a specific technical problem be solved. Finally, in the flagship projects, the problems become increasingly broad, where solutions need to become multidisciplinary and may combine expertise from a wide variety of fields. This requires students to develop their problem identification skills, focusing on exploring the problem space to find the point of high impact. Our structured progression of students through their PBL journey maps directly to the exposure to and practice with these increasingly advanced problem-solving skills.

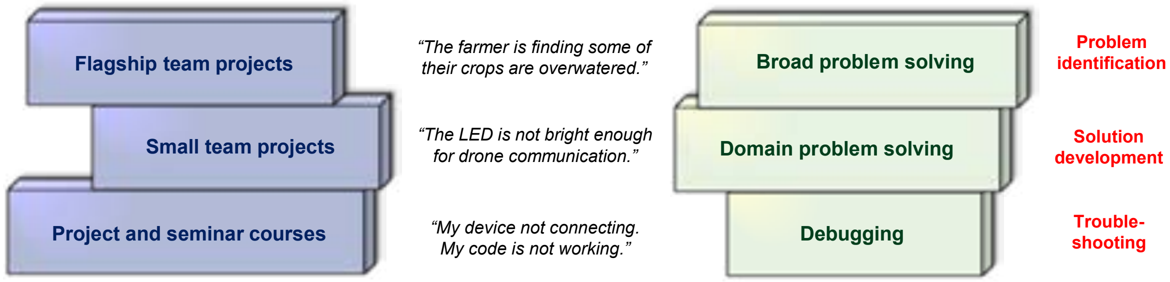

Fig. 2. Progressive development of problem solving skills

Note that, as suggested by Figure 1, there is crossover between the functional aspects of curriculum (course work versus thesis) and the structural aspects (stages in our model). A student's bachelor thesis, for example, can take the form of a small team project or be integrated into a flagship project. On the other hand, a flagship project may involve a heterogeneous team of students, with some being involved as part of their Bachelor thesis, others as part of a semester project and yet others as part their Masters thesis, with roles within the project commensurate with students' level of expertise. We also encourage interested students to write and publish papers on their projects. In the next section, we will elaborate on each of the three stages of our model in turn.

3 IMPLEMENTATION OF THE COMPREHENSIVE PROJECT-BASED LEARNING APPROACH

3.1 Stage 1: Building a strong theoretical foundation with practical applications

The initial stage of our model focuses on providing students with a solid theoretical foundation through project-focused courses. These courses convey fundamental knowledge in various engineering disciplines, ensuring students grasp the principles and concepts that form the basis of their future projects. The theoretical parts of each of these courses is supplemented with hands-on experiences, including laboratory work and small-scale projects. By combining theory and practice, students gain a deeper understanding of engineering principles and the ability to apply them to real-world scenarios.

At the bachelor level, the center offers over 15 project and seminar courses, where students engage in laboratory experiments and fieldwork, working with actual equipment, analysing data, and troubleshooting problems. This stage bridges the gap between theory and practice, enhancing students' problem-solving skills, specifically troubleshooting, and equipping them with a practical mindset. The projects are carefully designed to provide students with a solid foundation and prepare them for more complex challenges ahead. Each course prioritizes student engagement and follows a structured format, with exercises to deepen theoretical understanding and self-chosen projects for practical application.

At the masters level, more advanced courses also combine theoretical study with more extensive project work and project-based course assessments. As an example of such a course, in Machine Learning on Microcontrollers, students engage in a comprehensive 5-week project in small groups, culminating in a live demo showcasing of their intelligent sensor systems. By emphasizing practical application, students gain valuable hands-on experience, a strong foundation in realistic implementation and important industry-relevant competencies.

3.2 Stage 2: Cultivating collaboration with small team projects

As students progress in their education, they enter the second stage, which revolves around collaborative small team projects during their thesis (at the Bachelor or Masters level) and/or semester projects (at the Masters level). Working in small teams of 2 to 4 students, these projects provide an ideal opportunity for students to apply and expand upon the competencies gained in the various courses The projects are specifically designed to foster teamwork, communication, and project management skills. Working in teams, students tackle engineering challenges that require the integration of knowledge from various disciplines. This stage not only enhances their technical expertise but also cultivates their ability to collaborate effectively and think critically as a team.

An example of a recent small team project is the Smart Sailing project, initiated in September 2021. This project involves the collaboration of 7 bachelor theses and one semester thesis. The goal of the project is to build a fully autonomous and energy-sustaining boat capable of sailing independently and competing in international student competitions. Another example is the Test Environment for Solar Cells, which ran from the autumn of 2022 to the summer of 2023. This project involved 5 bachelor theses dedicated to developing a comprehensive test environment for solar cells. By utilizing approximately 3000 LEDs within the testbed, adjustable between 1 and 100,000 lux, the environment allows for evaluation under a wide range of lighting conditions, from indoor room lighting to outdoor sunlight, offering a unique vehicle to optimize energy harvesting circuits.

3.3 Stage 3: Confronting real-world complexity through flagship team projects

The third stage of our education model immerses students in advanced team projects, called flagship projects. By this stage, students have acquired a solid theoretical foundation, practical experience, and the ability to work collaboratively. The flagship projects are ambitious undertakings that simulate real-world engineering scenarios. Students can get involved with multi-year efforts, some revolving around engineering competitions, while others are conducted in collaboration with external stakeholders, such as industry or community partners, resulting in the development of real products. These projects immerse students in the complexities of budget constraints, time management, and interdisciplinary coordination, preparing them to tackle the challenges they will encounter in their future careers.

An example of a flagship project is our Autonomous Robot Dog for Assistant Living. The primary objective of this project is to develop an intelligent sensor subsystem that enables autonomous control of the robot to assist individuals with visual impairments. Since its inception in February 2022, this project has already involved two bachelor theses, a group project comprising three bachelor students, nine semester projects, and two Master theses.

4 An Evidence-Based Approach to Continuous Improvement

To support the center's evidence-based mission, it has a learning scientist affiliated with it. This learning scientist conducts regular surveys, consisting of pre-tests and post-tests, to assess improvements in various areas, including entrepreneurial education and motivational aspects. Additionally, students are assigned weekly reflective journals, providing a dynamic overview of their progress. Regular meetings between the learning scientist, lecturers, and supervisors ensure that course design and supervision are constantly refined based on insights derived from survey results. The monitoring results are compiled into bi-semester reports, which are shared with the instructors, accompanied by individual feedback. These reports incorporate the components of all three stages, i.e., bachelor courses, small team projects and flagship team projects.

Figures 3, 4 and 5 show extracts from an evaluation report of the project-focused courses (Stage 1), which is based on surveying 70 students at the semester's end. Figure 3 presents both technical and soft skills that students self-reported learning during the semester. The most prevalent technical skills reported were Python and microcontrollers programming, while the most prevalent soft skills included communication, teamwork, and presentation skills.

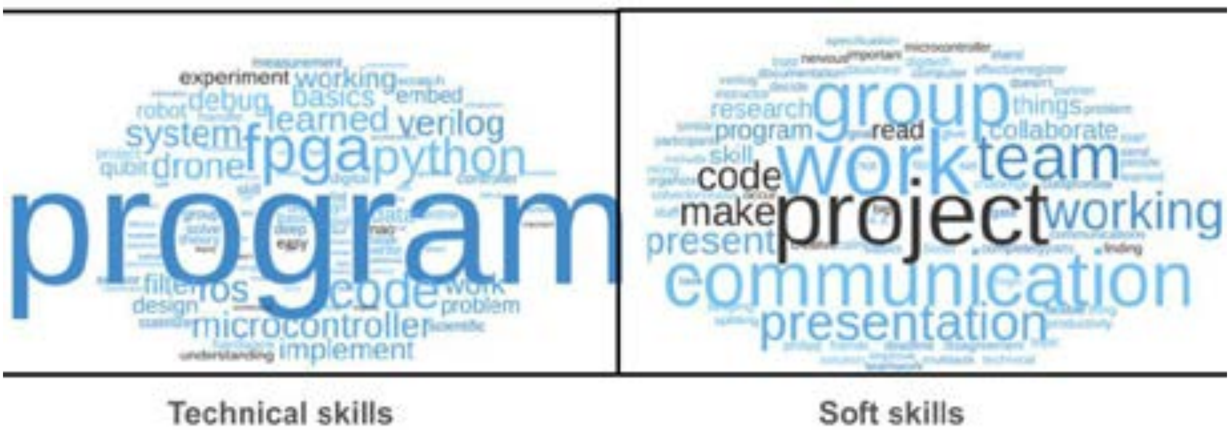

Fig. 3. Word cloud based on the answers of the students to the question "Which technical/soft skills did you learn during this course? Write N/A if you did not learn any."

Looking at student sentiments, Figure 4 illustrates that around 70% of students reported gaining deeper insight into their future aspirations after completing the project. In Figure 5, a comparison of student satisfaction across the six following courses is presented: Introduction to program Nao Robots for Robocup competition, Embedded Systems with Drones, iCEBreaker FPGA For IoT Sensing Systems, Autonomous Cars and Robots, Embedded Deep Learning with Huawei Atlas 200 AI Dev Kit, Microcontrollers for Sensors and Internet of Things, and FPGA in Quantum Computing with Superconducting Qubits.

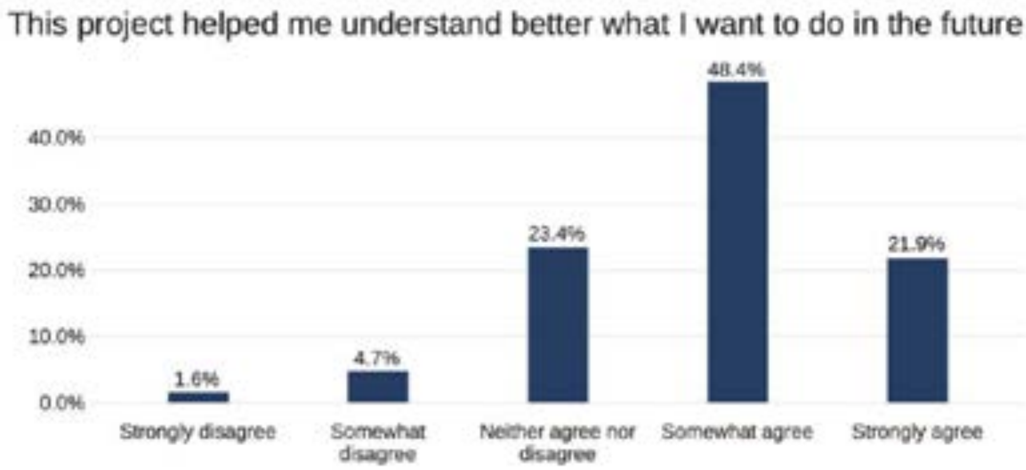

Fig. 4. Student sentiment data on future aspirations

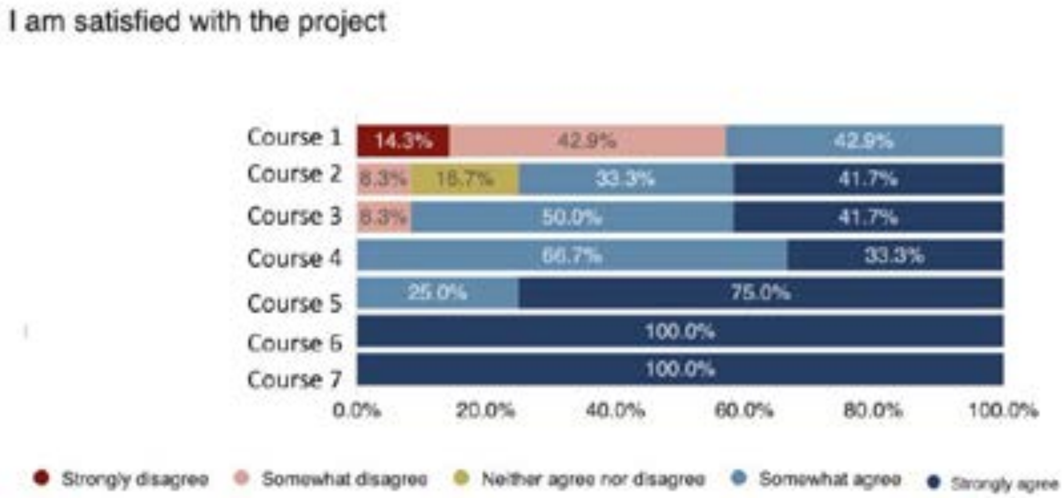

Fig. 5. Student satisfaction with project-focused courses

In addition to these formative assessments of our PBL program, a formal pedagogical study was also conducted in the center. It showed that the project-based learning activities that are integrated into the practical courses offer students more opportunities to develop professional skills compared to traditional exercise sessions(Abou-Khalil, Magno, and Kapur 2023)

3 CONCLUSION

In this paper, we have described the organizational model of PBL in the Center for Project Based Learning at ETH Zürich. It is built upon a strong commitment to student engagement, interdisciplinary collaboration, industry alignment, and sustainability in engineering education through project-based learning. Through a three-stage education model, encompassing bachelor courses, collaborative small-team projects, and flagship projects, we provide students with comprehensive learning experiences that combine theoretical knowledge with practical application. By explicitly fostering student engagement through various tools, methods, and measures, we ensure that students acquire not only technical expertise but also the ability to collaborate effectively and think critically in a team. Moreover, our flagship projects serve as a platform for interdisciplinary collaboration, allowing students to pool their diverse skills and perspectives to tackle complex, real-world challenges. These projects also provide students with valuable industry exposure, aligning their education with industry expectations and preparing them for successful careers. By participating in competitions focused on sustainability, energy efficiency, and other relevant areas, students can showcase their skills, gain recognition, and establish connections within the professional community.

ABSTRACT

The purpose of this practice paper is to present the approach we have undertaken at WMG, University of Warwick, UK, to use popular films to support Research Methods (RM) teaching and learning. RM is a vital component of postgraduate engineering courses, as students build skills for evidence-based practice. Students' learning and grasp of RM threshold concepts can be improved by using active learning approaches. Popular films have been used to support teaching and learning in various disciplines. Evidence suggests that using them can enhance student engagement and learning. However, literature discussing the use of popular films to

[1] *NI Makrinov*
n.makrinov@warwick.ac.uk

teach RM is scarce. We present a case study of our current practice organising a RM Film Club as a co-curricular activity for postgraduates. The Film Club has been co-created by an academic member of staff and three PhD students who are also Graduate Teaching Assistants in a RM module. We share our experience and the films we have curated to support reflection. We present an outline of ongoing research in which we are exploring how postgraduate students perceive the use of popular films in supporting the teaching of RM. To finalise, we reflect that our experience organising the RM Film Club has been positive as we perceive students enjoy the event and have learnt about RM in a fun environment. Further research on the impact of the intervention is needed. We encourage educators to consider similar approaches.

1 INTRODUCTION

The purpose of this practice paper is to present the approach we have undertaken at WMG, University of Warwick, UK, to use popular films to support Research Methods (RM) teaching and learning. We provide a literature review of common approaches of teaching research methods, the use of films in teaching and learning, and how films can be used as a part of engineering education's pedagogical toolbox. We then present initial reflections from our practice in using popular films in teaching RM to engineering and management postgraduate students, and preliminary results from an ongoing research project on how postgraduate engineering and management students perceive a co-curricular Research Methods Film Club in supporting their learning. This is an exploratory project focused on students' reflection on their learning RM, such as how research can be conducted, how to design experiments, and understanding of research paradigms. We invite engineering educators to explore further how films might be used in their settings and areas of expertise.

1.1 Teaching Research Methods to engineering students

Teaching research methods is an important part of many academic programmes. The aim of these courses is to provide skills that students can use during their studies and in their careers, when they need to gather, evaluate, and utilise data or research information. In engineering courses, where students are required to design, test, or enhance engineering solutions -such as optimizing manufacturing flows or improving material properties -RM is foundational (Escudero-Mancebo, 2023). RM in engineering courses supports students to learn to evaluate, conduct research and apply this knowledge to practical problem solving and product assessment (Baekgaard and Lystbaek, 2019). To successfully identify what and how to teach research methods to engineering students can be a challenging task because engineering research involves a wide range of disciplines, and it can adopt many methods. In a recent review of engineering design RMs, Escudero-Mancebo et al. (2023) found that no single method or approach could be applied. Instead, a wide range of data collection methods and approaches have been adopted. Notably, qualitative methods have been significantly preferred, possibly due to the recognition of engineering design as a complex process that affects humans and their environments (Escudero-Mancebo et al., 2023). The diversity of RMs in engineering research is also evident from recent calls for more transdisciplinarity and convergence with methods commonly employed in social science research, as engineering researchers see the value of involving human and organisational considerations within their practices (Szajnfarber and Gralla, 2017; Lenberg et al. 2023). Hence, postgraduate RM courses in engineering must provide students with the understanding of a variety of methods which they might use in their academic and professional research.

Threshold concepts can provide a framework to define foci for RM teaching. Defined as topics or themes that transform student's understanding of a subject, they hence play a crucial role in development of knowledge (Barradell 2013; Olaniyi, 2020). Threshold concepts in RM include the research process, setting a problem, question, and objectives, understanding constructs and operational definitions, and research approaches and designs (Manyiwa 2003). In addition, writing up research findings might also be considered a threshold concept (Harlow and Peter 2014; Humphrey and Simpson 2011; Johnson 2014). In our experience working with diverse postgraduate students enrolled in postgraduate education in engineering and management, the concepts students find most troublesome and transformational include diverse research paradigms, research ethics, and the integration of human participants in engineering research. To help students grasp threshold concepts requires a teaching approach that helps to understand, interpret, and apply content (Zepke, 2013:99). For example, Olaniyi (2020) used flipped lessons to increase active learning and comprehension of threshold concepts in thermodynamics lessons. Other pedagogical approaches should also be considered, such as using multimedia to support delivery.

1.2 The use of popular films in teaching and learning

The idea of using popular films in teaching and learning is not new. For example, in the UK the membership organisation Learning on Screen (n.d.) has been working to promote the use of film in higher education and research since 1948. This method has also been used in primary and secondary education, for instance teaching history in US ninth-grade classes (Stoddard, 2012). Films have also been recognised as one of the most effective ways to engage with students from different cultural backgrounds, helping to learn about different cultures and languages (Wang, 2009; Nur, 2016). Some research suggests that university teachers integrate popular films in their practice (Goldenberg, Lee and Obannon, 2010). However, in our experience it is a method that is not widely used in engineering education. Despite that, the use of popular films in teaching can function as an active learning method and provide an opportunity for students to reflect deeply on issues covered in class (Blasco, Moreto, and Pessini 2018).

Kankal et al. (2023) presented a systematic literature review on the use of films as a pedagogy tool in management education. They report that three themes emerged from their study: at the 'Teacher-level' research points to the need to prepare, select and connect themes from films to the subject, at the 'Teacher-student-engagement-level' films encourage active learning and deep learning, and at the 'Students learning experience-level' films encourage reflection, camaraderie and challenge perceptions of the subject. Yesildag and Bostan (2023) found that, for undergraduate health management students, watching a feature length film followed by discussion with a teacher had a significant impact on students' exam results, when compared to students who did not watch a movie or watched it without guidance. Additionally, they found that student satisfaction with this teaching method was high due to its more engaging nature in comparison with traditional lecturing. Rather than watching full feature films, some teachers use film excerpts: Blasco, Moreto, and Pessini

(2018) used film clips to teach ethics to medical students. They found that sharing life stories from films increased discussion and the recognition of emotional responses to case studies. In a similar approach, Moskovich and Sharf (2012) integrated films in their “Introduction to Sociology" and "Organizational Behavior" courses to enrich sociological and organizational learning, engaging students through cinematic examples to concretize abstract concepts, facilitate critical analysis, and encourage reflective discussions on theoretical applications. It is evident from this research that the decision to integrate films into teaching should consider the aims for which they are used and the format in which they will be shown.

Moreover, the choice of films is also an important consideration. Pandey and Ardichvili (2015) employed the film "Outsourced" for teaching intercultural concepts within higher education settings in India and the United States, effectively raising awareness of cultural differences, stimulating discussions on stereotypes and adaptation processes, and enriching students’ comprehension of cross-cultural communication and cultural intelligence. Toye et al. (2015) utilized the film 'Struggling to be Me' in clinical education to present insights into chronic pain, fostering students' deep understanding of patients' personal struggles, the limitations of the medical model, and emotional responses to despair. Considering the messages to be picked from each selected film requires the active involvement of the teaching team.

1.3 Research methods teaching and learning through popular films

Despite its widespread application across various fields, the use of films in teaching research methods seems uncommon, with relevant research being very limited. Tan and Ko (2004) explored the use of feature films in an undergraduate research methods course, addressing the challenge of teaching the fundamental role of empirical evidence in sociology. They concluded that using a film as part of an observation task allowed students to observe the same phenomenon and learn through reflection by comparing their findings. It must be noted that full length feature films were used as examples of social phenomenon and not as research methods examples. Only the article by Saldaña (2009) outlines the use of film in graduate-level qualitative research methods courses as an innovative instructional strategy. By employing cinematic excerpts, Saldaña aims to clarify complex concepts, stimulate classroom discussion, and enhance students' understanding of qualitative inquiry. For example, they use an excerpt from The Matrix (Wachowski and Wachowski, 1999) to discuss epistemology and ontology, and an excerpt from The Silence of the Lambs (Demme, 1991 in Saldaña, 2009) to explore phenomenology. Feeback from graduate students indicated that using film clips is “novel, motivating, enjoyable to watch and help clarify concepts” (Saldaña, 2009: 259).

Building on this foundation, our practice seeks to extend the application of the use of films within educational settings, specifically focusing on using films to deepen postgraduate students' understanding of research methodology, including aspects such as research paradigms, ethics in research design, and formulating research questions.

2 CASE STUDY: RESEARCH METHODS FILM CLUB

Since January 2024, we have offered a Research Methods Film Club as a co-curricular activity open to all current postgraduate students at WMG, most of whom are enrolled in full-time master's courses (around 1,500 vs around 250 PhD students). In this section, we describe the Film Club and present our initial reflections.

2.1 Co-creating a Research Methods Film Club

One of the authors wondered how popular films could be used to enhance the student experience around RM learning. They were aware of the excellent resource provided by Learning on Screen (n.d.), which makes copyright approved video and film recordings available for teachers. They proposed that a Film Club might provide a fun experience, while also giving space for reflection on research related threshold concepts. Three Graduate Teaching Assistants (GTAs) joined the project as student co-creators; as current PhD students, they brought their personal perspective and understanding of RM.

We agreed that each session would include a teacher led introduction to the week 's theme and how the firm relates to it, a film screening, and a plenary Q&A session. Including students as co-creators in this project provided insights on what contents might be useful for attendees. For example, GTAs suggested that reflection questions were posed before watching each movie. They also provided guidance on which concepts might need deeper explanations and which methods we could use to introduce them (e.g. choosing existing videos, teacher talk).

The teacher chose the first two films. Attending students have since been able to choose which film will be scheduled next, from a curated list of films that relate to research methods and are available to watch through Box of Broadcast (Makrinov, n.d.). Students have been invited to share ideas for further movies to be added if they can demonstrate how they relate to RM. Details of films and themes covered are presented in Table 1.

Table 1. Film club timetable

	Film	Theme
12 January 2024	The Matrix (Wachowski and Wachowski, 1999)	Research paradigms
7 February 2024	The Stanford Prison Experiment (Alvarez, 2015)	Ethics in design
8 March 2024	Inception* (Nolan, 2010)	The research process
19 April 2024	The Truman Show* (Weir, 1998)	Observation
10 May 2024	Gorillas in the Mist (Apten, 1988)	Action research
Other curated films	Kinsey (Condon, 2004)	Interviews and coding
	Experimenter (Almereyda, 2015)	Research design and deception
	Miss Evers' Boys (Sargent, 1997)	Participant engagement
	Radioactive (Satrapi, 2019)	Lab research

* Films chosen and voted for viewing by students

All postgraduate students at WMG are invited to attend the events; they can choose how many and which they take part in. Due to the size of the room, up to 99 students can book into each.

The Film Club was announced through various means, including mentions on the Student Experience weekly newsletter, module announcements for a research methods module offered to most master's students, listings on a university's event booking system, and digital posters displayed in screens across the department (see Fig. 1).

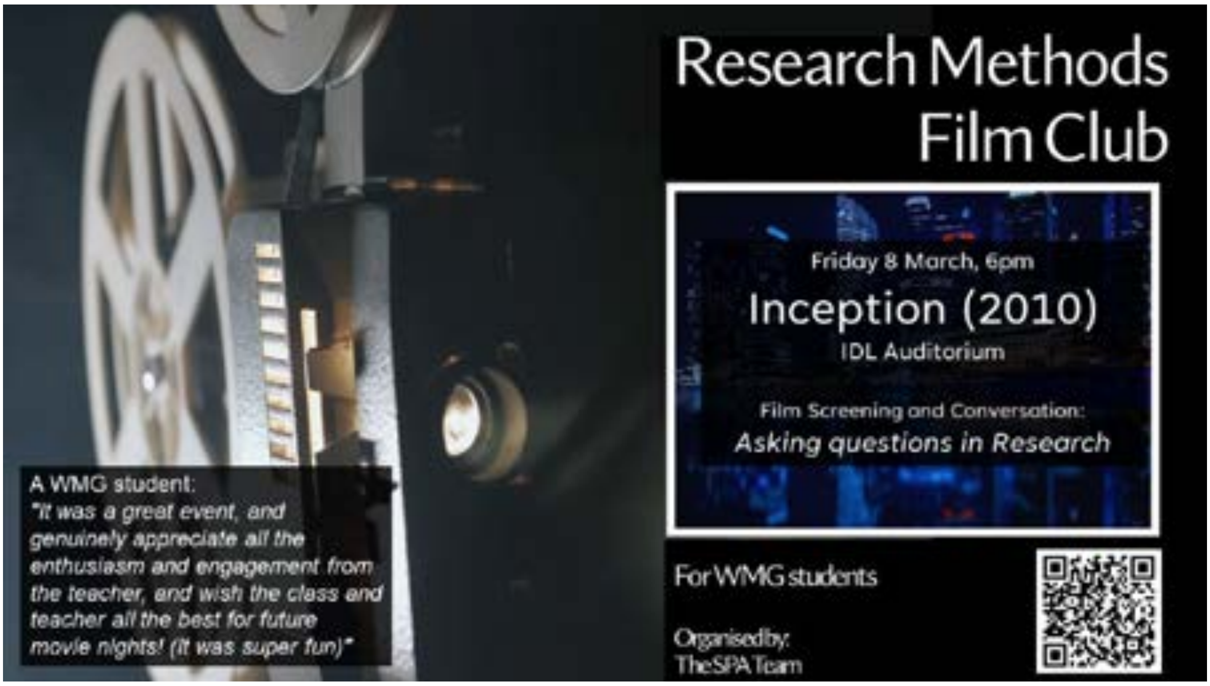

Fig 1. Digital screen poster example

3 ONGOING RESEARCH

We are currently conducting a study which will provide additional evidence through the evaluation of the student's perception of the pilot Research Methods Film Club. The study addresses the research question: How do postgraduate students perceive the use of popular films in supporting the teaching of research methods?

This exploratory study follows a participatory action research approach (Baumfield, Hall and Wall, 2013; Dickens and Watkins, 1999; Kemmis, McTaggart and Nixon, 2014). The research team includes two current PhD students at WMG, their involvement reflects the participation of users in the design of the Film Club as an intervention, in line with the University of Warwick's (n.d.) commitment to co-creation. Following action research approaches, the study will include cycles of reflection and (re)design of 5 guided RM Film Club sessions.

At the end of each session taking place after ethical approval was granted, participants are invited to complete a short online survey designed on Qualtrics, including questions about demographic characteristics and participants' reflections after the event. Participants are also being invited to take part in a semi-structured focus group taking place after each session. Additional focus groups will be offered after the final session so all students who want to participate in the study can do so.

It is important to note that the study focuses on student perceptions, as an initial exploratory analysis of the potential effectiveness of using a Film Club to support Research Methods teaching and learning. We expect results will provide an insight on the reaction of participant, but does not represent a full evaluation. Following Kirkpatrick's model (Kirkpatrick and Kirkpatrick, 2016), future research can be conducted to evaluate the impact on learning, behavioural change, and results.

Participants are selected through convenience sampling. All full-time master's students at WMG in 2034/24 and all PhD students at WMG in the same period are invited to participate in the Film Club (an estimated population of around 2,000 students). Up to 99 students can participate in one or more Film Club sessions, places are allocated on a first come first served basis.

Quantitative data will be analysed using SPSS. Descriptive statistical analyses will be conducted with demographic data, to ensure the sample is appropriately described. Closed questions in the survey will be reported through descriptive statistics. If response rates allow, inferential statistics will be used to compare responses between groups (e.g. students in different courses or from different countries).

Qualitative data will be analysed following using thematic analysis to allow deep understanding of the experiences of participants (Braun and Clarke, 2021). Qualitative data to be analysed includes open questions in the survey and data collected through focus groups and/or interviews. Text data will be coded and grouped into themes, using a reflexive collaborative coding approach that is informed by the positionality of the researchers.

4 REFLECTIONS ON OUR PRACTICE

So far, our experience of organising the RM Film Club has been positive and we would encourage educators to consider similar approaches. We participate because it is an innovative approach to teaching and engaging with students. Using films, students have discussed RM themes in settings that are unusual. Moreover, informal feedback from students and staff has related to how fun and learning have been brought together in this activity. We expect that participation in the film club will help students develop an understanding of the whole picture of what research looks like, and an in-depth grasp of some of the threshold concepts that will allow them to succeed in their research projects.

Many of our students watch films for entertainment, they enjoy watching them. By participating in the Film Club, they have had the opportunity to watch older films in a big screen. RM, in contrast, can be perceived as boring. A short add on reflection to a fun experience can support student engagement with the subject and that may positively influence their learning. We believe the balance between a brief period focusing on RM context and a long time spent watching a full-length feature film has been important to achieve this. RM seems like an add on, while when clips are used as part of teaching the films theory takes precedence over fun.

Adding reflective questions and an opportunity for discussion has provided a no pressure environment for students to participate. We have observed that they engage more with the conversation during Film Club than they do in small group teaching sessions. In both scenarios, attendance is optional. However, it is possible that students perceive that they have different motivations from taking part. There are also variations in the level of engagement as a response to the theme and movie. We believe Stanford Prison Experiment (Alvarez, 2015) has been our most successful screening so far. The film stuck a cord with our students, who seemed to display a strong emotional reaction. This led to a long 30-minute question and answer session in which we shared concerns about the importance of research ethics and reflections on power and powerlessness. In comparison, the question-and-answer sessions for The Matrix (Wachowski and Wachowski, 1999) and Inception (Nolan, 2010) where shorter, at just around 10 minutes each.

The role of organisers as curators is also important. For example, we did not watch Inception (Nolan, 2010) before presenting it to the group and chose the theme based on a student recommendation. We were all (students and staff) baffled by how we could relate the film to RM, until one of the GTA organisers suggested the film would provide an excellent opportunity to reflect on the research process rather than our planned discussion on research questions.

Others may wish to implement a similar approach in a different university or with different content matter. From our experience, we would recommend considering the intended outcomes of such an activity. Using full movies, as we have done, has the potential to support deep learning but also takes time which may be limited. Hence, a Film Club might work best as a co-curricular activity that aims to develop a community of practice and improve the student experience, as well as supporting learning in a particular subject. We would also recommend that educators co-create the activity with students, this adds value as it considers diverse perspectives. Curating and planning how each film relates to the subject matter provides a basis for conversations that allow students to construct their knowledge in an active way. It should be noted that using media such as popular films in teaching requires consideration of copyright and permissions; educators should make informed decisions, which an be supported through their local libraries.

Our current research project is exploratory and focuses on student perceptions. It is important to us that those who take part report that they enjoy the event and that they have learnt. Future research should focus on an impact evaluation, as we are aware that the perception of learning does not equate to learning. We would like to answer the research questions “Do students learn by participating in the RM film club?” and “Does participating in RM Film Club make a difference in students’ research performance?”.

ABSTRACT

Artificial Intelligence (AI) is transforming our world by enhancing efficiency and supporting decision-making across various sectors. It enables machines to learn from experience, adjust to new inputs, and perform human-like tasks. In education, AI is revolutionizing learning, teaching, assessment, and administrative work. AI enables personalized learning experiences, assists educators in curriculum development, and offers real-time feedback. Additionally, AI streamlines assessment by automating grading and providing insights into student performance. For administrative tasks, AI improves efficiency in student admissions and resource management. This integration of AI in various educational aspects enhances the overall quality and effectiveness of the educational process. This research paper explores the multifaceted role of AI in higher education, examining its current applications, opportunities, and challenges. It delves into various AI methodologies such as Machine Learning, Neural Networks, and Natural Language Processing, applied in educational settings to enhance teaching, learning, and administrative processes. The paper addresses three critical questions: what the AI techniques are currently used in education, what are the potential benefits AI brings to the higher education sector, and what are the challenges of integrating AI in educational contexts. Based on the findings, we have delineated the gradual steps we are implementing to incorporate AI into the framework of our universities.

1 INTRODUCTION

The concept of Artificial Intelligence (AI) often sparks extensive debate regarding its precise definition and meaning. For instance, one definition frames AI as a specialized branch within computer science, focusing on creating computers capable of performing tasks that typically require human intelligence. These tasks include the ability to learn, reason, and self-correct, mirroring human cognitive processes. This perspective emphasizes AI's goal to replicate or simulate human-like thought and reasoning in a computational context (Kok et al., 2009). AI is a transformative force in various fields, including education (Gruetzemacher and Whittlestone, 2022). Its integration into education has opened new avenues for enhancing teaching and learning experiences (Ng et al., 2023). The application of AI in higher education is multifaceted. It includes personalized learning experiences through adaptive learning systems, automation of administrative tasks, and provision of intelligent tutoring systems. These applications aim to enhance student engagement, improve learning outcomes, and optimize educational processes. This paper presents a review of AI technologies in higher education, focusing on the current AI techniques used in educational tools, their positive impacts on various aspects like learning, teaching and administration, and the challenges associated with the use of AI in education.

The importance of this research lies in its potential to influence future educational strategies and policies. This understanding is vital for educators, administrators, policymakers, and students, as it guides the development of more effective, efficient, and equitable educational systems. This paper is organised as follows: Section 2 presents a review of AI technologies in higher education, focusing on the current AI techniques used in educational tools, their positive impacts on various aspects like learning, teaching and administration, and the challenges associated with the use of AI in education. Section 3 elaborates on the strategies for incorporating AI at Bahria University (Pakistan) and University of Warwick (UK). Finally, conclusions are presented in Section 4.

2 LITERATURE REVIEW

In this section, we present a review of AI technologies in higher education. We delve into the current AI techniques utilized in educational tools, explain their positive impacts on various aspects such as learning, teaching, and administration, and identify the challenges associated with their integration into education.

2.1 Current AI Techniques used in Educational Systems

AI techniques, such as machine learning, deep learning, and natural language processing, are being increasingly applied in the field of education to improve the teaching and learning process. Machine learning plays a crucial role in education by automating tasks like grading, generating questions, and providing personalized learning experiences (Alpaydin, 2020; Kučak et al., 2018; Asthana and Hazela, 2020; Nafea, 2018). Various machine learning algorithms, including Linear Regression, Logistic Regression, Neural Networks, Decision Trees, Naïve Bayes, Support Vector Machines, Fuzzy Logic, and a combination of these techniques, are commonly used in educational systems for enhancing the overall learning experience (Halde, 2016; Korkmaz and Correia, 2019; Shrestha and Pokharel, 2019; Farhat et al., 2020).

Linear Regression is frequently employed in forecasting student achievement, whereas Logistic Regression acts as a preemptive alert mechanism for underperforming students (Halde, 2016; Poh and Smythe, 2014; Sagala et al., 2022). A linear regression model was devised by Gadhavi and Patel (2017) to aid students in predicting their grade in a specific subject. Nonetheless, the limitation of linear regression is its inability to accurately capture nonlinear patterns among the variables (Rao and Nagaraj, 2014). Adaptive tutoring systems have successfully incorporated neural networks, such as artificial neural networks and reinforcement learning, resulting in impressive levels of accuracy (Fenza et al., 2017; Lukic and Acuna, 2012). Automated essay scoring and the categorization of students' study habits have been effectively carried out using Naïve Bayes classifiers (Mulyati and Setiani, 2018). Gutierrez and Atkinson (2011) devised an AI technique for adaptive feedback in foreign language Intelligent Tutoring Systems by combining support vector machines and Conditional Random Fields (CRF). By analyzing classroom interaction data, they were able to predict effective feedback strategies. Their approach demonstrated superiority over traditional methods, as it dynamically adjusted feedback based on the dialogue state, guiding students towards correct answers with minimal intervention.

Deep learning plays a crucial role in natural language processing (NLP). Recurrent Neural Networks (RNNs) are particularly adept at tasks such as language modeling and machine translation, while Convolutional Neural Networks (CNNs) excel in text classification and sentiment analysis. Long Short-Term Memory (LSTM) networks, a subtype of RNN, are valuable for sentiment analysis and text generation. A significant advancement in NLP is the emergence of transformer models like BERT (Bidirectional Encoder Representations from Transformers), which are highly effective in question answering and named entity recognition tasks. Transformers leverage self-attention mechanisms to grasp intricate word relationships, thereby enhancing performance and contextual understanding in NLP. This breakthrough has resulted in substantial enhancements across various NLP applications (Otter et al., 2021). Generative Pre-trained Transformer (GPT) is an advanced NLP model that utilizes transformer decoder blocks. It operates in a unidirectional manner, focusing on preceding words, unlike BERT which predicts masked words. GPT does not incorporate an encoder or cross-attention. Its primary function is to predict the next word in a sentence based on previous words, generating coherent and contextually relevant text extensions. For example, if the initial content revolves around psychology, the trained GPT model will continue generating words and sentences related to psychology, thereby completing the text. It is important to note that GPT functions as an unsupervised model (Topal et al., 2021). Following the launch of the GPT known as ChatGPT, in November 2022, there has been a surge of interest worldwide in generative artificial intelligence (AI) (Van den Berg and du Plessis, 2023). Numerous researchers have delved into the potential and challenges posed by AI and tools like ChatGPT in the field of education. Many explore the opportunities it offers and how it could potentially reshape educational environments and practices (e.g. (Javaid et al., 2023; Adeshola and Adepoju, 2023)). Simultaneously, they express concerns regarding the potential for AI-generated misinformation and biases, delving into the ethical implications that arise (e.g. (Kasneci et al., 2023; Saunders, 2023; Adeshola and Adepoju, 2023, Huallpa, 2023).

2.2 Current opportunities in AI enhanced Education

In this section, we present an overview of educational tools which are utilized by several authors to automate their learning, teaching, assessment, and feedback process. This section also covers how AI can help teachers to do course designing, planning and complete administrative tasks.

2.2.1 Learning and Teaching

Computer-based learning is being progressively merged with AI methods to create personalized educational systems, commonly referred to as Intelligent Tutoring Systems (ITSs). These systems leverage AI to recognize students' comprehension levels and tailor learning materials, accordingly, supporting them in reaching their full potential (Mousavinasab et al., 2021; Liriwati, 2023). Among AI tools, chatbots play a significant role in educational activities. Studies have shown that AI chatbots in programming courses can significantly enhance student learning by providing timely support and fostering independent work (Verleger and Pembridge, 2018). For example, Ismail and Ade-Ibijola (2019) developed an interactive AI chatbot using IBM Watson API, assisting beginners in programming, and addressing academic questions effectively. Additionally, AI chatbots like EnglishBot and "Ellie" have shown effectiveness in improving fluency and engagement in language learning classes (Ruan et al., 2021; Yang et al., 2022). Moreover, systems like Robo-Sensei, TAGARELA, and E-Tutor have been successfully integrated into language classrooms, offering personalized learning environments, and supplementing existing pedagogical materials through a combination of NLP and AI approaches (Slavuj et al., 2015).

2.2.2 Assessment and Feedback

Automated Essay Scoring (AES) systems offer efficient essay grading by reducing the need for human assessors, with recent advances in deep learning enhancing their capabilities (Uto et al., 2020; Hussein et al., 2019). Studies have developed AES using methods like regression and clustering, focusing on text features such as word count and syntax, with evaluations revealing satisfactory correlations with human grading (Ramalingam et al., 2018; Salim et al., 2019; Song and Zhao, 2013). Advanced AES models have been developed focusing on detailed essay traits like organization, coherence, and language proficiency (He et al., 2022; Hussein et al., 2020). Question Generation models have been developed for educational purposes using machine learning methods, including NLP and image captioning, to generate questions from text and images (Kokku et al., 2018; Srivastava et al., 2020). Large Language Models (LLMs) like ChatGPT have been explored for generating high-quality quiz questions, delving into different facets of the topic (Lee et al., 2023; IONESCU and ENESCU, 2023; Zhu et al., 2023). Automated Question Generation aims to ease the task of making evaluations and assessments for teachers, with various techniques producing a variety of question types, including multiple choice and true/false questions (Hsiao and Chung, 2022; Killawala et al., 2018). Overall, Question Generation models have been created for educational objectives, providing a range of question types tailored to different learning needs (Chung et al., 2023; Lu et al., 2021).

2.2.3 Course Designing, Planning, and Administrative Function

Educators are utilizing AI capabilities for curriculum development and lesson planning. In addition, generative language models like ChatGPT enhance educational equity and accessibility by providing free resources like lesson plans and supplementary materials through generative language models such as ChatGPT (Somasundaram et al., 2020; Revelle, 2023; van den Berg and du Plessis, 2023). Some studies have only briefly mentioned lesson planning and course design, leaving a noticeable gap in the literature on this topic. Adoption of AI-based technologies relieves teachers of routine administrative tasks, allowing them to focus more on personalized advising, coaching, and counseling (Kuleto et al., 2021). AI chatbots are handling inquiries from students and parents, with their interaction improving over time, and institutions like Siglo 21 University are leveraging them to provide support to its extensive student body (Kurni et al., 2023; Aivo, 2023). Additionally, AI models are optimizing university admissions processes, although concerns have been raised regarding potential biases in such systems (Vohra, 2011; Waters and Miikkulainen, 2014; Marcinkowski et al., 2020; Martinez Neda et al., 2021).

2.3 Challenges associated with applying AI in education

Current challenges in applying AI in education are multifaceted, spanning accuracy, biases, explainability, and ethical deployment.One of the concerns about the reliability of the process of making decisions through algorithms is the utilization of surrogate indicators, where quantified data serves as a substitute for complex phenomena (Marjanovic and Cecez- Kecmanovic, 2017). These systems, lacking true understanding, may assign high scores to flawed essays, presenting challenges in reliable assessment (Berrett, 2013). Biases in AES systems, inherited from human assessment data, pose another hurdle, potentially perpetuating and amplifying existing biases (Marcinkowski et al., 2020). Moreover, the lack of explainability in AI algorithms hinders trust and raises questions of fairness and accountability, especially in contrast to human assessors who provide clear feedback (Aloisi, 2023).

The introduction of ChatGPT further complicates matters, with educators worried about its potential to facilitate plagiarism and compromise academic integrity (Rudolph et al., 2023; Dibble, 2023). A review by (Sallam, 2023) of 60 studies on ChatGPT revealed various concerns and potential risks associated with its usage. These encompass ethical considerations, the risk of bias, plagiarism, copyright issues, transparency concerns, legal implications, lack of originality, potential for incorrect responses, limited knowledge, inaccurate citations, the generation of misinformation, and the provision of incorrect or nonsensical answers. Moreover, the constrained knowledge base, which is limited to information available up to the year 2021.

Ethical deployment of AI in education encompasses privacy, anonymity, surveillance, autonomy, non-discrimination, and data ownership concerns. The collection and analysis of extensive student data raise privacy issues, necessitating measures to protect personal information (Kamenskih, 2022). Additionally, anonymity comes as a concern because its challenging to balance personalized learning with privacy rights arises due to AI's ability to identify individuals (Sweeney, 2000). Surveillance in AI-driven education may restrict student autonomy and raise fairness concerns, highlighting the need for transparent data ownership and control measures to safeguard individuals' rights (Dabbagh et al., 2021);

The use of AI in education facilitates a more detailed and continuous observation of students by collecting data on their learning processes and capturing learners' patterns of reviewing the content or responding to questions to gain insights into their thinking processes. All this information is then fed into predictive analytics programs to ascertain student learning patterns, strengths, weaknesses, and generate personalized recommendations based on their needs (Regan and Jesse, 2019). However, students' engagement in the learning process may be restricted if they know that their online interactions and activities are monitored and tracked, as it may make them feel unsafe about freely expressing their thoughts (Remian, 2019; Akgun and Greenhow, 2021). Surveillance systems give rise to autonomy-related concerns (Akgun and Greenhow, 2021). Different previous studies have highlighted various concerns related to autonomy in AI-based systems, revealing instances where these systems may compromise or limit human autonomy. AI technologies are currently employed to dynamically tailor and personalize the options or choices presented to individuals using previously unseen methods (Yeung, 2019; Pariser, 2011) and the increase in effectiveness brought by AI is not enough to justify giving up decision-making authority to the machines. Autonomy constitutes another concern linked to AI, specifically focusing on the principle of treating individuals fairly and impartially, without discrimination based on attributes such as race, gender, or age, and even considering factors of which they may not be aware. As more and more judgements are left to artificial intelligence (AI) methods like machine learning, digital discrimination is turning into a major problem (Ferrer et al., 2021). Lastly, it has long been acknowledged that issues pertaining to data ownership and control over their interpretations are crucial to AI in education (Bull and Kay, 2016)

3. INTEGRATING AI TO SUPPORT STUDENT SUCCESS

To effectively integrate AI to support student success, a structured framework is essential. This framework should encompass several key elements. First, identify student needs by analysing the student population to understand their backgrounds, learning styles, and any specific challenges they may face. Next, develop AI-powered tools that address these identified needs. Following this, pilot and refine the tools by starting with a small-scale pilot programs to test the AI tools and gather feedback from students and instructors. Finally, adopt continuous improvement by continuously monitoring and evaluating the impact of the AI tools. This could involve analyzing student performance data, satisfaction surveys, and focus groups. Use this data to further improve the AI tools and ensure they are meeting student needs.

3.1 Bahria University

The thorough literature review enabled us to propose AI based student centered support system at Bahria University where we will blend AI harmoniously into the life of each learner to ensure continuity, accountability, and support on their educational path. One of our key initiatives involves the development of a prototype aimed at facilitating access to information across multiple books and summarizing it for students. This prototype leverages AI technology to enable students to answer questions sourced from various textbooks efficiently. Rather than relying on a single source, students can benefit from insights gathered from a diverse range of materials. The prototype operates through a series of integrated features: Multi-Source Data Retrieval retrieves pertinent information from diverse educational resources. Students can input queries into the interface, prompting AI-driven question-answering models to analyse and generate accurate responses sourced from various texts. Additionally, the prototype offers a summarization feature, condensing information from multiple sources into concise summaries for easier comprehension of key concepts. We are currently working on Its interface to facilitate seamless navigation including search functionalities, filters, and visualization tools. Furthermore, a feedback mechanism will be incorporated to allow students to contribute input on the relevance and accuracy of answers and summaries, aiding in the refinement of AI algorithms for continual improvement. The prototype is now ready. We will identify few courses in the Department of Computer Engineering to test it during the Fall 2024 semester.

Another initiative is to equip students right from their start at campus, helping them choose modules corresponding to their potential and preferences during the duration of their studies at the University.

It involves assisting students in selecting their modules based on their academic performance. By analysing their previous grades and performance data, AI algorithms can provide personalized recommendations on which subjects students may excel in and which ones may not be suitable. This tailored guidance aims to help students make informed decisions about their course selections, ultimately enhancing their academic journey and improving their overall learning experience. Currently, our dedicated student advisors guide students who have encountered academic setbacks (failing one or two subjects) towards suitable modules for the following semester. This personalized approach considers both a student's academic record and their interests, ensuring a manageable work load and minimizing the risk of future failures. This process currently occurs at the start of each semester for each student facing academic challenges. We aim to develop an AI-powered course recommendation system aimed at alleviating the workload of our advisors. We're in the phase of collecting this data that will be used to train the AI model. This AI system will automate a significant portion of the data analysis currently performed by the faculty, freeing up valuable time for advisors to focus on deeper student engagement and personalized support.

3.2 WMG, Warwick University

At WMG (one of the largest department at the University of Warwick) , our objective is to leverage AI to enhance our understanding of students' needs. Our goal is to employ AI methodologies to deliver personalized learning experiences to our students Our student body comprises undergraduate and postgraduate students from the UK and various other countries, alongside participants in our industry-led degree apprenticeships at Warwick, where apprentices engage in industry work alongside pursuing their degree programs. The diverse nature of our student population necessitates a nuanced approach to addressing their needs, which is influenced by factors such as the mode of provision they receive and whether they are actively engaged in industry work.

Our first initiative is to develop AI support system for our degree apprenticeship students as they struggle with work life balance because they are studying and working at same time. In degree apprenticeships, we conduct a comprehensive skills assessment prior to the start of the program for each apprentice, aiming to ascertain their existing skills, learning requirements, backgrounds, strengths, and prior knowledge. We will allows us to tailor the module content delivery according to the individual preferences and needs; for instance, adapting content for visual learners or those who prefer textual materials. Additionally, we recognize the importance of accommodating students with physical or mental disabilities, and thus, we are working on leveraging AI to customize content and delivery methods accordingly. The implementation of AI based support tool for DAs is in progress and prototype will be ready in next three months.

Looking ahead, we plan to implement diagnostic testing for both undergraduate (UG) and postgraduate (PG) students to gain insights into their unique learning requirements. By doing so, we aim to offer flexible learning opportunities that cater to individual strengths and areas for improvement. This proactive approach aligns with our commitment to providing inclusive and effective educational experiences for all students, regardless of their learning styles or challenges they may face.

With numerous AI tools like Dall-E, Microsoft Co-pilot, ChatGPT, and Stable Diffusion accessible online, our goal is to enhance the skills of our teaching and administrative staff in using these technologies. By doing so, we aim to automate routine administrative tasks, increasing efficiency and reducing workload. Furthermore, we plan to leverage AI capabilities to predict enrolment trends accurately, allowing us to optimize resource allocation effectively. This initiative will not only streamline our operations but also ensure we are better prepared to meet future demands and improve overall institutional performance.

4. CONCLUSIONS

This paper presents extensive research into AI's application in education, envisioning a future where education is deeply intertwined with AI technologies. The remarkable potential of AI in personalizing educational experiences is underscored. It is envisioned that future educational systems will progressively incorporate AI to customize learning materials and assessments based on individual student profiles. This approach includes providing tailored feedback, focusing on each student's unique strengths and areas for improvement. Predictive analytics will play a pivotal role in forecasting student outcomes, thereby enabling educators to offer proactive support and interventions where necessary. The utility of AI extends to being a supportive tool for educators. AI can significantly reduce the administrative workload and refine instructional methodologies. It is recommended that educators need to upskill themselves with AI tools to assist in curriculum development, lesson planning, and in offering personalized student feedback. However, to fully harness the potential of AI in education, substantial investments are necessary in both technological infrastructure and professional development.

Educators and administrators need comprehensive training to effectively integrate AI tools into their teaching methodologies. Classrooms should be equipped with advanced computer systems that can support AI-based learning modules. Additionally, there is a pressing need to develop secure online learning platforms that utilize AI for more intelligent learning, assessment, and feedback processes. Given the rapid evolution of AI technology, educational institutions are advised to engage in continuous evaluation and adaptation of AI tools. This process involves regular assessments of the impact of AI-powered learning platforms on student outcomes, with subsequent updates or modifications to these platforms to align with changing educational needs and advancements in AI technology. Furthermore, despite the advancements and integration of AI, it is crucial that education systems continue to emphasize and nurture critical thinking, creativity, and interpersonal skills. These skills are indispensable in preparing students to work effectively alongside AI technologies and in professions where human skills are paramount. The curriculum should, therefore, include subjects and activities that foster problem-solving, ethical reasoning, and emotional intelligence. Classrooms should be designed to be interactive environments that promote debate, collaboration, and the development of interpersonal skills.

ABSTRACT

The integration of digital media in university teaching has transformed the learning landscape, particularly in engineering disciplines. The students need digital competence to be able to use the media made available to them. Often these competences are not distinctive on a sufficient level. Therefore, this paper discusses an innovative educational initiative designed to integrate a reflection of digital actions with media for first-semester students. The given basic mathematics course in the first semester will be adapted through inputs such as questions for reflection in the e-learning platform, group and plenary discussions in the attendance parts. After the basic description of the course, initial experiences with its implementation are discussed. A main positive experience is the acceptance of the students with the new concepts through a clear communicated and recurring structure. An essential point for future improvements is the time management with the additional course content through the reflection phases. At the end, important requirements for the new course with reflection of digital actions are identified so that the concept can also be used in other areas of higher education.

1 INTRODUCTION

Digital media are an integral part of university teaching and learning. Students use digital applications such as internet resources, video platforms like YouTube and mathematical work benches as WolframAlpha to support their learning in various engineering disciplines. Lecturers use learning platforms to provide subject-specific content and interactive assignments to get feedback about the learning progress. There is a wide range of possible tools and digital media that can be used to obtain information. In addition to standard tools, AI-powered programs such as ChatGPT and Google Bard hold significant potential. Especially, these tools also necessitate a critical approach to the content they generate. The study about learning with digital media by Marten and Thiele (2023) has revealed that there is a notable lack of reflection regarding their potential applications and the methods employed in digital learning.

Dealing with the selection of media and their content leads to better research results. Reflecting on these digital actions is the aim of the method.

The digital actions are considered embedded in a subject-specific framework (Berthold 2006). In the described context, the reflection method is embedded in the basic mathematics course of engineering degree programmes in the first semester. A digital action refers to the incorporation of computer-supported/digital media into learning processes within a subject-specific framework.

An essential part of the concept is to introduce a reflection on the digital activities. The reflection phase is followed by group and plenum discussion. By this, the students get a more critical view of their use of digital media and can start to adapt their behaviour. Already, Konrad (2014) described that the reflection of learning processes could support the learning outcome. Additionally, the classroom climate and the student motivation play a crucial role in effective teaching (Biggs and Tang 2011).

The concept is deliberately used at the beginning of the degree programme. In this phase, students seem to be open to new methods. They can benefit from it for their study. In this specific case, it is implemented in the mathematic class. It is an important but often challenging course for students. They therefore typically use digital media to understand and process the content. In this context, we initiate reflection on the use of digital media.This helps the students to be aware of the importance.

Marten and Thiele (2023) determined the students' behaviour with digital media in the course using interviews. Information about how digital content is used in a mathematical context was collected. These described practical solutions to learn with digital media by the students in the mathematics course are the basic for the future developments in the course. Based on these results, a specific programme for reflecting on digital activities in the basic mathematics course was developed and implemented. This paper will share the insights and experiences gained from the course.

2 METHODOLOGY

2.1 Concept of the current lecture

The concept is integrated, in a mathematic course for first year engineering students. It focuses on activating teaching and learning. Beside standard learning, flipped classroom (Kenner and Jahn 2016) and Just in Time Teaching (Novak et al. 1999) are integrated. The attendance parts of the courses are characterised by peer instruction and active communication with the lecturers. The lecturers attach great importance to a culture of open dialogue. There is an atmosphere in the courses, which makes it easy to address questions and understand weaknesses. Part of the self-learning phases of the course are weekly tasks which are assigned on an e-learning platform. The following questions were added to reflect on the mathematical content after completing the tasks on the e-learning platform.

Please answer one of the following questions. If you have questions about the content, you should answer the first question. The answer should consist of at least 3 sentences:
1. Explain what you did not realise about the topic. Which point did you not understand or where is the meaning not clear to you? What question should be clarified in the lecture? 2. Explain what you found most interesting. Why is the material worth learning? Can you think of an application for it?
3. What could an exam task look like that checks whether the content has been understood?

Fig. 1. Previous questions in the E-Learning platform for the reflection of the mathematical topics

Based on the concept of Just in Time Teaching, students note questions and difficulties with the content covered material to answer the questions in Fig. 1. The students have to reflect on difficulties they have. It helps to get a self-evaluation regarding the actual content. Furthermore, it serves as feedback for the lecturers regarding the subject-related difficulties. The answers are processed by the lecturer and incorporated into the subsequent lecture.

2.2 Introduction of reflection on digital media into the lecture

Digital competences are becoming increasingly important for students, especially in the first semester of university studies (Händel 2024). Higher education can be considered as part of the lifelong learning process. For the digital competences in the lifelong learning process, the "Digital Competence Framework for Citizens 2.2" according to European Commission et al. (2022) was developed.

The framework describes the competence fields and the individual competences in detail and offers the opportunity to place them in an application context. A whole range of digital competences are explained in the competence model. We have made a suitable selection from these.

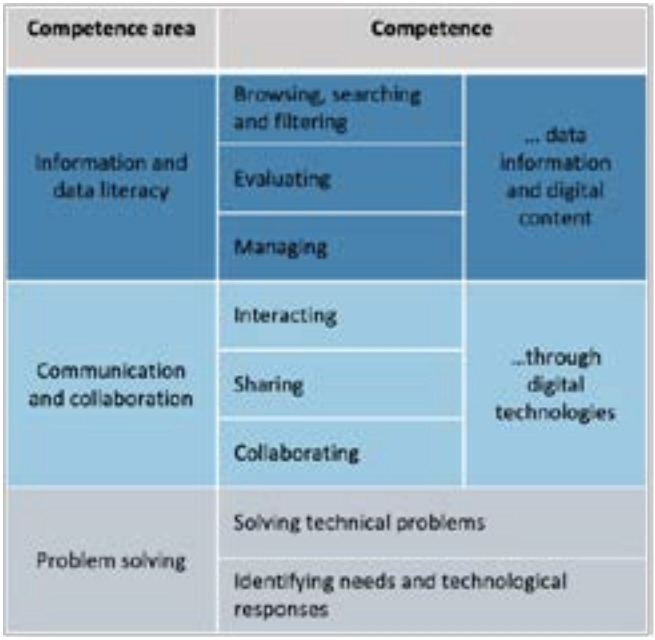

Fig. 2. Overview of the competences applied according to the DigComp 2.2 model (Vuorikari et al. 2022; Marten and Thiele 2023)

The competences shown in Fig. 2 form the basis for the reflection developed later. The focus is on three out of five skill areas from the competence model. It is information and data literacy, communication and collaboration, and problem-solving. The chosen competencies then provide the basis for a practical reference to the students' digital actions, which were already described in the study of Marten and Thiele (2023). In addition to digital actions, the study identifies key elements of media in the students' usage scenarios like online websites, learning videos, artificial intelligence, and digital communication. These key areas of the digital media and the associated digital actions of the students are now to be reflected on during the semester.

The motivation to engage with the reflection should be increased (Berthold 2006). This is done by reducing abstraction and concretising it based on references to the mathematical tasks. Therefore, the use cases are assigned to subject-specific topics of the maths course.

First year students are affected by many new impressions.In the first five lecture weeks they need to familiarise with the procedures in the university and in the course. Therefore, we start the reflection on digital media in lecture week six (LW 6). In table 1 there is the course content shown together with the allocated focus of digital actions.

Table 1. The digital actions in the mathematic lecture

Course content (Lecture week)	Focus of digital actions
Transformation of functions (LW 6)	Digital media (general)
Sequences and limits (LW 7)	Digital media (general)
Trigonometric functions (LW 8)	Digital media (general)
Rules of differentiation (LW 9)	Learning videos

Tangent and Taylor series (LW 10)	Websites
Techniques of integration (LW 11)	Artificial Intelligence
Complex numbers (LW 12)	Digital communication

For students in engineering education, it is less common to reflect on one's own actions and critically examine them within a group setting. Therefore, in LW 6 to LW 8, the focus is on the use of digital media in solving mathematical problems in general. The process of reflection and consolidation is practised in this phase. Uncertainties are resolved in this first general phase by a predefined structure that creates confidence to communicate. The specific areas of application are then addressed in the further course. The allocation of the reflection areas is based on the interview statements of the students (Marten and Thiele 2023).

The process of reflection is divided in four parts.The start is the weekly-based self-reflection on the e-learning platform. It is based on additional questions for the digital action reflection. Fig. 3 shows the questions added in the chapter “Rules of differentiation” to reflect the use of learning videos.
Please answer the following questions. The answer to each question should consist of at least 3 sentences.

1. If you have used a learning video to explain the derivation rules for this topic section, please answer this question with the corresponding link to the video. If you have not used a video, please search for a video explaining the derivation rules that you like. Send the link to the video here as well. Note: Please do not use just any learning video. It is important for the reflection in the lecture that you have learnt or could learn effectively with the corresponding video and its content.
2. Why did you choose this particular video? Justify your statement. For what reasons are you able to draw information particularly well from this learning video?
3. Do you regularly learn with learning videos or do you prefer other learning materials? Give reasons for your statement here too.

Fig. 3. Additional questions in the E-Learning platform to reflect the actions with learning videos

The questions encourage students to reflect on their behaviour in relation to the use of digital learning materials (Fig. 3). They give the answer on the e-learning platform, which should not take longer than 15–20 minutes. The answers are used as a base for the discussion and additional reflection in the lecture, which is divided in three phases. Here, approximately 35 min each time is planned.

The joint reflection is initiated by a presentation of common answers of the self-reflection by the lecturer, which also sets the focus on certain aspects. Student statements can be presented anonymously, for example, describing a specific action in relation to learning videos in the context of the rules of differentiation. This phase needs around 5–10 minutes, it depends on the previous online answers of the students and their need to discuss the topic before the group discussions.

For the subsequent group discussion (around 20 minutes) the students gather in groups of max. six person. Here a position is taken on the statements presented, and a discussion is held on how to optimise the procedure or alternative actions.

Students are encouraged to record essential results and aspects of their discussions on a whiteboard.

The notes on the whiteboards are the basis for the following plenary discussion (about 10 minutes). The plenary discussion serves to collect the most significant aspects and also to discuss differences between the group results. The aspects have been objectified through the previous group work. It is no longer about personal views and actions, but about the results of the group. The results are summarised by the lecturer and distributed to the students after the course.

An essential rule for the discussion is that critical remarks are allowed, but no final judgement is made. All participants respect the individuality of each person's approach. It is important to create an environment of confidence when discussing one's own behaviour. The small groups make it easier to discuss openly.

Nevertheless, the descriptive processes and the discussion will trigger reflection on the own approaches. The aim is to figure out different procedures, to critically examine them and to reflect them based on their actions in the context. In the end, serval students might adapt their ways to learn with digital media.

3 RESULTS

During the adapted course framework for mathematics in the summer semester 2023, we gathered valuable practical experiences, which are described in this chapter. The mathematic lecture takes place three times a week. The reflection on digital media took part ones a week. 25 students regularly attended the course. The time spent each week on reflection is closely linked to the progress of the subject content in the lecture.The insights reflect both the positive aspects and successful practices, as well as the challenges and areas for improvement that emerged over the semester. At the end, requirements for a possible application in other subjects of higher education teaching are presented.

3.1 Positive aspects

It was observed that the type of lecture is accepted by the students. Initially, there were reservations about the extra effort and scepticism about reflection and subsequent group discussions. This can be attributed to the fact that this type of engagement with students' own behaviour is rather unusual for engineering students. Through a clear structure and recurring procedures, the students became familiar with this approach. A trusting and communicative atmosphere was established, which facilitated a good exchange. All phases, self-reflection, group discussions and plenary discussions were carried out effectively and had positive results. The students showed a high level of participation by actively sharing their opinions and following the discussions. The topic of artificial intelligence particularly gave rise to very intensive discussions. It could be observed that there was a great need for dialogue among the students and that they actively took advantage of the opportunity to exchange ideas. The observations suggest that actions in this context were reflected particularly strongly as soon as there was a direct reference to current problems, in this case in mathematics, and these could be answered with digital support.

Another positive aspect was the acceptance of the self-learning phases, which were based on the concept presented from the first lecture onwards, on a weekly basis. Around 70% of the students regularly participated in the self-reflection phases. The introduction of the reflection questions for the digital activities in the e-learning platform was initially an additional effort. The students' overall reaction to them was positive throughout the semester.

3.2 Challenges

The intense commitment and willingness of the students to get involved in the discussion meant that we couldn't always meet the time limit. The need for dialogue became apparent. Significantly more time was needed, particularly regarding artificial intelligence. It is sometimes difficult to bring these phases to a reasonable conclusion in a reasonable amount of time.

Answering the reflection questions also places an additional workload on students. Some students showed only sporadic participation in the e-learning platform, despite the introductory events and repeated reminders of the importance of the reflection questions for their studies. This could be due to the high workload in the first semester. The introduction of additional content to reflect on digital media without reducing the subject-specific content could have a negative impact on morale and acceptance. Despite a high level of interest in digital media, students reported limited capacity for in-depth reflection on their approaches due to the high workload. In the future, the development of digital competences should be part of the curriculum and included in the semester planning.

3.3 Requirements for the application

There are certain essential requirements for a successful implementation of reflection processes in university courses to ensure effective integration into existing concepts and increase student acceptance.

It is necessary to create appropriate time slots. A balance must be found between subject-specific parts and the reflection of digital actions. If the program is successful, it can be anticipated that students will be more efficient in their use of digital media. In the end, this will reduce the workload for the students during their studies and beyond.

A central aspect of the method is a structure consisting of self-reflection, group discussions and plenary discussions. The establishment of such a structured process is necessary to integrate reflection processes both in self-study and during the lecture, and to familiarise students with this type of thematic discussion. A lack of a structured process could otherwise lead to a reduction in acceptance of the necessary feedback.

It is important that the first step of self-reflection is encouraged. In the concept shown, this could be linked to an existing e-learning programme. If such regular self-learning programmes are not available, other ways of providing feedback must be found. This is also possible, for example, on study organisation platforms such as Moodle. To increase the motivation to participate in these reflection processes, the awarding of additional points for the examination when relevant questions are answered can be considered.

Just in Time Teaching means that the lecturer has to analyse the students' feedback on the e-learning platform and decide what to do in the next course (Novak et al. 1999). The quality of the course depends on sufficient preparation. If there is a huge number of participants, it is sufficient to randomly review the students' responses (Riegler 2019). With increasing routine and experience, the time required is reasonable.

It is important that the additional tasks on digital media are directly related to the subject content of the course and are tailored to the students' learning processes. This is the only way to create direct added value for the students and encourage deeper reflection on the use of digital learning methods and media. The reference to current content increases students' motivation to engage with the topics.

4 DISCUSSION AND CONCLUSION

The paper demonstrates that reflection on the use of digital media can be integrated into the mathematics course in the first semester. It is beneficial for this reflection to take place very early in the studies, as students extensively use digital media for studying. Engineering students are often not accustomed to reflecting on and discussing their behaviour. Therefore, sufficient time and a solid structure are needed to integrate this into their studies. Due to the workload of the students, it was only tested in one year. The future plan is to implement it into voluntary courses on basic mathematics.

The concept described here can be implemented for all types of university courses, considering the points from chapter 3. Of course, the aspects mentioned, such as self-reflection in the e-learning platforms, may need to be supplemented to initiate multiphase self-reflection. The familiarisation phase of this new approach depends largely on the structure of the event, but also on the communicative atmosphere that needs to be created.

In fact, a long-term anchoring of the reflection of learning methods with digital media in the curricular would be an important step so that the reflection of the procedures can also take place and be applied in further courses. This would effectively promote the acceptance of the approach as well as the ability to study regarding a critical examination of student's own learning processes.

ABSTRACT

In graduate school education, the acquisition of transferable skills is the basis for implementing social change and contributing to more wide-ranging career development for students. Specifically, these skills include problem-solving abilities, innovation, time management, career management, professional development, teamwork, leadership, and communication. Thus, this study focused on improving the leadership behavior of graduate students, especially among first-year master's students in science and engineering programs. For this purpose, we not only examined the acquisition of knowledge, but also the promotion of positive behavioral changes through the reflection of individual growth and related experiences. Specifically, we developed a framework and found that three elements can promote positive behavioral change in leadership: 1) Personal characteristics; 2) A place for leadership experience; and 3) Reflection process. Additionally, the students exchanged feedback with one another based on the actions recorded in their e-portfolios. Those who connected their peers' reflections with their own behavioral changes in "simulated experiences" and continually applied new learning to "actual experiences" significantly improved their leadership skills.

1 INTRODUCTION

1.1 Transferable Skills

In graduate school education, the acquisition of transferable skills is vital for implementing social change and improving career development. Specifically, these skills include problem-solving, innovation, time management, career management, professional development, teamwork, leadership, and communication.

1.2 Leadership Skills

This study develops a framework for improving the leadership skills of graduate students. In this case, the term “leadership” refers to the ability to develop one’s strengths and encourage continuous self-transformation. In order to foster such skills, it is not only important to accumulate actual experiences, but to also reflect on such experiences. Thus, we propose a systematic educational program that demonstrates leadership and promotes self-transformation among graduate students.

2 TRENDS RELATED TO TRANSFERABLE SKILLS

According to a 2009 European Science Foundation report, transferable skills are defined as “skills that are acquired in one context and effectively applied in other contexts (e.g., research, business, employment).” In February 2020, the Ministry of Education, Culture, Sports, Science and Technology in Japan stated in the Council for Science and Technology’s Academic Subcommittee report titled, “Improving the Constitution of Graduate School Education,” that graduate schools are expected to play a central role in the development of future intellectual professionals. It also mentioned the importance of acquiring transferable skills.

After graduation, master’s and doctoral students not only work as researchers and professionals, but they also use their highly specialized knowledge to discover various issues, launch projects to solve them, and lead project teams to bring about social change. In this regard, expectations are high for such individuals. In the United Kingdom (U.K.), the British Research Council categorized the transferable skills that doctoral students and researchers should acquire into seven types and published the “Joint Statement of Skills Training Requirements of Research Postgraduates”' in 2001. Vitae (2011) further developed this joint statement and published it as the “Researcher Development Framework (RDF),” which describes the background and skills of high-quality researchers.

Although some of these transferable skills can be obtained through existing research activities, British graduate schools have incorporated learning opportunities into their curriculums, by using RDF as a reference. In this regard, transferable skills frameworks have been established in Europe, including the U.K., along with the required training.

However, in Japan, there are only a few examples of such training being incorporated into the curriculums of graduate schools, indicating that there is much room for research. For graduate students, society demands that they continue to develop and enhance their skills after graduation. In order to proactively develop one’s career, it is becoming increasingly important to cultivate leadership skills that encourage self-transformation.

3 LEADERSHIP EDUCATION DESIGN

3.1 Systematic Educational Program

In order to acquire soft skills, such as leadership, it is necessary to experience the real world by using one's body and sensibilities. Since 2008, we have been providing leadership education to first-year master's students in science and engineering graduate programs. In order to connect knowledge to practice, such education includes five modules: 1) Knowledge acquisition; 2) Experiential learning; 3) Practical application; 4) Reflection; and 5) Evaluation (see Fig. 1).

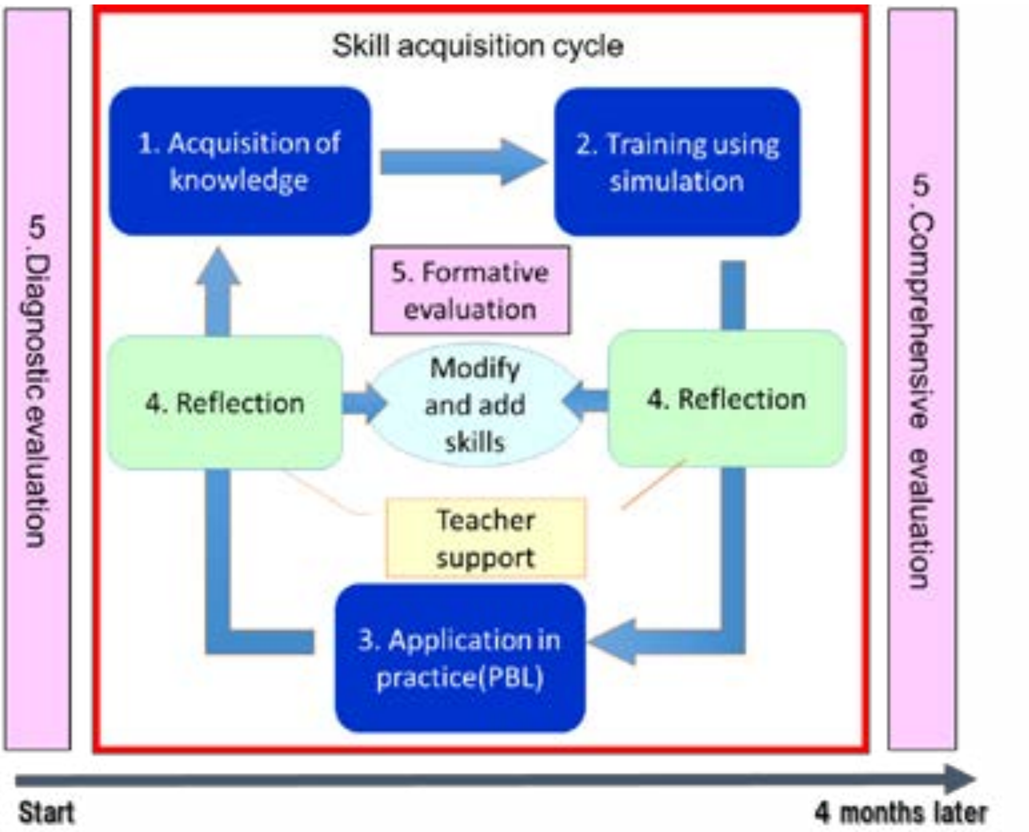

Fig. 1. Leadership Education Model

In this study, we employed a simulator to strengthen interpersonal relationships in the "Experiential learning" module and create a link from knowledge to action. In this regard, simulated experiences can serve as a bridge between knowledge and practice as well as improve leadership behavior. During the COVID-19 pandemic, the use of not only simulators, but also virtual reality, augmented reality, metaverses, e-books, etc., has attracted increasing attention from scholars and practitioners. Meanwhile, the development of experiential learning through these technologies can help expand the number of learning strategies and support students with diverse backgrounds.

Finally, there are differences in the quality of individual students' experiences in the "Practical application" module. In this case, some students tend to choose challenging experiences and recognize the need to transform themselves, while others prefer “safe” areas that do not place excessive stress on them. In this case, the quality of experiences also influences the quality of reflection.

3.2 Utilization of an E-portfolio

In this study, the graduate students reflected on their leadership behaviors, while using a simulator. For example, during “actual experiences,” the students examined their leadership behaviors in various activities, cycled through their experiences, and recorded the key details of their leadership experiences in an e-portfolio (see Fig. 2). Here, the students not only reflected on their own learning, but they also electronically stored records of the learning that occurred during the process. Although some students have the ability to continually self-evaluate and find areas for improvement, a mentor can track their progress and provide any necessary support during the program.

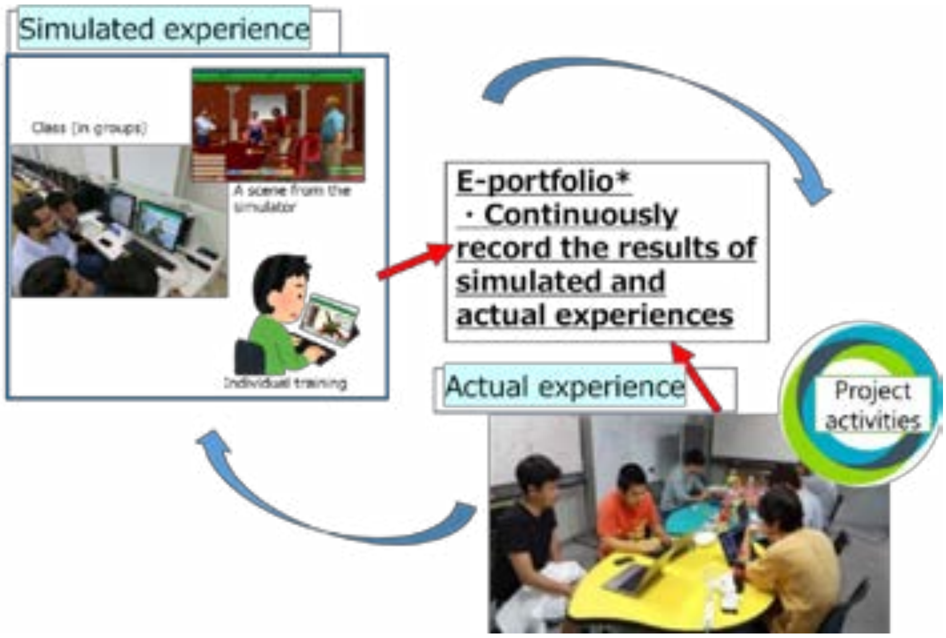

Fig. 2. Ongoing Recording of Experiences in an E-portfolio

4 RESEARCH HISTORY

To date, we have devised the contents of each module of the leadership education program and repeatedly improved them in related research. The timeline is as follows:

- We conducted leadership education by using active learning for first-year master’s students in science and engineering programs. Specifically, we introduced peer reflection in which the students exchanged feedback with one another based on the actions recorded in their e-portfolios. Those who connected their peers’ reflections with their own behavioral changes in “simulated experiences” and continually applied new learning to “actual experiences” significantly improved their leadership behaviors (Maruyama 2019).
- The students reflected on their own leadership experiences and conducted quantitative and qualitative evaluations based on their recorded e-portfolios.

After analyzing the evaluations, we conducted interviews with the students who showed positive changes in their leadership behaviors in order to determine how they carried out their reflections (Maruyama 2020).

- In 2020, the spread of COVID-19 made it difficult to hold face-to-face classes, after which different methods for conducting remote classes were explored. In this regard, we devised a virtual environment for leadership education and project-based learning activities. For the latter, 17 teams worked on various real-world problems relevant to local governments and businesses. We also investigated the improvement of online team formation development. The results indicated that team formation can be developed, even in a virtual environment (Maruyama 2021).
- Finally, based on the results of the students' quantitative and qualitative evaluations as well as our analysis and literature review, we proposed a reflection teaching strategy that promotes student growth (Maruyama 2023).

Based on these results, we created a framework that promotes behavioral change in leadership among graduate students (Maruyama 2020) (Maruyama 2022) (Inoue 2023).

5 A FRAMEWORK FOR PROMOTING POSITIVE BEHAVIORAL CHANGE IN LEADERSHIP

The three elements that make up this framework include: 1). Personal characteristics; 2) A place for leadership experience; and 3) Reflection process (see Fig. 3).

Fig. 3. Framework for Promoting Positive Behavioral Change in Leadership

(1) Personal characteristics

In general, students who make a positive behavioral change through reflection include the following characteristics.

< Use of reflection >

・The ability to recognize the importance of reflection to connect experiences to growth.

・The belief that something new can be generated from continuous reflection.

・The ability to not only analyze failures, but also successful results.

< Metacognitive ability >

・The ability to recognize and utilize one’s strengths.

・The ability to evaluate one’s abilities and discover the characteristics of one’s learning method.

・The ability to determine what is lacking and recognize the need for change.

< Attitude toward learning >

・The ability to consider learning opportunities as something special, instead of something taken for granted.

・The ability to realize that the time spent on learning can be meaningful by reflecting on knowledge/experience and connecting it to one’s personal growth.

・The ability to recognize that learning results are the responsibility of each individual.

(2) A place for leadership experience

During university life, students have limited opportunities to demonstrate leadership skills. However, students need a place in which they can feel safe and make mistakes in order to learn from them. In this leadership education for graduate students, we used a simulator in which the participants can hold meetings with avatars in a virtual environment to encourage leadership in project learning. There is also a need for opportunities of leadership experiences within the intended educational setting, as well as those in the real world that go beyond the framework of education. In order to encourage behavioral change, the quality of the experience (which is the subject of reflection) is important. In this regard, the question of what types of experiences can enable deeper reflection and encourage behavioral change will be a topic for future research.

(3) Reflection process

< Personal reflection >

・The importance of re-examining oneself, becoming aware of one’s learning, and reconsidering the learning process.

・The ability to monitor and determine whether one’s approach is working, and develop a growth mindset that encourages effort.

・In this case, metacognition is important for recognizing opportunities for improvement and having the mindset that such improvement will be successful. It is also important for determining how to adapt one’s learning and behavior to new situations and environments.

・The ability to determine how one’s involvement in the learning process can influence the interpretation of tasks and the selection of learning strategies.

< Reflection with others >

・The perspectives of others play an important role in promoting personal growth through reflection.

・By understanding the frameworks in which others view different aspects and comparing them with one’s perspective, it is possible to gain a broader perspective.

・When it is possible to independently choose what to learn through reflection, metacognition plays a significant role in individual learning. In this case, interactions with others are involved in the formation of metacognition.

・In addition to personal reflection, the process incorporates reflection with others who can provide critical feedback and support.

< Feedback from teachers >

・Instead of simply relying on the students to decide on how to interpret learning outcomes, it is important to convey other interpretations and different behavioral approaches from the instructor’s perspective.

・In this case, it is important to tell the students that there are various learning strategies and spend time considering which strategies are suitable.

・It is necessary to determine how the results of the reflection can be applied.

・In this process, a two-way interaction is required, instead of one-way feedback.

・Since there are limits to individual instruction, especially in large classes, it is desirable to introduce digital technology when responding to certain individuals.

By following this framework, students will not only develop essential leadership skills but also cultivate a mindset and approach that promotes continuous personal and professional development. This holistic approach ensures that students are well-prepared to take on leadership roles and navigate complex challenges in their future careers. Several expected outcomes are as follows.

The first is to improve self-awareness and metacognitive skills. Students learn to recognize their strengths and weaknesses, choose how to learn, and identify areas for improvement. They also develop a growth mindset that allows them to view challenges as opportunities for growth.

Second, students will understand the importance of reflection. Students will understand the importance of looking back to connect experiences to personal and professional growth. They will be able to draw lessons from both successes and failures. Students will learn to monitor their approach and adjust their behaviour.

Third, effective leadership skills can be developed. Through simulations and real-life leadership experiences, students practice and refine their leadership skills in a safe environment. Students gain confidence in leading project teams and managing projects.

6 Conclusion

In graduate school education, the acquisition of transferable skills is the basis for implementing social change and contributing to greater career development, since such skills can be useful for applying specialized knowledge to various situations. In this regard, it is important to develop the ability to reflect, which is the foundation for demonstrating one's strengths and self-transformation. Thus, this study focused on improving the leadership behavior of graduate students, especially among first-year master's students in science and engineering programs. Specifically, we developed a framework and found that three elements can promote positive behavioral change in leadership: 1) Personal characteristics; 2) A place for leadership experience; and 3) Reflection process. In addition, the students exchanged feedback with one another based on the actions recorded in their e-portfolios. Those who connected their peers' reflections with their own behavioral changes in "simulated experiences" and continually applied new learning to "actual experiences" significantly improved their leadership skills.

Keywords: Absenteeism, attainment

ABSTRACT

In recent decades, the issue of university class attendance has gained significant attention due to its impact on institutional reputation and the need to enhance student engagement, especially in light of the European Higher Education Area's establishment in 2015. Extensive analyses of absenteeism determinants underscore its complexity, highlighting the necessity for tailored interventions to effectively address this issue. This study, conducted by a team of educators from Barcelona

[1] *E. Mas de les Valls*
elisabet.masdelesvalls@upc.edu

School of Industrial Engineering affiliated with the Universitat Politècnica de Catalunya BarcelonaTech (Spain), aims to assess absenteeism rates and propose mitigation strategies by examining factors influencing attendance and educators' perspectives. The study employs a mixed-method approach, incorporating surveys from students and educators, daily attendance records, as well as interviews and discussions.

Preliminary findings indicate elevated absenteeism rates, particularly in mass enrollment programs featuring more expositive teaching methodologies, attributed to perceptions of redundant class material and dissatisfaction with teaching methods. Notably, undergraduate students often seek supplementary instruction from private academies. Promising strategies include adopting contextualized teaching approaches and transitioning exams to non-standardized formats. However, the long-term effectiveness of these measures necessitates further evaluation.

The methodology and insights derived from this study have the potential to inform strategies aimed at addressing absenteeism in engineering-focused institutions and beyond.

1 INTRODUCTION

In recent decades, attendance in university classes has become a concerning issue, as noted by St. Glair and St. Clair in 1999, who highlighted the potential decline in institutional reputation if students could earn degrees without attending classes. The establishment of the European Higher Education Area in 2015 further emphasized the importance of enhancing student engagement and adopting a student-centered learning approach (European Commission 2015). Absenteeism not only hampers the learning process but also represents a misuse of economic resources, particularly in public university systems. Despite these concerns, a comprehensive global analysis of absenteeism remains elusive. Only specific studies provide insights into absenteeism rates. For example, Kousalya, Ravindranath, and Vizayakumar (2006) found absenteeism rates ranging from 30-50% in an Indian engineering college, a figure mirrored by Summers, Higson, and Moores (2021) among nearly 2000 undergraduate STEM (Science, Technology, Engineering and mathematics) and business students in the UK.

Similarly, research conducted at a chemical education program in Nigeria (Nja, Cornelius-Ukpepi, and Chinyere Ihejiamaizu 2019) revealed absenteeism rates ranging from 25% to 45%. Conversely, in a study by Vicéns Moltó, Hervás Avilés, and Zamora Parra (2019), absenteeism rates were reported to be as high as 70% during the initial year of an engineering degree, steadily escalating throughout the program and peaking at nearly 80% in the final year. These few cases of study highlight the widespread nature of the issue.

The correlation between attendance and attainment has been extensively studied, with literature suggesting a significant link (Credé, Roch, and Kieszczynka et al. 2010; Kassarnig et al. 2017; Keyser 2019; Moores, Birdi and Higson 2019; Rendleman 2017; Shaaban and Reda 2021). However, the causal relationship between attendance and attainment remains debated, with some researchers suggesting that poor attainment can lead to low attendance, and vice versa (Credé, Roch, and Kieszczynka 2010; Kahu 2013). Indeed, attendance alone does not imply active participation (Kassarnig et al. 2017; Moores, Birdi, and Higson 2019). This is the reason why mandatory policies do not have a clear positive impact on attainment (Rendleman 2017).

Various factors influence students' attendance decisions, including institutional policies, psychological factors, and socio-demographic characteristics. These factors interact in complex ways, producing sometimes apparently inconsistent results. For instance, research findings vary depending on the country, funding system, publication year, student demographics, class size, and discipline (Moores, Birdi, and Higson 2019). For instance, in a study carried out in an Indian engineering college (Kousalya, Ravindranath, and Vizayakumar 2006) and based on a multicriteria decision-making method, parents' involvement and counselling were the most relevant factors for absenteeism, followed by peer pressure and punishments for absence, in front of making lecture more attractive, improve the infrastructure or increase the coherence between the curriculum and the assessment. In (Al-Labadi et al. 2022), a quantitative study of roughly 15200 students in a Canadian university showed that the main reason for absence in class was to study and prepare for other courses, followed by the students' mental health and poor sleeping habits. In a Spanish study with nearly 1900 students from the Business Administration, Economics and Sociology degrees (Triado-Ivern et al. 2020), the main reasons for the absenteeism are student's own planning, teaching methodology, learning methodology, course characteristics and external sources.

In Qatar, difficulty reaching the learning center has been identified as a primary reason for absenteeism, prompting the implementation of measures like mandatory attendance rates and transportation services (Shaaban and Reda 2021). Gender differences in absenteeism have also been noted, with male students typically exhibiting higher rates (Al-Labadi et al. 2022; Nja, Cornelius-Ukpepi, and Chinyere Ihejiamaizu 2019). Other factors, such as balancing work and study or the availability of online materials, also impact attendance (Moores, Birdi, and Higson 2019; Rutherford and McGrath 2022).

The study reported by López-Bonilla and López-Bonilla (2015) states that the quality of teaching is a crucial factor influencing absenteeism, with students citing educators' teaching methods and competence as primary reasons for their absence. However, while poor-quality lectures may discourage attendance, high-quality lectures do not necessarily increase it. Aligning teaching and assessment practices may enhance the perceived value of classes (Moores, Birdi, and Higson 2019).

Social factors, including peer interactions and educator-student relationships, also influence absenteeism. Students tend to attend classes more if their peers do, particularly high achievers (López-Bonilla and López-Bonilla 2015; Kassarnig et al. 2017). In a study performed by Leufer and Cleary-Holdforth (2010) it was observed that large class sizes and perceived lack of interest from lecturers can discourage attendance, highlighting the importance of personalized attention and a sense of belonging in reducing absenteeism (Moores, Birdi, and Higson 2019; Webb and Cotton 2018).

In conclusion, absenteeism is a complex issue influenced by various contextual factors, necessitating tailored interventions for effective reduction strategies.

1.1 Aim and research questions

The Barcelona School of Industrial Engineering (ETSEIB) is one of the 17 schools of the Universitat Politècnica de Catalunya · BarcelonaTech (hereafter UPC), a Spanish public institution of research and higher education specializing in engineering, architecture, sciences and technology. ETSEIB's facilities accommodate more than 3,400 students, and 350 educators. The school offers 2 bachelor's and 13 master's degree programs, in addition to 5 InnoEnergy master's programs, which can be categorized into either mass enrollment or specialized degrees. Notably, mass enrollment programs are the bachelor's degree in Industrial Technology Engineering (GETI), and the master's degree in Industrial Engineering (MUEI), with about 1900 and 680 enrolled students each, while specialized degrees typically have less than 120 enrolled students.

Absenteeism rates at ETSEIB have been steadily increasing, causing concern among educators. The first attempt to evaluate absenteeism occurred in 2022 through a survey distributed to all students, yielding a 33% participation rate with 1060 valid responses (ETSEIB 2022). Analysis of GETI students' responses, with a participation rate of 67%, revealed that 78% of students do not attend all subjects equally, their attendance being contingent on perceived class relevance. Additionally, it was observed that a majority of the 22% who attend subjects equally do so for all subjects. The underlying reasons for the high absenteeism rate among the 78% of students need further investigation. Furthermore, the survey highlighted that absenteeism is notably higher in mass enrollment programs like GETI and MUEI, though this observation requires further validation due to the survey's approximate nature and the post-Covid-20 pandemic adjustment to in-person attendance. The survey's impact led to absenteeism becoming the central theme of the third ETSEIB teaching conference in 2023.

This study aims to assess the current absenteeism situation and propose mitigation strategies by addressing the following research questions (RQ):

1. What is the extent of absenteeism at ETSEIB, and which degree programs are most affected?
2. What are the underlying causes of absenteeism at ETSEIB?
3. Is there a correlation between attendance and attainment at ETSEIB?
4. Which teaching strategies do ETSEIB educators deem most effective in improving attendance?

Given the universality of absenteeism, the methodology and findings of this study may offer insights applicable to other institutions, particularly those specializing in engineering studies.

2 METHODOLOGY

The study is part of the ASAP-UPC teaching innovation project initiated in 2023. The project aims to identify active methodologies that promote a significant and in-person learning process. Fourteen educators are participating in the project, nine of whom teach at ETSEIB, with the others teaching at the Barcelona School of Nautical Studies. The educators at ETSEIB are involved in teaching the mentioned mass enrollment degrees (GETI and MUEI), as well as the bachelor's degree in Industrial Technologies and Economic Analysis (GTIAE), the master's degree in Automotive

Engineering (MAUTO), the master’s degree in Nuclear Engineering (MUEN), and the master’s degree in Energy Engineering (MUEE). This wide coverage across various degrees enables the team to gather substantial information from enrolled students and provide a comprehensive overview of absenteeism at ETSEIB.

A diverse set of data is gathered and analyzed to address the research questions. This includes surveys from both students and educators, daily attendance records, interviews, and discussions. The processing of this information follows a mixed methodology, combining quantitative and qualitative analyses. The main data from the surveys are detailed in the following sections. Interviews with students include both scheduled sessions with those who consistently miss classes and spontaneous discussions during or after lessons. Educator’s perceptions are gathered through surveys and supplemented with informal discussions among colleagues and debates during ASAP-UPC project meetings. Daily attendance is tracked for subjects taught by ASAP-UPC members and analyzed alongside students’ grades at the end of the first semester of the 2023-24 academic year.

2.1 Students’ survey

A survey was designed to identify the factors contributing to students’ absenteeism, strategies educators could employ to enhance attendance, the skills they deem most relevant for their profession, being this latest driven by the potential disparity between contents and students’ perceived relevance. The survey targeted students enrolled in subjects taught by members of the ASAP-UPC project during the second semester of the 2022-23 academic year. This encompassed 6 bachelor’s and 7 master’s subjects, totaling 563 students, constituting approximately 18% of ETSEIB’s student body. Students were prompted to complete the survey either during the final lessons of the semester or via the subjects’ online learning platform. The participation rate of 22.7% reflects a relatively low level of engagement, indicative of either students' limited interest or a saturation of surveys and emails from the institution.

2.2 Educator’s survey

Educators’ perceptions were collected through a survey where they were asked to focus on a single subject they teach. Initially, basic questions were posed regarding the subject type, whether attendance is compulsory, and the evolution of absenteeism over the years. Subsequently, more specific questions concerning potential actions to improve attendance were presented as open-ended inquiries, necessitating a thorough examination of responses and subsequent clustering. The survey was distributed to ETSEIB faculty by email, facilitated by the ETSEIB director. Eighty-eight educators responded, constituting 25% of the teaching staff at ETSEIB. Similar to the participation rate observed in the student survey, this relatively low level of engagement is noteworthy in itself. Among the responses, 67% correspond to GETI subjects, with MUEI subjects accounting for 10%, aligning with the distribution of enrolled students.

A second survey was conducted among the members of the ASAP-UPC project to collect information regarding ongoing modifications of their subjects aimed at boosting attendance. This survey presented a list of potential actions to implement, including new methodologies and assessment methods, which were selected based on team debates held during the initial months of the project. The participation rate for this survey was notably higher, reaching 93%.

3 RESULTS

3.1 Attendance rate

Results for each degree are presented in Table 1. In general terms, it can be asserted, and this is supported by the week-by-week data obtained, that absenteeism tends to be higher in the case of mass enrollment degrees and undergraduate courses. Notably, both MUEE and MAUTO exhibit very high attendance levels, attributed to their status as specialized masters' programs with a single group, fostering high student motivation. Regarding MUEI, a mass enrollment master's program, attendance levels vary depending on the specific subject, ranging from 65% to 22%. In the case of undergraduate degrees, absenteeism is more pronounce in mass enrollment programs such as GETI, compared to programs with a single group like GTIAE. Similarly to MUEI, attendance rates for undergraduate degrees depend on the specific subject analyzed but consistently remain below 60% across all studied subjects. These findings align with previously obtained data from 2022 (ETSEIB 2022).

Table 1: Attendance rates for each degree, 1st semester 2023-24

GETI	GTIAE	MUEI	MAUTO	MUEE
44.29%	65.13%	43.18%	96.67%	95.92%

3.2 Students' opinion

According to results presented in Figure 1, the primary reasons for absenteeism among students in mass enrollment bachelor's and master's degree programs are their preference for self-study and the perception that class materials are redundant as they are readily available online. In the case of bachelor's degree students, a third common cause of nonattendance is the need to retake the subject, while for master's degree students, it is dissatisfaction with educator's methodology. Consequently, students who do not attend classes perceive them as not being beneficial to their learning.

Specialized bachelor's degree students share the same primary reasons as mass enrollment students, with the addition of external work commitments emerging as a significant factor influencing absenteeism. Conversely, work commitments are the primary reason for non-attendance among specialized master's degree students, distinguishing them significantly from their mass enrollment counterparts.

The percentage of students selecting the 'other' cause for absenteeism in Figure 1 is notable. Through in-person interviews and informal discussions with students, it has been observed that one of the most common reasons is the perception that certain subjects are too challenging. Consequently, students opt to attend private academies to supplement their studies. Further research is necessary to delve deeper into and analyze these reasons comprehensively.

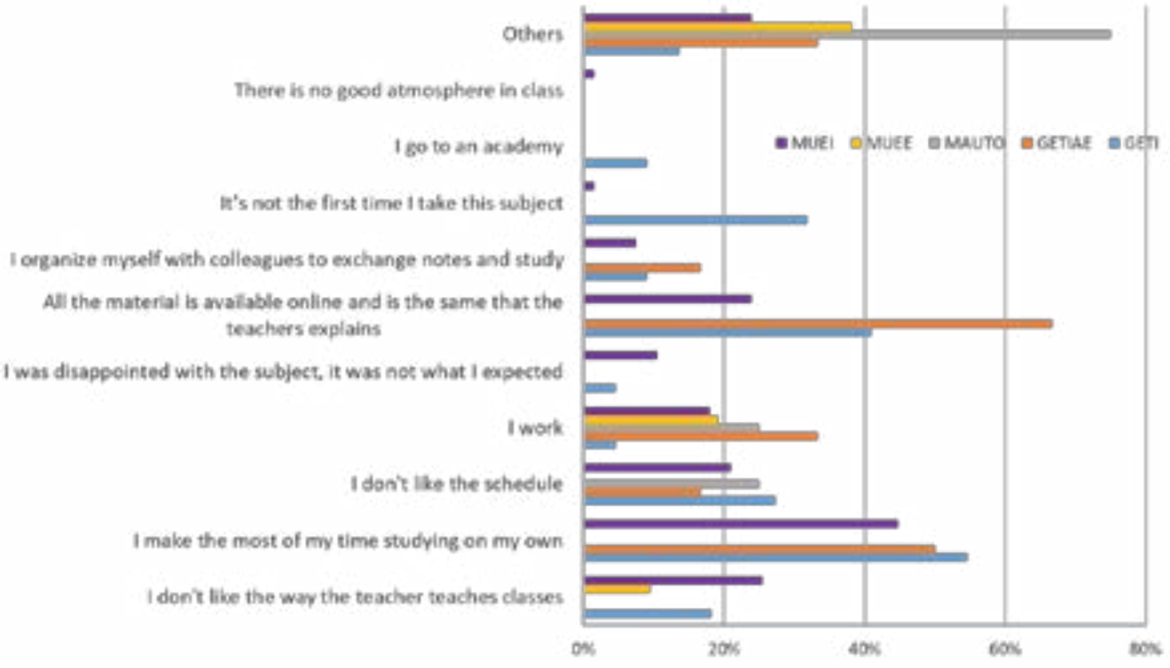

Fig. 2: Causes of absenteeism (according to students' responses)

Figure 2 illustrates factors that could potentially increase students' attendance. Contrary to expectations, methodologies aimed at increasing cooperative work or social interactions, utilizing ICT resources, or fostering connections with the degree program's environment are not perceived as motivating factors for students. Instead, students are primarily motivated to attend classes when they perceive them as contributing to their subject's approval and learning process.

Hence, there is a need to investigate and adjust methodologies and lesson content to encourage students to attend classes effectively.

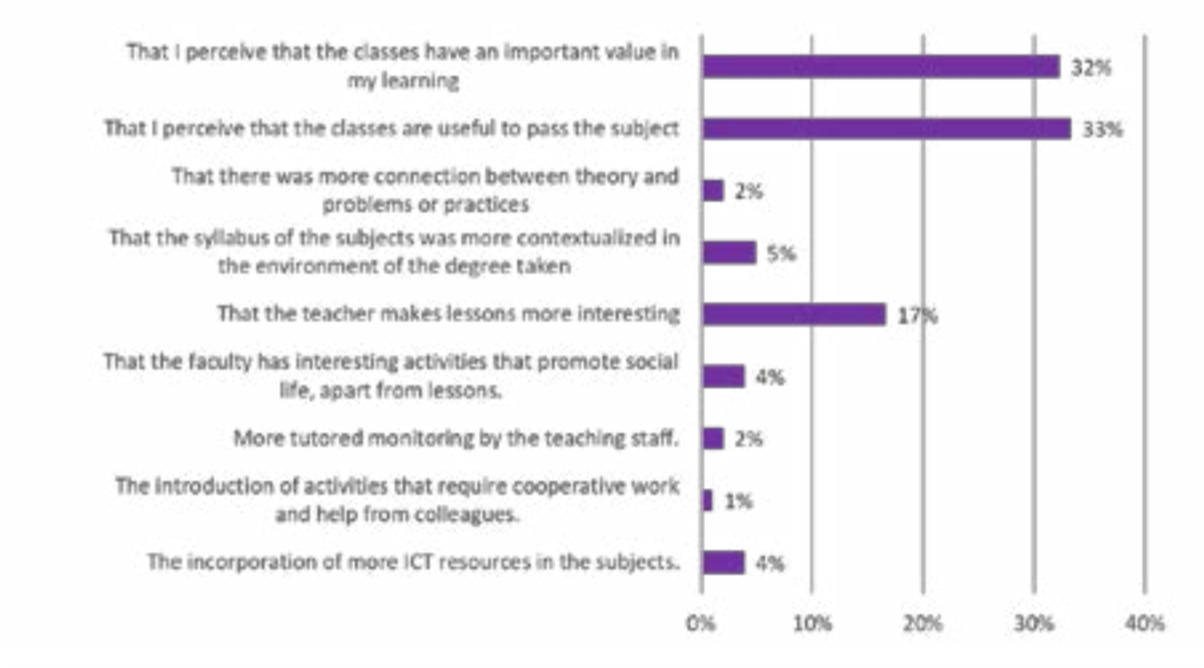

Fig. 3: Factors that could increase students' attendance (according to students' responses)

3.3 Educators’ opinion

Across all responses, it was found that 61% of lessons primarily focus on delivering theoretical knowledge, 25% are centered on problem-solving or exercises, and 14% involve laboratory experiences. However, this proportion varies among different degrees, being GETI, GTIAE and MUEI the ones with a higher proportion of expositive lessons. A surprising finding is the elective nature of the attendance, with 94% of expositive lessons, 92% of the problem-solving sessions, and 63% of laboratory experiences being non-mandatory.

Seventeen percent of educators have made adjustments to their teaching based on student satisfaction survey results at the end of the semester. The most common modifications (33%) include increasing the number of exercises solved during sessions and discussing the current absenteeism situation and the relevance of attending lessons. Additionally, 20% of educators focus on enhancing the relevance of learning outcomes to students’ professional lives.

In the subsequent survey conducted among members of the ASAP-UPC project, the proposal of exercises or problems to be done during the sessions is the most feasible mitigation strategy identified. In fact, 71% of ASAP-UPC members already incorporate student-solved exercises into their classes, a significantly higher percentage compared to the first survey. Furthermore, 91% of subjects include exercises resolution as part of the assessment system, with many educators planning to further enhance this aspect. Laboratory experiences are included in 65% of subjects, and 77% of educators aim to increase their number. Interestingly, only 50 % of the laboratory experiences are mandatory, even among ASAP-UPC members. Another noteworthy finding is that 35% of subjects are revising exams format to avoid standardized exams that can be solved without a deep understanding of the topic.

3.4 Absenteeism and attainment

Figure 3 depicts Gaussian curves representing the probability of achieving a particular grade based on attendance. A typical Gaussian shape is obtained for those students attending at least 50% of the lessons, with a mean grade of 7.5±1,01 out of 10. However, for students attending less than 50% of the lessons, an almost flat curve is obtained. This suggests that while attendance increases the likelihood of obtaining a higher grade, it is not the sole determinant of subject approval.

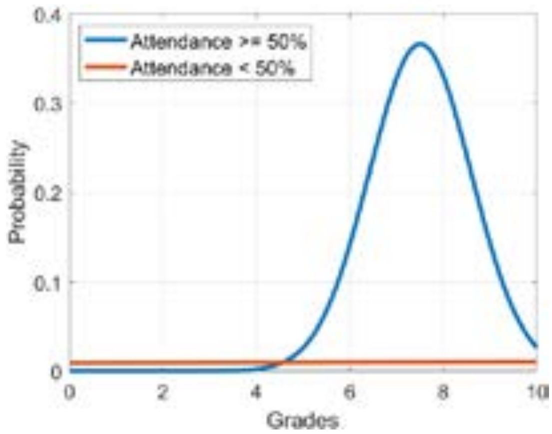

Fig. 4: Gaussian curves of the students’ grades based on their attendance

4 DISCUSSION

The findings indicate that absenteeism rates vary significantly across subjects, with an absenteeism higher than 40% in mass enrollment programs and undergraduate degrees. In these cases, students often skip lessons because they perceive them as unhelpful for passing exams. Coinciding with Triado-Ivern et al. 2020 and López-

Bonilla and López-Bonilla (2015) results, this perception stems from the believe that the material covered is already available online or dissatisfaction with the educator's methodology, leading some to opt for attending private academy to complement their learnings. These findings seem to demonstrate the existence of a casuistry typical of Spanish culture. Moreover, it has been demonstrated that attendance increases the likelihood of obtaining a higher grade also in the ETSEIB context.

Considering that (1) teaching is recognized in the same way regardless of the number of students enrolled, and (2) a direct proportion is associated between the educator's workload and the number of students enrolled, it is common to find a majority of expositive lessons in mass enrollment programs in the ETSEIB context. However, absenteeism tends to be more pronounced in expositive lessons, what indicates that a key absenteeism mitigation strategy is to minimize expositive lessons and maximize hands-on activities without increasing excessively the educator's workload. According to the results of the study, interesting mitigation strategies are: (i) the presentation of exercises or problems to be solved during class, with the specific guidance of the educator, (ii) the introduction of mandatory attendance at laboratory experiences, and (iii) the transformation of exams to a non-standardized format. All activities must be implemented so as the active participation of the students is considered in the assessment methodology. Also, if standardized exams are avoided, the fact that online materials are available, including a compendium of solved exams, should not penalize attendance.

These are the measures that ASAP-UPC members will implement. However, the effectiveness of these measures will ultimately be determined over time.

5 ACKNOWLEDGEMENTS

The ASAP-UPC innovation-teaching project has received funding from the UPC Teaching Innovation Projects 2023 Call Resolution (Agreement CG/2023/02/30, of 21 February 2023).

ABSTRACT

This paper presents the lesson learnt the first implementation of an online course, 'Soil Mechanics', in a Joint International Education Programme in partnership between the University of Strathclyde (UK) and a Chinese University. While the original plan was to deliver this course face-to-face (F2F), the online mode of delivery was later adopted due to the spread of the COVID pandemic. This prompted the implementation of alternative pedagogical approaches, such as the flipped classroom approach (FLA), and offered to opportunity to assess new modes of learning. The new delivery method presents a number of learning and teaching challenges, such as the effectiveness of online resources, the language barriers of students, and the customization of traditional assessments based on the need for online courses. The paper discusses all aspects of teaching and learning strategies utilised in this module and compares them with a similar module taught F2F by the author in a traditional framework at the University of Strathclyde. Academic achievements (as demonstrated through assessments), students' satisfaction and engagement, and instructor reflection are among key measures used to evaluate the performance of the new approach. As the module is intended to be presented F2F class format in the upcoming years, the idea of maintaining the same teaching and learning strategy or revoking it will be discussed.

1 INTRODUCTION

Joint international undergraduate programmes in STEM hold immense importance as they foster international collaboration among staff and students, promote cross-cultural competence, and prepare the workforce with innovative thinking, adaptability, and resilience. In pursuit of this objective, a collaborative joint international undergraduate programme has been established between the Civil and Environmental Department at the University of Strathclyde and a Chinese university. The plan was to develop a joint Civil and Environmental Engineering(CEE) curriculum in which some modules are delivered in Mandarin by Chinese staff and others are delivered by staff from University of Strathclyde. The start of this programme coincided with the spread of the COVID pandemic. To adapt to the educational restrictions, online mode of delivery has been selected for the first implementation of the module.

This allowed alternative pedagogical learning theories to be implemented. Among them, the flipped classroom approach (FLA) has been dominantly employed for this module, in which instructional videos, interactive virtual labs, and online quizzes have been provided to students as pre-class teacher-centered content, and they were actively engaging in the class for student-centered activities like questions and answers(Q&As) sessions and teachers' feedback and recaps (Akçayır and Akçayır 2018). It has been shown that the FLA is a cost-effective learning method that can generate high students' satisfaction and performance (Baytiyeh and Naja 2017, Prevalla and Uzunboylu 2019). Hardebolle et al. (2022) implemented FLA in engineering education and concluded that this method can eliminate the prior knowledge gap observed between different genders. However, effectiveness of FLA under the challenges associated with joint international programmes, such as language barrier and disparities in students' prior knowledge, remains to be addressed.

In this study, a comprehensive overview of the pedagogical methodologies employed for the administration and instruction of the Soil Mechanics module are summarized and discussed. Since the online mode of delivery has been adopted for teaching and learning activities, innovative teaching strategies such as virtual labs, virtual study groups, and online discussion forums have been created to enhance students learning experience.

2 METHODOLOGY

The soil mechanics module is among the fundamental modules taught in the early years of civil and environmental undergraduate studies. The purpose of the soil engineering module is to provide civil engineering students with an introduction to the physical and mechanical properties of soils used in construction and landscaping. A critical review of the existing curriculum between two universities has been performed to ensure academic rigour and standards across both universities. Upon reviewing the curriculum, it was found that there were a number of educational challenges. Particularly for the Soil Mechanics module, these challenges, along with the remedial pedagogical strategies, have been briefly reviewed.

2.1 Curriculum Alignment

The soil mechanics class is not the first module covering geotechnical engineering topics at University of Strathclyde. UK students have the chance to sit for the 'Fundamentals of Civil Engineering' module to briefly learn the basics of soils as engineering materials. However, this module was the first to aim at covering geotechnical engineering and geology at the Chinese University. To prepare Chinese students, the FLA has been implemented, in which preparatory materials (e.g., online videos and worked examples) have been provided to them before the live classes, and classroom time is then dedicated to interactive discussions, problem-solving, and collaborative activities. The use of online pre-class content also helped the program to be delivered in a compact version compared to the normal F2F program.

2.2 Language barrier of overseas students

The key obstacle for overseas students is the language barrier, which impacts students' ability to comprehend lectures, read module's materials, and complete assignments. Through communication with Chinese students, it was found that they experienced unequal language proficiency, affecting their academic performance (Zhu and O'Sullivan, 2022). As demonstrated by Fass-Holmes and Vaughn (2019), non-English-speaking students can achieve academic success if suitable teaching and learning strategies are implemented. One remedy was to provide transcripts of all oral materials, such as lectures and recorded videos, to allow students to have a self-paced learning experience. Also, various types of assessments, such as laboratories, online quizzes, and final exams, have been designed to provide equal opportunities for students with varying levels of language proficiency to showcase their learning capabilities. The laboratory assessments have been done in groups to establish peer support systems among students of different language levels.

2.3 Assessment and Grading Consistency

The traditional system of assessment has been replaced by a good diversity of assignments and feedback content such as mini-test quizzes, laboratories, and final exams. In all assignments, one of the main concerns was the lack of transparency, where students could not distinguish which learning outcomes were being measured (Hunt and Chalmers 2012). So the targeted learning outcomes have been vividly explained in the assignment descriptions. The questions of why we assess, what we assess, and how this assessment triggers learning opportunities were addressed. It was noted that Chinese students were not fully aware of Strathclyde policies on late submission, personal circumstances, and avoiding plagiarism. These details have been formally provided to them via the Strathclyde Online Learning Platform (MyPlace) and informally raised during the live class sessions.

2.4 Global pandemic challenges

The rapid spread of the COVID pandemic enforced the joint international programme to be delivered online. While overseeing digital tools has been established to assist students, limited hands-on activities and limited social interaction were feared to impact the success of these programmes. A key strategy employed for online instruction in soil mechanics involved leveraging the resources developed by University of Strathclyde's distance learning programme for integration into the current curriculum. The primary advantage here was breaking down the significant topics of each week into smaller segments, providing students with the opportunity to address and fill their specific knowledge gaps before live sessions. Another educational intervention was to develop virtual laboratories in which students watched the lab videos and worked out the laboratory report(May et al 2023). Here, interactive laboratory videos have been created in which informal quizzes along with instant feedback have been developed to assist students in their learning process. Interactive technologies have also been implemented in online quizzes (mini-tests), where instant feedback has been generated for MCQs to allow immediate clarification.

3 RESULTS AND DISCUSSION

To assess the success of the delivery, the assessment results and students survey have been analysed for the soil mechanics module taught in the joint international programme (referred to as the online module) and compared with the performance of UK students in the F2F educational setting (referred to as the F2F module). Similar assessments have been used in both online and face-to-face modules, which consisted of online quizzes (20%), laboratories (20%), and final exams (60%). Students were required to achieve 40% to pass the module. In order to determine student satisfaction, the results of a survey conducted in both online and F2F modules are depicted in Figure 1. It should be noted that a response rate of approximately 10% was recorded for both surveys. Students were overall satisfied with the taught modules in both programmes, but the level of satisfaction is higher in the online module with an embedded FLA. In the online module, they expressed the following comments for improvement:

‘Hopefully each test will give you a specific process, not just an answer’

‘Please add a detailed explanation to the answer to each section of the test. It might be helpful, thank you’

‘It is suggested to advance the opening time of tutorial.’

From these comments, it appears that students need further feedback for automated online quizzes and additional feedback on their laboratory reports. Also, it should be planned that learning materials for all teaching weeks, including online tutorial questions, are available at the start of the module. This will ensure that students have high preparation time before the class, which can foster higher level of thinking in the class. A similar observation was made by Sandnes et al (2006) regarding the delivery of modules from Western universities to Chinese universities, highlighting that students' language proficiency should be considered when designing course content.

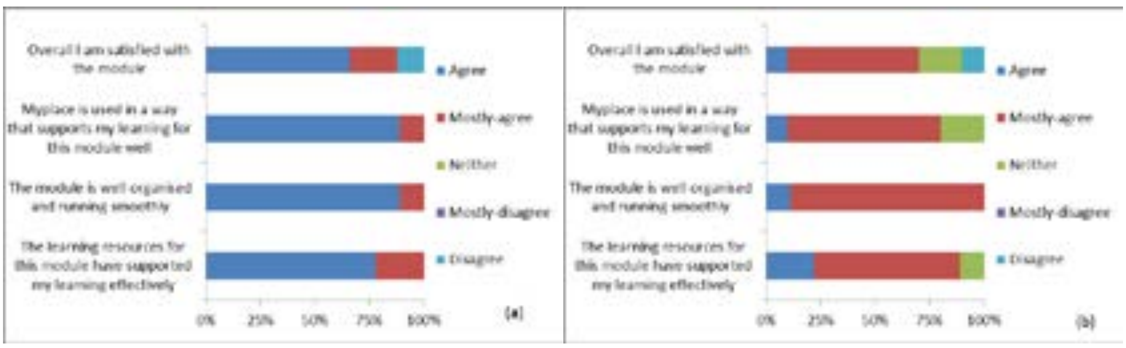

Fig. 1. The module evaluation survey in a) an online module b) a similar F2F module

The overall performances of students for two programmes is plotted in Figure 2a, where an average mark of 61% is achieved for F2F module compared to 59% in the online module. It should be noted that 93 students were participating in online module, compared to 101 students registered in F2F module. It can be seen that similar learning performance has been achieved among students attending F2F modules, which can be attributed to the opportunities for live interaction between instructor and students and the excess number of F2F sessions compared to online sessions. In the online module, it seems medium to high achieving students could efficiently use the online resources and achieve better performance with few non-engaging students noted in comparison to the F2F module. Overall, since similar average marks have been achieved between these two programmes, it can be confirmed that the FLA could be an effective alternative to the traditional F2F learning environment.

Among assessments, one laboratory was similar between the two modules and used here for comparing students' specific performance. The physical laboratory has been arranged in an F2F module, while this has been replaced with a virtual laboratory in online module. In both programmes, students could achieve high marks for this assessment, as shown in Figure 1b, with average marks of 83% and 76% recorded for the F2F and online modules respectively. Students' lack of familiarity with online labs and uncertainty about expectations can contribute to the low performance of Chinese students. (see May et al 2023). While the use of interactive videos with embedded Q&As features could promote an active learning experience, they need to be enhanced by allowing students to manipulate virtual apparatus, embedding adaptive learning paths in the videos, and including simulation-driven experiences.

4 FUTURE PEDAGOGICAL IMPROVEMENTS

4.1 Technology enhanced learning environment

Students' survey revealed that STEM students are enthusiastic to see tangible engineering solutions used in real-world engineering practice. Although educational technologies have found their way into the soil mechanics module through the incorporation of virtual laboratories and interactive quizzes, their potential for reinforcing theoretical concepts with real-world practical applications, particularly through the rigorous implementation of engineering simulations, has yet to be fully harnessed. Due to a lack of prior knowledge in the early years of the undergraduate (UG) study, the integration of simulations into the curriculum will pose a challenge to a fundamental module like soil mechanics, as students have not been prepared for in-depth analysis of complex engineering problems in 3D.

One pedagogical approach here is to incorporate recent digital technology to allow students to explore and visualise real engineering problems without the necessity of prior knowledge (Rehman, 2023). In soil mechanics, students understand the flow of water in 1D and 2D. In the upcoming teaching period, it is intended to use ANSYS Discovery, a real-time FEM software, to expand the application of soil mechanics beyond simple 1D and 2D geometry. Although year 2 students are not fully aware of the theory behind FEM, they are still able to utilise ANSYS Discovery as this software requires a minimum number of input parameters, such as mesh types and sizes. For example, the multi-stage dewatering system has been taught in the class and students did a simple 2D simulation to estimate the flow of water in soils. Using ANSYS Discovery with extensive drawing tools, students can quickly build complex 3D geometry and obtain the total head and flow vectors without knowing the rigor mathematical framework, as shown in Figure 3.

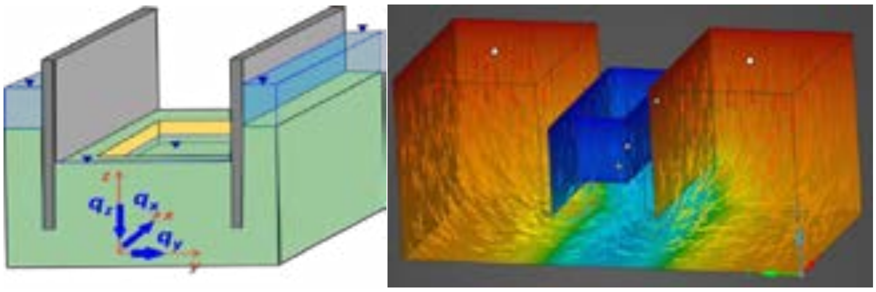

Fig. 3. Dewatering methods a) schematic representation b) numerical simulations

4.2 Revised methodologies for a F2F teaching module

The ongoing teaching round for this module is a F2F. It is essential to adapt existing pedagogical methods to accommodate this change for the future planning of engineering education. Examining various studies incorporating FLA in teaching, Van Alten et al (2019) indicated that students' perceptions and achievements can improve when FLA is integrated with F2F activities, rather than completely replacing them. This approach addresses a common drawback of FLA, where students often lack sufficient opportunities to ask questions during the lecture(see Hotle and Garrow 2016).Similarly, the author’s experience revealed that pre-class activities could offer accessibility and flexibility options to students and that they could use them to develop self-regulation skills. Also, students’ surveys confirmed that students prefer to have teaching materials in advance to use them as excellent revision tools for exam preparation. Therefore, it is planned to keep some pre-class resources, such as introductory videos for each subject and online quizzes. However, it is expected that more student-centred activities, like problem-based learning opportunities in laboratory sessions and extra tutorial sessions, can be organised in the new curriculum design. Also, the online virtual laboratories are worth being preserved even if teaching is delivered F2F round, and can be augmented with in-depth feedback sessions and ‘virtual’ teaching technology (e.g., simulation-driven software). This can create an autonomy-supported teaching environment, where students can change the design parameters and see instant outcome. The previous students’ survey was conducted by the university, which could not measure all aspects of teaching in a joint international program. A revised survey aims at measuring the students experience with the FLA, the influence of language barriers, students' preferences on keeping online resources for F2F teaching, and the use of technology-enhanced teaching has been prepared and attached in Appendix A.

5 CONCLUSION

The paper have addressed the educational methodologies and resources used for the first delivery of the soil mechanics module in a joint international programme involving the University of Strathclyde. The COVID pandemic imposed unprecedented restrictions and challenges on both instructors and students, which made traditional F2F classes an unfeasible option. The paper describes innovative educational solutions, such as using a flipped classroom approach and virtual laboratories, to overcome not only these challenges but also those typically faced in joint international programmes, such as language barriers and curriculum alignment between partnered universities. Since a similar F2F module has been run in Strathclyde, it has been used for comparing two different programmes in terms of assessment performance and students' engagements. Despite the challenges, similar students' performance in terms of overall assessment has been observed between the F2F module and the joint international module. However, it was clear that students experiencing physical laboratories could show better performance compared to those performing virtual labs in an online setting. A pedagogical remedy here would be to equip the soil mechanics module with a technology-enhanced learning framework. As an example of this technology, simulation-driven engineering software has been suggested, and its application in soil mechanics has been demonstrated. Finally, the revised teaching strategies have been suggested for future implementation of the class in a compacted F2F setting. Overall, the study offers empirical evidence regarding academic performance, student satisfaction, and engagement, aiding educators in making informed decisions regarding the adoption of FLA within challenging joint international programs.

APPENDIX A-REVISED STUDENTS' SURVEY

Flipped classroom experience:

1. How effective did you find pre-class content in preparing you for in-class discussions and activities? Very effective-effective-neutral-not effective-not at all effective

2. During in-class sessions, how beneficial were the activities and discussions facilitated by the instructor in reinforcing the pre-class content? Very Beneficial-Beneficial-Neutral-Not Beneficial-Not at All Beneficial

3. To what extent do you believe virtual laboratories (LABs A and B) enhance your understanding of geotechnical engineering concepts? Significantly enhance -Enhance neutral- do not enhance- detract from understanding.

Language barrier:

4. Did you face any language barriers while engaging with the online content or live class? If yes, please elaborate.

5. What strategies do you personally use to overcome language barriers in your academic endeavors? (Select all that apply.) Seeking help from professors or tutors-collaborating with classmates- utilising language support services- Self-study and practice- other (please specify)

Keep online resources for FTF class (blended learning)?:

6. If you prefer to continue having online resources, what are the main reasons for your preference? (Select all that apply.) Flexibility in learning; access to recorded

lectures for review; convenience - Improved understanding of course materials;- Other (please specify)

7. If you are against continuing online resources, what concerns or drawbacks do you have? (Select all that apply.) Lack of personal interaction- technical issues Reduced engagement with course content- other (please specify)

Technology-enhanced learning:

8. Do you prefer to learn engineering software in the lecture to understand real-world problems such as water flow in 2D and 3D? strongly prefer - Prefer neutral- do not prefer -strongly do not prefer

9. Do you prefer to use engineering software instead of a physical laboratory? strongly prefer -Prefer- neutral-do not prefer- strongly do not prefer

Students' engagement and satisfaction:

10. How satisfied are you with the overall blend of live classes and online learning? very satisfied- Satisfied- Neutral-Dissatisfied, and Very Dissatisfied

Educating the whole engineer through dialogue, ethics, reflection and stakeholder analysis

Keywords: *Engineering ethics, values*

ABSTRACT

This paper presents teaching and learning activities conducted throughout a one-year master's program with the aim of developing the whole engineer, so that students can engage on complex issues, and contribute to a sustainable and just world in their professional practice. In addition to technical knowledge, engineers

---

[1] *K. R. C. Mok*
c.mok@hhs.nl

must also possess professional ethics, critical thinking, an open attitude, advanced communication skills to navigate different stakeholders, as well as the ability to work in multidisciplinary team with diverse perspectives. The teaching and learning activities can be broadly categorised into four categories: strategic dialogue skills, engineering ethics, reflection and stakeholder analysis. Most students found strategic dialogue skills to be most useful to them in their personal development, while they perceived stakeholder analysis to be most useful for their graduation project. Majority of the students agree that the program has contributed to developing them into a more empathetic and responsible engineer. From students' feedback, these activities should be more integrated in an engineering context.

1 INTRODUCTION

The UN Sustainable Development goals (SDG) provide a list of urgent moral goals for innovation and applied science on a global scale (United Nations 2015). While all the goals are linked across the economic, social, environmental and governance pillars of sustainable development, the transition path to inclusive and environmentally sustainable economic development must come intensively from Science, Technology and Innovation (Walsh et al. 2020).

The SDG's can only be attained by confronting many complex and uncertain "wicked problems" that are facing the world. These problems are dynamic, multifaceted and involve many stakeholders with conflicting interests (Rittel and Webber 1973). Therefore, it is not sufficient for engineers to focus single-mindedly on finding technical solutions. The impact of engineers' work inevitably affects society. Poor design is responsible for many environmental and societal problems, so key design criteria, such as renewability, recyclability and nontoxicity, should be met (Wann 1996). The profession comes with a high burden of moral responsibility from the engineers themselves. On the other hand, the success or failure of certain outcomes may be influenced not only by the technical effectiveness of the solution but also by the public's subjective perception of risks and openness to innovation.

In order to contribute to a sustainable and just world, engineers must be able to combine fundamental technical knowledge with professional ethics. In addition, engineers must possess critical thinking, an open attitude and advanced communication skills to navigate different stakeholders, as well as the ability to work in multidisciplinary team with diverse perspectives.

The need to develop the modern engineer with such desired attributes has been addressed by the CDIO concept, which stands for Conceive-Design-Implement-Operate (Crawley 2007). One key aspect of the CDIO approach is the development of professional skills like teamwork and communication. The Hague University of Applied Sciences (THUAS) is a member of CDIO learning community of universities. THUAS technical programmes are implemented based on the CDIO framework, including an integrated curriculum, active learning and effective assessment.

Another educational approach, which has also been developed to achieve the goal of developing engineers that can navigate the complexities of the modern world and contribute positively to society, is to integrate engineering and the liberal arts (Hitt et al. 2023). There is a strong need for engineers to understand the social, ethical, cultural, political and environmental contexts of their work. It is proposed that integrative learning creates connections across liberal arts, disciplinary boundaries and professional domains, facilitating creative, interdisciplinary problem-solving.

This paper discusses comprehensive teaching and learning activities that are implemented regularly throughout a full-time, one-year Master of Science program (Next Level Engineering) at THUAS with the objective of educating responsible engineers, so that they can engage with care and curiosity on complex issues, and contribute to a sustainable and just world in their professional practice. The program is open to students with a bachelor degree from any technical discipline and has admitted the first cohort of students. The program aims to broaden the students' horizon by dealing with specific key enabling technologies, particularly applied data science, as well as developing their applied research skills. As part of the curriculum, students work on a design research project as a group in semester 1 and on an applied research graduation project individually in semester 2 with one of the THUAS research groups. The teaching and learning activities that were aimed at developing responsible engineers can be broadly categorised into four categories: strategic dialogue skills, engineering ethics, reflection and stakeholder analysis. It seems clear that value-sensitive design should be included (Cummings 2006), but a limitation of this work is that this topic was only briefly mentioned under ethics and not thoroughly covered.

2 IMPLEMENTATION

In academic year 2023-2024, the first cohort of students was admitted to the full-time, one-year master program. Out of the cohort of 23 students, roughly one-third of them have done mechanical engineering as their bachelor program, roughly one-third of them have done industrial design engineering as their bachelor program and the rest of the students come from other diverse technical bachelor programs, like information technology and health technology. 15 of the 23 students are local, Dutch students. Of the international students, 4 students have completed their bachelor studies in the Netherlands, while the other 4 students joined the program directly from abroad. In addition, 70% of the students are male and 30% are female.

The physical teaching space is a classroom with a maximum capacity of about 40, which is dedicated for the program. The tables are not fixed and can be flexibly arranged, usually in such a way that groups of 4 students can face one another in discussion and still see the teaching staff at the same time. Students are encouraged to form diverse groups of different (bachelor) backgrounds to provide different perspectives during discussions and to use the strengths of one another in group project. A whiteboard and markers are available for each group to write or sketch their ideas during their discussions. In addition, a "feature" of the learning environment is the extensive use of Post-it sticky notes. While the size of the cohort is conducive for engaging discussions, the use of Post-it notes is a low-barrier way for all students to freely express their opinions. Each opinion can be discussed objectively and fairly anonymously. More importantly, they can be moved around and clustered according to themes on a whiteboard.

In the beginning, as part of the introduction week activities, students learnt about ten categories of basic human values and selected top 3 values that represent themselves (Holmes et al. 2011; Schwartz 1992; Schwartz 2012). Students had to think about how they prioritise what is important to them, since everyone is motivated by all values but to different degrees. Values influence attitude, guide behaviour and motivate decision-making, especially in complex issues with conflicting interests. Meeting people where they are is important in engaging them, making it possible to work together to create common ground to reach a certain goal.

2.1 Dialogue

To that end, students are taught strategic dialogue skills. In this context, strategic dialogue is defined as a conversation between two or more people with clear purpose to gain new insights and solutions, through open exchange of experiences, knowledge and feelings, to reach a certain goal. It is in contrast to a debate, where opposing parties defend their own opinion, in order to win over an audience. As part of discussion on communication, students were asked to watch a documentary "Merchants of Doubt" (Kenner 2014), which exposes how a handful of scientists manipulated public perception on topics from tobacco to global warming. When asked how they felt, a student bluntly said "Disgusting". This brings up issues of professional ethics and moral responsibility.

2.2 Ethics

Ethics was dealt deliberately not from philosophical theory or analytical moral reasoning that do not meaningfully integrate into real-world engineering problems. Instead, ethics is discussed using examples in professional practice to engage technical students, especially on an emotional level. Firstly, the professional code of ethics was examined and applied to particular cases. Secondly, students were introduced to the notion that technologies are inherently value-laden (Van Grunsven et al. 2021). When students learnt that the low-hanging overpasses in New York in the beginning of the 20th century were low by design for the purpose of racial segregation (Winner, 1980), a collective gasp was palpable in the classroom. Thirdly, engineering ethics in practice was discussed using case studies to enhance students' understanding of the social dimension of the engineering profession (Martin et al. 2018; Martin et al. 2021). For the case studies to be impactful, they should be real, contextually relevant, and preferably recent or well-known. In addition, they should provide information to raise awareness of social and personal characteristics of engineering situations, as well as management pressure that can induce engineers to engage in misconduct (McGinn 2018; McGinn 2021). The case-studies should also address students directly, allowing them to identify themselves in the role of the engineer in a difficult situation, especially from the point of view of young starting professionals. It should be noted that Hitt et al. identified ethics education as a key future direction for integrating the liberal arts and engineering (Hitt et al. 2023).

2.3 Reflection

For students to tackle complex, difficult situations where not all factors are known, it is crucial for students to handle uncertainty in order to perform well. Alongside technical solutions, the approach of working and communicating with multiple stakeholders will be significant in contributing to an effective, overall solution. Therefore, students are coached on several tools available from "Reflexive Monitoring in Action" (Van Mierlo, B. and Regeer, B. 2010), which explains that system innovation projects benefit from a type of monitoring that encourages the 'reflexivity' of the project itself, the ability to affect and interact with the environment within which it operates. This lets them develop new ways of dealing with things, which makes the institutional context change too.

2.4 Stakeholder analysis

Students are taught to make a stakeholder analysis by mapping all potential stakeholders, prioritizing them according to their influence or interest, understanding their needs and if necessary, developing a plan to engage them. Furthermore, workshops were conducted on how to conduct interviews with stakeholders. Students apply the knowledge gained in their applied research graduation project, where they have to consider research ethics and intended, possibly unintended implications for different stakeholders. The technical solution or advice should take social, ethical, economic and sustainability issues into consideration, if applicable.

3 RESULTS AND DISCUSSION

The ten categories of human values (Schwartz 1992; Schwartz 2012) are illustrated in Figure 1. Based on descriptive keywords, such as *independent, curious, equality, protecting the environment, meaning in life* (Holmes 2011), which the students selected as most important to them, the top three categories of values turn out to be universalism, benevolence and self-direction. Universalism is defined as understanding, appreciation and protection for the welfare of all people and nature. Benevolence is defined as preservation and enhancement of the welfare of people with whom one is in frequent personal contact. Self-direction means independent thought and action. The categories least selected by students are hedonism, stimulation, conformity and tradition.

Theory postulates that values form a continuum of related motivations (Schwartz 2012). Adjacent values of universalism and benevolence share the motivational emphases of enhancement of others and transcendence of selfish interests, while adjacent values of self-direction and universalism share the characteristic of reliance upon one's own judgement and comfort with the diversity of existence. It is clear that the values that are important to the students show that they are open, curious, and intrinsically motivated to do good and contribute to a better world. They are least likely to be motivated by a desire for affectively pleasant arousal and would not likely subordinate themselves in favour of traditions or social expectations. It is gratifying to note that the values of this group of students closely align with the core values of THUAS, which are *Curious*, *Connecting* and *Caring*. These core values entail being open to others and curious about the world, embracing diversity and helping one another for a sustainable and just future. From these results, it is clear that the students are motivated to become responsible engineers from the outset and would be receptive to mastering professional skills.

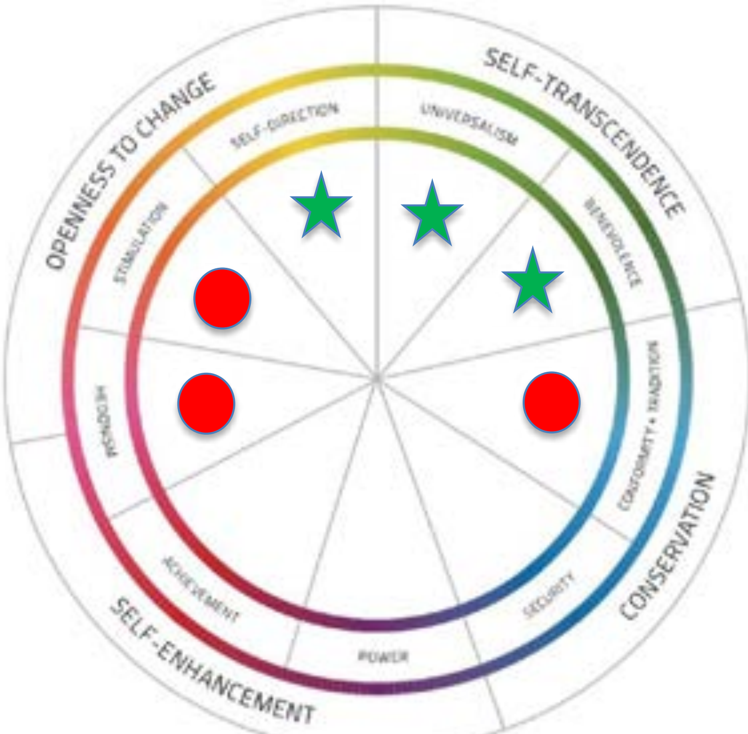

Fig. 1. The ten categories of basic human values as illustrated in The Common Cause Handbook (Holmes 2011). Green star symbols represent the values most selected by students and the red circle symbols represent the values least selected by students.

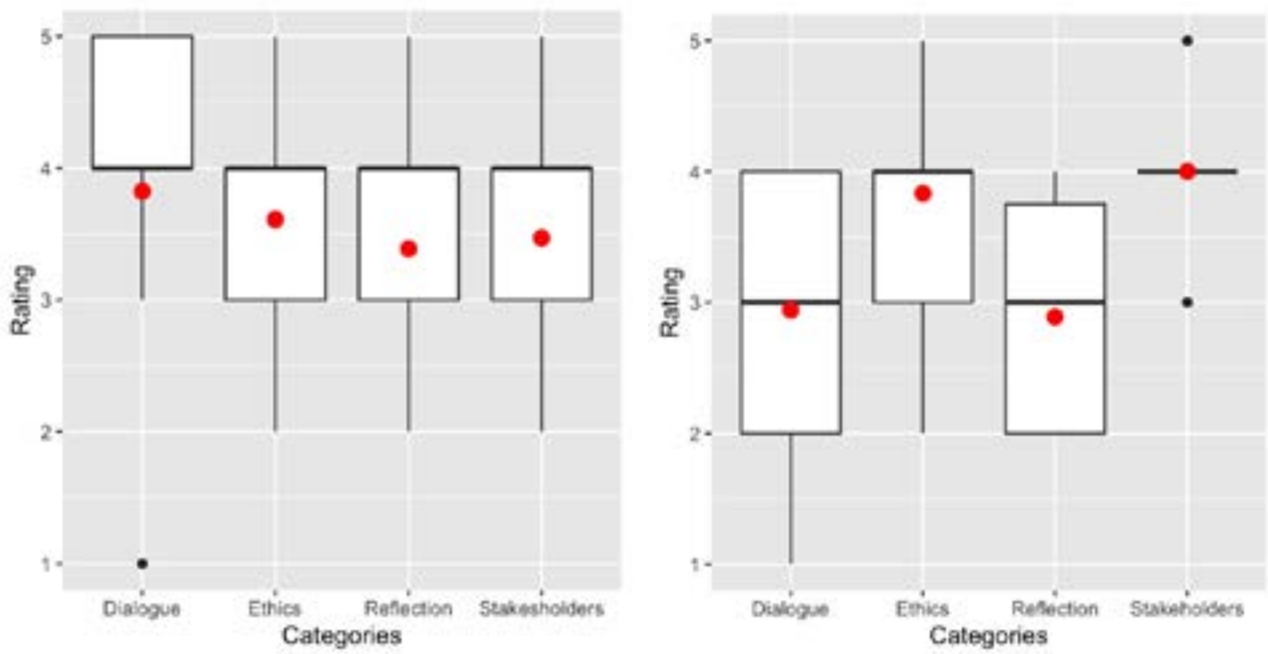
In order to find out the opinion of students regarding the 4 categories of teaching and learning activities mentioned in the previous section, a survey was carried out when students have approximately completed three-quarter of the academic year. Response was collected from 18 students out of a cohort of 23 (78% response). Students were asked if the teaching and learning activities mentioned in the previous section were useful to them in their personal development as a (socially)-responsible engineer or in their applied research graduation project. A 5-point scale was used with 1 representing “No, not at all” and 5 representing “Yes, very much”. Although the 18 respondents may not be representative of all engineering students in general, the results indicate a reliable trend within this group. Furthermore, their open-ended responses support the conclusion from the 5-point scale survey.

Figure 2(a) shows the box-plot representing the perception of students with respect to their personal development as a (socially-)responsible engineer and figure 2(b) shows their perception with respect to their applied research graduation project. Surprisingly, most students found strategic dialogue skills to be most useful to them in their personal development. The usefulness of ethics, reflection skills and stakeholder analysis to their personal development were rated very similarly. While strategic dialogue was deemed useful for their personal development, it was deemed less useful for their applied research graduation project. Students perceived stakeholder analysis to be most useful for their applied research graduation project. A student offered a tip on how some other students can be encouraged to be more receptive to strategic dialogue. *“Dialogue was more useful than expected, could have been framed as important to stakeholder communication.”*

In response to an open question that asked which activities students would like to have more of, ethics was mentioned by the most (6) respondents. 3 of them explicitly mentioned that they would like more of the case studies and debates. As a student aptly wrote *"Some ethical considerations I thought were surprising. As an engineer you have to think from your perspective but definitely <u>not</u> forget to think in someone else's perspective."* Another student wrote *"I enjoyed the workshop about ethics. I didn't expect it, but the legal aspect of the whistle blowers and who was found at fault at the trials was also interesting".*



(a) (b)

Fig. 2. Rating of students with respect to their (a) personal development and (b) graduation project. Red points represent the average rating. Black points represent outliers.

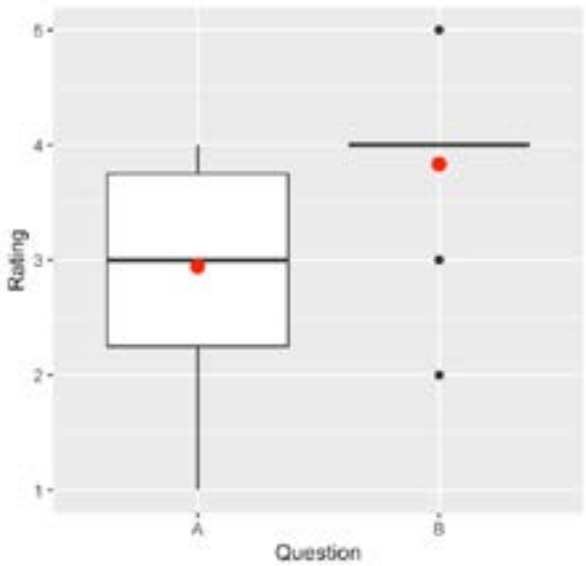


Fig. 3. Rating of students to Question A: "Did you expect before enrolment that the above activities would be useful?" and Question B: "Do you think that the program has contributed to developing you into a more empathetic and responsible engineer?"

Red points represent the average rating. Black points represent outliers.

Technical students remain resistant to time spent on non-technical content. At least 7 respondents mentioned something to the effect of *"less soft skills, more hard skills."* Figure 3 shows that although many students were neutral about the usefulness of dialogue, ethics, reflection and stakeholder analysis before enrolling in the program, it is encouraging that majority of the students agree that the program has contributed to developing them into more empathetic and responsible engineers.

In general, all four categories of teaching and learning activities can be adapted and implemented in different engineering programs. The primary objective of strategic dialogue, as part of general communication skills, is to foster an open exchange of ideas towards achieving a common goal. Reflection and stakeholder analysis are also not engineering discipline-specific. For ethics, it would be more interesting for students to discuss some relevant discipline-specific case studies. However, it is imperative to conduct such activities as interactive workshops in a classroom with no more than forty students to facilitate active discussion. A risk to the current program would be an unexpected increase in intake, such that there is a lack of suitable, dedicated classrooms and a teaching staff to student ratio that is impractical to facilitate discussions. In addition, appropriate projects that allow these activities to be embedded would enhance students' interest and learning. For instance, strategic dialogue and stakeholder analysis would be most useful when applied to technical projects that have significant societal relevance. Such projects often involve multiple stakeholders that students must interview and consider their interests. Regarding teaching hours, strategic dialogue, ethics and stakeholder analysis took around three 1.5-hour workshops each. For reflection, time is dedicated roughly once a week in semester 1 for coaching on several tools from "Reflexive Monitoring in Action" (Van Mierlo, B. and Regeer, B. 2010). The assessment of these professional skills takes place in the projects. For example, there are indicators in the assessment rubric that consider if students have considered the stakeholders in the formulation of their research objectives and if relevant ethical or sustainability perspectives are discussed.

4 CONCLUSION AND FUTURE PLANS

Although the results obtained from this short questionnaire are motivating, this is the first year of running a new master program and a lot of useful feedback has been collected from the first cohort of students. Majority of the students agree that the program has contributed to developing them into a more empathetic and responsible engineer. It is interesting that students perceive a difference in usefulness of dialogue, ethics, reflection, and stakeholder analysis to their personal development and for their applied research graduation project. Most students found strategic dialogue skills to be most useful to them in their personal development, while they perceived stakeholder analysis to be most useful for their graduation project. A student suggested to connect these activities directly *"to more engineering concepts would make it better in my opinion"*.

In future, these teaching and learning activities should be framed better to be more integrated in an engineering context, so that technical students who enjoy problem-solving can see more practical use of such activities in their applied research graduation projects. More concretely, value sensitive design (Cummings 2006) will be more explicitly incorporated in the curriculum, as this topic naturally involves values, ethics, reflection and stakeholder analysis.

ABSTRACT

The work presented in this practice paper illustrates how the use of immersive 360º video and photographs, viewed in virtual reality headsets or via 360º media players, can enhance and broaden student knowledge and experience when undertaking Project Based Learning (PBL) assignments. This paper will highlight an array of mediums in which a Virtual Site Visit (VSV) can be shared with students. By using coverage of real buildings, PBL assignments can be set for students which are real and innovative. This pedagogical approach allows educators to use particularly interesting or challenging buildings and case studies, once a VSV has been generated. This is particularly useful: for students who may have accessibility issues due to

[1] *M Moloney*
mary.moloney@mtu.ie

physical disabilities; the sharing/experiencing of interesting structures from around the world in a much more meaningful way; or for distance/online learning.

This practice paper will share the equipment specification for recording the VSV, a suggested workflow in preparing for the recording of the visit along with the video recording methodology and editing process, with proposed mechanisms for sharing the VSVs with students. Feedback was gathered and is shared in this paper from a cohort of students undertaking a Health and Safety module, in which a VSV video was used to share the building on which a PBL assignment was based.

1 INTRODUCTION

1.1 Project Based Learning and Virtual Site Visits

The work presented in this practice paper illustrates how the use of immersive 360^o video and photographs, viewed in virtual reality headsets or via 360^o media players, can enhance and broaden the student experience when undertaking Project Based Learning (PBL) assignments. It has long been a practice of setting civil engineering students a PBL assignment based on a field trip or site visit. The literature clearly links the use of PBL assignments as a means of enhancing the engineer's education by improving their technical skills, and providing context for real-life engineering issues and challenges (Ríos et al. 2010, Kokotsaki, Menzies, and Wiggins 2016). However, there is an ever-present problem around ensuring that all students have access to the visit material particularly where, for example they were sick on the day of the visit or have accessibility issues. Indeed, the recent COVID-19 pandemic clearly illustrated the need for an alternative to the physical 'site visit'. (Ríos et al. 2010, Kokotsaki, Menzies, and Wiggins 2016)

2 PROJECT MOTIVATION/BACKGROUND

Student visits to construction sites and manufacturing facilities are a key component in the education of engineers (Shojaei et al. 2023, Wang et al. 2021). Engineers Ireland, the accrediting body for engineers in Ireland, have identified seven programme areas that need to be addressed in the development and design of engineering programmes (Engineers Ireland 2021). Two of these programme areas, PA2 Discipline-specific Technology, and PA5 Engineering Practice, identify industrial or commercial site visits, and real-world-based case studies and projects, as key measures to meeting these two programme areas.

However, the question arises, in the design of programmes and the integration of such industrial visits, case studies or project-based learning assignments, how can the issue of limited or no access to such facilities be addressed? There could be students with limited mobility in a class cohort; there could be a site/industrial location with sensitivities around accessibility and confidentiality; or in an extreme situation, a general lockdown on movement as was seen during the COVID-19 pandemic. Moreover, restricting options to in-person site visits places limitations on the pool of structures that can be visited, and/or are expensive to conduct for entire student groups.

To address these issues since the onset of COVID-19 in March 2020, work has been underway within the Department of Civil, Structural and Environmental Engineering at

Munster Technological University (MTU) to develop a more innovative approach, with the development of the ‘virtual site visit’ (VSV).

There is a growing body of literature investigating how students learn from VR and 360º videos and their benefits/short falls (Marinelli et al. 2023, Wolf et al. 2023). Whilst these VSVs may not replace an actual site visit; they are an excellent substitute when site access is not permitted or possible. They aid the development of critical thinking, problem-solving, spatial awareness, demonstrate construction technologies etc.

To ensure accessibility for all within the class cohorts, research was undertaken to see if there was a more innovative approach than using 2D photographs and videos to preparing these VSV. This has resulted in the purchase of equipment and the development of immersive 360º videos. This work was prepared in partnership with MTU’s Technology Enhanced Learning unit (TEL).

3 PROJECT EQUIPMENT AND SOFTWARE

3.1 Previous Equipment for VSVs and software

Previous equipment used in creating 2D virtual visits included a Nikon Z50 digital camera, with a tripod and recording equipment. This equipment was used for a number of VSVs, and whilst the photo and video quality were excellent, there were several issues encountered. These included the tripod set-up: the setting up of the tripod for the 2D Nikon camera is difficult when visiting a live construction site with moving vehicles etc. It takes time to level the device, only to have a large machine move towards you and you must re-level it again. A gimbal is needed for capturing video, if the camera is not on the tripod. Walking with the camera – without a gimbal leads to very ‘jumpy’ video footage.

3.2 360º video equipment for VSVs

This project investigated a number of alternative 360º cameras with the Insta360 the preferred choice. The following is the equipment specification of what was used in this project.

- Insta360 X3 camera with a tripod and stand as illustrated in figure 1 below.
- InstaStudio: The purchase of the Insta360 camera is accompanied by a licence for the editing software, which is downloaded via an app to your smartphone and also to your computer/laptop.
- DJI wireless mic and receiver set as illustrated in figure 1 below.

Figure 1: Insta360 camera and DJI wireless mic set with receiver and charging case

The Insta360 was first developed in 2015, by Arashi Vision Inc. In 2018 they introduced the FlowState stabilisation algorithm into their cameras, thus enabling the user to shoot video as though using a gimbal (Arashi Vision 2024). The X3 model, which was used in this project, can record 5.7K 360° video, 360° photos or 180° field of view photos. The camera can be controlled from an app on your smart phone or via the camera itself. Whilst the small screen on the back of the camera makes it slow to use, the mobile app has an excellent user interface. The recorded video can be shared as a 360° video on, for example, YouTube or the video can be reframed in the Insta360 studio for the best angles.

The camera has a ¼ inch (6mm) socket at the bottom which allows the camera to be mounted on a selfie stick or a tripod. If using the camera remotely outside, it is possible to mount the camera on an extension, or 'selfie' stick and use a heavy base plate for stability.

3.3 360° video software for VSVs

The Insta360 camera is linked to the user's mobile phone via the Insta360 app. This app allows the user to remotely operate the camera for either photos or videos. The user can edit the photos and videos recorded via the app – using the Snap Wizard, or import them into the InstaStudio on their laptop via the SD card or USB connection.

Captured photos and videos can also be shared on the users' social media accounts of Instagram and Facebook directly from the app or they can be uploaded to the Insta360 Album and can be accessed whilst not connected to the camera. Photo and video can also be mixed with music before sharing. All this is managed within the App or in InstaStudio. If wishing to combine videos for more detailed post-production then each Intsa360 video can be exported from InstaStudio as an MP4 file and imported into video editing software like Adobe Premiere Pro or Adobe Rush.

4 INSTRUCTIONAL DESIGN AND WORKFLOW METHODOLOGY

The instructional design approach for these VSV using immersive 360° video integrates multiple theoretical frameworks to enhance the learning experience for students. The ADDIE model underpins the development of these visits, ensuring a comprehensive process from initial analysis through to evaluation. This has been complemented by Mayer's Cognitive Theory of Multimedia Learning, which advocates for the integration of words and pictures to deepen understanding and retention. The rich media utilised in this project aligns with Mayer's principles by engaging both visual, spatial and auditory channels, thereby facilitating a more robust learning experience. Additionally, Constructivist Learning Theory informs the pedagogical strategy, emphasising the importance of learners constructing knowledge through authentic, experiential activities.

4.1 ADDIE Model

Each phase the Addie Model (A - Analyse; D- Design; D – develop; I -Implement; E – Evaluate) will be expanded in the following sections explaining how each of these steps have been conducted on the preparation of the VSVs.

4.2 Analyse phase – the need for VSVs

The VSVs were 1st developed within the Department to support student learning during the COVID-19 pandemic. They were used in various PBL assignments across structural engineering, civil engineering, architecture, architectural technology, and programmes in Building Information Modelling (BIM). They included modules in: Project Management; Health and Safety; Construction Technology; and Structures.

However, with the emergence for more 360º video technologies and the use of VR in engineering, the decision was made to explore and develop immersive 360º VSVs which could be used for PBL assignments. There are also some students in a department with accessibility issues, and thus not able to visit the site. In selecting the case study site, a public building was identified which was easy to understand from a structural engineering perspective, with an exposed structural frame etc. Recording a public building ensured that there are no copyright issues regarding the sharing of the building's images, and also the tender drawings for the structure were available on the eTenders website (Procurement 2024).

The selected building was a new public building in Cork, the Central Hall or 'Red Shed' at Cork's new Marina Park 2.

Figure 2: 'Red Shed' - Central Hall, Marina Park, Cork

The 'Red Shed' project and the VSV material have formed the basis for a PBL in a Health and Safety module. Students were tasked with undertaking a risk assessment and preparing a method statement for the construction of the Red Shed at a (hypothetical) site on the University's campus..

4.3 Design Phase - Scripting/pre-production

When preparing a video, and getting the line-up and script ready there are a number of questions which need to be addressed: what is the purpose of the video; what is it trying to share; who is the audience; what is the message that we want them to take away from it; have we many audiences – if so, does the video need to be more generic? This will influence the script/storyline of the video. What is the optimum length of the video? What length will students watch?

Always answer each of these before preparing your video structure and script. In the example of the case study for this paper, the primary focus was to capture a building so that students could understand how it was made, and that they could replicate it on campus.

4.4 Development Phase – video capturing and sound recording

There are several items to consider when preparing for video recording. The primary one which had an impact on the preparation of this video was the weather, with many lessons learnt. This video was to be recorded during the month of November, however with the low angle of the sun and if you have a bright day, the 'invisible' stick supporting the camera will cast a shadow on the ground, which will be very visible in your video.

The DJI independent voice recorder was used in making the case study video, as the wind etc can interfere with the sound captured in the Insta360 (see section 3.2 above). A recording device could be fitted to the Insta360 camera – like a receiver for the DJI speakers, but this receiver would then be very visible in the video. Also ensure that there is a windscreen fitted to the microphone to ensure as little wind interference in the recording as possible.

Editing and post-production

Premiere Pro from the Adobe suite was used in the post-production of this video. This was used over InstaStudio as it allows multiple clips to be edited together, providing students with a more contextual visit of the site.

4.5 Implementation phase – sharing of 360º immersive videos

There are several options to share the videos with students. In this instance YouTube was chosen as the sharing medium of this project as seen in Figure 1. A channel was set up and made public. It is important to note, that when editing and publishing 360° video you will be dealing with very large files. For example, depending on the export settings, one minute of video at 4K will be in typically be in excess of 1GB of file storage.

The case study site for this project has been shared via YouTube and the Matterport app, which uses Artificial Intelligence (AI) to generate a virtual walkthrough or 'Dolls House' of the building. Access to this walkthrough is then shared with the students via a link on Canvas, the University's learning management system (Canvas 2024).

Figure 1: YouTube video and QR for access to video

Matterport is an online 3D data platform which allows a space to be scanned and a 3D walkthrough developed (Matterport 2024). A Matterport licence was purchased for this project. The licence permits you to prepare a digital twin of the case study space. The licence includes an online account and a smart phone app. This smart phone app then communicates with the Insta360 camera which scans the case study building. The data is uploaded to Matterport and after some processing time, your 'dolls house' of the case study space is ready.

4.6 Evaluation phase – The Student Survey and their feedback

A survey of 47 students in the department who have participated in the PBL assignment using the Red Shed VSV was undertaken, with the survey receiving Human Research Ethics (HRE) approval, HREC-MR-23-059. Students were asked to evaluate each of the options of learning about the 'Red Shed'. These included 2D photographs, 2D video, a narrated slideshow on YouTube using 360º video clips or the fully immersive 360º video on YouTube and the Matterport walkthrough.

Regarding 2D material for the Red Shed, students were asked which gave them the best understanding of the structure. They ranked 2D photos as best, followed by 2D videos, engineering drawings and architect's drawings.

Regarding the 3D material for the Red Shed, students were again asked to rank which medium gave them the best understanding of the structure. They ranked the Matterport walkthrough as the best followed by the 360º YouTube video, which they viewed using their own phones. The MetaQuest 3 headset was also used during the survey to share the 360º YouTube video. There were several issues encountered with using the headset. These included a lack of connectivity for the headset, the need for an additional lecturer to share the headset with students, and students not wishing to use the headset citing health issues – vertigo and migraines. In total 10 students got to use the headset in the one hour lecture slot versus all 47 being able to undertake the Matterport walkthrough and view the YouTube 360º video.

Students were asked to *'Describe any specific aspects of the* 360º *immersive videos that you found particularly helpful or challenging in understanding the site / building',* with some very insightful responses. They particularly appreciated the personal independence of being able to check out the area they were interested in. Because they can use their own phones to undertake the virtual walkthrough it is so easily accessible for all of them.

'Being able to see all around'
'getting a better idea of the size of the structure, more realistic look on it'
'I like that you can look/move to wherever you want.'
'Having a free view of what I wanted to look at'
It is the closest you can get to being there through media so it is very effective'
'It's very helpful providing digital prototypes of designs'
(Mary Moloney 2024)

The immersive nature of 360° video allows students to interact with realistic environments, fostering problem-solving and critical thinking skills essential for engineering education. This multi-faceted approach not only addresses diverse learning needs but also enhances accessibility, providing all students with the opportunity to engage with complex, real-world engineering contexts.

5 SUMMARY AND ACKNOWLEDGEMENTS

This pedagogical approach of using 360º video could allow educators to use particularly interesting or challenging buildings / case studies, once a VSV has been generated, allowing access for all. This project was developed with support and funding from the National Forum for Teaching and Learning under the Strategic Alignment of Teaching and Learning Enhancement Funding in Higher Education (SATLE) call and the Erasmus+ project 2021-1-FR01-KA220-HED-000035699.

ABSTRACT

This paper explores the use of Virtual Reality (VR) and Augmented Reality (AR) in university-level engineering education, particularly within Mechanical and Manufacturing Engineering fields. It highlights the potential of these immersive technologies to enhance student's understanding of complex engineering principles and develop essential transversal skills, thus preparing them for the diverse challenges of today's workforce. This paper investigates various VR and AR applications, from improving public speaking and communication skills to facilitating

[1] J.H Moolman
Hans.Moolman@mtu.ie

hands-on learning of engineering principles in a risk-free, simulated environment. It also covers the use of AR in interactive design challenges, which helps students visualise and manipulate engineering concepts in real time, leading to a better grasp of mechanical and manufacturing concepts. The paper argues that VR and AR technologies have the potential to significantly transform engineering education and recommends a strategic approach to their integration into the curriculum. By offering insights into the benefits and challenges of using immersive technologies in education, the paper aims to provide a roadmap for universities to enhance the preparation of future engineering professionals with a blend of educational and technical skills.

1 INTRODUCTION

AR and VR technologies provide a three-dimensional (3D), interactive learning environment that allows for a more experiential learning process that enhances spatial understanding, problem-solving, and engagement (Kozov, Ivanova and Ivanov 2019). However, the adoption of these technologies in engineering education faces hurdles such as technological barriers, high costs, and resistance to change (Boyle, et al. 2022). The paper aims to assess the incorporation of immersive technologies into engineering curricula through an undergraduate degree course currently in progress under the Rethinking Engineering in Education (REEdI) (Rethinking Engineering Education in Ireland 2024) program at Munster Technological University (MTU). It will propose strategies for integrating these technologies, considering accessibility, curriculum design, faculty training, and student feedback. The paper seeks to recommend best practices and solutions for educators and institutions, propose pedagogical approaches, and suggest areas for future research.

2 LITERATURE REVIEW

Immersive technology is increasingly being utilised within education contexts as a tool for increasing student learning outcomes such as knowledge retention and engagement (Kaur, et al. 2022). These technologies have been proven beneficial in imparting knowledge or providing experiences in scenarios where a demonstration in the real world is not possible or feasible (Dinis, et al. 2018). Kaur, et.al. examine several use cases of these technologies in the education context and conclude that they "*have been tested and proven to be beneficial in the engineering education domain*" (Kaur, et al. 2022).

Dinis, et. al. illustrates how the use of VR can allow users to visit environments and view elements that are typically hidden within the classroom environment (Dinis, et al. 2018). In this paper, an Interactive Virtual Environment (IVE) was created based on an existing building. Users can visit this virtual building and view or hide elements of the environment to observe hidden details, such as the rebar hidden within concrete slabs. This experience is intended as an introductory education piece for prospective civil engineering students (Dinis, et al. 2018).

VR has also been used to increase student engagement and foster creativity within existing curricula (Krajčovič, et al. 2022). Krajčovič et. al. examine an existing assignment and retrofit it with the addition of a VR-based experience that students could access both in class and in their free time (Krajčovič, et al. 2022). The assignment tasked students with suggesting optimizations to a workplace based on an existing space. This case study resulted in increased student engagement, with 90% of students within the study group interested in working on the assignment outside of classes as compared to previous years' 10-20%. Additionally, the average number of optimisations increased from previous years, with a significant amount of those optimisations relating to ergonomics within the space. The paper's authors hypothesise that this is due in part to the fact that the VR experience gave the students the ability to view the space from an employee's perspective, which was not possible in previous years (Krajčovič, et al. 2022).

Kozov et. al. finds that the use of immersive technologies in mechanical engineering education enhances student concentration by isolating them from distractions and providing a dedicated learning environment (Kozov, Ivanova and Ivanov 2019). Kozov et. al. outlines the use of 3D models, virtual simulations, and motion-tracking technologies to enable students to engage in hands-on activities and interactive learning experiences, and can incorporate game-based approaches to education, making learning more engaging and facilitating faster knowledge absorption (Kozov, Ivanova and Ivanov 2019). Kozov et. al. conclude that immersive learning focuses on creating realistic virtual environments for experiential learning, which aim to enhance student understanding, retention, and practical skills in mechanical engineering education (Kozov, Ivanova and Ivanov 2019).

Problem-solving skills are a critical tool for engineering. According to Roopaie et. al. immersive technologies provide the ideal solution to help students develop problem-solving skills (Roopaei and Klaas 2021). For instance, immersive technology gives students the ability to control the pace of their learning, allowing them to spend more time on challenging concepts and move quickly through familiar topics. Furthermore, immersive environments allow students to make mistakes in a controlled setting where they can learn from them without consequences, fostering a growth mindset and resilience in problem-solving. Immersive technologies are not limited to engineering concepts and principles. Graduate engineers are expected to be well-rounded employees who also possess soft and transversal skills. Roopaie et. al suggests that students can develop various social and emotional skills using immersive technology by enhancing collaboration among educators and students by engaging them in interactive and motivating virtual environments, where they can share experiences and work together on challenging tasks (Roopaei and Klaas 2021). Furthermore, by exploring new cultures and environments through immersive technology, students can develop a sense of respect and appreciation for diverse cultures and people, fostering empathy and cultural understanding. Through immersive experiences that simulate real-world scenarios, students can practice emotional regulation and coping strategies in a safe and controlled environment.

While immersive learning methodologies offer numerous benefits in terms of student engagement, understanding, and accessibility, they also present challenges related to teacher preparation, technological limitations, and assessment practices (Boyle, et al. 2022). Effective implementation of these methodologies requires careful planning, support, and ongoing evaluation to maximise their potential impact on student learning outcomes.

3 REEDI: CASE STUDIES AND IMPLEMENTATION EXAMPLES

The REEdI initiative presents a pioneering undergraduate program in engineering that embodies agility and innovation and integrates an advanced approach to disseminating knowledge through immersive technologies.

The curriculum was designed from the ground up and is currently in its second year of delivery. Figure 1 shows the extent to which immersive technologies are incorporated across various modules throughout the 4-year degree course, constituting 55.6% of the curriculum, and is discussed in detail in this paper. For instance, Gadgeteer, an off-the-shelf solution is used in *Engineering Challenge 1,* to simulate real-world engineering challenges and settings. Students also present their final year project – *Engineering Challenge 2* - in VR using the ENGAGE (Engage XR 2024) platform. Similarly, *Professional Development 1 & 2* leverage VR technologies to simulate environments conducive to the development of soft or transversal skills. *Production Engineering* introduces students to AR technologies, providing hands-on experience in constructing a LEGO Technics motorcycle (A/S, LEGO System 2024). This approach employs AR tools such as the Microsoft HoloLens v2 (Microsoft 2024), enriched with overlay information including images, videos, audio, and animations, as opposed to traditional paper-based instruction manuals.

Figure 1. Integration of immersive technologies throughout the 4-year Mechanical and Manufacturing degree course

3.1 Hardware

Each student is given a META Quest 2 headset, which they keep for their studies. This headset was chosen for its relatively inexpensive price point, technical support and documentation, content availability, hand tracking, standalone capabilities, and ease of use. These devices allow students to explore interactive 3D environments, exploring engineering concepts in a safe, virtual setting.

This method extends beyond mere visualisation, enabling practical application in simulations that replicate real-life scenarios. AR devices like the Microsoft HoloLens v2, are available to students in limited numbers and under supervision due to their high cost. HoloLens v2 enhances real-world environments with digital information, making educational content more engaging.

Furthermore, students get to interact with immersive technologies in the VR Suite (Agritech Centre of Excellence 2024) at MTU, a purpose-built virtual and physical collaboration space that hosts an array of AR, VR, and other platforms, enabling students and educators to explore and work differently in a unique technology-rich environment.

Figure 2. Students interacting with various hardware solutions such as the META Quest 2 and Microsoft HoloLens 2 in the VR Suite.

3.2 Software

The REEdI program implements numerous software solutions and is in the second year of the newly designed curriculum. A few of these use cases are outlined by highlighting case studies.

Bodyswaps (Bodyswaps 2024) is integrated into *Professional Development 1 & 2*, offering soft skill training through VR, emphasising the importance of communication, teamwork, and leadership, alongside technical abilities. Students actively use the pre-designed and approved modules to prepare them for interview training and workplace conflict resolution.

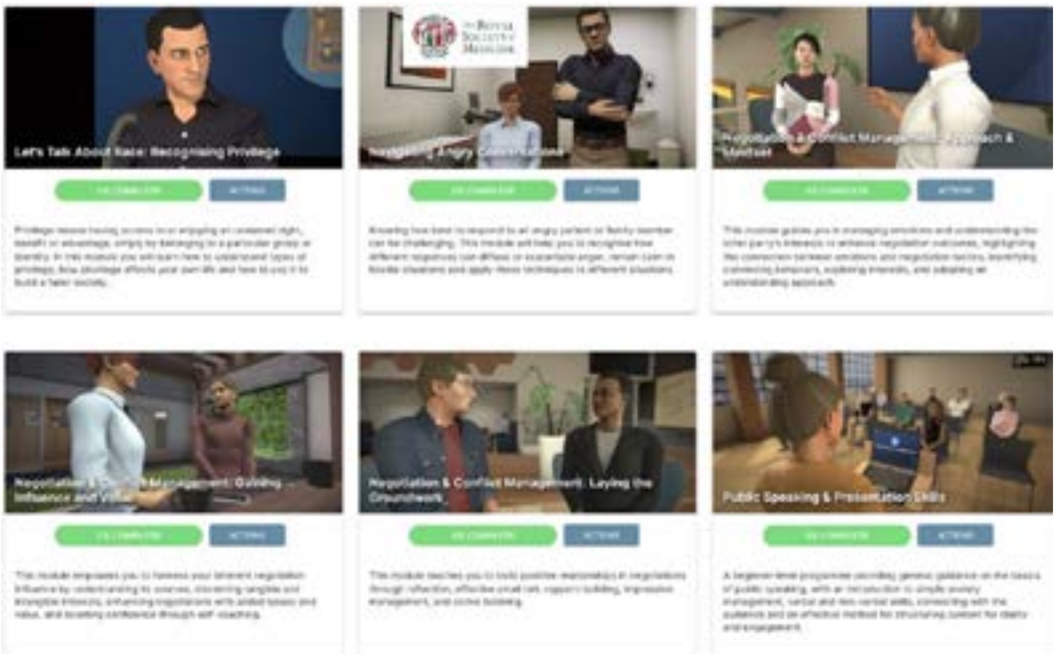

Figure 3. Bodyswaps offers an array of simulations, rich analytics, and gamification.

PNX Labs (PNX Labs 2024), offers off-the-shelf content, as well as bespoke or highly customised VR applications. Various engineering simulations are utilised throughout various modules, including a highly customised Tensile Strength Testing

Lab as part of the *Quality Engineering* module. Additional VR labs available to students include Bending SS Beam, Bending Cantilever Beam, Torsion and Rockwell hardness Testing; Force, Mass, Acceleration, and Rotational Mechanics; and Metallography. Additional VR labs will support the students while geographically dispersed include SEM Microscope, EDAX Experiment, AFM Microscope Lab, Laser 3D Printing, Fluid Flow in Pipework, Ventilation and AC, Heat Exchanger, Steam Distribution, and Porosity Characterization. Students and educators will be able to participate in these virtual labs remotely, which not only makes it more engaging and effective but also safer and more cost-efficient.

Engage (Engage XR 2024) is being implemented as a collaborative VR tool. Engage is a multi-platform application with a library of spaces and 3D models that students and educators can access in public experiences, private groups, or individually. Students can access Engage through their desktop/laptop, mobile, or using their VR headset. Engage is used for *Engineering Challenge 2* where students present their final year projects in an Engage VR space. A remote Masterclass Series was introduced with a guest lecturer in preparation for 3rd-year students' remote work placement and remote VR lectures. Furthermore, REEdI is working on various solutions that will be launched in 2025 which include a space to showcase MTU and the REEdI program to prospective students containing past student works, and interactive immersive lab experiences.

Figure 4. Prototype of public showcase space within Engage

Gadgeteer (Metanaut Labs Inc. 2024) simulates complex machinery and systems in *Engineering Challenge 1*, enabling students to build and interact with a digital Rube Goldberg machine featuring components like dominoes, balls, catapults, and funnels. It provides a safe virtual space for students to explore physical principles and machinery dynamics, observing cause-and-effect relationships without physical limitations or damage risks. The platform supports detailed component behaviour, such as using a pen as a pusher or simulating a hammer's pendulum motion, and allows for the integration of timing elements, such as triggering an E-stop system. Students' machine reliability is tracked and graded through multiple runs to emphasise the importance of repeatability and reliability.

Figure 5. Module requirements (left) and student implementation (right)

Gravity Sketch (Gravity Sketch 2024) offers an immersive, hands-on learning experience that enables students to design, visualise, and manipulate 3D models in a virtual environment, and is introduced as part of Engineering Technology. Learners are tasked to design a more ergonomic headband for their META Quest 2 headsets through a combination of LiDAR scans, CAD, and Gravity Sketch.

4 CONTENT INTEGRATION AND IMPLEMENTATION STRATEGIES

Universities wishing to implement immersive technologies should adopt a strategic roadmap that starts with integrating affordable, widely available devices like the META Quest 2. The META Quest 2 is chosen due to its [relative] affordability, which makes it accessible for educational institutions with limited budgets. Currently, the META Quest 2 retails at €249.99 (Meta 2024), compared to the recently launched Apple Vision Pro which retails at € 3,257.08 (converted from USD) (Apple 2024). Furthermore, the META Quest 2 has widespread availability for procurement and replacement. Additionally, the META Quest 2 offers extensive support and a content library, which is estimated at 2,860 apps including the newly available App Lab content (RoadToVR 2024). Best practices for educators include starting with pre-made content to facilitate quick integration and gradually developing bespoke materials as proficiency increases. This will ensure enhanced learning experiences while managing costs and resources efficiently (Kaur, et al. 2022) (Dinis, et al. 2018). Furthermore, the strategic guidance provided through examples like the LEGO Technics motorcycle assembly using Microsoft HoloLens v2 and the use of Engage for immersive guest lectures illustrate how immersive technologies can be seamlessly woven into curricula with minimal effort.

Curriculum design should embed immersive technologies into core modules, leveraging VR for simulations and AR for interactive projects. Faculty training is crucial; educators should participate in workshops and ongoing professional development to effectively use these tools. Gathering regular student feedback through surveys and focus groups will help refine the implementation process, ensuring that the technology meets educational goals and student needs. Pedagogical approaches should focus on hands-on, interactive learning experiences that mirror real-world scenarios, fostering critical problem-solving skills.

5 NEXT STEPS AND FUTURE DIRECTIONS

Future research into the impact and effectiveness of the immersive technology tools currently being used as part of the REEdI program is planned, which will be measured by feedback gathered from both students and lecturers. They will be asked about their experience using immersive technology, for instance, "*How difficult/easy it was to use these tools, any negative health effects experienced from the use of immersive technology, and the impact of these issues on their teaching/studies",* or *"How they felt immersive technology tools impacted their experience/engagement, benefits/disadvantages, and their preference between real-world and immersive-technology-based learning/teaching*".

Additionally, the immersive technology tools used within the REEdI program are being investigated for their effectiveness in other educational fields. This includes the MTU Veterinary Nursing department integrating BodySwaps and introducing a VR-based veterinary skills training application, titled "*VetSkill Companion Animal OSCE Practise Stations*".

6 CONCLUSION

Through evidence-based implementation and research, the REEdI program has concluded that pre-made immersive technology content stands out as the optimal method for seamless integration into engineering education due to time, cost, and other constraints. Moreover, the META Quest 2 headset emerges as the preferred choice for this purpose due to its affordability, widespread availability, and comprehensive support in terms of content and resources. This research paper highlights the transformative impact of immersive technologies on engineering education, identifying critical gaps in implementing immersive technologies in curricula, and offering insights for educators, curriculum designers, and policymakers. The study advocates for a strategic framework for integrating immersive technologies into curricula, acknowledging challenges such as technological accessibility, curriculum integration, and educator training. It emphasises the importance of strategic implementation and support for overcoming these barriers. Ultimately, this study serves as a call to action for educational institutions to adopt immersive technologies strategically, ensuring engineering education remains innovative and effective in preparing students for future challenges.

ABSTRACT

The world is rapidly changing due to the evolution of society and technological developments; these, together with the challenges from the Sustainable Development Goals (SDGs), demand new knowledge and skills for future employment. Making engineering education more flexible increases students' choices to enrol in the labour market successfully. From the perspective of students, lecturers, and institutions, flexibilization in higher engineering education can take a dimension to *(1)* develop lifelong learning skills, *(2)* create individual learning paths by providing choices, *(3)* generate mobility, *(4)* support the learning process regardless time and location; *(5)* meet individual learning demands as students have diverse backgrounds (age, previous education, work experience, nationality, etc.), different needs (learning style, learning pace, etc.) and intrinsic motivation and ambitions to learn (job motivation, themes, etc.). Universities and higher education

[1] *P, Caratozzolo*
pcaratozzolo@tec.mx

institutions (HEIs) look for ways to integrate flexibilization in the curriculum and the provision of study programs. In this study, an investigation of the role of HEIs in developing engineering skills to join the labour market successfully takes place through the lens of three universities by mapping the model of Education 4.0 from the World Economic Forum 2020 report and the 2019 framework for enhancing students' success. Results indicate the various approaches and practices each university offers to elucidate how flexibility can be leveraged to enhance skills development and meet the dynamic needs of the labour market (employability). Finally, the developed model used to map flexibilization strategies is a suitable tool to capture examples of flexibilization in engineering education.

1 INTRODUCTION

The education field is dynamic and changes based on each generation's unique socio-cultural, economic, and technological challenges and by industries' requirements. To guarantee a sustainable society and economy and fulfil students' expectations and industries' requirements, two things need to be accomplished: *(i)* understand the challenges brought by each generation to re-shape/change academic teaching approaches and *(ii)* ensure that our graduates are provided with the tools and skills to thrive in the 21st century. As mentioned, each generation brings its challenges and expectations. Generation X are individuals born between 1965 and 1980. They tend to be more independent. They value flexible workplaces and a healthy work-life balance. Compared to other generations, Generation X employees tend to be more concerned about an uncertain future. Generation Y, known as millennials (born 1981-1996), is the first generation to grow up with personal technological advances; however, they engage more by connecting their learning with real-world applications. Their expectations evolve around opportunities to use their skills to gain experience, a guaranteed income, and to work in a caring, well-being environment (Sezin Baysal Berkup 2020). Generation Z (born 1997-2012) is the first generation to grow up in an entirely digital world. A short attention span and a preference for digital and interactive learning experiences characterize it (Chillakuri 2020; Caratozzolo et al. 2021). To meet their expectations, an investment in digital resources is required. They prefer flexible working hours and an environment where social responsibility and diversity are prioritized (Impact. 2022). To contribute to the overall success of students across generations, academics need to understand each generation's expectations and make necessary changes in the curriculum and teaching approaches to meet the diverse needs and expectations of each (Gómez Puente 2020). These changes must guarantee the involvement of an inclusive learning environment to foster a sense of belonging and the embedment of global awareness to understand global challenges and promote ethical and cultural sensitivity.

The ever evolution of society and technology and the dynamic challenges of daily life demand to move from a conventional structural education, which was designed for an industrial-era model, to a flexible education, which aligns with the Fourth Industrial Revolution, where a workforce with versatile skills is needed to guarantee a sustainable society and economy. These skills, which are sought to be reached by employers by 2025, include critical thinking, creativity, emotional intelligence, and complex problem-solving (World Economic Forum 2022; 2020b). Flexible learning serves as a nurturing ground for the development and refinement of these skills previously mentioned and other skills such as global citizenship (e.g., Collaborative Online International Learning, COIL) (Munoz-Escalona et al. 2022), technology skills, and personalized and self-paced learning, where learning must be based on the diverse learner's needs and flexible enough to enable each learner to progress at their own pace (World Economic Forum 2020a).

Flexible learning accommodates individual learning styles, where learners can tailor their educational experience to suit their needs, pace, and preference learning style to succeed in a volatile job market, where resilience and adaptability are crucial to targeting new opportunities/job paths for professional growth. It also provides opportunities for an inclusive and diverse environment and enables lifelong learning and national/international collaborations, among others (Brennan 2021). However, it must be highlighted that flexible learning requires a balance of power between institutions and students and must be economically viable and appropriately manageable for both parties (AdvanceHE 2019). Also, the social perspective of flexibility towards contributing to economic development, the institutional view, and the financing aspects are important elements to realize flexibility (Brennan 2021). Furthermore, a pivotal role in the realization of flexible education/distance education is the integration of digital technologies, online learning platforms, virtual classrooms, etc.

The authors had previous academic collaborations as co-authors at the following international conferences: SEFI2022 (related to a comparison of institutional practices), SEFI2023 (a comparative study of Continuing Engineering Education frameworks), EDUCON2024 (related to the future workforce), and IACEE2024 (with a taxonomy for Continuing Engineering Education), and they were co-authors in an article in Education Sciences Journal, in November 2022 (exploratory and comparative study of Challenge-Based Learning practices).

This study investigates how different universities integrate the concept of flexibilization in their educational practices from various perspectives, e.g., employability, work-related learning, flexible learning, and globalization; and compares three universities from different countries, Tecnologico Monterrey (Mexico), Eindhoven University of Technology (TU/e) (The Netherlands), and Glasgow Caledonian University (United Kingdom), to answer the research questions about the role of flexibilization in HE in developing future skills and full employment.

The Research Questions are:

RQ1: To what extent will training students in technology skills facilitate future work-related learning?

RQ2: To what extent does teaching global citizenship skills facilitate flexible working in the future?

2 THEORETICAL CONSIDERATIONS

Higher education institutions (HEIs) are essential in preparing students as future employees to develop the skills needed to join the labour market. Within this rationale, preparing students for professional life emphasizes developing generic "transferable" skills in the workplace on the one hand (Mason, Rincon-Aznar, and Venturini 2020). Flexibility in higher education refers to providing opportunities for education as there are diverse types of students with different ambitions and interests, regardless of time, distance, and space. Flexibility in the curriculum, the learning environment, and the provision of content and spaces for developing skills become a vehicle for meeting the ambitions of diverse learners. Flexibilization is deeply rooted in educational theories that emphasize how students learn and, more specifically, the learning environment that may affect the development of competencies (Mathou, Sarazin, and Dumay 2023). As an example, *Situated learning* theory and *Cognitive Apprenticeship* center around the relationship between learning and the social situation in which, for instance, the learning of a skill occurs (Julien 2021). In situated learning, social co-participation activities in which social engagements occur are favourable elements to provide a context and facilitate learning. In this regard, creating learning experiences in which real-life activities resembling and taking place in practical work environments are suitable contexts that promote deep learning and develop skills. Likewise, *self-regulated learning* theories are guided by reflecting on one's learning. In self-directions, students become conscious of their learning strengths and weaknesses. They can make use of a variety of strategies to reflect upon and monitor the learning process and be able to generate change in study attitude and progress (Yan 2020). Curriculum transformation to accommodate students' ambitions and learning goals, together with approaches to teaching and learning and the support of technologies and digitalization in education, make possible flexibilization of learning to empower students by offering them choices in how, what, when, and where they learn: the pace, place, and mode of delivery (Halverson and Graham 2019). Differentiation, individualization, and flexibility constitute the current challenges of education, which are critical elements to give form in the study programs (Talip et al. 2020)In this regard, digitalization, blended learning, and hybrid education facilitate flexibilization in higher education, which supports knowledge and skills development to meet future employment demands.

3 METHODOLOGY

The methodology chosen for the study included a brief overview of Education 4.0 as outlined in the WEF 2020 report (World Economic Forum 2020a), emphasizing its focus on shifting learning content and experiences toward future needs and the comparison to the Essential Frameworks for Enhancing Student Success from the AdvanceHE 2019 report (AdvanceHE 2019), highlighting its significance in promoting student success within higher education. Table 1 contains the answers to each of the proposed Research Questions.

Table 1. Mapping of WEF and Essential Framework for Enhancing Students about employability and flexible working

WHAT	Employability	Flexible Working	HOW	Employability	Flexible Working

Global citizenship skills	Developing global citizenship skills, fostering cultural competence, and effectively communicating across cultures prepare individuals to thrive in diverse, interconnected professional environments.	Flexible education equips individuals with the intercultural competencies, adaptability, and communication skills necessary to thrive worldwide in diverse and dynamic work environments.	**Personalized and self-paced learning**	Allowing individuals to tailor their educational experiences to specific skill sets and learning preferences fosters adaptability and autonomy.	Personalized and self-paced learning empowers individuals to acquire skills and knowledge tailored to their needs, fostering adaptability to work effectively in diverse professional settings.
Innovation and creativity skills	Equipping students with the ability to think critically, contribute to innovative solutions, and compete in a rapidly evolving and competitive job market can significantly increase their employability.	Including innovation and creative skills training in HE cultivates students' ability to think outside conventional boundaries and find inventive solutions, enabling them to excel in diverse professional environments.	**Accessible and inclusive learning**	Diverse skill sets, cognitive adaptability, and inclusivity awareness are all crucial attributes employers value in an increasingly diverse and dynamic global workforce.	Empowering students with diverse learning styles and equipping them with adaptable skills and broad perspectives fosters a future workforce that can thrive in flexible, professional environments.
Technology skills	Providing students with the expertise to navigate a technology-driven job market enhances their versatility and readiness to contribute to various industries and professions.	Technology skills significantly empower students to leverage digital tools, collaborate remotely, and adapt to evolving technological trends, ensuring they are well-prepared for flexible work environments.	**Problem-based and collaborative learning**	Cultivating critical thinking, teamwork, and problem-solving skills prepares students to navigate complex professional challenges and enhances graduates' future employability.	Cultivating effective communication and collaborating across diverse perspectives equip students with innovative problem-solving and teamwork skills to cope with tasks' uncertainties and ambiguities.
Interpersonal skills	Training students in interpersonal skills sharpen their ability to communicate effectively, collaborate seamlessly, and build positive relationships in diverse professional settings.	Interpersonal skills nurture students' capacity to communicate persuasively, collaborate seamlessly, and adapt to diverse team dynamics.	**Lifelong and student-driven learning**	Cultivating a proactive and adaptable mindset, encouraging continuous skill acquisition, and instilling a commitment to ongoing personal and professional development, ensuring graduates remain competitive in the ever-evolving job market.	Instilling a proactive and adaptable student mindset empowers them to acquire new skills continuously, stay abreast of evolving industry demands, and navigate the dynamic nature of flexible work environments.

4 RESULTS

Considering the mapping developed in Table 1, Table 2 shows the results of the approaches taken by each university to increase employability, and Table 3 shows the approaches taken to foster flexible learning.

Table 2. Approaches taken by each university to increase employability.

WHAT	Tecnologico de Monterrey* (Mexico) Total Students: 50,400 International students: 4,800	Eindhoven University of Technology (TU/e)* (The Netherlands) Total Students: 11,000	Glasgow Caledonian University (United Kingdom)* Total Students: 15,500 International students: 2,800

	Faculty Staff: 6,300	**International students: 3,200** **Faculty Staff: 1,000**	**Faculty Staff: 750**
Global citizenship skills	• Embedded Collaborative Online International Learning (COIL) in modules • Opportunities for international exchange • Multicultural campus fostering DEI. • Participation in international events and competitions.	• 'Sustainability' as a theme in courses • Organizing 'challenges' with other universities and industries meeting SDGs • Organizing learning communities to create interaction and exchange ideas with national and international peers.	• Embedded Collaborative Online International Learning (COIL) in modules • Opportunities for international exchange (Virtual and physical mobility) • Multicultural campus, fostering EDI. • Participation in international events and competitions • Follows SDGs • Promotes different societies. • Participates in Engineers without border
Innovation and creativity skills	• Interdisciplinary collaboration that promotes innovation, critical thinking, and problem-solving, • Provide dedicated spaces to foster hands-on practical labs to foster creativity skills. • Offers entrepreneurship programs. • Collaborations with industry partners in each CBL course expose students to real-world challenges and opportunities.	• Challenge-Based Learning (CBL) • Interdisciplinary collaboration that promotes innovation, critical thinking, and problem-solving. • Internships, practical labs, extracurricular activities, collaboration with industry or research institutes.	• Interdisciplinary collaboration that promotes innovation, critical thinking, and problem-solving. • Provide dedicated spaces to foster hands-on practical labs to foster creativity skills.
Technology skills	• Labs AI, VR/AR; Blockchain; Internet of Things (IoT) and Cybersecurity). • Interactive simulations, Avatar Professor, digital platforms, and remote laboratories. • Offers external data science and analytics courses.	• Technology design and programming. • Integration of technology skills into school curricula. • Artificial Intelligence (AI) in education.	• Offers courses on learning digital technology. • Provide laboratory sessions in robotics, VR/AR, programming, cybersecurity, etc.
Interpersonal skills	• The Challenge-Based Learning (CBL) approach encourages collaboration, teamwork, group projects, discussions, and interactive activities. • Encouragement to participate in extracurricular activities. • Compulsory 480 hours of community service • Peer Mentorship • Implement an Ambassador Program to promote the institution. • Storytellers Program.	• Diversity, Equity & Inclusion (DEI) policies and educational practices integrated into existing curricula. • Persuasive writing and presentations in a public setting. • Professional and Personal Development programs.	• Diversity, Equity & Inclusion (DEI) policies and educational practices integrated into existing curricula. • Teamwork along the degrees • Multidisciplinary work across the university • Courses in academic writing. • Encouragement to participate in extracurricular activities. • Engages students in the delivery of public engagement and outreach activities.

Table 3. Approaches in each university to foster flexible learning to facilitate flexible work.

HOW	Tecnologico de Monterrey* (Mexico) Total Students: 50,400 International students: 4,800 Faculty Staff: 6,300	Eindhoven University of Technology (TU/e)* (The Netherlands) Total Students: 11,000 International students: 3,200 Faculty Staff: 1,000	Glasgow Caledonian University (United Kingdom)* Total Students: 15,500 International students: 2,800 Faculty Staff: 750
Personalized and self-paced learning	• Competency-based education model, • Access to digital libraries and materials in all disciplines. • Gamification approaches. • Students can create individualized learning plans in collaboration with academic advisors. • Online and blended learning formats.	• Elective courses. • Extra-curricular activities (Student teams). • Competencies development. • Access to digital platforms and materials in all disciplines. • Coaching individuals and groups of students, including coaching on competencies. • Adopting personalized learning. • Professional and Personal Development of competencies at different levels/paths.	• Elective courses • Access to digital libraries and materials in all disciplines. • In an exchange program, students can take courses online of pre-requisite modules not delivered by host institutions.
Accessible and inclusive learning	• DEI policy • Training staff on accessibility best practices • Hotline platform – integral well-being through Emotional Counselling.	• DEI policy • Train staff/organize learning communities on DEI, sustainability topics, etc.	• DEI policy (Recommended adjustment pages) • Training staff on accessibility best practices. • Well-being support
Problem-based and collaborative learning	• Challenge-Based Learning (CBL) involves team-based assignments and projects where students work together in real-life challenges. • Industrial partners in every course. • Interdisciplinary and Collaborative learning.	• Challenge-Based Learning (CBL) as an educational concept • CBL as curriculum and course/project level.	• Challenge-based learning (CBL) is offered in a few modules. • Interdisciplinary and Collaborative learning in different modules. • Attend guest talks virtually or face-to-face.
Lifelong learning & student-driven learning	• Opportunities for internships, co-op programs, and industry projects. • Program mentors guide students in making informed decisions about their learning paths.	• Courses for industry professionals. • Continuous Professional Development (CPD) learning pathways for teachers.	• Graduate apprentice scheme (students are employed in industry while studying) • Part-time courses

*Updated data extracted from https://www.topuniversities.com/world-university-rankings

5 DISCUSSION, CONCLUSIONS, AND FUTURE WORK

The three universities involved in the study are examining the methods they use to enhance students' employability to create individual learning paths and offer opportunities to select elective courses or activities to provide work experience. Typical offerings to deploy practical experience are via internships (placements), paying attention to the internationalization of education (e.g., exchange programs, mobility, and similar measures), or creating a link between education and research as a vehicle of learning and innovation. Flexibilization in education implies allowing students to take greater responsibility for their learning and engage in learning activities that meet their needs”.

In this regard, flexible learning is strongly linked to student-centered learning. In implementing flexibilization, the concept does not stand alone. Flexibilization in higher engineering education offers multifaceted benefits, catering to students, lecturers, and institutions' diverse needs and motivations. By fostering lifelong learning skills, creating individualized learning paths, promoting mobility, and accommodating diverse backgrounds and learning demands, universities can better prepare students for success in the labour market. The study demonstrates how three universities leverage the Education 4.0 model and the 2019 framework for enhancing students' success to explore their respective roles in equipping learners with the necessary future skills for successful integration into the workforce. Although the number of universities is limited, it is an interesting exploration that will be extended to the consortium with other universities already working on similar themes. The findings underscore universities' pivotal role in fostering skills development and enhancing employability, offering valuable insights into innovative approaches and practices. As higher education institutions embrace flexibility, they prepare the way for a more responsive and inclusive educational landscape, poised to meet the dynamic demands of the labour market. Despite the universities being different in focus, e.g., engineering (Tecnologico Monterrey and TU/e) and broader disciplines (Glasgow Caledonian University) all follow a similar educational approach to integrating flexible education in the curriculum, in the programs, and at the course level to promote employability. Regarding the framework used to map flexible learning and future skills in these institutions has proven to be a suitable resource for mapping experiences in universities and engineering education institutions. This framework supports the mapping of institutions from both a learning and technology perspective.

Future research will focus, therefore, on analyzing strategies to facilitate skills development while studying the learning and technology approaches of the HEIs, exploring the long-term impact of flexible learning environments on student outcomes and career trajectories, and including comparative studies across different regions -particularly in Europe- and educational systems that could provide deeper insights into the effectiveness and scalability of these flexible learning models. Another avenue for future work involves investigating the role of emerging technologies, such as artificial intelligence and virtual reality, in enhancing flexible learning and skills acquisition. Finally, in the context of Industry 4.0 transitioning to Industry 5.0, future research will also explore how educational frameworks need to adapt to this evolution, including initiatives regarding human-centric solutions, sustainability, and resilience, and going beyond the automation and digitalization focus of Industry 4.0.

ABSTRACT

Global engineering competences and skills have become increasingly vital to the practice of engineers. Consequently, developing these competences becomes an imperative in today's engineering education. This research explores how an international project-based learning experience, involving solutions to engineering problems provided by different industries, allowed students to enhance global competences and skills.

Specifically, the aim of this research is to explore students' perception of personal benefits gained from attending a one-week multidisciplinary international experience, and secondly, to explore how self-set goals align to Global Competences for Engineers (GCEs) and World Economic Forum (WEF) Education 4.0 skills. The study involved the delivery of an online survey which intersected both GCEs and (WEF) Education 4.0 Framework.

The initial results show the significant impact of international experiences on students' development of global citizenship, through exposure to a diverse cultural context, with participants describing how the experience allowed them to develop awareness and appreciation of cultural differences. Furthermore, the study highlights tangible improvements in various engineering competences, including problem-solving, communication, and interpersonal skills.

1 INTRODUCTION

The World Economic Forum Education 4.0 Framework has identified skills/competences that are essential to address economic and societal issues. These skills are divided in two main groups: **Group 1: Skills for adaptation** include: i) global citizenship skills, ii) innovation and creativity skills, iii) technology skills and iv) interpersonal skills and **Group 2: Skills of leveraging innovative pedagogies** include: i) Personalized and self-paced learning, ii) Accessible and inclusive learning, iii) Problem-based and collaborative learning, and iv) Lifelong and student-driven learning (World Economic Forum, 2020). This research will focus just on Group 1 skills, as the context of this research is focused on an international exchange week focused on team-based problem solving.

1.1 Skills for Adaptation

For Group 1, i) Global citizenship skills: Physical mobility contributes significantly to the development of global citizenship skills as it offers individuals the opportunity to engage with diverse cultures, perspectives, and environments. In some cases, individuals may face constraints that limit their ability to travel or relocate due to financial constraints, family responsibilities, work commitments, and when this occurs, virtual mobility through experiences such as Collaborative Online International Learning (COIL) can be used to enhance students' abilities to develop as responsible global citizens, allowing them to develop their intercultural competences and international perspectives without the associated logistics and costs of travel (Kayumova AR, Sadykova GV, 2016).

ii) Innovation and creativity skills: these are crucial skills for engineers enabling them to develop new solutions to complex problems and to adapt to changing circumstances. Creativity is the ability to generate new ideas, while innovation is the ability to turn those ideas into reality (Nagai, Y et. al, 2020). In the context of engineering, creativity and innovation are essential for developing new technologies and improving existing ones. Engineers who possess these skills are better equipped to develop solutions that are both effective and efficient, and can be adapted to different contexts and cultures.

iii) Technology skills: In today's world, technology is an integral part of engineering, and engineers must be proficient in a wide range of technologies to be effective. Technology skills include knowledge of software, hardware, and other tools that are used in engineering. Technology skills are essential for communication and collaboration, which are critical for global engineering projects (Ortiz-Marcos et.al, 2021).

iv) Interpersonal skills: these skills determine the ability that the engineer must have to communicate and interact effectively with other people. These skills include communication, leadership, teamwork, effective listening, and empathy. It is not enough to have the technical skills of the profession, increasingly more importance is given to the relationships and human interaction with which the engineer works. Developing these skills favors professional and social success and encourages cross-cultural humility. Although interpersonal skills may be related to innate personality traits, they can be taught and developed through experiences and innovative teaching methods (Willmot, P. and Colman, B, 2021).

The World Economic Forum’s (WEF) Education 4.0 Framework is designed to apply to all disciplines. Within the field of Engineering, a similar framework of Global Competences for Engineers ((Ortiz-Marcos et.al, 2021) (see Table 1 below) has been used as a lens to explore the attributes needed by today’s engineers to thrive in an interconnected world, where engineering projects and teams often span multiple countries and cultures. While technical expertise remains important, engineers must possess a range of competences beyond technical skills to be successful in the global engineering profession. These competences include cultural awareness, communication skills ethical decision-making, and leadership abilities, among others and align to the WEF Education 4.0 Framework.

1.2 Developing Skills for Adaptation through International Study Opportunities

Our previous work (Munoz-Escalona et al., 2023) explored how engineering programmes in different countries attempted to develop these skills and competences in student engineers. The work highlighted the importance of international study opportunities in fostering the development of these skills. In this paper, we set out to explore student perceptions of international study through the following research question:

‘How do self-set goals set in an international study opportunity align to Global Competences for Engineers and WEF Education 4.0 skills?’

In the current study we aim to investigate how engineering students' self-set goals in an international learning opportunity align with Global Competences for Engineers and WEF Education 4.0 skills. Our findings reveal that while students' goals strongly align with skills around global citizenship, teamwork, and communication, there is less emphasis on competences such as systems thinking, innovation, and creativity.

2 METHODOLOGY

The adopted methodology for this exploratory study is largely quantitative, based on a pre- and post-survey method with students self-assessing their perceived level of competence and confidence in a range of skills. Ethical approval was sought, and granted from the authors' institution. Respondents were from a range of backgrounds, nationalities and disciplines (engineering, computing and physics programmes) participating in-person in an international project week from around the world, although as the event was hosted at one European university there were more students attending from the host country. An invitation to contribute to the surveys before and after this International experience was circulated to all students. Surveys were administered through MS Forms. Gender, age and degree level were not included, as these were not aspects to be measured in this research.

The questions from the survey focused on the skills/competences which are essential to address economic and societal issues, as outlined in Section 1. In addition, the instrument explored respondents' previous experience of learning. In the survey students were asked to articulate two goals each related to their: i) learning and ii) wider experience during the international project week; students were not guided in setting goals and were not aware of the WEF or GEC categories. The authors mapped the answers for these questions against the four categories related to World's Economic Forum's Education 4.0 Framework, specifically the Skills for Adaptation (World Economic Forum 2020) which were also aligned to the Global Competences for Engineers (Ortiz-Marcos et.al, 2021). Table 1 shows the mapping of these categories.

Table 1. World Economic Forum's Education 4.0 Framework aligned to Global Competences for Engineers

WEF Education 4.0 Framework (Skills for Adaptation)	Global Competences for Engineers
1. Global Citizenship skills	GC1: Communication GC2: Communication in a foreign language GC10: Understand the connectedness of the world
2. Innovation and Creativity skills 3. Technology skills	GC3: Holistic system thinking GC7: Problem solving
4. Interpersonal skills	GC4: Negotiation GC5: Conflict management GC6: Cooperation GC8: Encourage and motivate others GC9: Teamwork GC11: Decision making

3 RESULTS

The survey was sent to 1327 students, from 10 countries with overall 13 universities participating in the experience. A total of 137 (10.32%) students completed the before-experience survey, while 75 (5.65%) students completed the after-experience survey. Despite the low response rate, the data offers valuable insights into students' before and after experiences during their participation in the event.

3.1 Students background

Table 2 shows participants' backgrounds, as well as whether they had engaged with previous international experiences, and whether this was a compulsory or voluntary participation. Results show that 43 (54.4%)/79 of first-time participants are attending the international experience voluntarily. This seems to indicate that students realise how much they can gain from an international experience and how they can develop GECs and skills from opportunities like this. Note that a substantial proportion of the participants in this international experience were from the host institution (1175 (85.5%)/1327) where repeated participation in these international project weeks is compulsory. For information, Table 3 shows the number of times participants have attended an international event and type of participation for those not attending for the first time (n=58).

Table 2. Students' backgrounds

Nationality	Is your 1st International Experience?	
	YES	**NO**
-European - 127 (92.7%)	79 (57.6 %)	58 (42.4%)
-Asian - 8 (5.84%)	36 (45.6%) - Compulsory	38 (65.5%) - Compulsory
-American - 1 (0.73%)	43 (54.4%) - Voluntary	20 (34.5%) – Voluntary
-No answer – 1 (0.73%)		

Table 3. Times participants attended an international event and type of participation

Times attending international event	Type of participation
2 times: 35 (60.3%)	Compulsory: 21 (60%) Voluntary: 14 (40%)
3 times: 12 (20.7%)	Compulsory: 7 (58.3%) Voluntary: 5 (41.7%)
4 times: 5 (8.6%)	Compulsory: 4 (80%) Voluntary: 1 (20%)
≥ 5 times: 6 (10.4%)	Compulsory: 4 (66.7%) Voluntary: 2 (33.3%)

3.2. Results related to learning and wider international experience

Table 4 shows the results related to goals achieved by the participants (after event). The goals were mapped towards the WEF adaptive skills and GCEs provided on Table 1, Methodology section.

Table 4. Goals related to learning and to the wider international experience mapped against WEF skills for adaptation and GCEs

WEF Education 4.0 Skills for adaptation	Global Engineering Competences	Goals related to learning	Goals related to the wider experience
1.Global citizenship skills	GC1: Communication	23	11
	GC2: Communication in a foreign language	19	13
	GC10: Understand the connectedness of the world	4 (Culture) 3 (Network) 26 (Skills for adaptation)**	23 (Social) 21 (Culture) 28 (Network) 3 (New City) 12 (Skills For Adaptation)**
2. Innovation And creativity skills	GC3: Holistic system thinking	1	0
3. Technology Skills	GC7: Problem solving	18	5
4. Interpersonal skills	GC6: Cooperation	6	1
	GC9: Teamwork	31	5
	GC4: Negotiation	0	0
	GC5: Conflict management	7	2
	GC8: Encourage and motivate others	3	1
	GC11: Decision making	1	1
Didn't answer/uncategorised answer		25	26

Sample of **students comment related to Skills for adaptation:

"Learn how to identify and rectify mistakes" (R34)

"Talk freely about my opinions and gained more confidence to speak for my ideas" (R39)

"To be able to interact extensively and connect with strangers" (R65).

"Work on my social anxiety"(R67)

"Step out of my comfort zone (R125)

"I'd like to stop being afraid of traveling alone to a city I don't know". (R130)

4 DISCUSSION

This study set out to explore engineering students experience of an international learning opportunity with reference to 'How do self-set goals set in an international study opportunity align to Global Competences for Engineers and WEF Education 4.0 skills?'

Overall results show that self-set goals aligned well to WEF Education 4.0 Group 1 skills, and the Global Competences for Engineering. There is stronger alignment to skills around global citizenship and soft skills such as team-work and communication, as well as traditional, easily conceptualised competences such as problem-solving. Given the project-focused nature of the international experience, then students setting problem solving goals, that reflect a systems approach would be expected. In contrast, few students articulated goals that mapped to more nuanced competences such as systems thinking, innovation, creativity, negotiation and decision making. Further work would be needed to determine whether these competences are valued even if not recorded in the goals collected here.

The data collected in this study is not without its limitations. Ensuring the anonymity of participants, a priority for this research, inadvertently compromised the ability to map responses before and after the intervention, as some participants forgot the code they were asked to remember. Additionally, the heterogeneous nature of the study population presents another challenge; the study included small numbers of voluntarily participating students from numerous individual institutions and a large cohort of students from the host institution, for whom repeated participation was compulsory. This mix potentially skews the data. Moreover, as this study relied on self-reported data, it may not fully capture the perspectives of students who had less positive experiences. Despite these limitations, the international context of this study is unique and offers valuable insights into student experiences across diverse educational settings. However, the methodology used here could be adapted and repeated in different contexts to explore the broader applicability of these findings in a range of different international study opportunities.

5. CONCLUSIONS AND FUTURE WORK

The experiences reported do illustrate how engaging with diverse communities and perspectives allows students to gain an appreciation for cultural differences and similarities, fostering the development/enhancement of a range of GCEs, particularly communication, cultural awareness and teamwork and how could the design of these experiences be further developed to more closely support the development of the full range of competences and skills defined in the CGE and WEF Education 4.0 Framework.

It is important to acknowledge potential biases in the interpretation of the data collected. One significant limitation is the low response rate, with only 10% of participants completing both surveys. This low participation rate raises concerns about the representativeness of the findings, as those who voluntarily chose to respond may differ in significant ways from those who did not. It is plausible that participants who were more engaged or had stronger opinions were more likely to complete the surveys, which could skew the results. Therefore, while the data provides valuable insights, it should be interpreted with caution, and future studies should aim to increase response rates to enhance the reliability and generalizability of the findings.

This ongoing project will next address the research question: ‘What personal benefits do students’ perceive that this international study opportunity provides? And analysis of the quantitative data related to students' perspectives of their own competencies before and after their participation in order to determine the impact of international experience on addressing GCEs and WEF Education 4.0 skills. Additionally, we plan to refine and extend the research instruments to more closely explore the full range of GCEs and WEF Education 4.0 framework skills in future studies, for example, through semi-structured interviews. By extending our methodological approaches, we aim to gain a deeper understanding of how international experiences contribute to the development of these critical competencies and skills.

Keywords: *Decoding the Disciplines, Thinking aloud, Bottleneck*

ABSTRACT

This study investigates obstacles hindering effective thermodynamics education, especially focussing on the bottlenecks imposed by setting up system boundaries and deriving energy balances. Methodologically, the study employs decoding interviews with experts and thinking aloud interviews with students. By comparing both perspectives, significant disparities in problem-solving approaches emerge. For

[1] *M. Neef*
matthias.neef@hs-duessldorf.de

example, experts travel intuitively between different levels of abstraction, while students tend to adopt a more linear approach. Interventions to address identified challenges include a memory game to reinforce symbol-component associations and online exercises with immediate feedback on suitable system boundaries, thus explicitly targeting different levels of abstraction while introducing physical modelling.

1 INITIAL SITUATION & APPROACH

Obstacles in educational processes that restrict the effective transfer of knowledge and learning success are referred to as “bottlenecks” and can have negative impact on learning success. Like threshold concepts, bottlenecks relate to students’ learning difficulties. However, bottlenecks as part of the Decoding the Disciplines method are analysed from an expert perspective to make this knowledge available for the design of learning activities (Wiemer and Kenneweg 2021).Bottlenecks can be identified by empirical observations (Middendorf and Shopkow 2018). In the STEM discipline of thermodynamics, bottlenecks can be imposed by insufficient comprehension of basic physical concepts (Foroushani 2019) or by the perception of thermodynamics as a purely theoretical subject without seeing the relevance of the systematics for real tasks and applications.

A bottleneck specific to problem solving in the field of thermodynamics can be defined as follows:

“Students regularly face difficulties in applying decision criteria for setting up meaningful system boundaries and for deriving energy balances.”

To address this bottleneck, the following steps were taken and investigated methodically (numbers relate to respective paper sections):

2) Design of a typical example task to investigate expert and student perspectives, and suitable to observe the identification of system boundaries

3.1) Interviews with teachers/experts to uncover their solution strategies for the task (Method: Decoding the Discipline)

3.2) Interviews with students to uncover their mental steps in solving the task (Method: Thinking aloud)

4) Synthesis: Comparing expert and student approach

5) Suggested implementations to improve overcome the observed bottleneck

2 EXAMPLE TASK

Here, a laboratory test rig with different components and different fluids was chosen as a typical exercise which requires the application of system boundaries:

> *“In a testing plant, a fan with a power of 250 W draws in an air mass flow rate of 0,119 kg/s at an ambient temperature of* 2 °C *and an ambient pressure of 1,05 bar and heats it to an outlet temperature of 50 °C in the downstream air/water heat exchanger. The heating water for the heat exchanger is heated in a storage tank using an electric heating rod. In steady-state operation, the water exits the tank at a temperature of 55 °C, is then pumped with a power of 100 W,*

and after passing through the heat exchanger, it is returned to the tank. (Material properties given.)

a. What is the heat flow absorbed by the air flow in the heat exchanger? Draw the boundaries of the subsystem you are considering in the sketch.
b. What is the electrical power of […]"
c. [… following subtasks c. to d., not relevant for this paper]

According to the theory of situated learning (Anderson et al. 1996), learning is an active construction process of learners that occurs in a realistic and context-bound manner. It is assumed that students, depending on their preferred learning strategies, approach tasks in thermodynamics differently and require varying degrees of situatedness or abstraction. Learning strategies are behaviours that can be used to master learning tasks. They include strategies for selecting, organising, and integrating information. Here, the focus is on the cognitive learning strategies of elaboration and critical thinking (Wild 2005). Therefore, the visualisation of the testing plant was designed in two alternative ways, "Near to reality" and "Abstract" (see Fig.1).

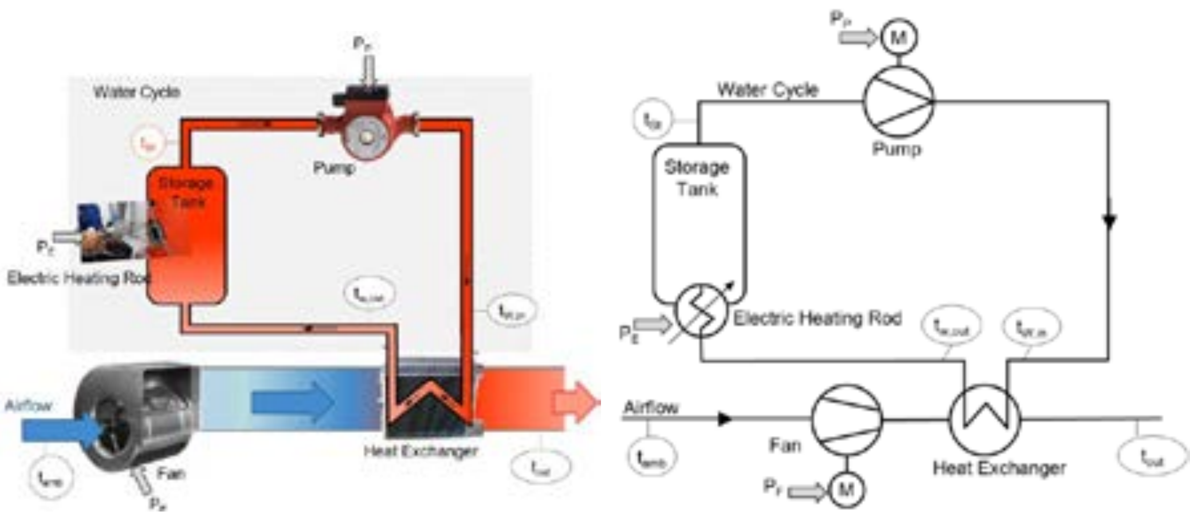

Fig.1: Visualisations of testing plant: "Near to reality" (left) and "Abstract" (right)

3 EXPERT AND STUDENT PERSPECTIVE

For the investigation of the bottleneck in focus, experts as well as students were asked to solve the example task.

3.1 Expert perspective: Decoding the Disciplines

The expert strategy related to the bottleneck was revealed using the method "Decoding the Disciplines". By explicating the expert strategy with the help of decoding interviews, implicit discipline-specific knowledge can be brought out in a structured way and thus made available for teaching (Riegler 2020). Therefore, Decoding the Disciplines can be used to narrow the gap between expert and novice thinking. Two experts completed the example task while external interviewers questioned them about their approach to decode their expertise and background knowledge.

3.2 Student perspective: Thinking Aloud

In order to analyse the mental actions used by students while working on the same exercise as the experts, interviews were conducted using the “thinking aloud” method. The goal was to analyse how students approach the exercise, which solutions they use and which obstacles they encounter. The research method known as thinking aloud requires test subjects to verbalise their thought processes, decisions, and considerations to make them traceable (Charters 2003). The students were also asked to assess the difficulty of the task and its comprehensibility. All participating students have signed a declaration of consent for the collection and processing of interview data for research purpose. The interviews were conducted with seven students in the middle to lower-middle range of performance which were identified using data from previous assessments competed within the course. As the teacher involved in the project was not present during the interviews and all personal data was anonymised during transcription, it was not possible to draw any conclusions about the identity of the students while evaluating the interviews.

4 SYNTHESIS: COMPARISON OF EXPERT AND STUDENT PERSPECTIVE

Both the expert interviews and the student interviews were analysed using inductive and deductive categories according to Mayring (Mayring 2015). The solution strategies were visualised in flow diagrams (see examples in Fig. 2) to compare the approach of students as novices and professors as experts. These steps towards a solution also include side aspects such as search iterations for missing information or solution approaches that were not continued or necessary for this case (yellow boxes in Fig. 2).

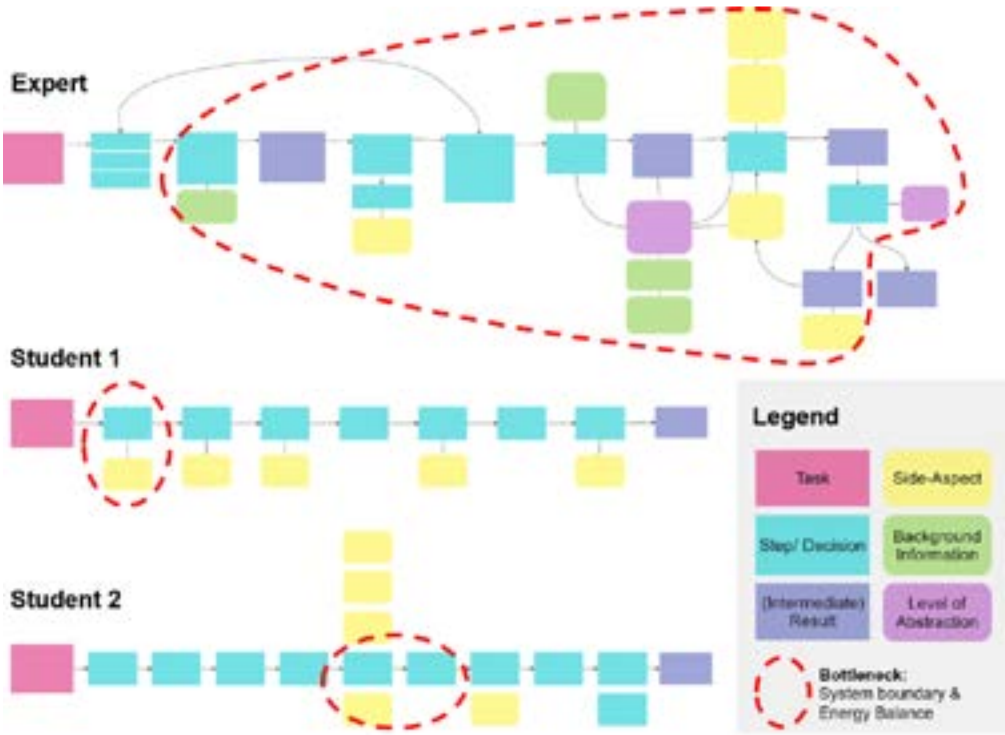

Fig. 2. Visualisation of solution strategies for example task: expert (top) and students (below)

Through analysis and visualisation of the decoding interviews, several aspects of the expert strategy stood out, mainly:

1. Experts in thermodynamics draw on several details of real-world knowledge and physical modelling expertise to identify subsystem boundaries, despite the subject's abstract nature, and they travel freely between different levels of abstraction. This marks a vital aspect of the solution strategy, which was only made explicit by the decoding interviews (purple boxes in Fig. 2). The process of differentiating between important and unimportant information to achieve a meaningful level of abstraction is second nature to the expert and as she/he is familiar with the various semantics of different modelling approaches and abstraction levels such as mathematical and physical modelling in various disciplines. The different languages which are used to articulate the respective modelling in include symbols and conventions (such as used in Fig. 2 / right) but reach far beyond graphical representations and simplifications of reality.
2. Defining suitable (sub)system boundaries is not a linear but an iterative process that involves defining and redefining the subsystems. Adjusting is as necessary if values are missing for a successful calculation.

In contrast to the experts, the students try a more linear approach, draw less on background information, and do not distinguish between different levels of abstraction. This is clearly visible when comparing the flow diagrams that visualise the solution process for the same task for experts and students (see Fig. 2). The comparison also highlights the proposed bottleneck: The attempts of the students to identify meaningful system boundaries are rare. In the end, this led to incomplete energy balances and – ultimately – wrong solutions of the task.

In the following section, key observations from the interviews are highlighted by exemplary extracts from the interviews.

4.1 Starting point: variables and given values

Starting from a look at the given values in the task, the expert considers the broader picture, the student looks for a procedure:

> Expert: *“[…] able to avoid setting up several subsystems […] Then I have two systems and I can cope with that.”*
>
> Student 2: *“I would have a look at the formulary now. Before I do that now, I would first ask myself the question, what do we actually want?”*

Observation: The expert combines the view on the given values with the determination of suitable system boundaries. Students try to replicate common formulae or look for formulae that contain the given values. Sometimes doubts arise as to whether the assumptions are correct (e.g. Student 3, Student 5). Student 1 is struggling to understand the overall system.

4.2 Identifying system boundaries

Fig. 3 shows all possible system boundaries that were sketched by the students. The results reveal that three students could find suitable subsystem boundaries. Student 1 set up two subsystems, one containing the fan and the other the heat exchanger, which can also lead to a correct solution. However, none of the students was able to apply the choice of system boundaries when setting up an energy balance: All the students neglected the power of the fan.

Decoding Interviewer: “Okay,[...] do I understand you correctly, […] you sort out for yourself what could be subsystems? So, regardless of the task up there, you start by

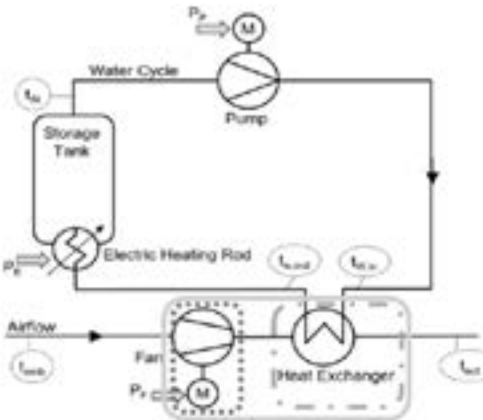
putting a kind of [...] search algorithm over it, what are subsystems? [...]"
Expert: "Mhm" ("yes").

Student 1: "I didn't quite understand where the water and air and everything comes from. [...] I wonder why there's such a zigzag in the heat exchanger, what that's supposed to tell me?"

Student 2: "In this case, an airflow system, that's clear, OK, there's an airflow and in order for this airflow to be produced, a certain amount of power has to be applied. So that this airflow is produced at all. […] I don't know myself exactly what it was, but perhaps it's simply the overflow of system components that makes you ask yourself the question, where do you start to develop a strategy that makes you say OK."

Observation: The expert automatically uses her or his "search algorithm", while the students struggle with system understanding or fail due to oversimplification due to the reason in the last paragraph (looking for formulae suitable for given values).

Student 1 has problems with the symbolic representation of the heat exchanger in process flow charts. Student 2 may have difficulties with the difference between heat flow and total enthalpy flow and the fact that all types of energy can be converted.



Student	System: Fan Only	System: Heat Exchanger Only	System: Fan + Heat Exchanger (Air Duct)	Correct Energy Balance?
Student 1	suitable	suitable		no
Student 2			suitable	no
Student 3		unsuitable		no
Student 4			suitable	no
Student 5		unsuitable		no
Student 6			suitable	no
Student 7		unsuitable		no
Total	1	4	3	0

Fig. 3. Choice of system boundary by the students

4.3 Applying the energy balance to the specific problem

As can be seen from Fig. 3, students struggled to use the information in the task and their view on the (sub)systems to come up with a meaningful energy balance (first law of thermodynamics).

> Student 2: "*[....] the first law of thermodynamics? But that's also a topic. So we're working on that at the moment* (i.e. in the course)*, I definitely wouldn't work on that yet, so I always leave it aside."*
>
> Interviewer: *"With the energy balance?"*
>
> Student 2: *"Yes, exactly, I mean, I know roughly how it works, but setting that up now...!"*

Student 3 performed quite well, but in the end her or his solution ended up too simple, due to the previously assumed unsuitable system boundary. Others did take decisions such as simplifying the problem but could not give physical explanations for their validity.

Observation: Students had only practised energy balancing on small problems previously. Hence, they are afraid of using and applying the energy balance on a general level thus out ruling the most central tool for tackling the task.

Overall, it became clear that setting up meaningful system boundaries as a first step to arrive at a suitable energy balance was not yet fully practiced and appreciated by the students. Although they were all active participants of courses that introduce and use energy balancing for simple thermodynamic problems, they had difficulties to take an approach that looks like an algorithm to the expert but requires a firm overview of the different levels of abstraction. It is concluded that using the different "languages" implicitly used to model a system must be learnt and introduced more explicitly.

5 IMPLEMENTATIONS TO IMPROVE LEARN SETTING

From the findings of the previous sections, it can be deduced that the first step in training energy balancing should include sketching system boundaries and setting up the energy balance in its task-specific form but should not be combined with calculations of specific numerical values. The latter is required for the final solution process, but if focussed too early, this misleads students to the start with looking for appropriate equations of state instead of getting the energy balance straight first. To be able to sketch system boundaries the reading and understanding of process flow diagrams is important.

5.1 Development of a memory game for process flow diagrams

A memory game was developed to improve the assignment of standardised symbols to real components and to bridge the gap between abstract thinking and the need for knowledge about the real components (see Fig. 4). The game is now used as an icebreaker in exercises to introduce the topic of process flow diagrams and was well received by the students due to the playful learning approach.

Fig. 4. "MemoR&I": Game to train standardized symbols used for energy systems

5.2 Designing learning exercises with JSXGraph in STACK

Exercises in online Learning Management Systems (LMS) can provide immediate feedback on individual errors. For the LMS moodle and ILIAS, the STACK plugin (STACK 2024) can be employed for this purpose. STACK is connected to a computer algebra system (CAS) that can verify equations such as energy balances. STACK also offers the possibility to integrate JSXGraph for interactive graphs. This allows both aspects, the proof of the equation of the first law of thermodynamics via STACK and the sketching of system boundaries via JSXGraph, to be carried out online with immediate feedback.

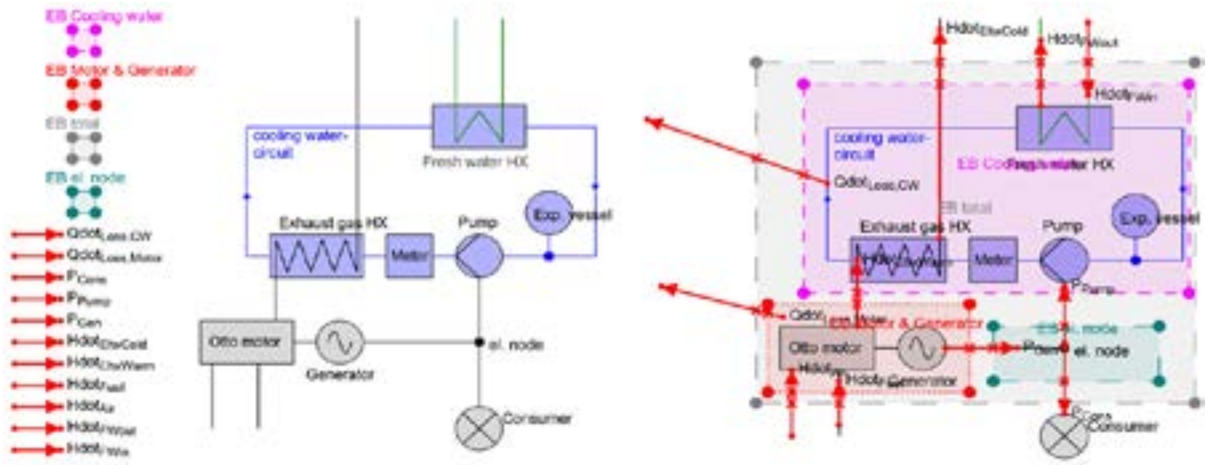


Fig. 5. STACK-JSXGraph task for balancing a micro-cogeneration unit. Left side: exercise layout, right side: solution.

Fig. 5 provides an example of a STACK-JSXGraph question that is now used as an exercise prior to a larger lab task in which students must derive an energy balance of a micro-cogeneration unit.

The students must identify where energy flows occur and move the corresponding arrows to the respective locations. In addition, the system boundaries must be dragged to appropriate positions. STACK is used to check whether the arrows are in the correct positions, have the correct direction and whether the energy flow exhibits correct intersection with the corresponding system boundary (represented by red crosses in the graphic on the right side of Fig. 5).

The authors are also working on experimenting with different forms of learning settings such as flipped classroom, learning diaries, group work etc. to direct more attention to the arguing needed in setting up system boundaries and energy balances. By this the interaction between experts and students is increased and the different techniques used in modelling thermodynamic systems can be made more explicit.

6 SUMMARY AND CONCLUSIONS

Obstacles hindering effective thermodynamics education are successfully targeted in this paper, particularly focusing on challenges related to system boundaries and energy balance derivation. The detailed analysis of expert and student approaches to problem solving highlighted significant differences: Experts demonstrated a nuanced understanding, leveraging real-world knowledge to define subsystem boundaries iteratively. In contrast, students exhibited a more linear approach, often overlooking crucial interactions between components on different levels of abstraction and struggling with symbolic representations. The findings highlight the necessity to tackle simple engineering tasks /exercise with a suitable modelling approach rather than with a procedure. For this purpose, it can be helpful to explicitly address the levels of abstraction and their role in problem solving, as it is common in computer sciences, see for example (Waite et al. 2018). For the bottleneck addressed here, at least three levels of abstraction can be identified: Focus on “reality” to extract system information, “physical modelling” to decide for relevant dependencies and “black boxes” to obtain a system overview. Such distinction is also relevant for other subjects e.g. classic physics of motion as addressed in (Lindsey et al. 2012).

The comparison between expert and student strategies underscores the need to rehearse the art of problem solving on all levels of abstraction. Proposed practical implementations include a memory game and online exercises dealing with system boundary identification with immediate feedback, thus improving the understanding and appropriate modelling of the problem before calculating absolute values. The excises can be further improved by using adaptive feedback to typical errors and an adaptive solution process as shown in (Alteri et al. 2020).

The common bottlenecks in thermodynamics are often related to subject specific terms such as understanding heat, internal energy, and enthalpy etc., see (Foroushani 2019). The bottleneck to decide for relevant system boundaries can be tackled by learning the language of system modelling. This learning process can be improved by decoding solution strategies of both expert and student. The findings and interventions presented here are also relevant in all disciplines that require abstract modelling from free boy diagrams (mechanics) to conservation laws in fluid mechanics.

ACKNOWLEDGEMENTS

This paper is the result of a Scholarship of Teaching and Learning as part of the Project “OK!Thermo” (online competence trainer for thermodynamics). It is funded by the Ministry of Culture and Science of North-Rhine Westphalia (Germany) as part of the funding programme OERContent.NRW. The Authors would like to thank Miriam Barnat and Britta Foltz (University of Applied Sciences Aachen) for conducting the Decoding the Discipline interviews.

Keywords: *Challenge-Based Learning, Interdisciplinary Education, Higher Education, Student-driven learning*

ABSTRACT

Challenge-Based Learning (CBL) is revolutionizing education by placing authentic challenges at the forefront of student learning, while enabling interdisciplinary education, as it allows students to define a challenge, based on their disciplinary competencies and interests. In this paper through the presentation of the redesign of the minor From Idea to Prototype, we aim to offer an example of the practical implementation of CBL within an existing interdisciplinary context, and help educators disentangle complex concepts related to the application of CBL. Key takeaways from this study are that CBL is a very good fit with interdisciplinary education, a low number of students is favourable for the initial application of CBL, and educators should pay close attention to managing the challenge providers to successfully apply CBL. Our findings suggest that CBL not only benefits students and educators but also creates value for challenge providers. Furthermore, it helps educators expand their professional networks and is in line with the concept of entrepreneurial education. However, it needs to be clear that the initial investment may need a significant effort before it starts paying off, and continuous evaluation and reflection is necessary. Future work will investigate the long-term value of CBL within the presented context.

1 INTRODUCTION

1.1 Challenge-Based Learning and Interdisciplinary Education

It is evident that students in higher education need, next to discipline-focused courses, also courses that focus on the development of 21st century skills (Beers 2011). This way students can use disciplinary knowledge for more than one thing (i.e. programming can help students structure their ideas better), if those connections are made explicit. CBL is gaining traction as a pedagogical approach within higher engineering education since it was first introduced in 2011 (Leijon et al. 2022; Doulougeri, van den Beemt, et al. 2022). Partly so, due to its ability to foster the development of 21st century skills, such as critical thinking, communication, and creativity (Vilalta-Perdomo, Mapfaira, and Michel-Villarreal 2022; Doulougeri, Bombaerts, et al. 2022). It combines the pros of both problem-based learning (PBL) and project-based learning (PjBL) while enabling students to define their own challenge from general problems or themes provided by industrial or research stakeholders, therefore promoting self-driven learning (Kohn Rådberg et al. 2020). It additionally cultivates creativity and communication by facilitating collaboration between students and external stakeholders towards solving complex problems (Mayer, Ellinger, and Simon 2022). As authentic challenges are inherently multifaceted, CBL is especially useful for interdisciplinary contexts (Malmqvist, Kohn Rådberg, and Lundqvist 2015; Petrová 2020).

1.2 Minor From Idea to Prototype

This practice paper focuses on the redesign of the 15 ECTS (420 hours of workload) Minor From Idea to Prototype, for which the author is the coordinator. This minor is part of the larger Science 2 Society minor package (30 EC). Over a period of 10 weeks, participating students are divided into 8 groups of 6-7 students each and immerse themselves in the state-of-the-art science behind a challenge provided by an external company or research department. Such challenges span from robots that can be controlled with eye-tracking to help people with only eye movement communicate, smart lights that help you communicate non-verbally with your grandparents, monitoring and managing work stress, to capacity building in developing countries through serious gaming. Concurrently, students are exposed to various scientific disciplines and aided in developing relevant skills through basic lectures, mini-lectures, and interactive workshops. All groups progress from a general idea to one or more scientifically and practically grounded prototypes for the challenge at hand. As we welcome students from other universities nationally and internationally, as well as from all programs within the University of Twente, student teams boast diverse disciplinary backgrounds (both engineering and non-engineering) and nationalities. The minor is an elective module that becomes available to the students in the beginning of the 3rd year of their undergraduate studies.

1.3 Objective of this paper

In this paper a comprehensive way of implementing CBL in higher engineering education is presented, by guiding the reader through the redesign of a university minor. This will be presented through the methodology followed for redesigning the minor, the evaluation from students, colleagues, and educational experts, as well as the presentation of improvements based on that evaluation. For a more detailed explanation of the redesign of the minor, you can refer to this work (Nizamis 2021).

2 METHODOLOGY

2.1 Redesign Methodology

As the minor is affiliated with various university departments and individuals, it boasts a diverse ecosystem of tutors and experts, that need to be considered in the redesign. The redesign process, was based on the concept of constructive alignment (Biggs 1996), a principle essential for effective education design as it facilitates effective learning (Smith 2008). This process was assisted using Bloom's Taxonomy (Bloom and Krathwohl 1956) to categorize intended learning outcomes (ILOs) by complexity levels and select verbs that compose clearer ILOs. The focus on crafting specific and measurable ILOs aims to enhance their effectiveness and facilitate comprehension for students. Additionally, outdated or irrelevant ILOs were removed to maintain relevance (for the ILOs see Fig. 3). Consequently, we ensured that teaching, learning activities, and assessments directly correspond to the ILOs (Fig.1). The 1st iteration was the first attempt in redesigning the minor after it was originally designed by its previous coordinator (which was not the author). This attempt helped into getting insights, and feedback from students, colleagues, and challenge providers, in order to again redesign the next year (2nd iteration).

2.2 Redesign – 1st Iteration

ILOs: The constructive alignment was supported by creating *alignment tables*

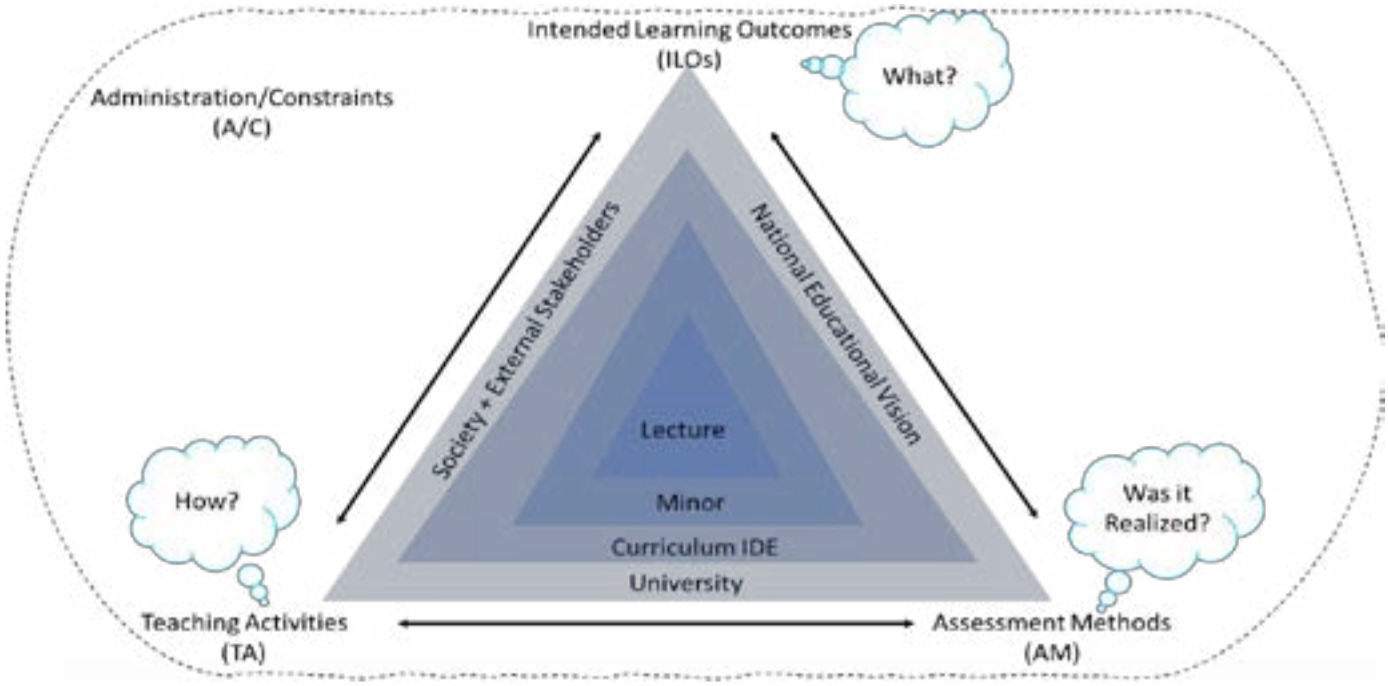

Fig.1 is an illustration of the principle of constructive alignment. The constructive alignment triangle can zoom out to more abstract ILOs (goals of the University, ILOs of the encompassing programme curriculum) and zoom in to a specific minor/module or even down to course/lecture level. All the aligned elements operate within constraints imposed by the context (time/capacity, university, resources, etc.

between ILOs, teaching activities, and assessment methods (See Fig. 3). These tables were used to make sure we cover sufficiently the ILOs.

Formative Assessment			Summative Assessment			
Motivation Letter (1)	Assignment Proposal (1,2)	Midterm Presentation (2,3)	Report (60%) (1,2,3,4a)	Individual Reflection (10%) (1, 4b)	Final Presentation (30%) (1,3)	
					Peer Assessment (10%)	Expert Assessment (20%)

Fig.2 This table is shared with the students in the minor manual. The weight of each of the summative assignments is given to enhance transparency. Each form of assessment is linked to the ILOs in line with constructive alignment (see numbers in brackets and Fig. 3).

Teaching Activities (TA): The introduction of CBL, catering to students from various programs and disciplines across applied and social sciences, necessitated the introduction of *workshops on CBL, and Stakeholder Analysis*, enhancing students' interactive experiences. By allowing students to define challenges based on their expertise and interests, CBL facilitates collaboration in addressing authentic, multidisciplinary challenges. Previously, student groups were assigned to challenges based on preference, and in cases of overlapping interests, a first come-first serve process was followed. This approach often left groups dissatisfied with their assigned cases, and in the worst-case scenario, resulted in lower quality results due to a lack of relevant disciplines. Therefore, we introduced an intermediate step requiring a *motivation letter*. This ensures that groups receiving their first choice do so based on merit rather than chance or timing.

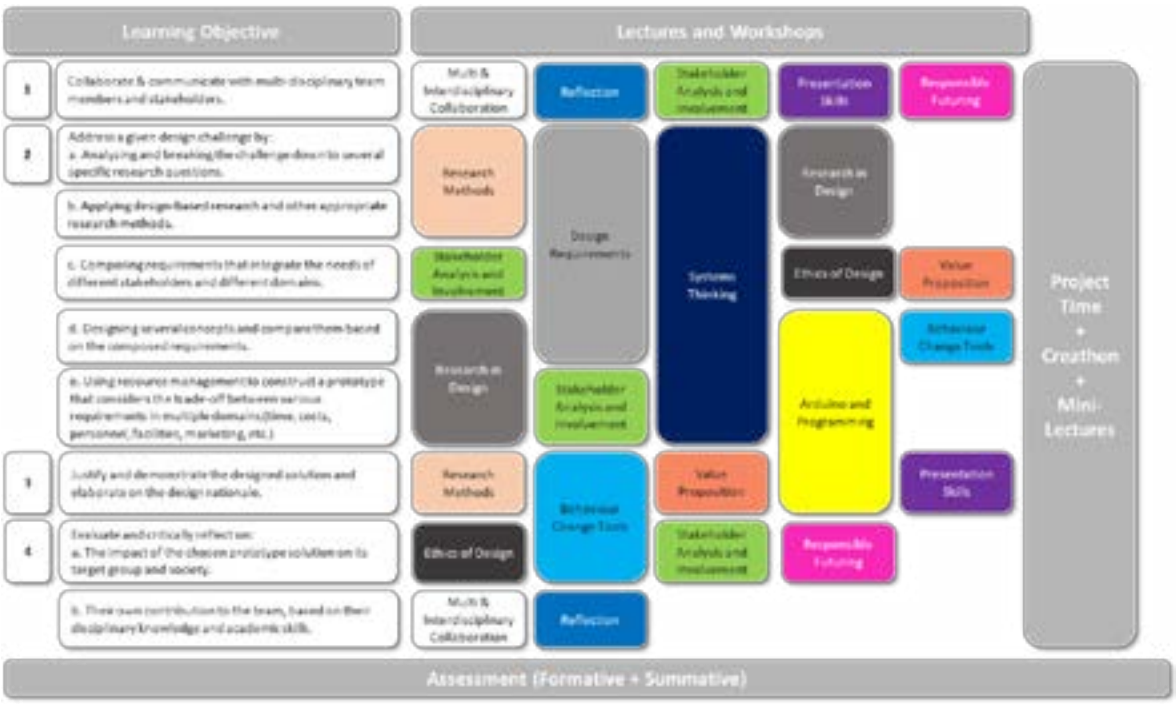

Fig.3 Alignment between the ILOs and the lectures and workshops of the minor based on discussions with the teachers. Some activities are presented more than once, as they contribute to more than one ILOs (i.e. presentation skills).

Assessment Methods (AM): Additionally, we created *detailed rubrics* that not only helped students align with assessors' expectations but also facilitated a better assessment procedure, ensuring consistency, transparency, and fairness in grading, particularly when multiple assessors were involved per assignment (Atkinson and Lim 2013). Lastly, we introduced a combination of *formative and summative assessments* to ensure students receive proper feedback (Fig. 2).

Each ILO is supported by teaching activities (lectures/workshops as seen in Figure 3), that aim to support the student in reaching those objectives. One such example is "Presentation Skills". This activity contributes towards 2 ILOs (ILO 1 and ILO 3), and that is why it appears twice. This activity is implemented right after the midterm presentation of the students, and includes a workshop on visual storytelling and the construction of impactful slideshows. This way the students try on their own in the midterm and subsequently rectify potential mistakes during this workshop. After the workshop, the lecturer provides office hours to every student group once a week until the final presentation. Consequently, each ILO is assessed by one or more types of formative and summative assessment (Fig.2 and Fig.4). The percentages of the summative assessment are motivated by the amount of ILOs assessed. Fig. 2, shows clearly that ILO 4b is only assessed by an Individual Reflection, bringing also forward the challenges of individual assessment in group work. This challenges was partially addressed in the 2nd design iteration (Section 3.2). Students are individually assessed for ILOs 1 and 4b as part of the Individual Reflection. ILOs 2, 3, and 4a, are assessed as group work. However, each students needs to have a passing score in all components to receive a final grade.

*Administration/Constraint*s (A/C): However, to maintain the element of authentic external challenges and keep the student groups between 6 students per group (as close as our capacity allows to the desired number of 4 students per group according to (Brickell et al. 1994; Chou and Chang 2018)), it was important to limit the number of students to a maximum of 48-50 per year. The final change implemented involves *changing process tutors* from student assistants to PhD students and assistant professors. This transition ensures that the process is overseen by more experienced tutors, enhancing the quality of monitoring and support provided to students, as well as safeguarding the CBL process.

Table 1 presents the types of evaluations performed, and the results and actions taken to address the feedback. The changes of the 1st iteration were evaluated with the use of evaluation surveys for the students (both by the coordination team (internal) and the university (central)), as well as by asking feedback from all the involved educators (teachers and tutors), to see how the changes resonate with them, and identify areas where we need to improve/adapt. Additionally, the minor was evaluated as to how it implements interdisciplinary education by an educational expert (results published in (Uthrapathi-Shakila et al. 2021) (external evaluation). To interpret feedback accurately, we examined the overlap between various evaluations and compiled a document outlining areas needing improvement. Subsequently, we collaborated with educational experts to propose realistic solutions and actions, considering time and logistics constraints.

3 RESULTS

3.1 Feedback

Table 1. The results from all stakeholders together with the planned actions by the coordinator.

Stakeholder	Feedback (Tops/Tips)	Actions
Students **(Internal Evaluation)** 	✓ The minor is well organized. ✓ Coordinator is very responsive and attentive. ✓ Good support to the group work by the coordinator - Make sure that challenge provider realizes the internationalization component. - Too many students lacking technical skills that are needed for the challenges.	➢ Include at least one student that speaks the local language. ➢ Promote actively the minor in technical programmes to attract more technical students and screen the challenges more thoroughly.
Students **(Central University Evaluation)** 	✓ The module was intellectually stimulating for me. ✓ As a whole, I learned a lot in the module. ✓ I have learned a lot from doing the project. ✓ The teaching methods enabled me to learn successfully. - In general, I did not have enough prior knowledge to successfully do the module. - The coherence between the module parts was not clear to me. - The number of feedback moments was sufficient.	➢ Have a balanced ratio between technical and non-technical students. ➢ Meet with all the teachers to align to the ILOs and assessment (Fig. 3). ➢ Create more feedback instances for the students and implement a double peer review.
Teaching Staff 	✓ Open issues were resolved quickly. ✓ Course information was clear. ✓ Great Organization. - Good to have a clear overview of grading tasks prior to the minor. - Help with the use of Canvas (The Learning Management System used by the University). - Unclear how the students use our lectures/workshops in their outcomes.	➢ Recruit tutors every year stating the amount of time expected to be invested. ➢ Be present on demand in a lecture when a teacher requires support. ➢ Since this was also a concern of the students we have decided to meet with all teachers and discuss the common thread of all courses and how they related to the ILOs and the assessment (Fig. 3).
External Evaluation (Uthrapathi-Shakila et al. 2021) 	✓ Both staff and students see the benefits of interdisciplinarity. ✓ Working on a real challenge from a provider is highly motivating. ✓ Students learn to appreciate approaches from other disciplines. - Staff team cohesion. - Minimal structure for guidance (for the process and group work) and interaction. - Support and clarity of expectations for staff to balance guidance and freedom for the students. - Recruitment and involvement of challenge providers. - Resources and content support.	➢ Introduce bi-weekly meetings, to introduce the minor, discuss progress, and address issues timely, by forming a teaching community. ➢ Manage our relationships with the challenge providers (as they can be too dominant or too absent) more explicitly and highlight to them our expectations. ➢ Create targeted activities with a clear contribution to the assessment of the students and a CBL creathon to showcase CBL in one day. ➢ Create a series of things described above (rubric exercise, peer review,

	- Lack of alignment between objectives, activities (challenge topic) and assessment.	better alignment between courses/workshops and ILOs, etc.).

3.2 Redesign – 2nd Iteration

The suggestions of the multi-stakeholder evaluation were implemented in the final structure of the minor, and grouped based on Fig.1 (ILOs, TA, AM, and A/C).

1. Aligning all the teachers, and subsequently illustrating the contributions of all teaching activities to the ILOs (as shown in Fig. 4, below). (ILOs)
2. The implementation of a one-day CBL Creathon in the beginning of the minor. (TA)
3. A double instance of peer review was introduced using Buddycheck[2]. One 3 weeks after the start of the minor, prior to the midterm and one at the end. The students are asked to reflect on this on their individual reflection essay. (AM)
4. Due to the introduction of the peer review moments, and in order to emphasize more individual assessment, we increased the percentage of the individual reflection for the final grade (Fig. 4).(AM)
5. Explicit communication with challenge providers, by creating a challenge recruitment word template. This helps align the expectations of all stakeholders. (A/C)
6. Support the tutors and teachers in order to create a teaching community, that in turn can support novice tutors. Tutors undergo training in CBL, in addition to receiving tutor guidelines based on past experiences. (A/C)

Formative Assessment				Summative Assessment			
Motivation Letter (1)	Assignment Proposal (1,2)	Peer Review (x2) (1,4b)	Midterm Presentation (2,3)	Report (50%) (1,2,3,4a)	Individual Reflection (20%) (1, 4b)	Final Presentation (30%) (1,3)	
						Peer Assessment (10%)	Expert Assessment (20%)

Fig.4 The new assessment structure of the minor after the evaluation. The addition of the peer review was aiming to enhance the assessment of ILO 4b that was under-represented in the previous iteration (see Fig. 2), and increase the contribution of the individual reflection to the final grade by asking the students to reflect on teamwork, based on their peer review evidence.

4 Discussion and Conclusion

A key factor for the implementation of CBL within the interdisciplinary minor From Idea to Prototype is the opportunity for students to define their own challenge. This way no matter their composition, groups can fit the challenge to their own capacity and interests. Previous research in this context has shown that CBL unlocks the potential for interdisciplinary learning (Uthrapathi-Shakila et al. 2021). Students have claimed to gain respect for other disciplines, better understanding, and the ability to integrate their work (Huutoniemi et al. 2010). However, this requires proper support

[2] https://www.buddycheck.io/

is given to all involved stakeholders, to make ensure cohesion and proper guidance of the students (Uthrapathi-Shakila et al. 2021).

Another key takeaway is the implementation of a whole day CBL Creathon in the beginning of the minor. This serves multiple objectives, as it gives both students and tutors a taste of CBL in one day, by including external challenge providers to give the opportunity to the students to experience working with them. And additionally, it demonstrates in one day what is expected by the students in the minor and let them practice without consequences. Lastly, this creathon can help manage stakeholders that do not want to have a longer commitment and give them a test to CBL in order to build a solid network for the future.

As more courses incorporate CBL in their curricula, challenge provider saturation may become an issue, therefore a stong network of interested stakeholders may prove valuable for CBL practicioners. Recruiting challenges is maybe one of the most important and time consuming parts for CBL practicioners. Our recommendation is that beside their own network practicioners can look for help in recruiting challenges externally, in local bussiness incubators, NPOs, and even companies that connect companies with teachers.

Last, but not least, providing enough information, attention, and training to the CBL tutors is very important (Uthrapathi-Shakila et al. 2021). This can be achieved by building a strong tutor community that can become independent over time, and able to incorporate and assist new tutors over time. However, we recommend that someone should have a specific pool of tutors, to maintain knowledge and experience, and ensure quality does not deop over time.

5 LIMITATIONS AND FUTURE WORK

Student numbers are rising, and despite the presented example being limited in the number of students, it may soon be necessary to accommodate larger numbers. This can be enabled by convincing external providers to take care of the supervision of more groups. Another way would be for universities to employ people that can provide connections to the industry and enable proper matchmaking between the industry and and academia. This will have multiple benefits for external providers that need to be explicit (access to young talent, innovative solutions, etc.)(Mayer, Ellinger, and Simon 2022). In the longterm future, it would be interesting to explore how AI can play a role in assisting CBL practice and help teachers deal with larger student numbers (Zhang and Aslan 2021). Additionally, rigorous methodologies such as SASER (Spiral Approach for SE Research) ((Bonnema, Pereira Pessoa, and Nizamis 2022; Pessoa and Nizamis 2023)), that claim to effectively bridge academia and industry, should be tested in a CBL context. Such approaches can facilitate challenge provider satisfaction and manage expectations in shorter cycles (that are desired by industry, and recently also implemented in agile academic programs). Lastly, in the future, we would like to observe and evaluate the longterm impact of the implemented changes by gathering data over the years to see which of the implemented changes work better and what are their strengths and weaknesses.

6 ACKNOWLEDGEMENTS

ABSTRACT

In an era where social and environmental responsibility are paramount, engineering education faces the crucial challenge of integrating these values into the core identity of its graduates. This paper discusses an innovative workshop that has been designed by the Rethinking Engineering Education in Ireland (REEdI) project to address this challenge by engaging students in a process that is both a fundamental learning experience for undergraduate engineering students and a method for collecting qualitative data on emerging engineering identities. Through group interactions, presentations, and reflections, the novel *Design an Engineer* workshop serves as a research instrument for exploring the themes that arise when students are tasked with envisioning the engineer needed to tackle current and future challenges. This study contributes to the broader discourse on the enhancement of engineering education by responding to calls for expanded frameworks of engineering role identity to better understand its development in the face of evolving professional landscapes.

1 INTRODUCTION

Higher education must rise to the challenge of developing curriculum that ensures both social and environmental responsibility is core to the identity of engineering graduates. This paper introduces the *Design an Engineer* (DAE) workshop. This is a novel concept that seeks to serve a dual purpose, as both a fundamental learning

[1] *M. Noctor*
Michael.noctor@mtu.ie

experience for engineering students, and as a (focus group) research instrument for gathering qualitative data through facilitating group interactions, presentations, and participant reflections.

As the engineering profession continues to evolve, so too must our approach to fostering the next generation's engineering identities. Rodrigues et al., (2018) call for scholarship in this area to focus on expanding forms of engineering role identity (ERI) frameworks and to facilitate a greater understanding of ERI development. Such frameworks are essential for comprehending the nuances of professional identity formation among engineering students, particularly in relation to their roles as future engineers, faced with complex societal and environmental dilemmas. This study is a component in a larger body of research that aims to address that call. The specific aim of this study is to explore the following question.

What themes emerge when a group of undergraduate students, from a mixed range of disciplines, are asked to design an engineer as the kind of person we need to solve the engineering challenges of now and the future?

This inquiry is not only about identifying the skills and knowledge that future engineers should possess but also about understanding how students perceive the role of an engineer, in society. By employing a workshop format that encourages active participation, collaborative design, and reflective practice, this study aims to uncover themes pertaining to underlying values, ethics, and responsibilities that participants associate with the engineering profession. We propose that the workshop holds the potential to serve a dual purpose. Firstly, as a pedagogical tool based on the principles of social constructivism, it enhances learning and ERI formation. Secondly, the workshop serves as a research instrument in the form of a focus group, that allows the researcher to gather insights into the evolving conceptualisation of what it means to be an engineer.

1.1 Defining Engineering role identity

Engineering role identity (ERI) encompasses the values, attributes, and core competencies that individuals associate with being an engineer. ERI plays a pivotal role in shaping the aspirations and motivations of individuals pursuing engineering careers (Patrick et al., 2018; Goodwin and Kirn, 2020). ERI is an individual's self-concept within the broader societal and professional context of engineering. It impacts both self-perception and interactions within professional communities (Rodrigues et al., 2018; Klaassen, et al., 2019).

1.2 Engineering role identity and social responsibility

ERI has been traditionally centred around technical proficiency and problem-solving skills (Niles et al., 2020), more recently it is undergoing a transformative expansion to include social responsibility as a core component (Crosthwaite, 2021). This shift is driven by the increasing recognition that engineering decisions have profound impacts on society and the environment. Consequently, engineering education must evolve to prepare students to navigate the ethical dilemmas and societal implications of their work (Niles et al., 2020). By asking participants to envision the engineer of the future, the DAE workshop serves as a crucible for exploring how these expanded responsibilities can be integrated into the ERI. The expansion of ERI to include social responsibility reflects an acknowledgment of the broader impacts engineering decisions have on society and the environment. This broader conceptualisation necessitates a curriculum that equips students not just with technical knowledge but with a moral compass to navigate the ethical dilemmas inherent in engineering practice (Rodrigues et al., 2018; Niles et al., 2020).

2 METHODOLGOY

2.1 Workshop format - Design an Engineer (DAE)

The DAE workshop is designed to consist of a series of interactive activities and discussion points. These activities were intentionally sequenced to facilitate active engagement and to scaffold participants in documenting their shared understanding and vision of an engineer. The pedagogical approach includes a brain-dump, mind-map, group discussion, presentation, and reflection. The selection of these activities was informed by constructivist and social constructivist principles (Von Glasersfeld, 1989). The workshop design allows for the incorporation of a central theme (figure 1) and discussion of topics related to ERI, such as values, attributes, stereotypes, and societal impact.

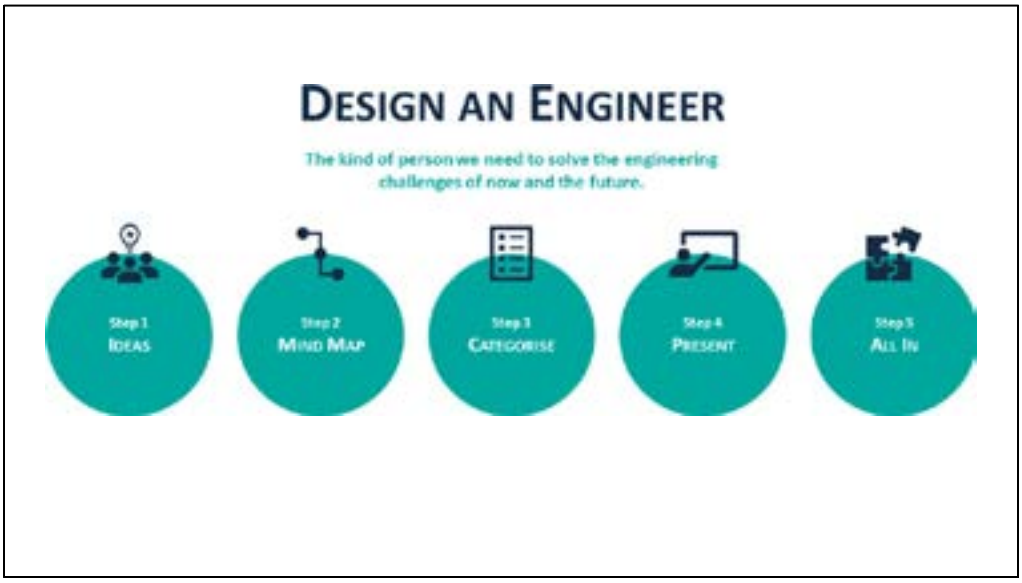

Figure 1 Overview of DAE workshop with theme and steps.

2.2 Adaptability and learning outcome

The DAE workshop is a 1.5-hour in-person activity for up to 25 participants, incorporating brain-dumping, mind mapping, categorisation, group presentations, and reflection (see figure 1). This format ensures active engagement and meaningful interaction, we propose it is adaptable for various educational and research contexts to explore professional identity in various disciplines. The workshop's simplicity allows for easy implementation, providing a versatile tool for educators to foster a deeper understanding of professional roles. Upon completing the workshop, participants will be able to identify and articulate the essential qualities, skills, and values of a modern engineer, demonstrating enhanced understanding of engineering role identity and its relevance to societal and environmental responsibilities.

2.3 Data collection

As a research instrument the DAE workshop generates qualitative data at each of the five steps outlined in figure 1. In addition, a reflection activity at the end of the workshop also yields qualitative data. Table 1 presents an overview of the data collection at each step of the workshop.

Table 1 Description of workshop steps and data collection method

Step	Name	Description	Data collection
1	Ideas	Participants are encouraged to "brain-dump" their initial thoughts on the qualities and characteristics required for engineers.	Activity artefact
2	Mind map	Through the creation of mind maps, participants visually organise and categorise their ideas, adding depth and detail. This step offers insights into how participants conceptualise the integration of various skills and ethical considerations.	Activity artefacts
3	Categorise	This step involves grouping similar ideas, which helps in identifying common themes and priorities among participants. It provides quantitative data on consensus areas and qualitative data on the reasoning behind these categorisations.	Activity artefacts
4	Presentation	Groups orally present their design of an engineer, offering an overview of their collective vision. This stage yields qualitative data through narratives that explain the integration of skills, experiences, and values envisioned for engineers.	Transcripts of recordings made during this step offers direct, verbatim insights.
5	All In	The consolidation of ideas from all groups into a single vision allows for the identification of universally valued traits and skills. This provides both qualitative insights into shared values and quantitative data on the most frequently mentioned attributes.	Activity artefacts
6	Reflection and Feedback	Participants reflect on their learning and changes in perception, providing qualitative feedback on the workshop's impact.	Activity artefacts

As outlined above each of DAE workshop steps generates data that can be analysed to understand the group's current conceptualisation of an engineer. The data collection method and management plan for this study has received approval from the university's human research ethics committee.

2.4 Participants

This study strategically leveraged the *Ingenium University Junior Winter School* as our participant selection pool. This decision was underpinned by the school's educational initiative to congregate students (n=50) from ten university members of the *Ingenium* alliance, to engage in innovative and creative learning approaches to enhance their educational experience. The setting fostered an interdisciplinary and multicultural collaboration, and the generation of innovative ideas within a narrative space that encouraged learning by way of social constructivism.

Opting to leverage this setting, allowed us to access a richly diverse participant pool without the logistical and ethical complexities of setting up a separate study. The research goal of exploring how undergraduate students from a mixed range of disciplines conceptualise an engineer as the kind of person we need to solve the engineering challenges of now and the future, was aligned with the participant selection approach. As per the conditions of the university's human research ethics policy each participant provided informed consent.

2.5 Data analysis

The data from steps 1, 2 and 3 (see table 1) of the workshop was analysed using thematic analysis, as described by Braun and Clarke (2006). This process removed duplications, organised the coded data in a structured way, allowed for the identification of themes within data and served to interpret various aspects of the research topic. It is important to note that the thematic analysis was conducted solely by the first author, which may affect the robustness of the findings. Recognising this limitation, this paper is submitted as a practice paper rather than a research study. The DAE workshop represents an innovative approach, and this submission seeks to explore new territory within engineering education. The aim is to gather initial insights and solicit feedback from the engineering education community to refine and improve the methodology.

3 RESULTS

Table 2 presents the core of our thematic analysis, directly addressing our research question: "What themes emerge when a group of undergraduate students, from a mixed range of disciplines, are asked to design an engineer as the kind of person we need to solve the engineering challenges of now and the future?" This question guided our inquiry into generating the initial codes on the attributes, skills, and values that students perceive as essential for the future engineer. Table 2 organises the initial codes extracted from the data generated during steps 1 and 2 of the DAE workshop (figure 1) data into broader themes, reflecting the diverse and comprehensive vision of engineering identity that students hold.

Table 2 Initial codes and themes extrapolated form data generated in steps 1 and 2 of DAE workshop.

Initial codes	Theme
• Problem solving • Innovative • Thinking outside the box • Addressing challenges creatively • Mental flexibility • Visionary	Creative problem solving

• Awareness of environmental impact • Long-term thinking • Responsible • Think of long-term impact of projects • Sustainable mind-set • Inclusive mindset • Mindful • Empathy • Integrity	Sustainability and Ethical Responsibility
• Willing to learn and improve • Persistent • Determined and goal focused • Self-awareness • Continuous learning • Discipline • Persistence in the face of adversity • Ambitious • Adaptable • Open minded • Enthusiastic	Growth and Resilience Mindset
• Team player • Change management • Social skills • Leadership • Composure • Relatable • Planning skills	Leadership and interpersonal excellence
• Technically capable • Proficient in maths and science • Highly educated • Solve technical problems • Detailed orientated • Accuracy • Logical	Technical Proficiency

3.1 Preliminary analysis of results

The thematic analysis reveals a multifaceted vision of the future engineer, encompassing Creative Problem Solving, Sustainability and Ethical Responsibility, Growth and Resilience Mindset, Leadership and Interpersonal Excellence, and Technical Proficiency. These themes collectively underscore the necessity for a holistic engineering education that goes beyond traditional technical training to include innovation, ethical stewardship, and social responsibility. Creative Problem Solving and Technical Proficiency highlight the essential balance between innovative thinking and foundational technical skills, suggesting an evolving pedagogical focus that fosters both inventive solutions and rigorous scientific understanding.

Sustainability and Ethical Responsibility, along with Growth and Resilience Mindset, reflect an emerging paradigm where engineers are seen not just as problem solvers but as responsible stewards of the planet, equipped with the resilience and adaptability to learn and grow in the face of challenges. This shift towards embedding ethical considerations and sustainability into the core of engineering identity aligns with global sustainability goals and the pressing need for ethical decision-making in engineering practices (Boshoff et al., 2013). This is consistent with Boshoff et al. (2013) and Niles et al. (2020) who advocate for educational frameworks that incorporate macro-ethics and societal responsibility, ensuring that future engineers are not only technically proficient but also socially conscious and ethically grounded.

The Leadership and Interpersonal Excellence theme emphasises the critical role of communication, teamwork, and leadership skills, advocating for an education system that prepares students to lead with empathy and integrity in a collaborative professional environment. This aligns with the conclusions drawn by Rottmann and Kendall (2022) in their exploration of engineering leadership education. Notably, they argue that educators must produce engineers who are not only technically competent but also capable of leading with empathy and integrity, addressing both professional and societal challenges effectively.

3.2 Summary of findings

The themes that emerged from the DAE workshop outline a comprehensive framework for engineering education. Such a framework can prepare students to meet the challenges of the future with a well-rounded set of skills and values. By integrating these themes into curriculum development and pedagogical strategies, engineering educators can cultivate a new generation of engineers poised to tackle global challenges with innovative solutions, ethical foresight, and effective leadership (Lavi and Marti, 2023; Rottmann and Kendall, 2022; Niles et al., 2020; Boshoff et al., 2013). The insights gathered from the DAE workshop underscore the importance of innovative educational practices to foster a diverse set of competencies, highlighting the role of pioneering pedagogical tools in shaping the future of engineering identity and practice.

3.3 Limitations

We recognise this study’s limitations in its approach to data collection and the workshop's design scope. Understanding these limitations is key to contextualising the study's findings and identifying areas for future research.

The DAE workshop is centred around group activities and discussions. This approach may limit the depth of qualitative data collected. This structure can result in varying levels of contribution among participants, potentially overshadowing less-dominant perspectives. Additionally, the once-off nature of a workshop cannot fully capture the evolving and complex nature of students' engineering identities. Methods allowing for more detailed individual analysis or longitudinal tracking could yield richer insights into the development of ERI over time.

Placing the emphasis on envisioning the engineer of the future with a focus on social responsibility provides valuable insights. However, it potentially narrows the scope of discussion, sidelining other vital elements such as technical skills and the impact of technological advancements. Expanding the thematic range of the workshop to include these aspects, could offer a more holistic perspective on ERI.

These limitations underscore the importance of adopting a multifaceted approach to research in engineering education. By addressing these areas, future studies can enhance the depth of data collection and expand the conceptual scope of the DAE workshop, thereby offering more nuanced insights into the complexities of ERI.

3.4 Future research

In addition to the addressing the research question, this study served to validate the DAE workshop as both a fundamental learning experience and research activity. This was a necessary step in advance of a larger research project which will focus on exploring similarities and or differences in how undergraduate engineer students and professional engineers conceptualise ERI. In addition, several other avenues for future research using the DAE workshop concept and format have been identified.

I. Conducting a longitudinal study to gain a deeper understanding of the evolution of ERI. This would involve capturing data to track the perceptions of the same individuals at different points in time. Exploring how ERI evolves as student engineers become professionals and advance in their careers and take on leadership roles within organisations. This may provide insights into the long- term impact of ERI on career progression and persistence.

II. Another possibility is to extend the scope of the research question(s) to examine cultural and global perspectives. This may uncover variations in ERI influenced by cultural norms, societal expectations, and education systems. Comparative studies may reveal culturally specific perspectives of an engineer. Investigating how factors such as gender, race, ethnicity, and socioeconomic background intersect with ERI would offer a more nuanced understanding of the experiences and perceptions of underrepresented groups in engineering.

III. Finally, future research could explore the impact of educational interventions such as mentorship programs, and workplaces in shaping students' perceptions of the engineer. Evaluating the impact of these interventions on ERI development has the potential for improving engineering education and practice.

4 SUMMARY

By focusing on understanding how participants conceptualise an engineer the DAE workshop serves as both a learning experience and a research instrument. This study’s initial findings validate that the DAE workshop has the potential to facilitate groups in documenting a broad and nuanced vision on an engineer. It is hypothesised that participating in the DAE workshop is a catalyst in the development of ERI, for engineering students. However, further research is required to measure and evaluate its effectiveness for this purpose.

As an innovative research instrument, the workshop contributes to the field of engineering educational research by providing a format for the generation and collection of data that reveals a nuanced understanding of how a group conceptualises an engineer. In addition, to contributing to the academic discourse on engineering education research the study offers a practical solution that enhances the curriculum by bridging the gap between technical competence and ERI development.

ACKNOWLEDGMENTS

The REEdI project is funded by Ireland’s Higher Education Authority under the Human Capital Initiative Pillar 3.

We extend our gratitude to the coordinators of the Ingenium University alliance for their support in facilitating this study.

ABSTRACT

Inclusive design in engineering is essential to enhance accessibility. Ireland's national Deposit Return Scheme (DRS) exemplifies the consequences of excluding inclusive design, as return machines are primarily designed for standing users, making them inaccessible to wheelchair users. Additionally, cramped spaces and narrow aisles can further hinder manoeuvrability, underscoring the need for inclusive design principles to ensure equal participation in recycling efforts.

This paper focuses on the development of a Socio-Environmental Framework that integrates transversal competencies to foster sustainable and inclusive designs in

[1] *M Nolan*
mary.nolan@atu.ie

engineering education. Transversal competencies, encompassing skills, values, and attitudes essential for comprehensive development and adaptability, are vital for advancing inclusive design. These competencies, which include communication, empathy, lifelong learning, and teamwork, are supported by frameworks such as LifeComp and GreenComp developed by the EU. LifeComp focuses on personal, social, and learning-to-learn competencies, while GreenComp emphasizes sustainability competencies.

By evaluating a professional development module for Level 7 engineering students, this study assesses the curriculum's effectiveness in preparing future engineers to create inclusive and sustainable solutions. Emphasizing empathy, critical thinking, and adaptability, the framework guides engineers to meet societal, ethical, and environmental responsibilities.

1 INTRODUCTION

Engineering education must embrace transversal competencies to address the complex challenges of a sustainable future. Inclusive design in engineering ensures accessibility for all individuals. The shortcomings of Ireland's national Deposit Return Scheme (DRS), where return machines are primarily designed for standing users and thus inaccessible to wheelchair users, highlight the consequences of neglecting inclusive design.

Transversal competencies, as synthesised by Cruz (Cruz, Saunders-Smits and Groen 2020), are defined by Care and Luo (Care and Luo 2016) as ‘skills, values, and attitudes required for learners’ holistic development and adaptability,’ are crucial for promoting inclusive design. These competencies are also known as employability skills (Markes 2006), generic skills (Bennett, Dunne and Carré 2000), key competencies (Organisation for Economic Co-Operation Development 2005), non-technical skills (Knobbs and Grayson 2012), non-traditional skills (Crawley, et al. 2007), professional skills (Shuman, Besterfield-Sacre and McGourty 2005), soft skills (Whitmore and Fry 1974), transferable skills (Kemp and Seagraves 1995), and twenty-first-century skills (National Research Council 2013).

Transversal competencies such as communication, empathy, lifelong learning, and teamwork are vital for promoting inclusive and sustainable engineering practices. This paper presents a Socio-Environmental Framework, based on the European frameworks, LifeComp (Sala, et al. 2020)and GreenComp (Bianchi, Pisiotis and Cabrera 2022), to enhance these competencies in engineering education. By evaluating a professional development module for Level 7 engineering students, this study examines the curriculum's effectiveness in preparing future engineers to create inclusive and sustainable futures. Emphasising empathy, critical thinking, and adaptability, the framework guides engineers to meet societal, ethical, and environmental responsibilities.

2 METHODOLOGY

2.1 Case Study Analysis: Ireland's Deposit Return Scheme (DRS)

The need for the Socio-Environmental Framework arose from analysing Ireland's national Deposit Return Scheme (DRS), an initiative to boost recycling rates for drink containers. The assessment, based on Jutta Treviranus'(2018) inclusive design principles, highlighted significant accessibility challenges, particularly for wheelchair users. Issues such as the height of return machines revealed that the DRS did not adequately meet the needs of diverse users. These findings underscore the necessity of incorporating social aspects into environmental contexts to create more inclusive and sustainable solutions.

2.2 Framework Development

Following the insights gained from the DRS case study, the Socio-Environmental Framework was developed by integrating competencies from two established European frameworks: LifeComp and GreenComp and applying Jutta Treviranus' inclusive design framework as a lens of inquiry.

Initially, a comprehensive literature review identified relevant transversal competencies from LifeComp and GreenComp applicable to engineering education. LifeComp focuses on personal, social, and learning-to-learn skills like self-regulation, empathy, and critical thinking, emphasising the social aspects. GreenComp emphasises sustainability competencies, including embodying sustainability values, embracing complexity, envisioning sustainable futures, and acting for sustainability, highlighting the environmental aspects.

The next step involved synthesising the framework. A framework was developed, combining the identified competencies from LifeComp and GreenComp. These competencies were organised into categories: Personal (P), Social (S), and Learning to Learn (L) from LifeComp, and Sustainability Values (1), Complexity in Sustainability (2), Sustainable Futures (3), and Acting for Sustainability (4) from GreenComp. The LifeComp competencies form the horizontal categories, while the GreenComp competencies form the vertical categories.

2.3 Module Assessment

Using the newly developed Socio-Environmental Framework, the Professional Development & Employability module for Level 7 engineering students was reviewed. This assessment aimed to evaluate how effectively the module prepares students to apply transversal competencies in real-world scenarios. The module's components, including the Personal Development Plan, CV Crafting and Optimisation, Teamwork Poster, and Reflective Essay, were analysed to determine their effectiveness in fostering key transversal competencies such as communication, empathy, lifelong learning, and teamwork. This assessment aimed to ensure that the curriculum equips students with the skills needed to address societal, ethical, and environmental challenges in their future careers.

2.4 Data Collection and Analysis

Data collection involved a qualitative method, specifically content analysis of students' submissions. Each curriculum component—Personal Development Plan (PDP), CV Crafting and Optimisation, Teamwork Poster, and Reflective Essay—was systematically mapped to the categories and competencies outlined in the Socio-Environmental Framework.

The coding scheme was developed based on the competencies identified in the Socio-Environmental Framework. These competencies are divided into three main categories: Personal (P), Social (S), and Learning to Learn (L) from LifeComp, which form the horizontal categories. The vertical categories are formed by the GreenComp competencies: Sustainability Values (1), Complexity in Sustainability (2), Sustainable Futures (3), and Acting for Sustainability (4).

To apply this coding scheme, relevant documents, including students' PDPs, CVs, Teamwork Posters, and Reflective Essays, were reviewed. Using qualitative data analysis, each piece of text that reflected a competency was tagged with the corresponding code. For example, a paragraph discussing self-regulation and adaptability in the PDP would be coded under the personal category. Thematic analysis was then conducted to identify recurring themes and patterns.

Each component was assessed for alignment with the framework using a color-coded system: red for little to no alignment, orange for some alignment, and green for strong alignment. This approach provided insights into how effectively the module components fostered transversal competencies.

3 Case Study: The Need for Inclusive Design in Engineering Solutions

The complexity of modern engineering solutions often reveals a critical gap between technical feasibility and user accessibility. Engineers play a crucial role in sustainability efforts, exemplified by Ireland's implementation of a national Deposit Return Scheme (DRS) aimed at boosting recycling rates for drinks containers. This initiative, aligned with the EU's Single Use Plastics Directive (European Parliament and the Council of the European Union 2019), under which, “Ireland must ensure the separate collection of 77% of plastic beverage bottles placed on the market by 2025, rising to 90% in 2029” (Department of the Environment 2022).

Ensuring these systems are accessible to all users, including those with disabilities, is challenging. The design of reverse vending machines, integral to the DRS, has come under scrutiny for not being universally accessible. Issues have been raised regarding their usability for wheelchair users and individuals with visual impairments, as some machines lack Braille instructions and rely on touch screens, which can be a barrier to access for some. This oversight not only restricts certain individuals from participating in recycling efforts but also inadvertently imposes additional costs on those unable to use the infrastructure. Ireland's national Deposit Return Scheme (DRS) exemplifies the consequences of excluding inclusive design, as return machines are primarily designed for standing users, making them inaccessible to wheelchair users. Underscoring the need for inclusive design principles to ensure equal participation in recycling efforts.

In the preamble of the Convention on the Rights of Persons with Disabilities (CRPD), section (e) states that disability arises from the interaction between individuals with impairments and “*environmental barriers*”, which obstruct their full and effective participation on an equal basis with others. This perspective is officially recognised by the United Nations, underlining the global commitment to understanding and addressing disability within the framework of human rights and societal inclusion (United Nations 2006). This concept is frequently described as the social model of disability, individuals are all different and it is not this difference that is disabling but rather the environments or designs that limit access. Acknowledging the diversity and evolving nature of human capabilities, underlines the imperative for environments and designs to ensure that accessibility keeps pace with our changing needs. The phrase "*Nothing about Us, Without Us*" (United Nations 2004), which became notable within the disability rights movement, emphasises the necessity of including those it concerns in the design process, highlighting that their participation in design is essential.

This scenario underscores a fundamental challenge: while technical solutions can address specific problems, their design and implementation must consider and include the diverse needs of users to truly be effective. This situation illustrates that engineers, despite their expertise and technical knowledge, cannot work in isolation. Collaborative efforts that include policymakers, community representatives, and inclusion of "*edge users*" (Treviranus 2018) are essential to ensure that engineering solutions are both effective and accessible. The case of Ireland's DRS serves as a reminder of the importance of inclusive design in engineering projects, emphasising that true sustainability encompasses not only environmental benefits but also equitable access for all members of society. *"Designing for inclusion starts with recognising exclusion"* (Holmes 2018).

To embrace inclusive design, engineers need a wide range of transversal skills such as collaboration, communication, and critical thinking. Key competencies from GreenComp, like valuing sustainability and supporting fairness, along with LifeComp skills such as empathy and effective communication, are essential for integrating diverse perspectives, especially those of users with disabilities.

This case study highlights the necessity for a socio-environmental framework in engineering, promoting solutions that are both inclusive and sustainable. Incorporating this framework into engineering education is crucial to equip future engineers with the needed transversal competencies. This preparation ensures they can meet society's diverse needs, making technological advancements accessible and beneficial to all, including marginalised groups.

4 SOCIO-ENVIRONMENTAL TRANSVERSAL COMPETENCE FRAMEWORK

LifeComp (2020) and GreenComp (2022), developed by the European Commission's Joint Research Centre (JRC), emphasise personal, social, and environmental competencies to guide policy formulation. Drawing insights from these frameworks, a new socio-environmental framework, detailed in Table 1, was created and applied to assess the Professional Development & Employability engineering module. This assessment aims to determine the module's alignment with social and environmental objectives.

Table 1 Socio-Environmental Framework

Category	**Personal (P)**	**Social (S)**	**Learning to Learn (L)**
Sustainability Values (1)	Self-regulation, Flexibility, Wellbeing Valuing Sustainability, Supporting Fairness, Promoting Nature (P1)	Empathy, Communication, Collaboration Valuing Sustainability, Supporting Fairness, Promoting Nature (S1)	Growth Mindset, Critical Thinking, Managing Learning, Valuing Sustainability, Supporting Fairness, Promoting Nature (L1)

Complexity in Sustainability (2)	Self-regulation, Flexibility, Wellbeing Systems Thinking, Critical Analysis, Problem Framing (P2)	Empathy, Communication, Collaboration Systems Thinking, Critical Analysis, Problem Framing (S2)	Growth Mindset, Critical Thinking, Managing Learning, Systems Thinking, Critical Analysis, Problem Framing (L2)
Sustainable Futures (3)	Self-regulation, Flexibility, Wellbeing Futures Literacy, Adaptability, Exploratory Thinking (P3)	Empathy, Communication, Collaboration Futures Literacy, Adaptability, Exploratory Thinking (S3)	Growth Mindset, Critical Thinking, Managing Learning, Futures Literacy, Adaptability, Exploratory Thinking (L3)
Acting for Sustainability (4)	Self-regulation, Flexibility, Wellbeing Policy Advocacy, Community Collaboration, Active Engagement (P4)	Empathy, Communication, Collaboration Policy Advocacy, Community Collaboration, Active Engagement (S4)	Growth Mindset, Critical Thinking, Managing Learning, Policy Advocacy, Community Collaboration, Active Engagement (L4)

5 THE PROFESSIONAL DEVELOPMENT & EMPLOYABILITY MODULE

The Level 7 Professional Development & Employability module for engineering students, delivered to online adult learners, was assessed using the Socio-Environmental Framework. Applying an inclusive design lens of inquiry, this evaluation considered the unique needs of these learners, who may be considered "edge users" compared to traditional campus students. It examined how well the module prepares these students to apply transversal competencies in real-world scenarios.

5.1 Personal Development Plan: Aligning Goals with Societal Needs

The Personal Development Plan (PDP) facilitates students' self-assessment, goal setting, skill development, networking, and continuous reflection. It emphasises self-discovery and strategic career planning, aligning personal growth with societal and environmental responsibilities. For a detailed assessment, see Table 2, which uses color-coded percentages: red for little to no alignment, orange for some alignment, and green for strong alignment.

Table 2 PDP Assessment against Table 1

Category	**Personal (P)**	**Social (S)**	**Learning to Learn (L)**

Sustainability Values (1)	90% self-regulation, sustainability, skill development, networking plan,, adaptability, well-being, continuous growth.	80% Networking: connection, understanding, sustainability, fairness, conservation, collaboration, best practices. Continuous Reflection and Adjustment: empathy, environment, communication, collaboration, sustainability focus.	95% Self-Assessment and Goal Setting: growth mindset, learning goals, challenges, proactive, overcoming obstacles, critical thinking. Continuous Reflection and Adjustment: learning management, strategy adjustments, learning objectives, embracing new ideas.
Complexity in Sustainability (2)	90% Self-Assessment and Goal Setting: systems thinking, critical analysis, improvement, sustainability challenges. Skill Development: problem framing ability.	80% Skill Development: complex systems understanding, sustainability, critical analysis, problem framing, social settings. Networking: diverse perspectives, sustainability challenges, systems thinking, social contexts.	90% Skill Development: systems thinking, critical analysis, problem understanding, solution framing. Self-Assessment: strengths and weaknesses identification, systems thinking, critical analysis, focused improvement.
Sustainable Futures (3)	90% Strategic Career Planning: futures literacy, anticipation, shaping opportunities, sustainability challenges. Networking, Continuous Reflection, and Adjustment: adaptability, exploratory thinking, navigating uncertainty, innovative solutions.	90% Continuous Reflection and Adjustment: futures literacy, open-mindedness, future scenarios, social dynamics, sustainability. Strategic Career Planning: adaptability, exploratory thinking, societal needs, sustainability challenges.	90% Strategic Career Planning, Continuous Reflection: futures literacy, anticipation, adaptability, exploratory thinking, uncertainties. Skill Development: future trends engagement, challenges, futures thinking capacity.
Acting for Sustainability (4)	60% Self-Discovery, Strategic Career Planning: policy advocacy, community collaboration, active engagement, sustainability action preparation	55% Networking, Skill Development: policy advocacy, community collaboration, active engagement, sustainability. Continuous Reflection and Adjustment: evaluation, advocacy, collaboration effectiveness, responsiveness.	60% Networking: influencers, decision-makers, peers, advocacy, collaboration, policymaking, community projects. Self-Assessment and Goal Setting: interests, skills, advocacy, engagement, development, action.

This analysis of the PDP illustrates how it aligns with the Socio-Environmental Framework, emphasising self-regulation, empathy, systems thinking, and sustainability. However, it also identified gaps in community collaboration and policy advocacy.

5.2 Summary of Other Module Components

The remaining components were also assessed, and the results are summarised below:

CV Crafting: This component aligns self-awareness and career planning with job market demands. Assessment showed strong alignment in self-reflection (85%), and continuous improvement (95%), but moderate alignment in ethical orientation (70%), social engagement (70%) and community advocacy (50%). This highlights the need for more focus on social impact and policy advocacy in CV preparation.

Teamwork Poster on "Walk the Walk in Ethics": This project focuses on wellness activities and ethical case studies. Evaluation showed high alignment with ethical practice (95%), collaboration (80%), and reflective learning (95%), and alignment in adaptability (80%) and future-oriented teamwork (80%). The project excels in ethical considerations and teamwork.

Reflective Essay: This component explores the student's learning journey, focusing on sustainability, self-awareness, and empathy. The assessment showed strong alignment in self-awareness (95%), ethical values (95%), and critical thinking (90%), but moderate alignment in civic engagement (55%) and policy influence (55%). This suggests the reflective essay supports growth but could better integrate community engagement and advocacy.

6. RESULTS: ADVANCING SOCIAL AND SUSTAINABLE ENGINEERING EDUCATION

This paper developed a Socio-Environmental Framework to evaluate and support inclusive design in engineering education, grounded in LifeComp (2020) and GreenComp (2022). The need for this framework emerged from a review of Ireland's Deposit Return Scheme (DRS) using inclusive design principles. The DRS highlighted significant accessibility challenges, particularly for wheelchair users, underscoring the necessity of integrating social aspects into environmental contexts. The Socio-Environmental Framework places a strong emphasis on transversal competencies, such as critical thinking, problem-solving, and adaptability. This approach ensures that engineering students are equipped to tackle complex socio-environmental issues and design inclusive solutions that address both social and environmental needs effectively.

Applying this framework to the Professional Development & Employability module for Level 7 engineering students revealed various strengths. The module showed strong alignment with competencies such as self-regulation, empathy, systems thinking, and sustainability. Students demonstrated self-awareness through personal development plans and reflective essays, a commitment to continuous improvement via CV crafting and teamwork projects, and a deep understanding of ethical values through ethics-focused assignments.

However, the evaluation also identified gaps in community collaboration and policy advocacy, underscoring the need for students' development to align more closely with societal and environmental responsibilities. While the module effectively fosters individual skills and values, it should place more emphasis on teaching students how to collaborate with communities and advocate for policies that support sustainability.

To address these gaps, future enhancements should focus on embedding social impact and policy advocacy more deeply into the curriculum. Future research could explore applying this framework to technical modules and integrating accreditation criteria from Engineers Ireland to align more closely with professional standards. Conducting empirical research to gather data on the framework's impact on student outcomes, including surveys, interviews, and focus groups, is crucial. Embracing transversal competencies is essential for promoting inclusive and sustainable engineering practices, ensuring engineers meet societal, ethical, and environmental responsibilities.

ABSTRACT

Teachers are increasingly encouraged to teach more attractive, dynamic and contemporary classes. In this sense, the teacher must seek to transform education based on the construction of experiences, with previously defined objectives and strategies that meet the needs and interests of the class and that allow them to participate in the construction of their knowledge, based on real situations and experienced by the group. This paper shares a diversity of collaborative teaching-learning experiences (CTLE) carried out in groups and teams, with the aim of a qualitative investigation to explore the impact of the subjects' contents on students' perceptions, as well as obtaining feedback from students on the group/team experience. The CTLEs were very enriching: (1) for teachers as education professionals because they allowed a reflection on the difficulties experienced by students in learning mathematics; (2) for students because the results show that students were involved in building their knowledge, solving problems and communicating their resolution both in groups and as a team, enabling the

[1] *C.M.R. Caridade*
caridade@isec.pt

development of the expected skills, which can contribute to improving the success of the curricular units.

1 INTRODUCTION

A high number of students in higher education have many difficulties in mathematics subjects because they require abstract concepts, the manipulation of symbols and signs, and the resolution of problems with a sequence of engaged steps (Muhammad and Angraini, 2023; Wang, et al. 2023). However, these concepts are fundamental to engineering studies and applications. The difficulty in learning mathematics content due to the students' lack of motivation, the absence of habits and working methods, and the difficulties they have in achieving the curriculum objectives, leads to abandonment of classes in these subjects and failure in higher education. Failure in the Mathematics subjects appears constantly associated with academic failure. This problem is not new, it has persisted over time, which is why the need to reflect on it and search for practices to implement to reverse the situation is justified. International studies and the results obtained by Portuguese students in national exams in this subject increase the visibility of this problem that worries educators, teachers, parents, students, and society in general.

Continuous collaboration is an essential part of learning and working in the 21st century (Millis 2023). There are many CTLEs of collaborative work in the classroom, including (Lailiyah et al. 2021), (Supriyadi and Kuncoro 2023) and (Gumiero, and Pazuch 2024). Collaborative practical classes improve the teaching of higher-level mathematics by providing engaging learning tools (Darmayanti 2023) and allowing students to increase the skills they acquire from these collaborative teaching-learning experiences (CTLE) (Du et al. 2013). There is a vast number of experiences described in the literature on collaborative learning of mathematics regarding the way of monitoring learning (Isohätälä et al, 2020, Nungu et al., 2023) and developing skills (Warsah, et al., 2021, Lewis et al., 2024) and evaluation (Darmayanti, 2023; Boud, and Margaret, 2023). Collaborative experiences can be applied using classroom work groups or teamwork (Wullschleger et al. 2023). In groups, tasks are distributed among all participants, each student is responsible for planning the tasks assigned to them and respecting deadlines. Members can share and respect opinions. On the other hand, in a team everyone works for a single purpose, exchanging knowledge and experiences to facilitate work optimization (Coers et al. 2009). One of the most notable differences is the way the experience is evaluated, as in a group, it is possible to evaluate each member of the group individually, which cannot happen in a team, as the work will depend on the joint performance of each member (Paulus et al. 2014).

This paper aims to share a set of CTLEs in mathematics for first-year engineering students. The objective of these CTLEs is to provide students with the necessary mathematical skills in a more motivating way, in addition to providing them with a wide range of soft skills that are equally necessary for the inclusion of future engineers in the job market. This qualitative study arose from the desire to better understand student and teacher perceptions of groups and team CTLE in classroom environments. Focused on groups and team learning based on CTLE proposed by teachers in different curricular units during a semester of classes or for one week. The use of questionnaires and direct observation allowed researchers to obtain answers about students' perceptions and provide valuable information necessary for the successful integration of group or team experiences into mathematics learning for engineers.

This document is organized as follows: after the introduction to the topic, in section 2 the materials and methods used in this study, in section 3 the parameters observed during the experiments carried out are presented, in section 5 the results according to performance and skills technological information of students, direct observation in the classroom and student opinion; in the last section (6) conclusions are presented.

2 MATERIALS AND METHODS

The CTLEs described in this paper refer to collaborative teaching and learning, applied in different formats: collaborative team experiences (CTE) and collaborative groups experiences (CGE) (Fig. 1). CTE involve all students working in the same environment, on the other hand, CGE involve students working in groups of elements, with several groups existing in the classroom. In each of the formats, the teacher participates as an observer, guiding student learning and providing all the support necessary for its completion.

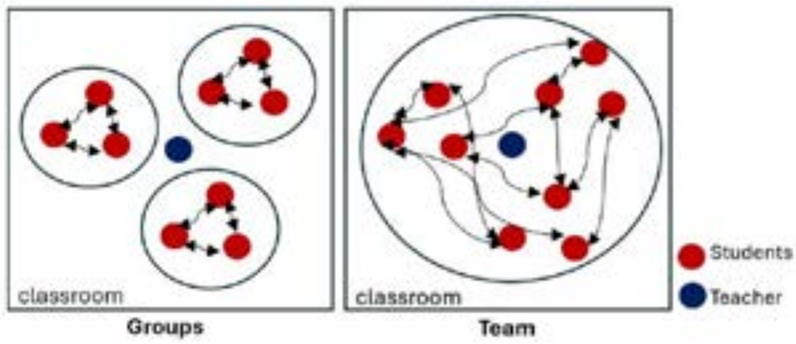

Fig. 1. Collaborative groups experiences (CGE) (left) and collaborative team experiences (CTE) (right)

2.1 Collaborative team experiences

In these experiments, different platforms for collaborative learning were used, such as Jamboard, Padlet, and Miro. These platforms allow joint access (students and teachers at the same time) to a mural, where exercises or work carried out by students are available. Students can write directly on the mural, or upload different formats of technologies, such as files, videos, images, apps, etc. On these platforms, students are invited to solve different exercises with different content and share them with their colleagues (Fig. 2). The teacher is responsible for monitoring, helping, and providing timely feedback on posts. To improve interaction between students and the exchange of knowledge, the teacher also gives students the opportunity to correct their colleagues' exercises or work, providing peer feedback. The mural is shared during classes and outside, as group learning and as support for independent and community study.

Fig. 2. Padlet (left) and Miro (right) mural.

2.2 Collaborative group experiences

In these CGE, teachers encourage collaborative projects in groups during classes and outside of classes, with the help of mathematical technologies such as GeoGebra and MATLAB. Students are encouraged to solve a given experience, made up of a set of tasks defined in a script, in groups using mathematical tools. The objective of the experience is for the student to be able to apply the syllabus contents in a motivating way. In Fig. 3 an experiment for the student to calculate the volume of liquid inside a container may be observed. The students must photograph their object, upload the photography to GeoGebra, and model the three-dimensional object and the liquid it contains, being able to control the amount of liquid inside the container. Then they must calculate the volume of the liquid when the container is full. In this experience, the syllabus contents covered are the construction of interpolating polynomials and the calculation of areas, curve lengths, and volumes using integrals. To captivate the student, objects can be introduced into reality through GeoGebra's augmented reality.

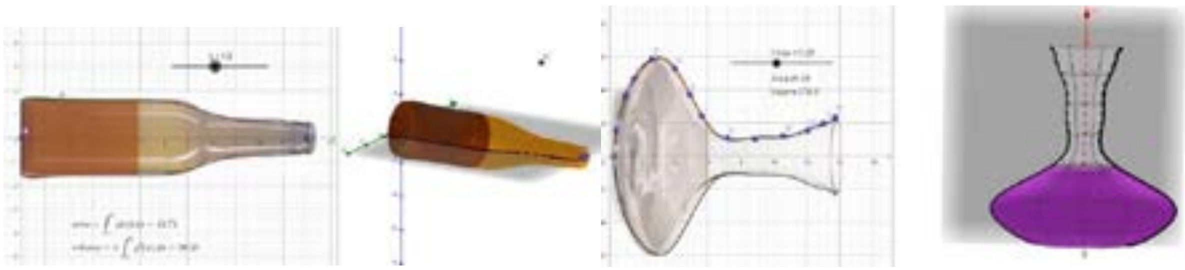

Fig. 3. Volume of liquid inside a container (bottle and decanter).

A second experience, also using GeoGebra, consisted of the story lived by each group of students entitled “An adventure on treasure island” (Fig. 4. left). Each group of pirates find the treasure island and intend to divide the area of this island between each other to search for the treasure. They must fortify the island with a net along its entire length to defend themselves from the other pirates that attack the island. To build this fortification it is necessary to take materials from the mainland into the island through a secret underwater tunnel. The entire story reflects the contents curriculum of Calculus I. Students, following the script, apply their knowledge and obtain solutions to the tasks proposed.

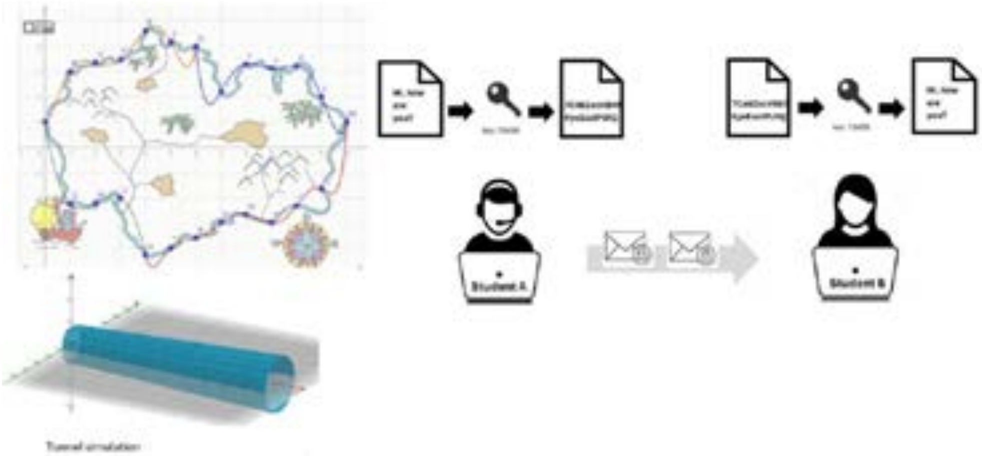

Fig. 4. An adventure on treasure island (left): island map and tunnel simulation; encode and decode messages (right)

Another experiment, using MATLAB, consists of encoding and decoding secret codes, using matrix calculation (Fig. 4 right). The students are led to become secret agents and to encode or decode messages between themselves and the teacher. In the end, after everyone discovers the messages, they play "secret group" and put a message in code for another group to decode and associate a group with that message. In this experience, the syllabus covered is specific to a theme.

2.3 Collaborative team and group experiences

Conjugating both CTE and CGE we proposed a challenge to our students that we believed would foster their holistic development, observe Fig. 5.

Fig. 5 Service Learning to a local NPO

Integrating Service Learning into curricular units has emerged as a powerful tool and this is particularly pertinent in the case of Statistical Methods, where the fusion of academic rigour with community engagement can yield profound benefits for both students and society. By its nature, the subject demands analytical thinking, problem-solving skills, and a deep understanding of data interpretation – all of which are invaluable in addressing real-world challenges. Through Service Learning, students not only acquire theoretical knowledge but also apply it in practical settings, thereby bridging the gap between classroom learning and real-life scenarios. Central to this approach is the formation of cohesive teams within the classroom. Through strategic division of tasks, students learn the importance of collaboration and effective communication. As they work together towards a common goal, they develop a deeper appreciation for the diverse skill sets each team member brings to the table. Moreover, the collaborative environment nurtures a sense of community and shared responsibility, essential qualities for success in both academic and professional paths. Students were challenged to serve a local Non-Profit-Organization (NPO) by building the necessary questionnaires, collecting, and analysing data, elaborating reports, and presenting them to the NPO's President. By engaging in projects that directly serve the needs of local organizations or underserved populations, students gain firsthand experience in using their mathematical knowledge for the benefit of others. Whether it's conducting surveys to assess community needs or analysing data to inform policy decisions, students witness the tangible effects of their work, instilling a sense of purpose and civic responsibility. The integration of service learning into any curriculum represents a symbiotic relationship—one where academic learning enriches community service, and vice versa. As students engage with real-world problems, they not only deepen their understanding of mathematical concepts but also become active agents of positive change. By nurturing a culture of students-teacher-society involvement, we not only enrich educational experiences but also cultivate a generation of empowered individuals committed to serving the greater good.

3 INTERVENTION AND OBSERVED PARAMETERS

The experiments were carried out either in classroom or outside and could be accessed or completed outside the classroom. Some of the experiments were carried out over 1 week (4 hours) and others over the semester. Classes were taught in mathematics laboratories, with computers, internet, and the necessary technologies. The teacher, as an observer, made the necessary notes on the students' participation, both individually and collectively. His role consisted of guiding students, when necessary, and observing the behaviour of the class, the functioning of the groups and the elements within the group. The activities involved in the CTE were saved on the collaborative platforms, while the activities involved CGE were saved in the reports and submitted in the Moodle or by e-mail. Assessment is done individually, and the exercises or reports were analysed by the teachers and feedback was given to each student. At the end of the experiments, satisfaction questionnaires were given to all students, to collect student feedback on the experiments they had just carried out.

4 RESULTS

4.1 Student performance

When analysing the grades obtained both in the assessment exercises and the scripts submitted, it was found that the quality was quite good, the number of positive grades was higher than in previous years, and most students acquired the mathematical skills that were intended. In the CTE, some students dropped out throughout the semester, as continuous study and constant participation on the part of the students were required. In CGE, this aspect was not visible, because in this case, the requirement was made for just one week.

4.2 Students' ability to use technology

Students currently have higher technological skills and digital proficiency. The major difficulties experienced in carrying out the experiments were: understanding the requested, having knowledge of the content involved, and the use of some mathematical software. Therefore, at first, some students felt lost and did not know what they should do. After the first contact and the ever-present help of the teacher, these difficulties disappeared, and the students felt capable and enthusiastic about their own knowledge and how they were able to apply it in solving the tasks asked.

4.3 Direct observation of teachers

At the beginning of each experience, the teacher supports all groups/teams and students, either guiding them because they sometimes feel lost, helping them because they cannot identify the content they should apply, or encouraging them because they show little willpower. But then, the classroom environment changes completely, students become autonomous in solving tasks, complement each other in groups, and know what they should do and what content to apply. They want to be the first to achieve success and to obtain the best classification.

4.4 Student opinion

To obtain the students' opinions about the experiments carried out, a questionnaire was given. Table 1 presents the Yes/No answers (in percentage) obtained in the questionnaire of one of the CGE. In the Fig. 6 the students' answers to another experience with CTE may be observed.

Table 1. Example of the answers obtained in the questionnaire from one of the CGE.

Questions	**“Yes”**	**“No”**
Was my contribution valuable to the group during the experience?	100%	0%
Am I confident in what I've learned about syllabus?	100%	0%
Did I enjoy carrying out this innovative experience?	100%	0%
Did I enjoy carrying out the experience on Padlet?	100%	0%
Can this experience contribute to the development of academic and professional skills?	94%	6%
Do I like innovative learning experiences in the classroom?	100%	0%
Do I consider that the teacher’s guidance was important in overcoming doubts when carrying out the experience?	100%	0%

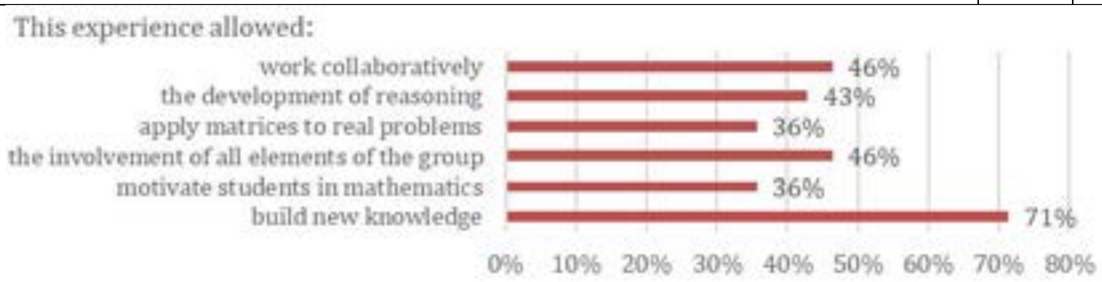

Fig. 6. Student answers in a CTE.

5 CONCLUSIONS

As Pereira and Silva (2018) state, teachers are increasingly encouraged to teach more attractive, dynamic, and contemporary classes. The diversity of experiences and strategies applied allow classes that motivate students in their learning, and thus promote student success. In this sense, it is necessary that the teacher developed experiences, with previously defined objectives and strategies that allow students to build their knowledge, based on real situations experienced by the group. Teachers who use groups and teams in the classroom should continue to use these qualitative research methods to explore the impact of the syllabus on student perceptions, as well as obtain student feedback on the group/team experience. This way, teachers better understand students' needs and can incorporate this information into developing new collaborative experiences. Furthermore, should be incorporated, group and team experiences into teaching (Barr et al. 2005, Astin and Astin 2000) because it plays an important role in developing the leadership skills needed and desired by employers and today's society. The experiences shared here are quite diverse, in relation to the courses, curricular units, syllabus, and teachers. They were very enriching for teachers as educational professionals because they allowed a reflection on the difficulties experienced by students in learning mathematics and encouraged the teachers to question themselves about the experiences they should provide to students, to support them in their learning. The results show that the experiences involved students in the construction of their learning, making it possible to solve problems and communicate the respective resolution both in groups and as a team. They also suggest a successful use of these experiences in the construction of mathematical knowledge, being a strategy to consider improving students' motivation for mathematics and enabling the development of the expected skills, which can contribute to improving the success on the curricular units.

Conference Key Areas: *Teaching foundational disciplines of Mathematics and Physics in engineering education*
Keywords: *Vector calculus, instructional design, 10-minute video, constructivism, cognitive load theory*

ABSTRACT

This rapid literature review explores the design and use of instructional videos for teaching vector calculus in engineering education. Drawing on constructivism, cognitive load theory, and multimedia learning theory, the review identifies key design principles and effective strategies for developing 10-minute videos tailored to the needs of engineering students. The review highlights the importance of clear explanations, visual aids, and interactive elements in enhancing student learning and engagement. The findings suggest that well-designed instructional videos hold the potential to improve student understanding and performance in vector calculus. The implications of this research are significant for educators and instructional designers seeking to enhance student learning outcomes in engineering education.

1 INTRODUCTION

1.1 Vector Calculus

Vector calculus plays a pivotal role in engineering education, serving as a foundational element to further studies in various engineering disciplines. However,

P Padayachee
Pragashni.padayachee@uct.ac.za

mastering vector calculus concepts can be challenging for students, often leading to a diminished understanding of fundamental principles, high failure rates, and even dropout. To address these challenges, educators have explored various instructional interventions, including the use of short videos, to enhance student comprehension of complex concepts in vector calculus. This project aims to develop more effective 10-minute instructional videos to cover key concepts, address misconceptions, and provide hints for mastering the course material.

Reporting on the first phase, this paper draws on theories like constructivism and cognitive load theory and a rapid review of literature from the past 10 years to present a framework to guide the design and use of videos to enhance student learning outcomes and engagement in vector calculus.

1.2 Educational Theories

Constructivism, cognitive load theory, and multimedia learning theory are not only foundational to this research but also directly applicable to the design and implementation of instructional videos for vector calculus instruction in engineering education. Constructivism's emphasis on active learning (Christie and de Graaff 2015) aligns with the goal of creating videos that engage students and encourage them to construct their understanding of vector calculus concepts. By presenting information in a way that prompts students to actively think and problem-solve, videos can facilitate deeper learning and comprehension.

Cognitive load theory (Sweller 1988; Sweller 2020) provides valuable ideas on how teaching design can be optimized to reduce cognitive load and improve learning. By designing videos to reduce the extraneous cognitive load, such as by presenting information clearly and avoiding unnecessary complexity, students can more effectively process and retain material.

Multimedia learning theory (Mayer, 1997) emphasises using multiple channels, such as auditory and visual. By incorporating animations, diagrams, and other visual aids, videos can cater to different learning styles and enhance students' understanding of abstract concepts in vector calculus. For instructional videos, Mayer et al. (2020) advise drawing graphics on the board while lecturing, shifting eye gaze between the audience and the board while lecturing, prompting to engage in summarizing or explaining the material, filming from a first-person perspective, and adding subtitles to a narrated video that contains speech in the learner's second language. They warn that people do not learn better from a multimedia lesson when interesting but extraneous video is added.

2 METHODOLOGY

2.1 Introduction

This paper reports on the first of three phases in a research project.

- Phase 1: Rapid literature review to provide an overview of existing literature on the design and use of 10-minute videos for vector calculus instruction.
- Phase 2: Develop pilot videos to cover various concepts in vector calculus, using the best practices extracted from the literature review.

- Phase 3: Iteratively develop videos based on analysis of student feedback and student performance in vector calculus following video use.

A rapid rather than systematic literature review was chosen as our aim was to develop a narrative summary of studies on instructional videos relevant to learning vector calculus. As a team of two researchers with assistance from a librarian, we felt our aims would be reached with a rapid review limited of peer-reviewed studies published from 2020. Our review followed the steps for conducting rapid reviews of educational research by Cirkony et al. (2022).

2.2 Research Question

The research question addressed in the rapid literature review is:

> *How can insights gained from literature since 2020 inform the design and use of concise 10-minute videos to improve engineering students' understanding and performance in vector calculus?*

2.3 Data Collection and Analysis

Prior to undertaking the review, the following protocol was drafted.

1. Inclusion Criteria: Peer-reviewed articles, conference papers, theses and reports published since 2020, relevant to instructional videos for vector calculus in engineering education. Results were not limited by language.
2. Exclusion Criteria: Non-peer-reviewed sources (to prioritise high-quality studies), articles not related to instructional videos suitable for vector calculus, and studies published before 2020.
3. Search Strategy: Use education-related databases: EbscoHost (40 databases), Engineering Village (2 databases), Scopus and Web of Science. Use the search string verified by a librarian: (“instructional videos” OR “video production” OR “making videos” OR “made videos”) AND (“mathematical sciences” OR “mathematics” OR “math”) AND undergrad* AND (“higher education” OR university OR college).
4. Screening Process: Screen titles and abstracts independently with ‘blind on’ on the app Rayyan (Ouzzani et al. 2016) to identify articles as included maybe and excluded. Both authors negotiate to reach consensus on included and excluded studies based on abstracts and titles, and full texts if necessary.
5. Data Extraction: Both authors tabulate key findings from each individual text to identify students’ preferences, and advice on video design and production.
6. Analysis: Led by the first author and verified by the second author. Summarise themes from all studies into a framework for video design and use based on the synthesized literature.

Bias was limited by using independent, blind reviewing by both authors of all results before meeting to reach consensus reaching on conflicts to decide on included results.

2.4 Further probing

Following reviewer suggestions, we were curious to see if more novel findings emerged if we changed the search. We broadened the search terms from a focus on mathematics to include STEM disciplines as they are likely to be similar needs in terms of reliance on definitions, examples with calculations, and they are often based on hierarchical knowledge systems. Addressing the fact that video production methods have advanced due to the rapid change in technology over the past decade, we narrowed the time span to focus on the years from 2020 to 2024. Guided by these two adjustments, we embarked on an additional search to augment the findings of our initial search.

3 RESULTS

3.1 Overview of Literature

The rapid literature review revealed several key findings regarding the design and use of videos for vector calculus instruction. Studies consistently reported that well-designed videos can improve student understanding and performance in vector calculus. Effective videos were found to incorporate clear explanations, visual aids, and interactive elements. Additionally, the review identified a need for videos to address common misconceptions and provide practice exercises to enhance student learning. Overall, the findings of the literature review support the use of tutorial videos as a valuable instructional tool in engineering education.

The additional search revealed more results than anticipated. We continued our focus of looking for guidelines to produce effective videos. However, instead we found many studies about the impact of using videos for learning in STEM and extracted video production advice based on positive experiences and perceptions of different uses of videos.

3.2 Emerging Themes

To create an effective mapping between the theoretical frameworks (constructivism, cognitive load theory, and multimedia learning theory) and the design suggestions from Seethaler et al. (2020) and other authors, we align each design suggestion with the principles of the respective theories.

Seethaler et al.'s three-part framework considers (1) context and sequencing, (2) cognitive supports, and (3) affective considerations, and serves as the primary design source due to its comprehensive and well-established nature. However, to enhance and expand upon this framework, additional categories and suggestions from other authors are incorporated. These additions are justified by their relevance and ability to provide a more nuanced understanding of effective instructional video design for vector calculus. By integrating these supplementary categories, the review aims to offer a more thorough set of guidelines for designing instructional videos, enriching Seethaler's framework with insights from a broader range of scholarly work.

CONTENT AND SEQUENCING

***Concepts*:**

- *Constructivism*: Seethaler et al. (2020) aligns with the idea that learning is an active process where learners construct their understanding. Clarifying concepts and linking them to prior knowledge supports this process. De Lima and da Cunha (2023) suggested that student-produced videos promote collaborative education. Fotiyeva and Shockley (2015) uses videos to address problems and concepts that typically cannot be resolved independently by students. Weinberg et al. (2022) asserts that pre-knowledge was needed for student engagement in video tasks.

- *Cognitive Load Theory*: Seethaler et al. (2020) ensures that concepts are presented in a way that minimizes cognitive load, allowing learners to process information more effectively.
- *Multimedia Learning Theory*: Seethaler et al. (2020) supports the use of visuals and animations to enhance understanding of abstract concepts. Barry et al. (2019) found that short videos (5-7 min) were preferred by students, while Rodemer et al. (2021, 2022) highlighted the importance of aligning audio with video to aid understanding. Johnston (2017) emphasized the convenience and flexibility of video learning.

Logic:

- *Constructivism*: Seethaler et al. (2020) emphasizes the importance of logical progression in learning where each concept builds on previous ones, while Johnston (2017) mentioned the mix of learning modes which caters for diverse learning styles and provides varied opportunities for learners to construct their understanding.
- *Cognitive Load Theory*: Seethaler et al. (2020) suggest logical sequencing reduces extraneous cognitive load, making it easier for learners to follow and understand the content. Rodemer et al. (2021, 2022) emphasised the use of signalling to guide learners through the content logically.
- *Multimedia Learning Theory:* Barry et al. (2019) found that short videos save time.

Story:

- *Constructivism*: Seethaler et al. (2020) supports the use of narratives or stories to engage learners and provide context for learning, making the content more meaningful while Barry et al. (2019) found that watching videos at one's own pace was beneficial. De Lima and da Cunha (2023) suggested creating "learning scenarios" to encourage questioning and communication.
- *Multimedia learning theory*: Seethaler et al. (2020) says that the relevance and motivation is enhanced by presenting content in a narrative format.

L*anguage*:

- *Constructivism*: Seethaler et al. (2020) encourages the use of language that is accessible and meaningful to learners, aligning with the idea of building on prior knowledge.
- *Cognitive Load Theory*: Seethaler et al. (2020) emphasises the importance of clear and concise language to reduce cognitive load. Rodemer et al. (2021, 2022) confirm the importance of clear, concise language.
- *Multimedia Learning Theory*: Johnston (2017) mentioned that videos offer better quality than lecture capture. Chand and Deshmukh (2019) say there is

a shortage of local language videos suggesting students make translation videos as part of community service.

COGNITIVE SUPPORTS

***Visualisations*:**

- *Constructivism:* Barry et al. (2019) found that 45% of students prefer watching videos while learning maths, while Lui and Elms (2019) highlighted the use of animations and illustrations for better understanding.
- *Cognitive Load Theory*: Seethaler et al. (2020) says that well-designed visuals can reduce cognitive load by providing additional support for understanding.
- *Multimedia Learning Theory*: Seethaler et al. (2020) advocates for the use of visuals to complement verbal information, as they can enhance learning and aid in understanding complex concepts. Abbasian and Sieben (2016) advise that a PC with pen-tablet and Camtasia video editor produce better quality videos than a tablet and Doceri software. However, they add that an instructor's time may be better spent making a viewing list of high-quality existing videos.

***Signals*:**

- *Constructivism*: Rodemer et al. (2021, 2022) emphasised the use of highlighting and other visual cues to aid understanding.
- *Multimedia Learning Theory*: Seethaler et al. (2020) supports the use of cues and signals to guide learners' attention and help them navigate the content. Rodemer et al. (2021, 2022) emphasized the use of signalling to guide learners through the content logically.
- *Cognitive Load Theory*: Seethaler et al. (2020) say effective use of signals can reduce extraneous cognitive load by directing learners' focus to relevant information.

***Synchronization*:**

- *Constructivism*: Chand and Deshmukh (2019) list the most common reasons for low-quality videos: inappropriateness for the target audience, problems in comprehensibility, inadequate use of visuals and technical glitches.
- *Multimedia Learning Theory*: Seethaler et al. (2020) emphasises the importance of synchronizing visuals and narration to enhance learning and reduce cognitive load. Johnston (2017) mentioned the synchronization of learning modes, and Barry et al. (2019) highlighted the convenience of watching videos at any time and place.

***Segmentation*:**

- *Cognitive Load Theory, Constructivism*: Seethaler et al. (2020) supports the idea of breaking down complex information into smaller segments to reduce cognitive load and aid in understanding.
- *Multimedia Learning Theory, Constructivism*: Barry et al. (2019) found that short videos are preferred, while Rodemer et al. (2021, 2022) suggested segmenting content to aid in information processing. Henley (2015) maintains

the use of visual aids and examples in videos made it easier to grasp concepts, adding that If videos are too long, students lose focus and get bored. Henley's (2015) advice includes: keep the time to watch video comparable to the time to read the same content; minimize extraneous words and images, highlight key pieces of information, have text captioning as closed captioning so that it can be turned off, have words and images presented at the same time and near each other on the screen, have the videos broken up into smaller pieces, summarize what will be covered in the video, have the text presented in a conversational style, and have the audio done in a human voice.

***Streamlining*:**

- *Cognitive Load Theory*: Seethaler et al. (2020) advocates for presenting information in a streamlined manner to avoid overloading learners with unnecessary distractions or conflicting information.

AFFECTIVE CONSIDERATIONS

***Relevance*:**

- *Constructivism*: Seethaler et al. (2020) Emphasises the importance of relevance and meaningfulness in learning. Making the content relevant to learners' experiences and interests can enhance engagement and learning outcomes.
- *Multimedia Learning Theory*: Johnston (2017) mentioned that videos offer a mix of learning modes, and de Lima and da Cunha (2023) suggest creating "learning scenarios" to enhance relevance. Chand and Deshmukh (2019) say that the most common reasons for low-quality videos are: inappropriateness for the target audience, problems in comprehensibility, inadequate use of visuals and technical glitches.

***Rapport*:**

- *Constructivism*: Seethaler et al. (2020) support the idea of creating a supportive and respectful learning environment. Depicting characters or interactions that model respectful and helpful behaviour can enhance the learning experience.

  Multimedia Learning Theory, Constructivism: De Lima and da Cunha (2023) suggested creating "learning scenarios" to empower students, while Barry et al. (2019) highlighted the convenience of watching videos at any time and place. Weinberg et al. (2022) reported that videos were designed to take the place of class discussions where actors portrayed calculus students attempting to solve problems and demonstrated various ways of thinking- this was scripted.

***Accessibility*:**

- *Multimedia Learning Theory*: Seethaler et al. (2020) advocates for designing materials that are accessible to all learners, including those with disabilities. Following universal design principles ensures that the content is accessible to a wide range of learners.

- *Multimedia Learning Theory, Constructivism*: Barry et al. (2019) emphasized the convenience and flexibility of video learning, while Lui and Elms (2019) highlighted the use of animations and illustrations for better understanding. Chen and Ho (2021) say that for low cognitive load videos, students used captions more than if the load was high. Captions were used less for videos with high cognitive load. Chen and Ho (2021) add that when content is more difficult, use graphics rather than captions.

By mapping each design suggestion to the relevant theoretical framework, we can demonstrate how the instructional design principles align with established theories of learning, enhancing the credibility and effectiveness of our framework.

These themes collectively illustrate the importance of designing video learning materials that are engaging, accessible, and cognitively supportive to optimise learning outcomes for diverse learners. These themes were extracted from the thematic analysis of the literature on design and implementation of video-based learning materials:

1) **Design Features:** Highlight the importance of video quality, synchronisation of visuals and narration, and segmentation of content to aid in information processing and reduce cognitive load.
    a) ***Video Quality*:** Ensure that videos are clear, well-produced, and visually engaging to maintain student attention and facilitate understanding of complex vector calculus concepts.
    b) ***Synchronization of Visuals and Narration*:** Align visual representations of vector operations, diagrams, and graphs with verbal explanations to enhance comprehension and reinforce learning.
    c) ***Segmentation of Content*:** Break down vector calculus topics into smaller, manageable segments, allowing students to digest information more easily and reducing cognitive load.
2) **Affective Considerations:** Stress the relevance and meaningfulness of content to enhance engagement and learning outcomes. Emphasise the importance of creating a supportive and respectful learning environment.
    a) **Relevance and Meaningfulness:** Demonstrate the practical applications of vector calculus in engineering, physics, and other fields to illustrate the real-world significance of the concepts being taught.
    b) **Supportive Learning Environment:** Foster a positive and encouraging atmosphere in which students feel comfortable asking questions, making mistakes, and actively participating in their learning process.
3) ***Student Involvement*:** Involving students in the creation of videos, such as through student-produced videos or translation projects, can promote collaborative education and enhance learning experiences.
    a) ***Creation of Videos*:** Encourage students to create their own instructional videos explaining vector calculus concepts. This promotes deeper understanding through the process of teaching others and allows for a variety of perspectives and approaches to be shared.
4) **Accessibility:** Focus on designing materials that are accessible to all learners, including those with disabilities, and following universal design principles to ensure inclusivity.

a) ***Universal Design*:** Design videos with accessibility features such as closed captioning, transcripts, and audio descriptions to ensure that all students, including those with disabilities, can access and benefit from the instructional content.

By incorporating these principles into your teaching of vector calculus, you can create a more engaging, inclusive, and effective learning experience for your students.

4 RESULTS OF THE FURTHER PROBING

Our extended search revealed several novel ideas that can significantly enhance the effectiveness of instructional videos for teaching Vector Calculus. One key insight is the active involvement of students in the video-making process. Research shows that when students create their own videos, their motivation and participation increase, leading to a deeper understanding of the subject matter (Vasilehenko, 2020). This active engagement allows students to take ownership of their learning, making the process more meaningful and reinforcing their comprehension through teaching others. Additionally, multilevel collaboration between undergraduate and postgraduate students during video production fosters diverse insights, which helps clarify concepts and ensure the reliability of the content (Peres & Hoffman, 2020; Box et al., 2024). Such collaborations not only enhance the quality of the educational material but also provide mentorship opportunities, enriching the learning experience for both groups.

Other research highlights the benefits of videos created by former students, which help embrace a sense of lost community and provide a fresh perspective that resonates with new students (Kong et al., 2022). This approach not only fosters a sense of belonging but also offers relatable content that enhances the learning experience. Videos made by peers or recent graduates can bridge the gap between instructors and students, making complex topics more accessible and understandable.

Moreover, incorporating these videos into collaborative platforms facilitates discussion, creates a feedback loop, and promotes collaborative learning with peers (Mutch-Jones et al., 2021; Adhami & Taghizadeh, 2024). Collaborative platforms such as discussion boards or group chats integrated with video content enable students to engage in meaningful dialogue, ask questions, and receive timely feedback, thereby deepening their understanding. Embedding interactive questions within the videos keeps students actively engaged and allows them to assess their comprehension in real-time (Petillion & McNeil, 2020). Tailoring the content to the learner's level and addressing specific needs further enhances engagement and understanding (Barnes et al., 2023; Larson et al., 2021; Rai et al., 2020; Yi et al., 2024).

Reflective activities, such as questions and prompts throughout the video, encourage students to think deeply about the concepts taught (Lasheen et al., 2024). These activities promote metacognitive skills, helping students to become more aware of their own learning processes and to develop critical thinking skills. Using real-world scenarios to show how vector calculus is applied in various fields can make the material more relatable and engaging. This contextualization not only enhances interest but also demonstrates the practical value of the subject matter, thereby motivating students to learn.

Finally, including mechanisms for feedback and evaluation within the videos ensures continuous improvement and relevance of the instructional content. Regular feedback from students allows instructors to refine their videos, address any misconceptions, and ensure that the content remains up-to-date and effective (Clark & Mayer, 2016). This iterative process of evaluation and improvement helps maintain high-quality educational resources that meet the evolving needs of students.

By incorporating these strategies, instructional videos for vector calculus can become powerful tools that not only convey information but also engage students, foster collaboration, and enhance learning outcomes.

5 SUMMARY

The review findings, guided by constructivism, cognitive load theory, and multimedia learning theory, offer insights into designing effective videos for teaching vector calculus. Educators can use these principles to create engaging videos that improve student learning outcomes in engineering education. It sets the stage for developing pilot videos in the next research phase.

Keywords: Engineering education, Professional competencies, Practical design project, Skill development, Student perceptions

ABSTRACT

This study examines the development and utilization of professional and engineering skills among first-year Electrical and Electronic Engineering students during a practical design project. Spanning five weeks, students engage in project work and reflect on their skill utilization through weekly surveys. Key skills include Science and Mathematics (SM), Engineering Analysis (EA), Design and Innovation (DI), Widening Engineering Context (WEC), and Professional Competencies (PC). Results reveal distinct trends in skill utilization, with some skills peaking at certain stages while others demonstrate consistent usage. Towards the project's conclusion, there is a shift towards greater utilization of professional competencies, underscoring their significance. Box plots offer insights into variations in student responses within each skill category. The findings highlight the importance of integrating professional skills development within engineering curricula, offering insights for curriculum development efforts. This study contributes to the discourse on engineering education reform, emphasizing the need for a holistic approach to skill development to meet the demands of the engineering landscape.

1 INTRODUCTION

The preparedness of engineering graduates for the job market is a crucial concern, underscored by numerous organizations and researchers who emphasize the necessity of a well-rounded skill set that extends beyond technical proficiency. In today's dynamic industrial environment, these interpersonal and professional skills are indispensable for engineers operating within a global and interdisciplinary context.

1.1 Background

The readiness of engineering graduates for the workforce has been a subject of ongoing debate, with various organizations and researchers highlighting the need for a comprehensive set of skills beyond technical knowledge (Deters et al., 2018, 2024; Munir, 2022, 2019; Al-Sharif et al., 2019). Employers increasingly seek graduates who possess not only strong technical acumen but also effective communication, teamwork, problem-solving, and leadership skills (Moir, 2018; Bennet, 2017). These "soft" or professional skills are essential for engineers working in today's global, interdisciplinary, and rapidly evolving industrial landscape (Deters et al., 2018, 2024; Munir, 2022, 2019).

Despite the growing recognition of the importance of professional skills, integrating them into engineering curricula remains a challenge. There is often resistance from faculty and students, with concerns that emphasizing soft skills may come at the expense of technical proficiency (Deters et al., 2018, 2024; Munir, 2022, 2019). However, research suggests that the integration of professional skills within engineering education can enhance graduates' employability and career success (Al-Sharif et al., 2019; Bennet, 2017).

In response to these challenges, many engineering departments have begun to explore innovative approaches to incorporate professional skills development into their programs. One such approach involves integrating soft skills training within design projects and modules, which are core components of engineering curricula (Al-Sharif et al., 2019; Bennet, 2017). By embedding professional skill development within authentic engineering tasks, students can contextualize and apply these skills in real-world scenarios, thereby enhancing their effectiveness and transferability (Al-Sharif et al., 2019; Bennet, 2017).

The Department of Electrical and Electronic Engineering at our institution undertook a comprehensive curriculum review in 2019 to address these issues. As part of this review, a decision was made to explicitly incorporate professional skills development into end-of-year design projects for first and second-year students. The rationale behind this decision was twofold: to underscore the importance of professional skills in engineering practice and to provide students with tangible examples to enhance their professional portfolios.

We are conducting a longitudinal study which aims to investigate student perceptions of their engineering and professional skills development as they progress through summer term design projects in their first and second years of the degree. By examining students' attitudes, experiences, and self-perceptions, this study seeks to gain insights into the effectiveness of integrating professional skills development within engineering education. The findings from this study can inform future curriculum development efforts and contribute to the ongoing discourse on engineering education reform.

This paper presents findings from the first-year design project conducted in May and June of 2023. Data from the second-year project will be collected in the upcoming summer term and will be included in a subsequent paper, which will feature detailed qualitative and quantitative analysis. For now, this paper focuses solely on data from the first-year project.

1.2 Comparative Analysis with Similar Educational Initiatives

To underscore the unique contributions of our practical design project, we conducted a comparative analysis with similar educational initiatives at different universities and in varying countries. This comparative approach enriches our understanding of the project's relative effectiveness and distinctiveness within the educational landscape.

For instance, a study by Smith et al. (2021) explored a similar project-based learning approach in mechanical engineering programs across several European universities. They found that while projects varied in scope and emphasis, the integration of professional skills alongside technical competencies consistently enhanced student employability and readiness for industry. Our study builds upon this foundation by focusing specifically on Electrical and Electronic Engineering, thereby providing a nuanced perspective on skill development within this discipline.

Furthermore, contrasting our findings with those of programs in Asia, such as the study by Li and Wang (2020) on innovative design projects in Chinese engineering education, reveals cultural and contextual differences in skill acquisition and project outcomes. Despite these variations, the overarching importance of integrating professional skills development remains a common thread across diverse educational contexts.

This comparative analysis not only validates the efficacy of our approach but also highlights its adaptability and potential for broader application within global engineering education frameworks.

1.3 Engineering and Professional Skills

The definitions of engineering and professional skills utilized in this study are aligned with the criteria outlined for the accreditation of degree programs by professional bodies. While the specific competencies may vary across different engineering disciplines, there exists a common understanding regarding desired graduate outcomes and student experiences.

In the United Kingdom, the criteria that graduates must satisfy to attain registration with the relevant professional institution are delineated within the UK Standard for Professional Engineering Competence and Commitment (UK-SPEC) (Engineering Council UK, 2023). These criteria are subsequently integrated into the Accreditation of Higher Education Programs (AHEP), which provides the framework, policies, regulations, and procedures for program accreditation. This study, therefore, adheres to AHEP 3, which serves as the current benchmark for accrediting degree programs. The five key areas specified in AHEP 3 (Engineering Council UK, 2020) are outlined in Table 1 below:

Table 1: AHEP3 areas of competence

No.	Competence Area
1	Science and mathematics

2	Engineering analysis
3	Design and innovation
4	The Engineer and society
5	Engineering practice

These domains of competence and commitment serve as the foundation for the ranking and reflection undertaken by students in this paper.

1.4 First-Year Project

At the conclusion of their first year, students embark on a group project wherein they design, construct, and test a practical application over the final six weeks of the summer term. In the academic year 2022-23, the first-year project took place from May 12th to June 20th, 2023.

The challenge presented to the first-year cohort was to create a self-driving rover capable of identifying different types of aliens based on their different electrical signals along a predefined course in the shortest possible time. Students were divided into groups of six and provided with a starter kit, as well as guidance and support from faculty members.

Each rover was equipped with a remote control interface accessible via a mobile phone app or laptop interface. Additionally, to detect various electrical signals emitted from sample rocks, each rover was outfitted with three distinct sensors:

- Radio sensor
- Infrared (IR) sensor
- Magnetic sensor

These sensors enabled the rovers to identify the types of aliens based on the detected signals. Throughout the project duration, students collaborated to design and implement the functionality of their rovers, integrating sensor data processing, control algorithms, and navigation strategies to accomplish the specified task. In addition, students received support through lectures and workshops covering the topics shown in Table 2.

Table 2: Supporting Activities for First-Year Design Project

Week	Date	Workshops and Lectures
1	May 19	- Problem-solving cycle - Design process - Introduction to ethics in engineering
2	May 26	- Teamwork - Project management - Introduction to academic writing - Product Design specifications

3	June 2	- Documentation and technical communication
4	June 9	- Formative feedback for report draft
5	June 16	- Report submission and project demo

In the final stage, students engaged in a competitive demonstration against each other. Figure 1 illustrates a snapshot from the demo, depicting two rovers alongside an alien.

2 METHODOLOGY

In this section, we outline the research design and methodology employed in our study to investigate the development of professional and engineering skills among first-year Electrical and Electronic Engineering students.

2.1 Study Design

This study adopts a longitudinal approach to explore students' perceptions regarding the utilization of their engineering and professional skills throughout the first-year design project. Weekly data collection via a questionnaire was implemented to gauge students' self-reported engagement with key skills. Notably, the same cohort will participate in a similar reflection

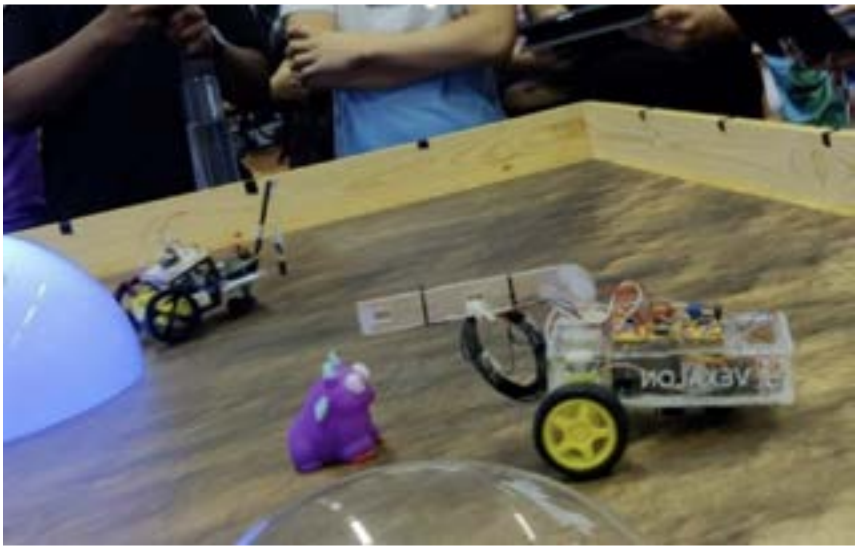

Figure 1: First year project demonstrations

exercise during their second-year project, thereby concluding the two-year longitudinal investigation. However, this paper focuses solely on presenting results from the first year.

Our longitudinal study aims to delve into students' evolving perceptions of their engineering and professional skills development across the first and second years of their degree program. By scrutinizing students' attitudes, experiences, and self-assessments, we aim to glean insights into the efficacy of integrating professional skills development within engineering education. The outcomes of this study have the potential to shape future curriculum enhancements and contribute to ongoing discussions on reforming engineering education.

2.2 Participants

Participants in this study were first-year students enrolled in the electrical and electronic engineering program during the academic year 2022-23. The cohort consisted of 180 students who were actively engaged in the design project.

2.3 Data Collection

Data were collected weekly through a questionnaire administered to participants. The questionnaire prompted students to reflect on the extent to which they utilized five key skills: Science and Mathematics (SM), Engineering Analysis (EA), Design and Innovation (DI), Widening Engineering Context (WEC), and Professional Competencies (PC). Students rated their utilization of each skill on a scale from ”Not at all (0%)” to ”Every day (100%)”. Additionally, qualitative comments were collected to capture students’ reflections on their experiences and expectations. The key skills and the rating scale are shown in Table 3. Additionally, qualitative comments were collected to capture students’ reflections on their experiences and expectations.

2.4 Data Analysis

Quantitative data from the weekly questionnaires were analyzed to assess trends in students’ perceived skill utilization over time. Descriptive statistics were used to summarize the frequency and distribution of skill utilization ratings. Qualitative comments were analyzed thematically to identify recurring themes and patterns in students’ reflections.

Table 3: Key Skills and Rating Scale

Skill	Rating Scale
Science and Mathematics (SM)	Not at all (0%), Somewhat (25%), Some of the time (50%), Most days (75%), Every day (100%)
Engineering Analysis (EA)	Not at all (0%), Somewhat (25%), Some of the time (50%), Most days (75%), Every day (100%)
Design and Innovation (DI)	Not at all (0%), Somewhat (25%), Some of the time (50%), Most days (75%), Every day (100%)
Widening Engineering Context (WEC)	Not at all (0%), Somewhat (25%), Some of the time (50%), Most days (75%), Every day (100%)
Professional Competencies (PC)	Not at all (0%), Somewhat (25%), Some of the time (50%), Most days (75%), Every day (100%)

2.5 Ethical Considerations

Ethical considerations were carefully addressed throughout the research process. Informed consent was obtained from all participants, and they were assured of the confidentiality and anonymity of their responses. Participation in the study was voluntary, and students were free to withdraw at any time without consequence. Data were securely stored and used solely for research purposes, adhering to principles of ethical conduct in research.

3 RASULTS AND ANALYSIS

The results can be broadly categorized into quantitative findings, derived from the numerical data collected through the weekly surveys, and qualitative insights obtained from the comments submitted by the students.

3.1 Quantitative Analysis

The number of first-year student who responded each week is given in the Table 4.

Table 4: Number of First-Year Student Responses

Date	Number of Responses
19 May (Week 1)	129
26 May (Week 2)	111
2 June (Week 3)	143
9 June (Week 4)	117
16 June (Week 5)	126

The survey results are depicted in Figure 2, providing a summary of the findings. Given the substantial participation of over a hundred students each week, the figure presents the averages of student responses across the five categories to elucidate general trends. Notably, discernible patterns emerge from the data.

There is a consistent upward trajectory in the utilization of skills such as Widening Engineering Context (WEC) and Professional Competencies (PC) as the project progresses over the fiveweek period. Interestingly, PC consistently surpasses WEC in terms of usage throughout the duration of the project. Conversely, the usage of Science and Mathematics (SM) shows a declining trend, which aligns with its higher significance at the project's inception.

Furthermore, the utilization of Engineering Analysis (EA) reaches its peak midway through the project before gradually declining below professional competencies towards the project's culmination. In fact, towards the project's conclusion, professional competencies emerge as the most frequently employed skill.

Additionally, Design and Innovation (DI) initially see a steady increase in usage but experience a decline towards the final deliverables, as students shift their focus towards the report and presentation of the completed project. These findings align precisely with the anticipated outcomes envisioned during the project's design phase.

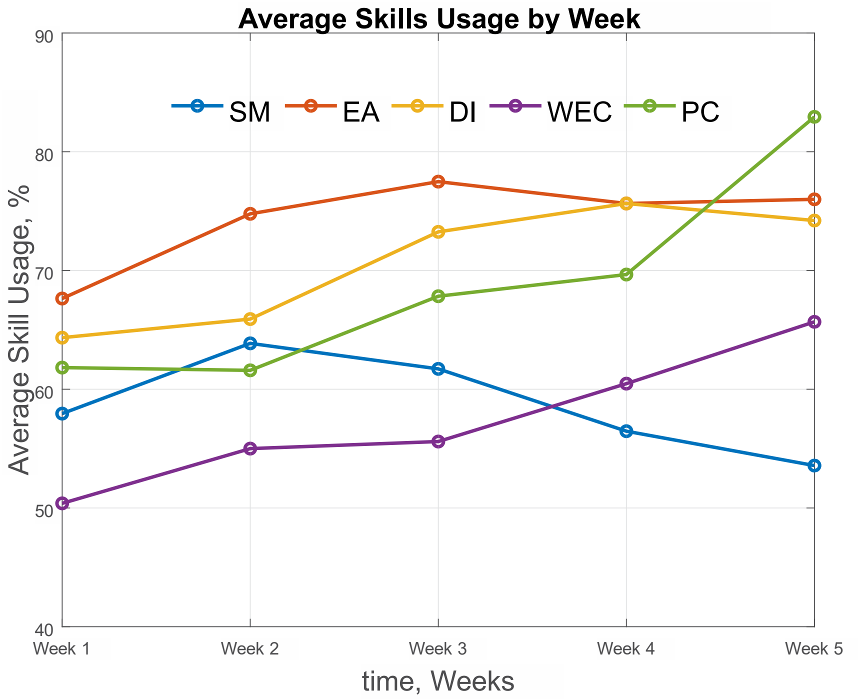

Figure 2: Utilization Trends of Key Skills Throughout the First-Year Design Project

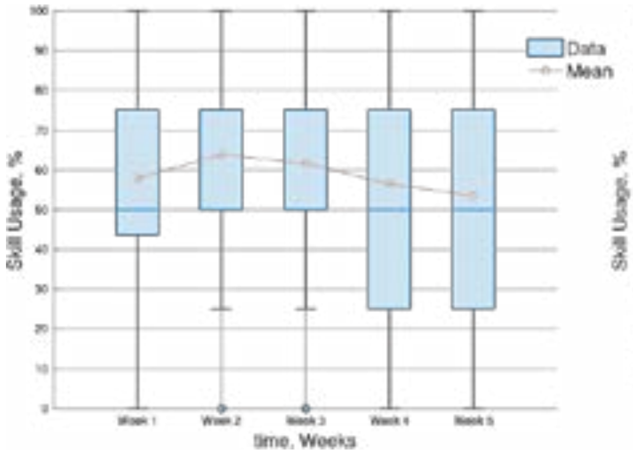
To provide a comprehensive view of the responses, box plots have been incorporated in Figures 3 to Figure 6 to illustrate student selections in four out of five categories. Box plots, also known as box-and-whisker plots, visually summarize the distribution of a dataset by displaying key statistical measures such as the median, quartiles, and outliers. They offer insights into the spread and central tendency of the data, allowing for a deeper understanding of the variability in student selections within each category. These plots complement the average values presented in the previous figures, offering a more detailed examination of the data distribution.

From Figure 3, it is apparent that not only does the student perception of the usage of Science and Mathematics (SM) decrease over the weeks, but there is also a noticeable increase in the disparity between students who perceive a greater need for SM towards the end of the project compared to the beginning. This is reflected in the larger interquartile range towards the end of the project, indicating a wider spread of responses. In contrast, at the start of the project, a smaller interquartile range suggests that most students chose similar responses.

Similarly, Figure 4 highlights that Engineering Analysis (EA) peaked in utilization during the middle of the project. Additionally, a smaller interquartile range indicates a consensus among students regarding the usage of EA during this period.

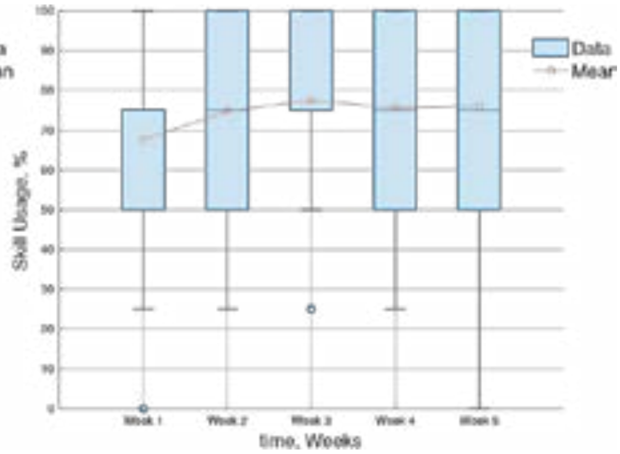
Similar observations can be made regarding the trends of Widening Engineering Context (WEC) and Professional Competencies (PC) from Figures 5 and 6, respectively. In both cases, the box plots depict trends over the course of the project, providing insights into the variations and consensus among student responses.

For WEC (Figure 5), there appears to be a gradual increase in utilization throughout the project, with a larger disparity between student perceptions as compared to other categories.



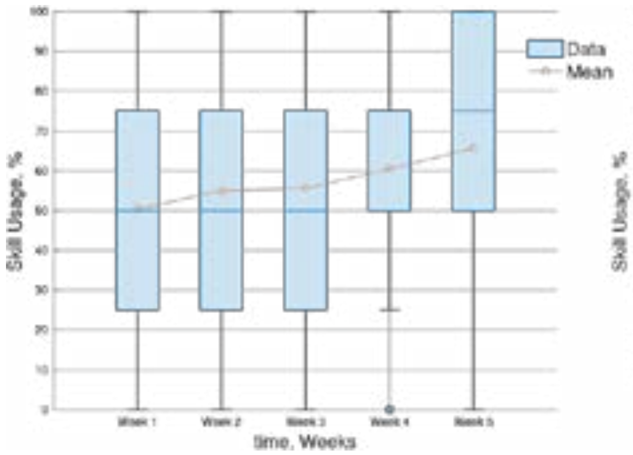
Science and Mathematics Usage by Week

Figure 3: Box Plots Illustrating SM



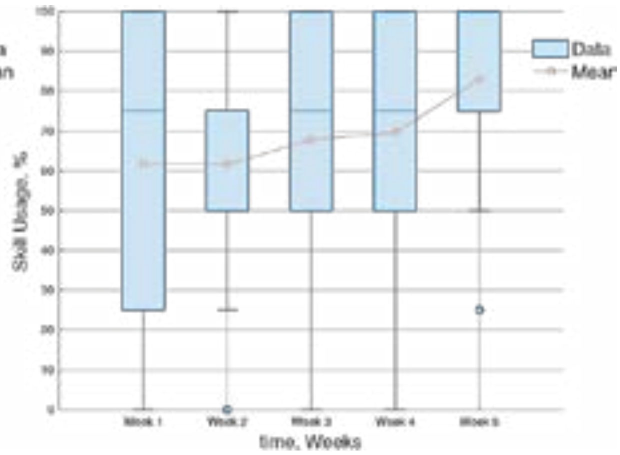
Engineering Analysis Usage by Week

Figure 4: Box Plots Illustrating EA



Wider Engineering Context Usage by Week

Figure 5: Box Plots Illustrating WEC



Professional Competences Usage by Week

Figure 6: Box Plots Illustrating PC

This is evidenced by the widening interquartile range, indicating a broader range of responses among students as the project progresses. This is however not true for Week 4.

Similarly, for PC (Figure 6), there is an increase in utilization of professional competencies throughout the project, with a smaller interquartile range at the end suggesting a consensus among students regarding their usage.

These trends, depicted by the box plots, provide valuable insights into the evolving perceptions and utilization of key skills among students throughout the first-year design project.

3.2 Qualitative Analysis

Upon performing a thematic analysis of the student comments, several key themes emerged regarding project management, lessons learned, and future applications.

3.2.1 Project Management

Students highlighted the significance of effective time management in project execution, stressing the need for better allocation of resources and schedules. Clear and consistent communication was identified as crucial for successful project coordination, enabling team members to stay aligned and address challenges proactively. Adequate planning and consideration of contingencies were deemed essential for project success, with students emphasizing the importance of anticipating and mitigating potential risks. Understanding others' tasks and roles within the team was recognized as vital for fostering collaboration and ensuring task completion. Additionally, students acknowledged the benefits of starting implementation earlier and allocating more time for testing to refine project deliverables and address any issues that may arise.

3.2.2 Lessons Learned and Future Applications

Students expressed a desire to invest more time in the initial planning phase of future projects, focusing on setting clear objectives, defining project scope, and establishing realistic timelines. They also recognized the importance of balancing personal development with meeting project deadlines, emphasizing the ultimate goal of team success. Furthermore, students valued both technical and non-technical skills, such as project management, teamwork, time management, and incremental idea development, underscoring the holistic nature of project success. Emphasis was placed on prioritizing effective team management, clear communication, task delegation, and fostering a collaborative environment in future projects. Additionally, students emphasized the need to verify technical strategies before implementation, assessing feasibility and potential challenges in advance to mitigate risks and ensure successful project outcomes.

4 DISCUSSION

Our project distinguishes itself from existing methods in several crucial aspects, thereby contributing to its innovation and potential impact on future educational practices. Central to its novelty is the intentional integration of professional and engineering skills development within a hands-on design project framework. Unlike conventional curricular approaches that primarily prioritize technical proficiency, our project emphasizes the holistic development of students' abilities to innovate, collaborate, and communicate effectively in real-world engineering scenarios.

Moreover, our approach incorporates interdisciplinary challenges, such as embedding ethical considerations into technical design decisions—an innovative facet that prepares students to navigate the multifaceted demands of modern engineering practice from an early stage in their academic journey.

The structured inclusion of workshops on project management, teamwork dynamics, and technical documentation further distinguishes our project. These workshops ensure that students not only acquire theoretical knowledge but also apply it in practical, team-based settings, thereby fostering deep engagement and retention of skills. This experiential learning paradigm is pivotal in preparing students for a seamless transition from academia to industry, aligning their educational experiences closely with real-world expectations.

While highlighting these innovative elements and their implications for educational reform, we recognize the importance of addressing potential criticisms and challenges alongside the benefits of integrating professional skills in engineering education. A notable concern is faculty resistance, rooted in traditional emphasis on technical training, which may conflict with the integration of soft skills development. This resistance often arises from concerns about curriculum saturation or the perceived dilution of core engineering competencies. Moreover, achieving a harmonious balance between technical rigor and soft skills training poses a significant challenge, given the densely packed nature of engineering curricula that leave limited room for additional modules without compromising depth in technical subjects.

To effectively address these criticisms, it is imperative to engage stakeholders in constructive dialogue aimed at refining curricular structures. This dialogue should emphasize the mutual benefits of blending technical expertise with essential professional skills, better equipping graduates to meet the diverse demands of contemporary engineering practice.

Furthermore, implementing adaptability in diverse educational and cultural contexts necessitates a thorough exploration of potential barriers and strategic solutions. Resource constraints and curricular rigidity are formidable challenges that can impede the integration of adaptability skills into engineering education. Strategies adopted by successful initiatives, such as flexible course designs, interdisciplinary collaborations, and industry partnerships, offer valuable insights into overcoming these barriers.

To enhance the discussion on impact, future studies could incorporate longitudinal assessments or follow-up surveys to track the long-term influence of acquired adaptability skills on student employability and career progression. This empirical approach would provide tangible evidence of the project's enduring effects on student professional development and industry readiness, thereby further substantiating its broader educational significance.

5 CONCLUSION

In conclusion, this study provides valuable insights into the development and utilization of professional and engineering skills among first-year Electrical and Electronic Engineering students during a practical design project. Our longitudinal investigation spanning five weeks reveals distinct trends in skill perception and application, with some skills peaking at specific stages while others maintain consistent usage. Notably, Science and Mathematics (SM) decline in utilization over time, while Professional Competencies (PC) emerge as predominant towards the project's culmination, underscoring their significance in the professional realm. Additionally, box plots offer nuanced insights into variations in student responses within each skill category, highlighting evolving perceptions and consensus among students.

Overall, our findings emphasize the importance of integrating professional skills development within engineering curricula to prepare students for the demands of the professional world. Future curriculum development efforts should encompass both technical proficiency and nontechnical competencies. This study contributes to the discourse on engineering education reform, advocating for a holistic approach to skill development that equips students with the competencies required to thrive in today's dynamic engineering landscape.

ABSTRACT

As engineering educators pivot towards implementing evidence-based pedagogical strategies, group work - or collaborative work - is being increasingly used in undergraduate classrooms. In mathematics, collaboration is a crucial disciplinary practice. Participation in collaborative learning not only correlates with better academic performance and deeper conceptual knowledge but also leads students to adopt better learning strategies. Moreover, working in groups can improve students' intrinsic motivation and self-efficacy and lower mathematics anxiety. Despite the

[1] *M. Pineros-Rodriguez*
manuela.pineros@epfl.ch

evidence, the implementation of group work in higher education mathematics courses has been slow, in part due to students' reluctance to engage in group work. This study describes the implementation of group work in a second-year university mathematics course taught in a flipped format, at an engineering university. We use quantitative and qualitative survey data from a student survey (N = 33) to analyse their perceptions of group work. We find that students are perceptive of the benefits of group work and especially value its affordances for access to feedback. Despite their positive experiences, we also find that students remain reluctant to group work being used more generally in other mathematics courses. We propose that even when students successfully participate in group work, they may not perceive the transferability of the skills they develop in the process. We suggest that teaching practices supporting those competencies and making them explicit may be necessary to improve student perceptions of group work beyond the classroom.

1 INTRODUCTION

Group work (or teamwork) is a pedagogical strategy involving students working in small teams toward a common goal. It has been implemented across a wide array of disciplines and levels of education. Group work is seen not only as a tool to improve disciplinary mastery (Kyndt et al. 2013; Laal and Ghodsi 2012; Apugliese and Lewis 2017), but as a way for students to acquire and master skills that are required by future employers (Craps et al. 2022; Robles 2012; Succi and Canovi 2020).

Working in groups can improve students' attitudes toward the discipline, the institution, and learning in general (Johnson et al. 2007). Students who participate in collaborative learning show higher motivation, including intrinsic and extrinsic motivation (Tran 2019; Slavin 2012), utility value (Volkov and Volkov 2015), and higher self-esteem (Johnson et al. 2007). Group work can also improve self-efficacy (Chiriac, Rosander, and Frykedal 2019), critical thinking skills (Gokhale 1995) and misconception remediation (Acar and Tarhan 2007). Moreover, group work can reduce self-efficacy gaps between women and men (Espinosa et al. 2019) and increase student perceptions of support (Johnson et al. 2007).

1.1 Group work in Mathematics.

Despite a prevalent social stereotype that mathematicians work in isolation, in a survey of 70 mathematics researchers Burton (1998) found that collaboration is perceived as an authentic disciplinary practice. Remarkably, all but three of the researchers reported regularly engaging in collaborative work. They noted that collaborating allowed them to generate more and better ideas which peers could critically evaluate and build on, to hold each other accountable in the face of deadlines, and to benefit from each other’s expertise. This suggests that collaboration is an important skill for mathematics students to acquire.

Moreover, in the context of education, the benefits of group work have been demonstrated across a range of outcomes. Students who work in small groups have better academic outcomes than those working individually (Springer et al. 1999; Smith et al. 2014), and with the acquisition of deeper knowledge (Koçak et al. 2009). These benefits could possibly be due to the need to organise knowledge well enough to provide explanations (Webb 1991), or because of increased self-efficacy, which is pivotal in mathematical problem-solving (Pajares and Miller 1994).

Collaboration in the mathematics classroom has contributed to students developing a sense of belonging (Rivera 2013) and lowering student anxiety (Lavasani and Khandan 2011). Moreover, the discussions involved in group learning make content more accessible to students (Webb and Farivar 1994).

1.2 Resistance to group work.

Despite the numerous and diverse benefits (both academic and otherwise), there is resistance from students to participate in group work, often based on fears of the free-rider effect (Shimazoe and Aldrich 2010; Latané et al. 1979) and worries about managing potential conflict. Instructors, too, resist implementation of group work due to the perceived higher load of managing group work (Gillies and Boyle 2010).

Group work is an active learning strategy, and the benefits of active learning have been well documented (Freeman et al. 2014) especially for non-traditional students (Theobald et al. 2020). However, studies have also shown that student buy-in to these active-learning strategies is related to their learning gains (Cavanagh et al. 2016; Hillyard et al. 2010; Reeves et al. 2023).

At our institution, there has been an increased focus on leveraging pedagogical strategies that have been shown to benefit non-traditional students and the development of transversal skills. The institution is implementing various initiatives, including increased intensity of group work. It is therefore important to understand the attitudes and opinions of our students concerning group work.

1.3 Research questions.

In the broader context of improving student learning outcomes, we aim to understand their perceptions about the affordances and constraints of group work in our institutional setting. To do this, we ask:

- What benefits do students perceive in relation to working in groups?
- What challenges do students face in relation to working in groups?

2 METHODOLOGY

2.1 Settings and participants

This study was conducted at a large, research-intensive Swiss engineering university. The students were enrolled in a second-year Bachelor’s course in abstract algebra for mathematics majors. The course begins with a thorough introduction to category theory and includes an exploration of group actions in various categories, the classification of finite abelian groups, and the Sylow theorems. The course is taught in flipped mode, so that the students have approximately one hour of video to watch each week, then attend a one-hour active learning session with the professor and a two-hour exercise session with the teaching assistants. Group work was mainly done during the exercise sessions, during which students were instructed to work in self-selected groups and solve assigned problem sets by applying course concepts. Working in groups was not mandatory, although it was highly encouraged at the beginning of the semester. Students did not receive instruction on how to work collaboratively but were expected to work in groups and consult with peers before reaching out to teaching assistants.

2.2 Data collection & analysis

Students enrolled in the course were asked about their experiences and perceptions of group work on the end-of-the-semester course evaluation survey which was anonymous at source[2]. The survey consisted of Likert-style questions (quantitative data), and three open-ended questions exploring their perceptions of group work (qualitative data). 35 students (37%) responded. The data was additionally filtered to remove two respondents who did not respond to the specific questions related to group work. Henceforth the word ‘students’ will be used to refer to these 33 respondents. Due to a small sample size, we used descriptive statistics to explore the quantitative data. The qualitative data was analysed for themes using the Qualitative Content Analysis methodology (Schreier 2014).

3 RESULTS

3.1 Most of the students worked in stable groups.

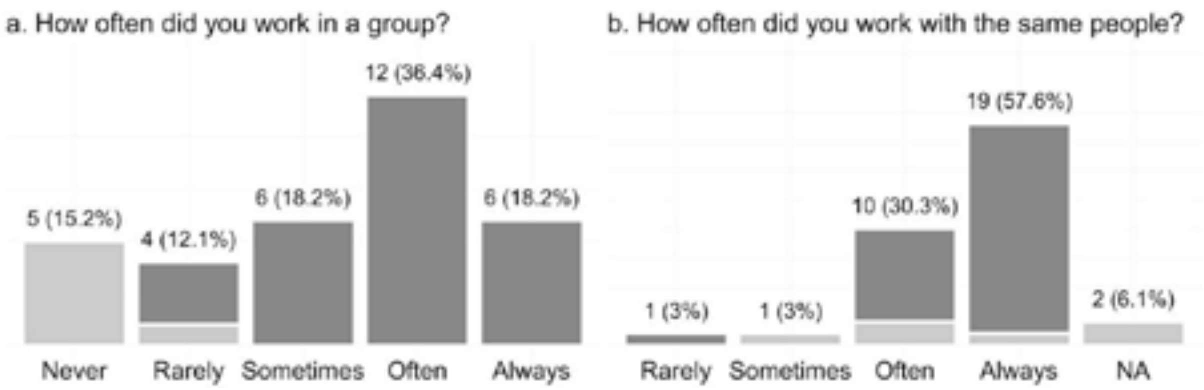

Fig. 1. Student participation in group work for students who claimed to take part in group work (dark grey, n=27) and students who did not (light grey, n = 6).

Most students (82%) reported participating in group work during the semester. Of these, 55% took part in group work often or always (Fig. 1a). Students were most likely to work in groups of five, but 41% of those working in groups worked in smaller groups. Group composition was stable during the semester, with two-thirds of the students who worked in groups always working with the same people (Fig. 1b).

3.2 Students had positive perceptions of group work.

Of the students who worked in groups, most (78%) stated that they liked to participate in group work in mathematics, with only three students stating the opposite (Fig. 2a). Similarly, 78% of them believe group work is a good idea (Fig. 2b); interestingly enough, three of the six students who did not participate in group work also believed so.

[2] Given the nature of the study design, it was exempt from a full review of the institutional ethics review board and was conducted in accordance with our institution’s guidelines.

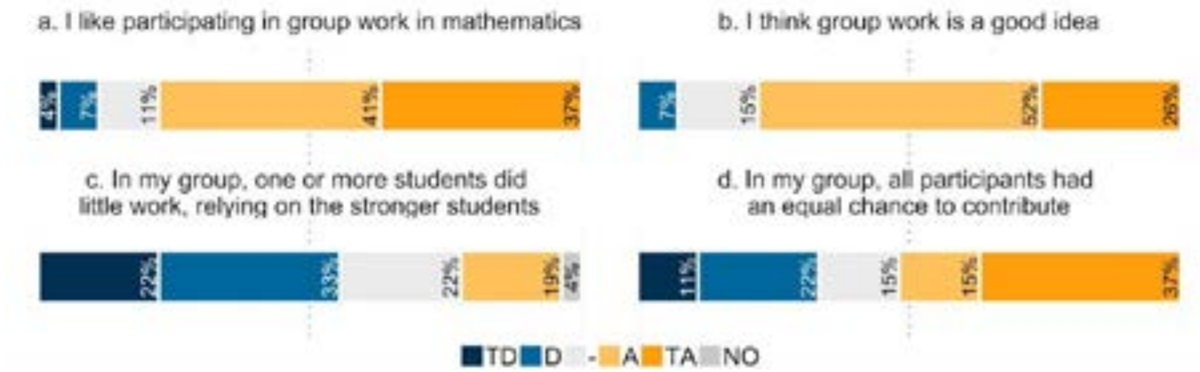

Fig. 2. Students who took part in group work had positive opinions about group work in general, and in the mathematics context in particular (n = 27). TD: Totally Disagree; D: Disagree; -: Neutral; A: Agree; TA: Totally Agree; NO: No Opinion.

Moreover, students did not perceive freeloading among their group mates, with only 19% of the students who participated in group work believing that some students in the group relied on the others to do the work (Fig. 3b). Still, just over half (51%) of the students who participated in group work believed all members in the group had an equal chance to contribute (Fig. 3a).

3.3 Students reported academic and non-academic benefits of working in groups.

Of the students who reported working in groups, 58% believed their groups solved problems efficiently (Fig. 3a), and 64% believed their group solved problems correctly (Fig. 3b). Additionally, almost half of the students felt like they learned the subject matter better when they took part in group work (Fig. 3c).

The large majority (82%) of students who participated in group work believed that group work improved their access to feedback, with only three students disagreeing with this statement (Fig. 3d). For example, students reported that "*Asking questions is very (sometimes too) easy*"[3] and that a positive aspect of group work was "*having to wait less time for help*"[3]. Several students stated that they appreciated the possibility of engaging with multiple viewpoints ("*It's also interesting to see how others think about a problem*"[3], "*having different ideas*"[3]).

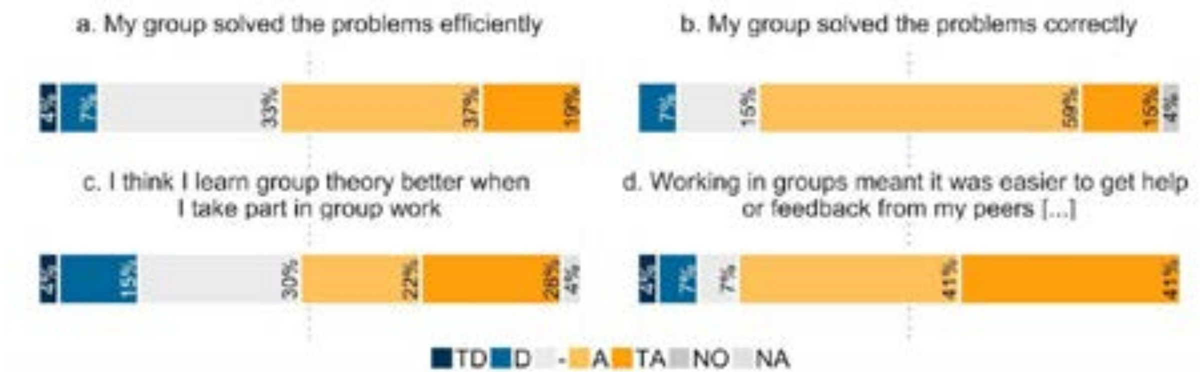

Fig. 3. Students who participated in group work had positive opinions about the academic benefits of working in groups (n = 27). TD: Totally Disagree; D: Disagree; - : Neutral; A: Agree; TA: Totally Agree; NO: No Opinion; NA: No Answer.

[3] Translated from the original French.

Some students also mentioned the affective benefits of group work ("*can take away the stress when you're struggling with certain things*"[3], "Less feeling stuck and demoralised"[3]), although they highlighted that these were due to the absence of a group-based graded component ("*the work is not graded, so there's no stress linked to the 'productivity' of group members*"[3]).

3.4 Students had some concerns about group work.

When prompted on what they disliked about group work, students expressed difficulties managing differences in the level of the team members and the pace at which the material was being covered ("*Feeling forced to progress through the exercises at the same pace as the others*"[3], "*The fact that there were disparities in level*"[3]). Some students also expressed concerns about whether the format of the problems they worked on was suitable for group work ("*The exercise series are too long for this work format*"[3]).

Finally, one student highlighted the importance of paying attention to student diversity in the class when planning group work: "*Care should also be taken with ASDs [Autism Spectrum Disorder], for whom group work can be more complicated and a greater source of stress, especially if there are graded reports*"[3].

3.5 Students do not perceive an increase in teamwork related skills.

Despite their positive opinions about group work and recognition of its academic and non-academic benefits, only slightly more than half the students who participated in group work (59%) said that they would choose to work with their group on a graded project the following semester. Additionally, less than half of them (44%) would prefer to have at least one course with a group work component.

When prompted on what they disliked about group work, students expressed difficulties managing differences in the level of the team members and the pace at which the material was being covered ("*Feeling forced to progress through the exercises at the same pace as the others*"[3], "*The fact that there were disparities in level*"[3]). Some students also expressed concerns about whether the format of the problems they worked on was suitable for group work ("*The exercise series are too long for this work format*"[3]).

4 DISCUSSIONS AND CONCLUSIONS

Our goal with this study was to explore how students perceived group work in a second-year mathematics course. Our results show that students appreciate group work and claim to see its value in mathematics. This is in line with previous research both in and outside of mathematics, which has found that students perceive group work as helpful and enjoyable (Sofroniou and Poutos 2016) and that students participating in group work tend to view it in a positive light (Burdett 2003).

Our data shows that the main benefit perceived by students was that it allowed them to feel more supported in their learning. In fact, the two factors that stood out the most were their increased access to feedback and the fact that they could better evaluate their learning relative to their peers. The contribution of these two aspects to student well-being is not minimal. Receiving timely feedback in a low-stakes environment can improve student academic performance (Abdullah and Osman 2020) and has also been linked to reduced mathematics anxiety (Bjälkebring 2019).

Moreover, understanding their relative placement in the class can help students assess whether they are using appropriate learning strategies and make adjustments as needed. In combination, just these two aspects can significantly improve student experiences in the classroom. This is especially pertinent in classes where the teachers' time is a limited resource, such as in large classrooms with or in difficult courses, where students are likely to ask many questions and teaching assistants may be in high demand. In both these cases, using group work allows for questions and problems to be addressed by peers, thereby alleviating the demands of the teaching team.

The main shortcoming mentioned by students regarding group work was dealing with disparities between team members. Students reported struggling to work within the group at a level and pace suitable for everyone. This could be because in this course, students were allowed to work at their own pace, which meant that some students could be working on exercises that had been assigned weeks prior. Previous research has found that students may perceive such inequities as barriers to collaborative learning, which could undermine the value of group work (Eddy et al. 2015). This highlights the importance for instructors to recognize this issue and step in when necessary.

Additionally, it is worth noting that the tasks used in this class were initially designed for individual work akin to those that students use in their other mathematics courses, which means that students have a reference point for the pace at which they usually advance. It is possible that when their performance differs from their expectations, they interpret it as a waste of time, which they attribute to group work. Conceiving tasks for group work which benefit from multiple viewpoints and are designed to scaffold discussions can be a way to counter this student perception. Moreover, between member disparities need not be a hindrance to learning. In fact, Johnson and Johnson (1989) argued that the productive resolution of disagreements can itself make teamwork more effective, provided team members are taught how to resolve conflicts.

Even though most believed that they learned mathematics better because they participated in group work, students remain hesitant to adopt group work more widely. This could be because students attribute their success in group work to chance rather than to their development of group work skills. Furthermore, although students report being less anxious due to group work, several students note that this is contingent upon the absence of a graded component associated with teamwork. This indicates a lack of intrinsic value attributed to group work by students, who may view it merely as a different way of learning rather than as a skill in its own right. Moreover, students don't feel like they learn how to collaborate.

In combination, these two aspects mean that students do not perceive that the group work skills they acquired are transferable and are thus reluctant to engage in group work in wider scenarios. As with all transversal skills, students do not spontaneously develop the skills needed to collaborate effectively; as a result, it is essential to provide them with guidelines and feedback on what productive collaboration looks like. Research has shown that group work also works better when students receive coaching on how to work together (Shimazoe and Aldrich 2010), since such skills do not develop organically (Channon et al. 2017) and need explicit instruction and scaffolding (Kovacs et al. 2023; Picard et al. 2022; Isaac et al. 2023). Moreover, informing students of the value of group work can improve student perceptions regarding its value (Hillyard et al. 2010; Clinton and Kelly 2020).

That said, even when students recognise the value of collaboration in their careers, this may not translate into greater willingness to participate in group work. In this class, for example, the instructor highlighted the importance of collaboration in mathematics as a disciplinary practice. However, although students appreciated group work in this class, they didn't perceive it as a priority beyond the specific course context. Students know that group work can be useful for their careers but are hesitant to be assessed on their collaboration skills. However, they also prioritise studying the material that is directly linked to their assessments, which can lead them to neglect the development of collaboration skills. This creates a contradiction, where students don't value what is not evaluated, but are reluctant to be evaluated on something that they understand is valuable. The challenge is therefore to develop group work activities that provide students with tangible feedback to monitor and develop their group working skills even when they are not evaluated on these skills. Our recommendations are provided below.

4.1 Our recommendations:

- Encourage group work as it is an authentic disciplinary practice in mathematics.
- Design tasks that are suitable for group work
- Provide explicit and scaffolded instruction on the development of skills related to working in groups.
- When possible, train the teaching team to facilitate group work.

ABSTRACT

This practice paper presents an aligned model for the training and recognition of Graduate Teaching Assistants (GTAs) in the engineering teaching laboratories at a UK-based Russell Group university. The model comprises four key elements: reflective and critical feedback through peer teaching, technical and pedagogical training informed by practice, equality diversity and inclusion (ED&I) training, and community-building/mentorship. Specifically designed to meet the Professional Standards Framework (PSF) requirements, this model facilitates GTAs' achievement of Fellowship of the Higher Education Academy (FHEA). The training has significantly increased successful FHEA applications among GTAs, enhancing both their teaching efficacy and professional development. By detailing the development, implementation, and evaluation of this model, the paper provides actionable insights for institutions aiming to enhance their GTA programs, particularly in engineering

[1]*M Di Benedetti*
m.dibenedetti@sheffield.ac.uk

education. These insights contribute to the broader discourse on effective training models and their impact on educational practices within engineering contexts.

1 INTRODUCTION

Graduate Teaching Assistants (GTAs) hold a critical position within higher education, particularly in disciplines like engineering where they often manage substantial teaching responsibilities in large classes. For instance, in the Multidisciplinary Engineering Education Department (MEE) at the University of Sheffield, where the model presented in this paper has been employed, GTAs play a vital role in facilitating laboratory sessions for groups of up to 80 students, alongside academic and technical staff. GTAs should therefore receive comprehensive training and development to ensure effective and inclusive teaching.

Numerous studies have explored GTA training and development programs, focusing on aspects such as program structure, self-perception, and efficacy measurement (Shum et al., 2020; Smith and Delgado, 2020; Bandura, 1977; Chiu and Corrigan, 2019). Notably, self-efficacy emerges as one of the crucial factors influencing GTA teaching quality, with scholars highlighting its significance in fostering effective teaching practices (Chiu and Corrigan, 2019, DeChenne et al. 2012). However, challenges persist in GTA development, including issues related to teacher identity, engagement, and role clarity. GTAs may struggle to perceive themselves as teachers, which becomes a barrier to embracing teaching responsibilities fully. Moreover, a lack of autonomy and unclear expectations can hinder their engagement and motivation. Mentorship emerges as a crucial component in addressing these challenges, providing guidance and support throughout the GTA's developmental journey.

GTAs occupy a unique position within academia, simultaneously serving as students, researchers, and teachers. This liminal space presents both opportunities and challenges, particularly concerning Equity, Diversity, and Inclusion (ED&I) in teaching. Research indicates that positive relationships between GTAs and students can mitigate inequalities in academic performance (Van Dusen and Nissen, 2020). GTAs, often reflecting diverse backgrounds, can serve as relatable mentors for students from various demographics, fostering inclusivity within educational settings. However, the blurred boundaries inherent in the GTA role can also pose challenges, particularly regarding confronting discrimination. A recent study in Switzerland concluded that whilst Engineering GTAs were overall quite confident in their readiness to take action, they rated the importance of addressing ED&I issues moderately higher than their ability to deliver them effectively (De Lima et al., 2024). They also point to research by Swim and Hyers in 1999 that shows a discrepancy between intention and action regarding prejudice. While most people believe they will intervene, less than half actually do so when faced with discriminatory behaviour (Swim and Hyers, 1999). Training interventions are thus crucial to empower GTAs in actively creating effective inclusive learning environments.

Existing literature offers valuable insights into GTA development programs and ED&I training; however, a gap exists in linking GTA progression with formal recognition pathways.

In the model presented in this paper, GTAs are encouraged to aspire to formal recognition from AdvanceHE, aiming for Fellowship of the Higher Education Academy (FHEA) over a structured two-year period. AdvanceHE, a leading organisation promoting excellence in higher education, offers professional recognition through its Professional Standards Framework (PSF). The PSF assesses individual competencies for university teaching against three key dimensions: 'Areas of Activity,' 'Core Knowledge,' and 'Professional Values.' (Advance HE, 2023).

Our model aligns closely with the PSF dimensions (but is widely transferable to other frameworks), forming the pathway for GTA development discussed in this paper. By integrating formal recognition pathways into GTA development, we aim to provide a clear progression structure for GTAs to attain FHEA recognition, enhancing the effectiveness of the GTA training program and GTA teaching practice as a result.

2 DEVELOPMENT ROADMAP FOR PROFESSIONAL RECOGNITION

Historically, GTAs had consistently felt unsure about both the value of and process of gaining formal recognition for their teaching ability (in this case, gaining FHEA recognition). GTAs were surveyed to find out about their incumbent understanding of FHEA and their perceived value of pursuing it - when asked what feels most unclear about the HEA recognition process, several answered "everything", others cited *the purpose, the process, what evidence is needed,* and *how to get started*.

Although central guidance around FHEA exists at the institution, an opportunity remained for tying this more tangibly to the GTA's specific teaching context.

GTAs were also asked how useful they would find having their training program mapped to the PSF. The average response was 4.1 / 5, giving a strong indication this would be valued, aligning with their earlier text-only answers.

This opportunity was addressed by creating a document mapping the GTA development experience to the FHEA requirements (the PSF) (Day and Di Benedetti, 2024). In conjunction, more structured support and mentoring were provided along with referring to competence development across the many training and team activities described in the following sections of this paper. The guidance document "FHEA Development Roadmap" was created which:

i. Describes the value of getting HEA recognition (incentives),

ii. Summarises the process of applying,

iii. Provides mapping to the PSF of the lab training/experience milestones,

iv. Provides guidance on compiling case studies for their FHEA application.

The mapping table presented by Day and Di Benedetti (2024) gives GTAs a clear progression route, which is discussed during individual training and mentoring sessions. This mapping table is essentially a step-by-step guide of the milestone activities a GTA will undertake, and how each relates explicitly to the PSF dimensions. The mapping helps GTAs form a narrative of their development journey and how their experience builds up towards applications for professional recognition. Elements of social learning theory are known to be of value in this context (Breau et al., 2020), so communities of learning are also encouraged within the team, with GTAs forming support groups while writing their applications.

Our model is thereby a combination of structured training and development elements, plus explicit mapping of those elements to the PSF (which GTAs can see in a concise document).

3 AREAS OF ACTIVITY AND CORE KNOWLEDGE

The ‘Areas of Activity’ section of the PSF groups together competencies relating to teaching design, delivery, student support, feedback, and assessment. Conversely, ‘Core Knowledge’ combines competencies related to the subject and pedagogical knowledge. To meet the requirements of FHEA, GTAs need to obtain sufficient competence in both. This is largely achieved through the specific training that is provided as part of their development plan.

3.1 Subject and Pedagogical Training

To support the development journey of GTAs a training methodology was devised to enhance their teaching skills while building sufficient knowledge of each teaching activity. This methodology, introduced by Di Benedetti et al. (2023) is summarised in an Open Educational Resource (Day and Di Benedetti, 2024); it relies on consistently alternating between training and teaching, interspersed with moments for self-reflection and feedback. This cycle is then repeated for all teaching activities delivered throughout the semester.

Before the academic year begins, a kick-off intro session and team-building exercise with all GTAs begin their journey. They are presented with role expectations, introduced to the HEA/PSF pathways, and work with their new colleagues on a pre-training exercise (Day and Di Benedetti, 2024).

As described in more detail in Di Benedetti et al. (2023), the training/teaching cycle (Fig. 1) starts with an Individual Training (IT) session, led by the academic and attended by a single GTA. This session supports the GTA’s activity-specific learning to reinforce their Core Knowledge of the subject. This would typically include a run-through of the lab activity, a revision of relevant background theories, and a discussion of the experimental results. In addition, pedagogical training is also offered as part of the IT to support the GTA development in the Areas of Activities, with particular emphasis on fostering a student-centred approach. Different pedagogical topics are covered, varying with the level of teaching experience of the GTA. Such topics, in line with the specific GTA skills prioritised by Tormey et al. (2019), include guidance on how to lead a teaching session (classroom management), a reflection on integrating theoretical frameworks such as Bloom's Taxonomy and constructive alignment into practical teaching contexts, and how to effectively use questioning strategies to assess students and provide constructive feedback. The duration of the IT session depends on the specific activity the GTA is being trained on, typically extending for one additional hour to account for the pedagogical training.

The Group Training (GT) session follows the IT. This is led by the same GTA trained during the IT but is now attended by other GTAs, while the academic is not present. The aim of this GT session is twofold. Peer teaching allows the lead GTA to practice before the in-service teaching, while the other GTAs learn the activity-specific content. As part of the GT, GTAs are also expected to collegially design a set of questions to assess students as well as to engage with self-reflection. For the lead

GTA, the latter involves self-assessment of their teaching, while for the other GTAs, it provides an opportunity to reflect on their learning and offer feedback to their peer (the lead GTA). The duration of the GT session also varies depending on the activity but is typically extended by 30 minutes to allow time for finalising the assessment questions and providing feedback.

Following the student teaching sessions, GTAs are encouraged to spend some time self-reflecting and using different lenses (i.e., self, students) to consider the effectiveness of their teaching.

The cycle is now ready to restart, with a different GTA receiving the IT for a new teaching activity. This cyclical nature where each GTA takes a turn in the leading role significantly aids community building across the wider team and responsibility levels in individuals.

Throughout the ITs and additional mentorship meetings, the leadership role of the academic is emphasised, providing deeper and more personalised support and encouragement for the GTAs. This, in turn, clarifies their current progress and greatly strengthens their sense of value individually and within the teaching team/community. In addition, the academic's absence during GT encourages GTAs' ownership of teaching sessions.

Finally, at the end of the academic year, all GTAs attend a workshop containing group exercises so GTAs can share their feedback/reflections and consolidate the team mentality.

4 PROFESSIONAL VALUES

To meet the requirements of FHEA, GTAs must demonstrate their integration of specific professional values throughout their practice. These include but are not limited to, V1: Respect individual learners and diverse groups of learners, V2: Promote engagement in learning and equity of opportunity for all to reach their potential, and V3: Use scholarship, research, or professional learning, or other evidence-informed approaches as a basis for effective practice (Advance HE, 2023). Inclusive education is essential for student retention and progress, therefore underpinning a sustainable pipeline of diverse and talented future engineers in both academia and industry.

The GTAs develop their professional practice in these ways through a combination of purpose-built training, community building, experience development, and mentorship.

4.1 ED&I training

Effective ED&I training becomes part of departmental culture through ongoing reflection and adjustments. It must address both the breadth of the topic and the nuance involved in both identifying and recognising the impact of often subtle discriminatory behaviours, whilst reinforcing the necessity for an ongoing commitment to the development of inclusive teaching practice through experience, reflection, and study. Based on these factors, a two-hour ED&I training was designed with a specific focus on the GTA teaching context. The two hours were divided between independent and group work. Follow-up reflective questions are shared with lead academics to use with GTAs working in their labs to continue their reflection and development of inclusive practice. Recommendations for support at the faculty level are also reported and implemented (Fig.2).

Teacher identity is a significant influence on the teaching approach and as discussed, can also impact how discriminatory behaviours based on different characteristics are recognised and addressed. As Lojdová et al. (2021) assert “Teacher identity is no longer acquired through professional standards but through teachers making sense of themselves and their teaching practice. Inclusive practice is brought into practice through teacher identity”. Identity awareness helps teachers bridge the gap between themselves and students with different backgrounds. Even when a teacher’s experience differs from students', that awareness can motivate them to compensate and be more vigilant about the issue (Drescher et al. 2023). The training was therefore designed around building GTA awareness of their identity to help them recognise their positionality and its commonalities and differences from their students.

A website of curated resources was designed (Plumb, 2024), giving the perspective of marginalised groups in STEM, grouped by different elements of GTA teaching practice such as facilitating group work, intervening and feedback. Resources include excerpts from pedagogic scholarship, short video clips and images to allow for quick engagement. It also includes local data on ED&I issues, from the faculties, university, and relevant student survey quotes from the Faculty of Engineering. Participants choose which resources they would like to explore independently. This approach offers participants a variety of “ways in” to the topics through engagement with a range of perspectives, prompting them to reflect on how their own identity impacts the way they teach and interact with students and the importance they place on incidents which stem from discrimination. They are also encouraged to think about the factors which affect their students’ approach and experience of education.

Fig. 1. Training & Teaching Activities Cycle

Fig. 2. ED&I Training Activities

Meaningful engagement with the material is elicited through a reflective exercise using a Google form where participants consider how identity and systemic barriers impact learning experiences and pedagogical approaches in their own context. This is followed by a workshop where participants discuss the ideas from the resources and their reflections with their peers. The workshop was designed in collaboration with colleagues from the English and Sociological Studies departments who have expertise in teaching sensitive topics to ensure that conversations were structured and facilitated in a way that ensured that participant views were respected even when challenged. Facilitators access the responses to the reflective tasks and if permission is given, leverage the information gathered to tailor discussion towards the topics of greatest collective interest or concern. Through these series of activities, participants are given opportunities to make sense of differing experiences and perspectives as well as to challenge their interpretations and those of others.

To further ensure that best practice is embedded, the ED&I training serves as a pipeline of inclusive practice feeding from GTA level upwards. Participants complete an action plan where they identify goals for making their practice more inclusive. Responses are made into a report and presented to the Faculty Director of Education so that relevant support can be put in place. Suggestions which have been implemented to date include clearer visibility and communication of reporting systems for GTAs to report instances of discrimination and bias.

5 RESULTS

5.1 Subject and Pedagogical Training

GTA teaching is assessed through multiple lenses, including instant student satisfaction ratings (Funnell, 2020), end-of-year student feedback, and well-established teaching observations conducted by both academics and students (Herrick and Shotts, in print). While student session satisfaction ratings provide valuable insights into students' engagement, independent teaching observations focus on GTA pedagogical skills.

The instant student satisfaction rating for the Lab in the past academic year averaged 4.5/5, closely aligning with the departmental average of 4.47/5. Both teaching observations and end-of-year feedback highlighted that GTAs acted autonomously and were instrumental in fostering critical thinking through questioning. Investing in GTA development significantly enhances their teaching skills, sense of responsibility, and identity as educators (Gardener and Jones, 2011), which in turn improves the quality of teaching they provide to students.

Observations also noted the need for a better balance in how and when GTAs engage with students. Future pedagogical training will focus on addressing this gap, ensuring continued improvement in GTA performance and student learning outcomes.

5.2 ED&I Training

Responses to the pre-workshop reflective task indicate how participants respond and interpret the materials. They also reveal misconceptions and questions before the second part of the training so there is time to respond to them. Participants often took the opportunity in the task to also give feedback on the resources they looked at with many of them saying that the materials had made them reflect differently on their approach and made them more aware and understanding of the perspectives and barriers faced by affected groups. The completed task is shared with the workshop facilitators who use the participants' ideas to structure the workshop discussions.

Participants also completed an action plan at the end of the workshop which evidences what they have taken from the session which is most valuable to them and outlines a specific commitment to introduce it to their teaching practice. These methods have proven useful in evaluating the effectiveness of the training as the written submissions evidence how participants interpret the content and how they intend to apply the ideas which have resulted from the activities.

5.3 Development Roadmap

The proposed training method combined with the development roadmap had a significant impact on GTAs achieving professional recognition. From an institutional equal opportunity document about PSF results, it was possible to infer that:

- Engineering historically had a disproportionately low number of FHEA applications compared to other faculties. However, in the past two years, this steadily increased with 9 (in 2022) and 12 (in 2023) applications to FHEA.
- Last year in Engineering, 50% of successful FHEA applications were by GTAs trained using the proposed training methodology.
- Finally, we have some direct feedback about the Development Roadmap; "*I found it very useful to help kickstart the process of filling out my "Statements and Supporting Examples" section and to give me an idea of potential case studies I could choose from my time as a GTA*".

6 SUMMARY

This practice paper presents a model for GTA development and recognition that is anchored in reflective peer teaching, technical, pedagogical, and ED&I training, as well as community-building/mentorship.

This model offers a practical framework that can be readily adopted by higher education institutions. By leveraging the structured training approach outlined by Di Benedetti et al. (2023) and by Plumb (2024) and the accompanying mapping tool (Day and Di Benedetti, 2024), institutions can establish highly effective GTA development programs with successful outcomes in attaining FHEA recognition.

Furthermore, because of the transferability of the principles it is anchored on, this model allows for adaptation to other professional recognition frameworks, ensuring its applicability across diverse institutional contexts. Implementing such a model promises substantial improvements in GTA teaching skills, ED&I practice, and professional recognition outcomes.

Future work will involve additional data analysis and broader adoption of the model within our Institution and partner ones. Specifically, our ED&I training will be further developed to include peer-led workshop sessions facilitated by trained GTAs. Follow-up assessments will gauge the long-term impact of the training on inclusive teaching practices, ensuring continuous improvement and development in this crucial aspect of GTA training.

ABSTRACT

This paper presents an open online course aimed at those Not in Education, Employment, or Training (NEET). The course aims to give school dropouts, unemployed, and immigrants the opportunity to return or to enrol on studies. There are plenty of labour market training available for unemployed, but this does not necessarily contribute to further studies and thus improve one's own social position. Most entrance examinations often emphasise mathematical competence, which, especially for school dropouts and for the unemployed, may have remained at a low level or been forgotten over the years. This online course under development aims to address this shortcoming. As the target group is those currently outside the labour force, special attention must be paid to promoting learning/studying skills in the design of the online course. Students' self-direction skills are tested and based on their results, they are given tips on how to improve different aspects, as taking responsibility for one's own study is essential in an online course. In addition, the technical implementation of the course must be clear, and the instructions given on the tasks sufficient. The target group may not be as experienced as typical online course students, in which case even minor adversities may lead to dropping out. To

[1] *P. Porras*
paivi.porras@lab.fi

maintain interest, the tasks are designed to be interactive, and they also provide feedback when doing the task, not only after the return.

1 INTRODUCTION

According to the recent results of the OECD's PISA study, there is a visible decline in the level of competence in literacy, mathematics, and science in young people in Finland. Furthermore, the discrepancy in learning outcomes between pupils with an immigrant background and those without is one of the largest in the reference countries (Ministry of Education and Culture 2019). Based on Pietiläinen’s report (2021), ninth graders' proficiency in mathematics has decreased compared to previous studies. Niemi et al. (2021) also reported that the level of competence in mathematics declines if a student does not enter upper secondary school. About 14% of young people do not have upper secondary education despite the unemployment rate being lower among the more educated (Witting 2021). Witting remarks that education has a generational component, as, on average, children from less educated families are less likely to enter tertiary-level education than others. In addition, students with less educated parents seem to have a higher dropout rate than students with highly educated parents. Addressing the underlying reasons is not the subject of this paper; instead, it frames the urgent need to help youth catch up with their studies.

The shortage of labour, especially in the technology sector, is growing, and the demands of digitalisation are not helping the situation. There are not enough technology students to fill the gap, as enthusiasm for studying technology is decreasing and only 60% of engineering students graduate according to Energiateollisuus (2021). Further, sufficient mathematics skills seem to predict the progress of engineering studies better than the actual educational background. Therefore, improving mathematics skills is important to support studying and improve graduation rates.

One principal factor in succeeding in professional studies is self-direction. Students who are excellent at regulating their studies usually progress well. Thus, it is important to understand the self-direction skills of students in order to provide them with the necessary tools and methods to succeed in their studies. Self-management and self-control are important skills that are also needed in working life.

The aim of this paper is to discuss psychological aspects needed to considerate in the course development for NEET and ways of implementing those aspects in course design. Those without recent education experience or a formal education may need more guidance to complete your studies independently, but also to work on online platforms in a technical point of view. Fostering their self-efficacy in mathematical subjects will aid their studies in mathematics (Niemi et al. 2021).

2 CHALLENGES IN ONLINE STEM EDUCATION

The popularity of online courses has continued to grow due to the continuous learning required in professional fields. Online courses offer flexibility in terms of time management, and they may be the only opportunity for those on the job to continue studying. Unfortunately, the reality is not as ubiquitous as one might imagine, and the dropout rates of courses are usually high. This section examines the reasons behind why students might drop out and how they could be considered in the course design.

2.1 Psychological aspects

Psychological aspects, like motivation and self-direction, are widely seen as key elements for academic success (Lao et al. 2017; Park, Moon, and Oh 2022). Henry et al. (2019) discuss how a student's own mindset (locus of control) or belief in their ability (self-efficacy, mindset) affects how they face challenges, their engagement in completing a task, and goal orientation. A fixed mindset refers to a person believing that intelligence and capacity are unchangeable, whereas a growth mindset refers to believing that these qualities are adaptable and can promote their skills over time and effort (ibid). Individuals with a fixed mindset place the blame on others when faced with failure, such as when the task is impossible, or a teacher does not explain things clearly. Whereas a person with a growth mindset sees difficult tasks as an opportunity to learn something new. In the case of failure, they just keep trying and find new ways to accomplish the task. Failure in this context refers to a gap between an expected or desired result and what is achieved (ibid).

Pintrich (2000) remarks that students have a mastery or performance orientation. Students with mastery orientation want to achieve competence and focus on the development of skills (ibid). Students with a performance orientation focus on external requirements, such as parental approval, grades, better salary, etc. These can also be further divided into approach (positive attitude) and avoidance (negative attitude). A mastery-approach orientation refers to a need to succeed in a task to meet an internally held standard, whereas a mastery-avoidance orientation tries to avoid failing an internally held standard (Henry et al. 2019). Performance approach orientation refers to non-negative and, often, positive associations with students' self-efficacy and academic performance (Bong 2009; Henry et al. 2019). Performance-avoidance orientation for avoiding failing to meet some normative standard may result in, for example, anxiety and the use of self-defeating strategies (Bong 2009). Individuals with a fixed mindset, performance goal orientation in general, or mastery avoidance goal orientation seem to have pessimistic thinking, make excuses, and seem to reduce effort already before failure. After failure, they think they are not good enough (ability), feel helpless, lose interest, or may even be burned out. As the target group of this paper is NEET, it is important to understand their orientation so that it can be addressed in course design and engagement.

2.2 Other reasons for dropping out

Several other attributes also influence the dropout rate: age, gender, academic experience, relevant technical and management skills, and personal variables (Shaikh and Asif 2022; Yılmaz and Karataş 2022). Bawa (2016) mentions that the learning level of college students seems to affect the probability of dropping out, as students with lower levels of learning are most likely to drop out. Students with prior experience of online learning seem to be more confident. It may be related to their technical proficiency, which is a factor of success when studying online (Bawa 2016; Shaikh and Asif 2022). That may be an issue with our self-study online course, as the target group may not have positive experiences with online learning. Shaikh and Asif (2022) also remarked that motivation aspects, like financial outcomes, may contribute to persistence in education.

A recent study from Brown (2023) describes the liminal experiences of students attempting to transition to tertiary education. In open university courses or online studies, students might encounter timetabling issues, alternative and new ways of studying and learning methods, and academic and institutional expectations. Brown also notifies that many students experience feelings of confusion, which may be perceived as a barrier to learning, as they adapt to a new learning environment where they are expected to demonstrate independence (Van Rooij et al. 2017; Pennington et al. 2017). Thus, the problems for those in transition are the same but much deeper in nature. Students may lack the prerequisite cognitive skills that are required in online learning environments.

2.3 Careful course design prevents dropping out

The previously mentioned aspects must be taken into account in the planning of the assessment and learning environment. The promotion of self-directed learning skills, the authenticity of the practice and well-timed feedback form the hallmarks of a good online learning model (Hurme, Porras, and Lähteenmäki 2023). Focusing on thinking and self-directed learning skills can therefore help our target group to complete the course.

Rasila et al. (2015) state that in order to build a pleasant user experience, the presentation of mathematics plays a key role. The mathematical content should be understandable regardless of the teacher's help, and the interaction between the student and the computer should be seamless. In addition, certain problems within materials and systems can later be identified indirectly by the students' training response data collected by the e-learning environment. User feedback and subsequent revisions to the e-learning platform and learning materials are necessary to improve the user experience.

Koedinger et al. (2015) showed that engaging in interactive activities within online courses yields more significant improvements in study outcomes compared to simply watching videos or reading theoretical material. Interactive activities foster active learning, which is more effective than passive knowledge acquisition, and the learning by doing method seems to be a reasonable premise for the design of an online course. However, combining the videos with interactive activities might help the students to get better grades. Rinneheimo (2017) found that students found videos useful for enhancing learning, with a majority wanting more videos in courses as they allow students to study at their own pace and revisit content as needed.

Paiva et al. (2015) emphasise that interactive learning modules such as interactive multimedia books, online quizzes, and educational videos create an effective online learning environment for studying mathematics in higher education. The study provided evidence that interactivity could effectively improve learning outcomes, as students with weaker basic math skills showed significant improvement. Velichová (2021) concludes that learning by doing enhances learners' motivation, enthusiasm, interest, attitude towards the whole learning process and desire to acquire new knowledge. An interactive approach improves opportunities to fill learning gaps in mathematics.

3 DESIGN OF THE ONLINE LEARNING ENVIRONMENT

On this course, all students have three modules to finish: learning skills, basics of mathematics, and professional-specific advanced tasks. Learning skills give basic knowledge on calculators, word processing, and spreadsheet computation. All skills required to successfully progress on mathematical subjects. Basic mathematics goes through lower secondary school mathematics and advanced tasks focus on professional field.

The theoretical framework (Hurme, Porras, and Lähteenmäki 2023) used for this online course is based on the idea of de Brujin and Leeman (2010). Four themes with descriptive features comprise the model: authenticity, activity design, guidance, and evaluation. Authenticity has a two folded meaning. It’s naturally considered with professional specific, advanced task. The idea is to use authenticity in to evoke an 'I can' identity (self-efficacy), for example, in people thinking about a possible career change. The pedagogical idea is to captivate the desire for learning by using suitable exercises from professional fields to promote further learning of the abstract terms and structures of mathematics and physics. These advanced tasks are divided into technology, business, social and health care, and tourism and nutrition. The student chooses one of these modules according to their professional interest.

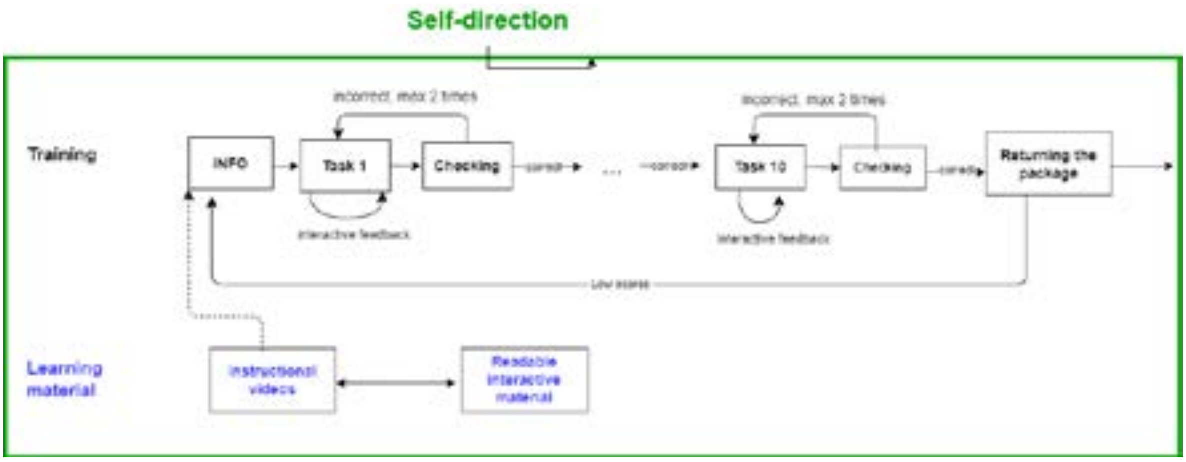

Fig. 1. Pedagogical model for online training

In the activity design, we follow the work of Bloom (1984) and Pelkola et al. (2018). The pedagogical model for online training of Hurme et al. (2023) to enwiden the basic conceptualisation and skills in mathematics is presented in Fig 1. This model emphasises the power of automated assessment and feedback to provide the seeds to support the growth in self-direction and learning for mastery of mathematical skills. Tasks are designed to provide feedback already during the execution, and not just after the checking. The purpose of this is to maintain student enthusiasm and reduce frustration. Winne (1982) states that if the learning environment is not inclusive, there is a risk of barriers for students who are less able to mediate or self-direct their own learning. If the interactive exercises and assessments performed are learner-centred, active student participation in a powerful learning environment will be promoted.

All students participate in competence level and self-regulation tests at the beginning of the course. These give them guidance which mathematical topics and self-direction aspects needs upgrading. The feedback in self-direction readiness test (Porras, Hurme, and Lähteenmäki 2023) will give the more detailed guidance the lower the scores received. After each module, students reflect their own learning with questionnaires. These include also self-direction aspects like planning and employment of time. The competence level test will be repeated after basics of mathematics to give feedback on learning.

3.1 Model for designing interactive exercises

Contemporary LMS (Learning Management Systems), such as Moodle, contain a range of interactive tasks, encompassing simple multiple-choice questions to sophisticated graphical queries, with automatic feedback being the unifying feature. STACK (System for Teaching and Assessment using Computer Algebra Kernel) is a prominent open-source e-assessment system operating within Moodle that integrates effectively with other platforms. The utilisation of tasks crafted by computer-aided algebraic systems requires extensive usage of STACK and Maxima (A Computer Algebra System). STACK utilises Maxima on calculations, but it also encompasses specific functions that are absent in Maxima but crucial for the generation of STACK tasks. For more detailed information on STACK, see Lähteenmäki et al. (2024).

A standard representation of interactive tasks requires students to type or select correct answers and passively receive immediate feedback. In this paper, interactive tasks are extended beyond that: students engage with interactive STACK tasks designed with JSXGraph, enabling them to interact with graphical interfaces using mouse or touch gestures. In the interactive task, hidden answer fields may contain diverse data types, such as coordinates of interactively manipulated objects, lists, or Boolean values.

Interactive tasks are increasingly prevalent in higher education, but effective design frameworks remain scarce. It is possible to generate interactive tasks with impact with open-source tools, but only if they utilise a learner-centred approach, simplify phenomena, and consider accessibility requirements to ensure compatibility with users' diverse needs. Interactivity should aid in comprehending underlying conceptual principles. Technical design should avoid complex structures, using clear instructions so the student can understand the task’s objectives.

3.2 Learner-centred task design and facilitative feedback

In an online course, when there is no student–teacher interaction, feedback plays a more significant role than in any other learning environment. The absence of a teacher and the live feedback without facial expressions and gestures truly challenge the learning process.

Feedback, whether it is related to guidance or assessment of activities, should be seen as an act affecting student’s future performance. Further, feedback should include answers as to why something is incorrect, how the error may be considered, and what may help solve the problem (Shute 2008; Torrance 2012; Brown 2023). These can enlighten the student on which areas are now under control, which positively affects learning. Brown (2023) and Hattie and Timperley (2007) also provide a way to provide feedback whilst maintaining a positive attitude in future learning by explaining how to reduce the identified gaps. By providing relevant positive feedback, we have the potential to affect the learner’s future performance and maintain the student’s desire for further studies.

The design of interactive tasks to ensure user-friendliness, intuitiveness, and inclusivity with a focus on pedagogically sound design play a central role. In designing interactive tasks for students, it is essential to adhere to a certain consistency: interactive elements should have consistent appearance and functionality to ensure they serve their purpose efficiently and intuitively. Particular attention must be paid to avoid confusing the student due to the perplexing functioning of the interactive task. In general, skilfully planned and executed programming should guide students so that incorrect answers do not result from syntax errors or improper response methods. It is crucial to strike a balance between simplicity and clarity of task presentation and avoid superfluous elements that may distract students.

The most common type of feedback is the immediate feedback received after the student checks the answer. If needed, the immediate feedback can be extensive, depending on the scope of the potential response tree. It has been demonstrated (Hurme, Porras, and Lähteenmäki 2023; Lähteenmäki, Hurme, and Porras 2024), that the graphical interface extends the ways of giving feedback. The graphical interface permits facilitative feedback to be shown dynamically based on the actual mouse interactions with the elements of the graphical interface. In Fig. 2 (left), there is an example of giving feedback for student during solving traditional equation task. A red question mark describes the stage at which an error occurs. Although we are not able to the specify the mistake, the instructions given below will give hints. This gives a student a possibility to fix the answer before checking.

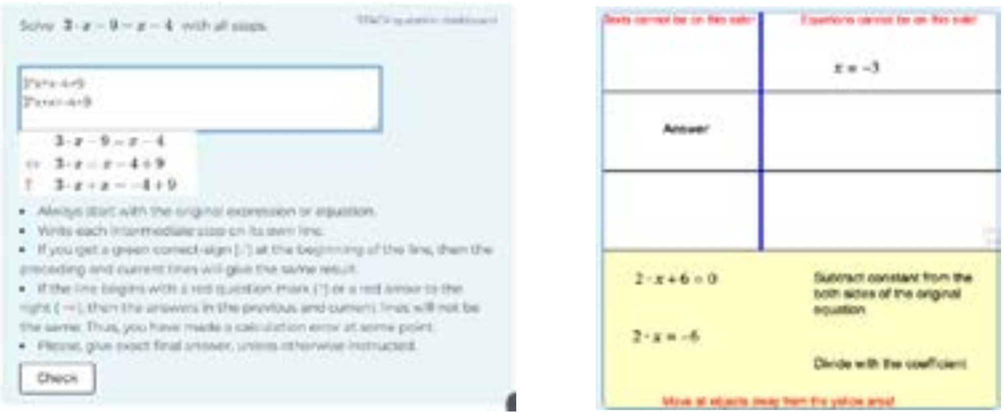

Fig. 2. Interactive feedback (left) and guidance (right) on solving equations

Gerhäuser et al. (2011) stress the benefit of using dynamical geometry software to introduce an innovative dimension to interactive tasks. Bach and Altieri (2021) confirm that dynamic geometry facilitates the development of challenging visual conceptual tasks while utilising JavaScript's versatility. In Fig 2 (right), the task utilises dynamic geometry. All steps are given but a student should order them correctly. This kind of drag-and-drop task enables forcing the student to understand intermediate steps (languaging) instead of simply following systematic instructions. The student is guided to drag objects to the correct side, but no feedback of correctness of the order is given during the task. Both kinds of tasks are needed to deepen the learning.

For example, in Figure 3, two different elements of facilitative feedback are used according to the inclusive design approach: dynamic attention messages and dynamic guidance messages. Only one row is intended to be selected in red. Thus, when a student selects another row, it turns red while the previous row reverts to black. If no row has been selected, a red dynamic attention message appears at the bottom of the window, reminding the student of the core task to be completed before checking the answer. Green arrow tips are the triggers of dynamic guidance messages that appear when hovering the mouse over them. Dynamic guiding messages can contain reflective questions or hints, just to mention a few. The main idea of dynamic guiding messages is that they point to one or many essential graphical elements and illuminate their meaning to students in a pedagogically sound way. All question types and their graphical elements must be explained thoroughly at the information part to decrease frustration.

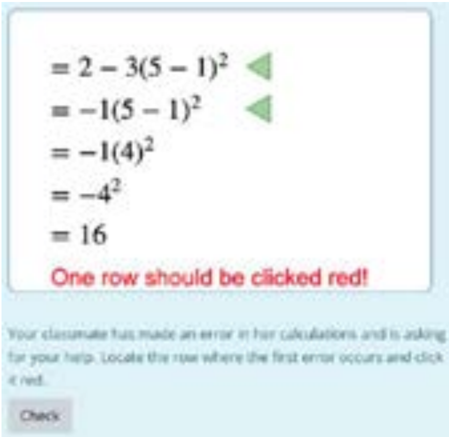

Fig. 3. Order of calculations

4 SUMMARY

The benefits arising from interactive tasks permeate all levels of education. In this paper, we demonstrate the effectiveness of these tasks in enhancing fundamental mathematical skills and solidifying foundational mathematical concepts in a purely online course. Although these aspects may not be the primary focus within higher education institutions, assuming students possess adequate competences in mathematical natural sciences, the decline in mathematical abilities is steep. Thus, there is an urgency to develop supportive measures to strengthen basic mathematical skills to facilitate successful higher education pursuits.

Poorly designed activities exacerbate the difficulties of learning online, so focusing on the level of assessment is a requirement. To promote students' learning in mathematics, both conceptions of mathematics and self-directed skills should be levelled up. Inclusive learning environments with interactive activities and learning by doing methods can address these issues.

This paper presented course aimed at NEET. We also introduced some interactive task types designed for the course to promote learning. The first pilot of this course will be during autumn 2024. At that time, we will see whether feedback and guidance has been helpful. The improvement in self-direction is not so easily explored, but indications of this are given by the ratio of students who passed the course to the number of participants. We are particularly interested in the feedback emerging on interactive exercise tasks: whether they are perceived as promoting learning, complicated, or more like gaming. This feedback affects course development.

ABSTRACT

To prepare students for employment at enterprises that are responding to more environmentally conscious consumers and investors, coupled with expanding environmental and resource efficiency regulations, the Life Cycle Assessment (LCA) approach is being integrated into various higher education engineering programmes. This paper outlines the integration of LCA education into a Problem Based Learning (PBL) structural engineering module at University of Limerick, Ireland for a large-scale design and build bridge project. In workshop format, students with limited prior

[1] *M Quilligan*
michael.quilligan@ul.ie

LCA experience, were provided with an overview of the global and local environmental challenges associated with construction, the existing and emerging policy context, and the LCA approach. The students then undertook LCA calculations to estimate the carbon footprint of their structures early in the design phase based on default life cycle inventory assumptions and impact assessment characterisation factors. Measured data for the actual amount of materials and energy utilised in fabrication, energy requirements in deconstruction and associated waste material was collected. The geographical locations of manufactured materials and the actual end-of-life destinations of materials used in project were identified. The process enabled students to make key decisions on the environmental impact of their structures during the design stage. Undertaking observations, measurements and calculations of the as-built carbon footprint of their structure engaged students in the LCA process in a practical and experiential learning approach. The process provided real-world context to theoretical concepts, and provides excellent preparation as they move on to more complex projects.

1 INTRODUCTION

1.1 Life Cycle Assessment Policy Developments for the Built Environment

Societal development patterns are placing increasing strain on the natural environment with over extraction of resources, generation of waste and associated pollution impacting human health and ecosystem functions. The input, output and stock of materials and energy needed to satisfy all human needs has accelerated greatly since the 1950s, driven by increases in human population, but also increasing throughput per capita due to rising affluence (Steffen et al. 2011; Brunner and Rechberger 2017). This increase in material and energy flows by human activities is leading to unintended environmental impacts whereby the ability of the Earth’s natural systems to self-regulate to a state of climatic and ecological stability is being disrupted by approaching or crossing safe operating limits for the nine planetary boundaries (Rockström et al. 2009).

Increasingly it is being observed that the LCA framework (ISO 14040 and ISO 14044) is being employed by policy makers and legislators to guide quantification of the environmental sustainability impacts of various products and services to identify hotspots for improvement. ISO 14040 highlights the direct applications of the Life Cycle Assessment (LCA) framework for informing public policy making, product development and improvement, strategic planning, and marketing among others (ISOa 2006). The International Life Cycle Database (JRC 2012) define LCA as a vital decision support tool to help make consumption and production more sustainable, providing a comprehensive and standardised method that quantifies all relevant emissions and resources consumed, the related environmental and health impacts, and resource depletion issues, along the entire life cycle of any good or service. The European Environmental Agency identify LCA a process for evaluating the effects that a product has on the environment over the entire period of its life thereby increasing resource-use efficiency and decreasing liabilities (EEA 2023). Key elements of LCA process involve (1) identify and quantify the environmental loads involved, e.g., the energy and raw materials consumed, the emissions and wastes generated; (2) evaluate the potential environmental impacts of these loads; and (3) assess the options available for reducing these environmental impacts (EEA 2023).

Within this context national and international policy makers are increasingly using the LCA framework to assess the environmental impact of the built environment. LCA calculation methods and standards such as EN 15978 ‘Sustainability of construction works’ (Figure 1) and the EU Level(s) framework for sustainable buildings provide a common language for assessing and reporting on the sustainability performance of buildings and is a simple entry point for applying circular economy principles in our built environment (EC 2023).

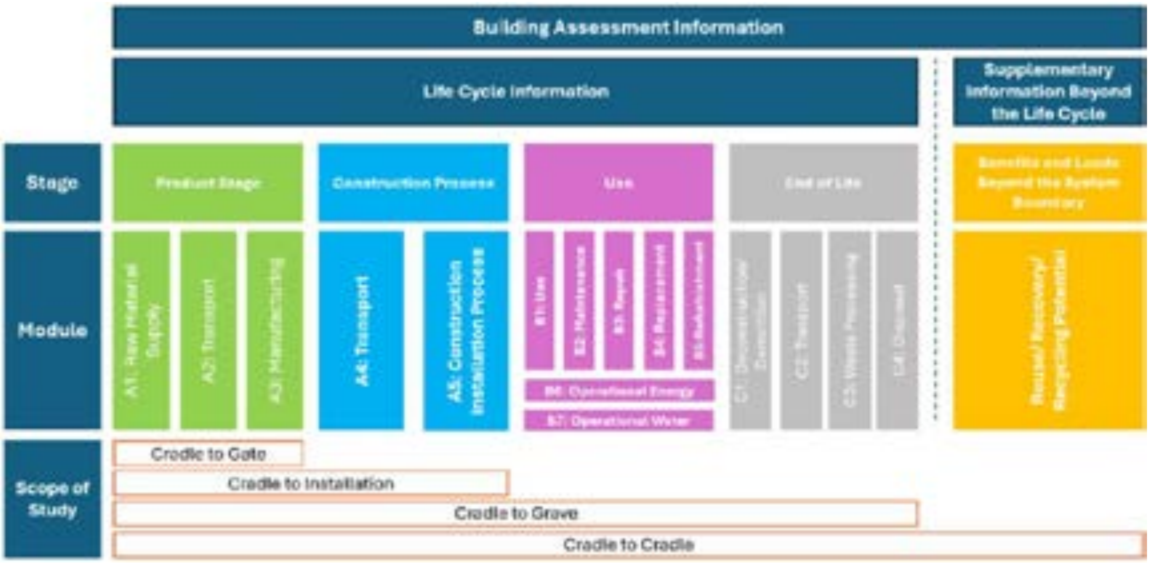

Figure 1. EN 15978 building life cycle modules

The revised Energy Performance of Building Directive was approved by the European Parliament in March 2024, with the upcoming requirement for calculating and reporting buildings' carbon footprints starting with larger buildings in 2028 and extending to all buildings by 2030 (OneClickLCA 2024).

From an Irish higher education perspective, the Irish Green Building Council have outlined the need for whole life carbon skills and competencies to be embedded in third level education with targets for third level curriculum to be infused with environmental education to increase carbon literacy and understanding of resource constraints (IGBC 2022a).

1.2 Integrating LCA into Engineering Programmes

Educating engineering students in sustainability is becoming increasingly important since engineering is expected to play a vital role in solving the sustainability challenges facing society (Olsen et al. 2018). By incorporating LCA into undergraduate and postgraduate programmes for the built environment, it is intended that upon entering industry the professionals of the future are up to speed with a method that can enhance the sustainability of buildings (Finnegan et al. 2013). It is worth noting that while there are a significant number of programmes, courses and modules focus on LCA globally, the academic literature relating to integration of LCA in educational engineering programmes is comparatively sparce (Burnley et al. 2019).

Finnegan et al. (2013) has suggested that the best way to teach LCA for the built environment is to integrate it into existing programmes instead of siloed standalone courses. Of the literature that does focus on integration of LCA into engineering programmes the predominant focus has been on integrating LCA learning objectives at programme level with increasing levels of complexity, ranging from bachelor's to PhD level, based on Blooms Taxonomy and revised Taxonomy (Olsen et al. 2018; Cosme et al. 2019, Viere et al. 2021).

1.3 The University of Limerick Civil Engineering Programme

The Civil Engineering programme at the University of Limerick, Ireland commenced in 2008 with a goal to develop people with a life-long research orientation who can address complex problems in the built and managed environment, developing solutions rationally but creatively by collaborating within teams (Cosgrove et al. 2010). Problem Based Learning (PBL) was identified as an effective means to achieve these ends as the programme team believe that attitudes and habits are not formed by transmitting content, but by embedding work with appropriate content within an effective process. PBL activities, or 'triggers', are integrated throughout the four-year undergraduate and five-year postgraduate degree programmes. Within these activities, technical content teaching endeavours to meet a 'just in time' delivery to coincide with the learning needs of the student at each stage of the PBL trigger (Phillips and Quilligan 2014). In addition, each PBL trigger requires students to complete a full design process from problem to solution. As students progress through the programme the PBL problem solving process remains the same, but the complexity of the challenges increases (Figure 2).

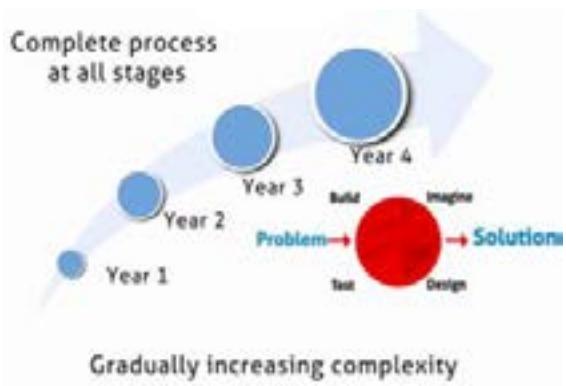

Figure 2. Progression of complexity in PBL triggers through programme

Figure 3. Tutor discussing LCA calculations with group in PBL workshop

2 METHODOLOGY

This paper outlines the integration of LCA education into the trigger which drives the 'Structural Engineering Design 2' module (6 ECTS credits) in Year 2 of the programme. The trigger challenges students to provide a safe means for a staff member to cross a specified body of water on the university campus. The aim of the trigger, before the consideration of LCA impacts, is to instil key engineering skills relating to structural design and optimisation through a PBL approach. Students work in 8 groups of approx. 7 students (Figure 3) to design a solution over a period of 12 weeks. Student contact time each week consists of 2 x 2-hour PBL sessions moderated by 2 tutors with significant industry experience and 1 x 1-hour lecture. The structures are fabricated over a 4-day period and then placed in position by the students with help of university technical staff. Due to nature of the brief with requirement for student fabrication, timber is the predominant material of choice for the structures, with structural forms typically spanning 5 m. The tutors encourage the groups to explore a range of structural forms which enables students to see the multiplicity of design choices available to them. While bridge structures are generally chosen to solve the brief, rafts have often been chosen as an efficient and effective solution.

This paper describes how integration of LCA education into the trigger was approached via:

- LCA Design Workshop: providing students with a background context for the need to perform LCA and an understanding of the LCA approach;
- LCA Design Stage Calculations: practical calculations based on default assumptions and characterisation factors provided from the literature;
- LCA As-built Observations and Measurements: observation and measurement of data relating to supplied product, construction process, end of life and benefits beyond the system boundary;
- LCA Review Workshop and As-built Calculations: real-world observation carbon footprint calculations based on project generated inventory data and Irish specific data sources and assumptions.

This is the 3rd iteration of LCA integration into the module. Spreadsheet templates were recently introduced to help improve data recording and presentation of key outputs.

2.1 LCA Design Workshop and Design Stage Calculations

The development of the LCA Design Workshop entailed a review of existing environmental education and engineering LCA literature. A high-level overview of the global and local environmental challenges associated with construction for the workshop drew on publicly available resources to contextualise the need for LCA in the construction sector. EU and national governmental and public body materials relating to upcoming LCA methodologies and regulations were also summarised.

The main phases of the LCA approach outlined in ISO 14044 provided the overarching framework for the workshop, i.e. (1) identification of the goal and scope of the LCA, (2) the life cycle inventory analysis phase, (3) the life cycle impact assessment phase, (4) the life cycle interpretation phase (ISOb 2006).

To aid with the LCA Design Stage Calculations, educational material and design stage calculation sheets were developed and aligned to these 4 phases with illustrative case studies for each phase of LCA from a construction perspective. Specific attention was given to EN 15978 for building LCA system boundary (Figure 1) due to its relevance to upcoming EU environmental regulations. A design stage calculation sheet was developed using default LCA assumptions and characterisation factors based on the Institution of Structural Engineers 'How to Calculate Embodies Carbon' (Gibbons et al. 2022).

2.2 LCA As-built Observations and Measurements

To aid students in collection of real-world observation LCA data associated with their as-built timber bridge project (Figure 3), a data collection sheet was developed to log volume and mass of ordered materials, source of materials, material losses during fabrication, waste material after deconstruction (i.e. all the wood used in project) and reused materials (i.e. metal screws, plates, and cables). Energy associated with construction and deconstruction was measured using kWh measurement devices at electrical sockets for the bench saw, sawdust collector and charging of electric drill batteries.

2.3 LCA Review Workshop and As-built Calculations

Based on the as-built data, an updated LCA calculation template was developed. Irish specific LCA assumptions and characterisation factors were utilised where available, for example, EPD Ireland Product Category Rules (IGBC 2022b), and IGBC National Inventory of Generic Construction Materials Data (IGBC 2024).

(a)

(b)

(c)

(d)

Figure 4. a,b) Structures fabricated by students in lab area; c) As-built structures in place over pond; d) Disassembly of structures undertaken by students

Characterisation factors not available for Modules C and D were sourced from the Ecoinvent V3.91 database for Ireland, and proxy data from Europe if Irish data was absent. Suppliers were contacted to ascertain if they had Environmental Product Declarations for their product or if not available the country of manufacture to allow for estimation of supply transportation distances and country specific production processes.

In addition, university department staff and waste service providers were contacted to identify end-of-life destination of wood after bridge deconstruction to estimate transportation distances, and potential impacts beyond the system boundary either through reuse, recycling, incineration, or landfilling.

2.4 Functional Unit and System Boundary

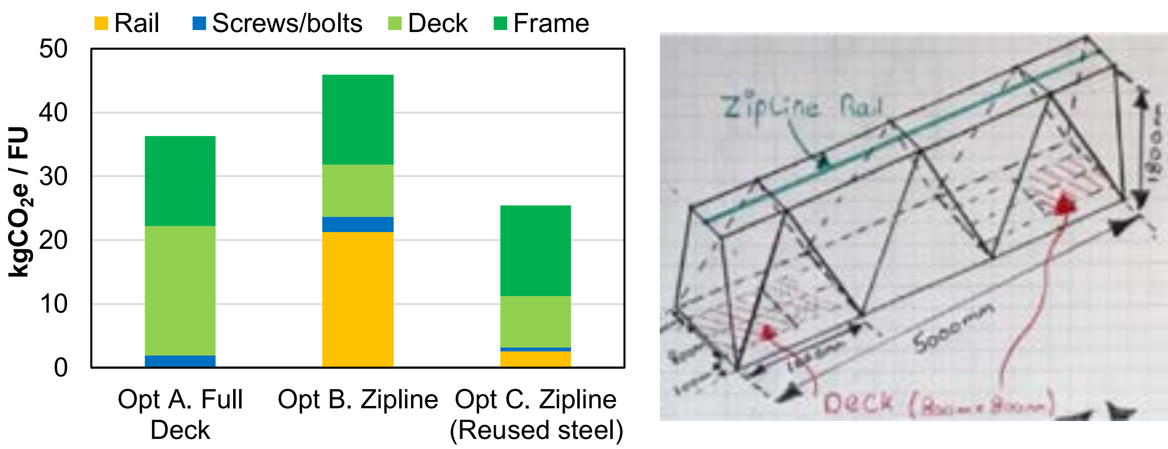
The Functional Unit (FU) of this study is a bridge structure to support a single person (1000 N characteristic load) over a 5 m span. A FU enables objective comparison of different systems that serve the same final function. The system boundary of the study included the environmental impacts of materials and energy associated with the bridge superstructure only. The substructure of the bridge was excluded as supports are reused every year and not part of student brief. The design stage workshop and calculations only included modules A1-5 of EN 15978 so as not overwhelm students with too much information as they had limited experience with LCA. Gibbons et al. (2022) state that biogenic carbon should not be included if only modules A1-5 are analysed due to uncertainties surrounding end-of-life. As such biogenic carbon was not included in this analysis due to the added complexity associated with accounting for sequestration and release of emissions. The as-built workshop and calculations considered C and D modules, due to data availability on end of life and loads beyond system boundary, providing students with experiential learning opportunities in tandem with introduction to theoretical concepts.

3 RESULTS

In this section a sample structure from a group in the 2023 running of the module is selected to illustrate and provide insights into the implemented process.

3.1 Design Stage

Figure 5a presents a breakdown of embodied carbon for a truss structure that was developed by a student group. It became apparent during the design stage that the deck material upon which the bridge user would walk accounted for a significant proportion of the structure's mass and resultant embodied carbon. The group proposed a design Option B whereby the deck would be replaced by a high-level rail from which the user would slide to create a 'zipline' (Figure 5b). This option had a lower amount of embodied carbon associated with the deck component, however overall emissions for Modules A1-3 increased from 36.3 to 46.0 kgCO_2e due to the higher emissions associated with the steel rail.



a) *b)*

Figure 5. a) Breakdown of embodied carbon for 3 design options for sample structure (Modules A1-3); b) Student sketch of proposed zipline structure

The calculation for Option B assumed that the rail was using virgin metal, however a rail was available for use that had been used in a number of previous projects. Based on tutor experience it was estimated that the rail would be available to provide

8 uses, whereas metal screws and cables are typically able to provide 4 uses. Calculated virgin emissions for the metal were therefore reduced proportionally by a factor of 8 to account for reusability. A significant reduction from 36.3 to 25.4 $kgCO_2e$ was therefore achieved compared to the full deck bridge. This information provided the student designers with key quantifiable LCA data to aid with decision-making.

3.2 As-built Stage

Figure 6 presents the results of the as-designed structure accounting for Modules A1-5, and the as-built structure accounting for Modules A-C, D. For Modules A1-5 which account for 'cradle-to-installation', the as-built emissions (34.2 $kgCO_2e$) were approx. 30% higher than the as-designed (26.3 $kgCO_2e$).

There were two main sources for the difference. First, at design stage a wastage in material of 10% for timber elements was assumed. Due to the overall length of the structure being 5 m and common timber lengths being 4.8 m, there was much more wastage encountered during fabrication. Secondly the A4 transport emissions associated with plywood for the as-built calculation was significantly higher due to the wood being manufactured in China, while at the design stage it was assumed that all wood was sourced in Ireland.

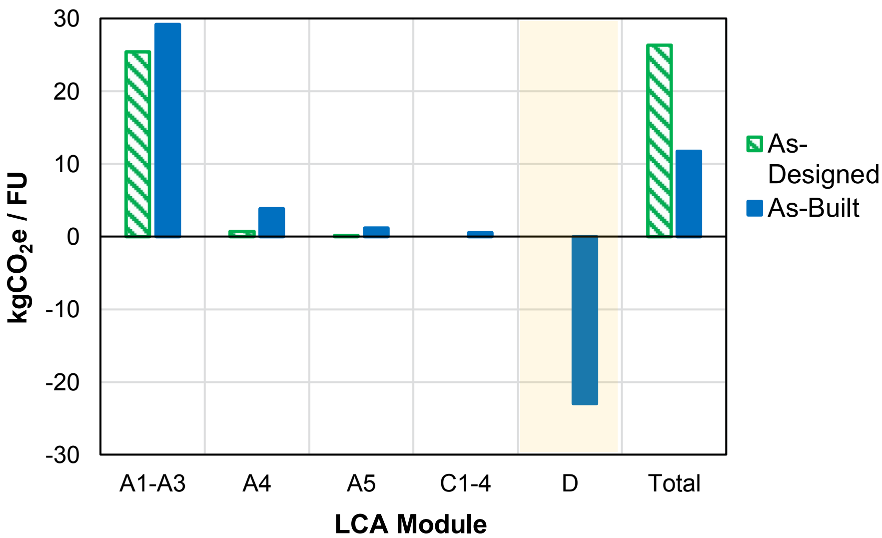


Figure 6. Breakdown of embodied carbon for sample structure as-designed (A1-5) and as-built (A-D).

The as-built structures were disassembled at their end of life (Modules C1-4) and 75% of the timber was reused for other timber projects in an education environment, while 25% was incinerated in a waste-to-energy plant. As biogenic carbon was not accounted for, the impacts associated with reuse were only due to local transportation impacts, while the wood that was burned was assumed to be transported locally and incinerated in a waste-to energy plant to generate heat and avoid heat production from natural gas as per Irish product category rules guidance. This resulted in a significant offsetting of net total emissions compared to the as-designed calculations due to the benefits beyond the system boundary in avoiding natural gas for heating. The as-built structure is associated with a total embodied carbon value of only 11.7 $kgCO_2e$.

4 Summary

This paper showcases an innovative approach to embedding LCA thinking and skills in a higher education PBL engineering design and build project. This was achieved via design stage workshops and calculations, as-built observations, measurements and calculations, and a review workshop.

The approach enabled students to make key decisions on the environmental impact of their structures during the design stage. For the sample structure a significant saving in embodied carbon was achieved based on LCA decisions at design stage.

Undertaking observations, measurements and calculations of the as-built carbon footprint of their structure engaged students in the LCA process in a practical and experiential learning approach. A comparison of the as-built and as-designed calculations has the significant benefit of showcasing the limits of theoretical assumptions and calculations which rely on default data, and the need for actual measurement of life cycle inventory parameters and assumptions to ensure transparent reporting of environmental impacts for construction projects.

The process provided real-world context to theoretical concepts, and provides excellent preparation as they move on to more complex projects.

Keywords: *Responsible Innovation, Scenarios, Ethics, Sustainability, Responsibility*

ABSTRACT

This paper explores the integration of responsible innovation into engineering education through a case study of UCL's Integrated Engineering Programme. Focusing on the Design and Professional Skills (DPS) modules, which includes scenarios designed to simulate real-world engineering challenges, the study investigates the perspectives of scenario leads on incorporating topics related to responsible innovation, such as ethics, sustainability, risk management, and inclusivity. Drawing on interviews with scenario leads, the paper identifies challenges and successes in integrating responsible innovation into DPS scenarios, including time constraints, disciplinary-specific contextualization, and means of assessment. Despite these challenges, certain success stories highlight the potential for meaningful integration of responsible innovation topics. Through a review of literature on responsible innovation and engineering education, the paper

[1] *V Ramachandran*
v.ramachandran@ucl.ac.uk

contextualizes the findings within broader discussions of curriculum development and interdisciplinary approaches to teaching ethics and social responsibility. Emphasizing the importance of ongoing dialogue and collaboration, the paper concludes by envisioning a forward-looking approach to curriculum development that prioritizes responsible innovation and prepares engineering students to address complex societal challenges in their future careers.

1 INTRODUCTION

Climate change stands out as one of the most pressing issues facing humanity due to its profoundly destructive effects on the livelihoods of numerous communities across the world (Fetting, 2020). Europe, in particular, has set ambitious goals, aiming for zero climate impact by 2050 (Tsiropoulos et al., 2020), supported by initiatives like the European Green Deal, spearheaded by the European Commission to foster sustainability in the EU economy (Fetting, 2020). Towards achieving these goals, efforts are underway to develop strategies for a more resource-efficient economy, reflecting a broader commitment to sustainable development (Fetting, 2020). European policies further emphasize transitioning towards a circular economy and promoting sustainable resource management practices (Kasinathan et al., 2022). These initiatives align with global frameworks such as the UN Sustainable Development Goals (SDGs), which play a significant role in shaping engineering education policies (Kasinathan et al., 2022; Scoones et al. 2020).

Indeed, engineers today face a growing demand to tackle intricate socio-technological challenges as part of their practice (Perkins, 2013). Within this context, the Accreditation of Higher Education Programmes (AHEP4) framework in the UK underscores the importance of the social dimension in engineering (Engineering Council, 2020). In fact, AHEP4 encompasses various facets of Responsible Innovation, such as sustainability, ethics, risk management, and inclusivity. Through its language and learning outcomes, AHEP4 underscores the importance of addressing these societal and ethical considerations alongside technical expertise in engineering curricula. (Engineering Council, 2020; Wint, 2022, Truslove et al. 2023). However, despite widespread acknowledgment, current higher education structures often fall short in adequately preparing engineering students for the complexities of social responsibility (Bowen, 2009). This deficiency is compounded by a lack of clarity regarding the exact societal role engineers are expected to fulfill (Zandvoort, 2008; Riley & Lambrinidou, 2015; Bielefeldt, 2018). Engineering student disengagement with societal issues poses a serious problem, because it limits their capacity to devise socially equitable and sustainable solutions (Litchfield & Javernick-Will, 2015; Dornick, 2023).

Universities are responding to accreditation requirements by developing specialized courses for sustainability by defining competencies that promote Education for Sustainable Development (ESD). However, there is a concern that these courses may lack a holistic understanding of sustainable development or general sustainability competencies (Giannopoulos et al. 2023). Studies indicate a lack of design and implementation of engineering courses that address both technical and sustainability-oriented issues simultaneously (Stock & Kohl, 2018; Block & Guerne, 2022; Bjornberg et al. 2015, Sanchez-Carracedo et al., 2020; Watson et al., 2013).

Despite this, sustainable practices are being integrated into engineering programs through stand-alone courses or integration into existing ones (Mesa et al., 2017).

One approach to better integrate Sustainable Development Goals (SDGs) into engineering curricula is by embedding them within existing technical courses, such as environmental engineering, where exploration of engineering solutions can align with specific SDG targets like clean water and sanitation or sustainable cities and communities (Leal Filho et al., 2022). Additionally, in engineering design courses, ethical considerations can be seamlessly integrated into design decisions to address potential social and environmental impacts (Leal Filho et al., 2022). Furthermore, creating dedicated courses or modules explicitly focused on SDGs and ethics can provide in-depth discussions on the ethical implications of engineering practice and the pivotal role of engineering in achieving sustainable development goals (Leal Filho et al., 2022).

Emphasizing the significance of SDGs and ethics across the curriculum is paramount. This comprehensive approach involves modelling ethical behaviour, promoting ethical inquiry and reflection, fostering open dialogue on ethical issues, and providing opportunities for students to engage in ethical decision-making exercises (Martin et al., 2021). Real-life events can serve as valuable contextual frameworks, enhancing understanding and competence in sustainable development (Leal Filho et al., 2022). Collaboration with external stakeholders and guest speakers further enriches the learning experience, facilitating the implementation of ethics scenarios within the curriculum (Martin et al., 2021). This integrated approach aligns with the proposition made by Holmberg et al. (2008) and Segalàs et al. (2010) that experiential active learning enhances cognitive understanding of sustainable development, advocating for a constructive and community-oriented pedagogical approach.

Since its inception a decade ago, the Integrated Engineering Programme at UCL has been actively exploring methods to incorporate various aspects of responsible innovation, including the integration of Sustainable Development Goals (SDGs) across engineering curricula (Hailes et al., 2021; Mitchell at al., 2021; Roach et al., 2022) . One avenue through which this integration occurs is via the courses Design and Professional Skills I and II (DPS). These courses are specifically designed for BEng/MEng students in Biochemical, Biomedical, Chemical, Civil, Electronic & Electrical, and Mechanical Engineering, as well as BSc/MEng students in Computer Science. Throughout the Design and Professional Skills courses, students delve into crucial aspects such as communication, academic research, ethics, teamwork, sustainability, project management, the engineering design cycle, and various technical skills pertinent to their chosen discipline. An integral part of Design & Professional Skills are the Scenarios - week-long team projects where regular lectures pause, allowing students to focus solely on a collaborative technical engineering design endeavour(Mitchell et al., 2014). Led by the department, Scenarios provide a platform to apply the coursework-related knowledge to subject-specific issues, offering invaluable insights into engineering practices. Participation in Scenarios is designed to offer UCL engineering students a first-hand glimpse into real-world engineering challenges.

This paper explores the experiences of scenario leads—lecturers who guide scenario sessions—examining their approaches, challenges, and successes in integrating responsible innovation during scenario weeks. By delving into their experiences, the paper aims to uncover strategies for embedding responsible innovation into scenario-based learning, offering insights for fostering sustainability and ethical considerations in engineering education. Identifying challenges encountered by scenario leads can inform the development of support mechanisms to address integration barriers.

2 METHODOLOGY

The methodology involved conducting semi-structured interviews with 10 scenario leads for Design and Professional Skills from each of the different engineering disciplines within the Faculty of Engineering. Each lead was interviewed individually, allowing for in-depth exploration of their experiences and perspectives. The interviews were guided by a set of predetermined questions, tailored to elicit insights into various aspects of scenario design and implementation.

The interview questions covered multiple dimensions of the scenarios, including their content, learning objectives, context, assessment methods, and connections to core modules or other scenarios. Additionally, the questions addressed the inclusion of key topics such as ethics, responsibility, risk, safety, sustainability, and societal/community impact within the scenarios.

Furthermore, the interviews sought to ascertain the scenario leads' familiarity with and coverage of the Accreditation of Higher Education Program (AHEP4) criteria. They also explored whether the scenarios were standalone or interconnected with others, as well as any perceived gaps or areas for improvement.

Importantly, the interviews aimed to highlight the extent to which the scenarios supported Education for Sustainable Development (ESD) competencies and Sustainable Development Goals (SDGs). Additionally, the scenario leads were asked about their preferences regarding the introduction of sustainability content to undergraduate students and their openness to embedding more ESD into the scenarios.

As part of each interview, we inquired about the barriers they faced in terms of incorporating topics related to responsible innovation and how they believed they could be best supported in overcoming these barriers. This aspect aimed to identify challenges and potential areas for intervention to facilitate the integration of responsible innovation into scenario-based learning effectively.

3 RESULTS

The results section provides an overview of the findings obtained from interviews conducted with scenario leads regarding their experiences - challenges, successes, and support needs in integrating responsible innovation into their scenarios within engineering education. Through a qualitative analysis of the interview data, key themes emerged, shedding light on the complexities and nuances involved in embedding sustainability principles, ethical considerations, and social impact awareness into engineering curricula.

3.1 Challenges In Integrating Sustainability

- Resistance from certain departments towards integrating sustainability due to differing priorities poses challenges in balancing technical knowledge with sustainability considerations, reflecting the varying perspectives within engineering education.
- Embedding sustainability into the curriculum presents multifaceted challenges, encompassing the necessity for contextualization and gradual introduction of concepts, aligning teaching activities with accreditation requirements while preserving flexibility for innovation, and addressing difficulties in mapping learning outcomes against accreditation criteria and aligning learning objectives across different levels of study.
- Time constraints within modules pose challenges in effectively delivering theoretical content and fitting it into structured curricula, while challenges associated with financial constraints, staff availability, and resource limitations hinder the implementation of sustainability aspects, such as securing external speakers.

3.2 Success Stories In Promoting Responsible Innovation

- Utilizing scenario-based learning integrates real-world problems, ethical considerations, and awareness of global initiatives like the SDGs, fostering student engagement, critical thinking, and social responsibility.
- Encouraging collaboration among student teams and with external mentors fosters diverse perspectives and enhances learning outcomes through assignments on varied scenario topics, promoting inclusivity and exposure to a range of sustainability issues and solutions.
- The implementation of practical sustainability projects, such as green hydrogen generation and waste-to-energy alternatives, showcases students' growing awareness in engineering sustainability, while integrating lifecycle assessment considerations into project design and material selection fosters environmentally conscious decision-making and innovation.

3.3 Call For Collaborative Resource Development

- There is a keen interest in joining workshops, communities of practice, and summer programs aimed at exchanging best practices and experiences regarding the integration of sustainability in engineering education.
- There's a demand for practical tools, resources, and support to scaffold sustainability education, contextualize topics, and integrate responsible innovation into the curriculum, reflecting an interest in early education on ethics and responsible innovation in engineering.
- Advocating for the importance of proper support mechanisms, including quick and detailed feedback for students, to enhance the learning experience, effectively integrate sustainability principles into teaching practices, and create signposting resources that draw connections to existing content without overwhelming students with new material.
- Acknowledging the necessity of continuous adaptation and innovation in engineering education to meet evolving challenges and industry demands,

there's an openness to integrating more sustainability aspects into scenarios without overwhelming students or lecturers, emphasizing the need for flexible approaches and ongoing support in curriculum development.

4 DISCUSSION

The insights shared by the scenario leads concur with findings in the literature that report the experiences of several engineering educators who are recognizing the possibilities and limitations of embedding facets of responsible innovation into their curricula. Instructors are pivotal in the integration of sustainable development into curriculum and course content (Park et al., 2022). However, successful integration requires professional development opportunities and faculty support. This also involves reaching out to individual academic staff because all instructors may not perceive sustainable development and ethics as relevant (Tepsa et al., 2023). The process of embedding topics such as climate justice into the curriculum necessitates more than just adding new content; it must become part of the paradigm and everyday thinking (Sterling, 2001). An integrated approach to teaching sustainable development is essential, providing students with a comprehensive understanding and raising awareness of sustainable practices (Perdan et al., 2000). Furthermore, Education for Sustainable Development (ESD) demands teaching and learning approaches that enhance knowledge, promote ethical reasoning, and motivate participation in community affairs. Accordingly, pedagogical strategies should be designed to support sustainability learning outcomes (Svanström et al., 2008).

The learnings from this paper should ideally serve as a practical guide for engineering programs at other universities that intend to incorporate responsible innovation into their curricula. By adopting the scenario-based approach highlighted in our study and heeding the experiences of our scenario leads, these universities can facilitate an immersive and collaborative learning experience for students. We share our methods and outcomes with the hope of inspiring other educators to implement similar strategies, but adapted to their local context. Thus, we may foster a community of practice dedicated to advancing climate justice and earth science topics in engineering education.

Engineers wield significant influence in addressing and responding to the challenges posed by climate change. Yet, the multifaceted nature of the problem and the far-reaching sociocultural ramifications of engineering interventions make it a complex issue to navigate. The work reported in this paper is part of an ongoing study to better understand the landscape of responsible innovation within the Faculty of Engineering. The aim is to help engineering educators foster a culture that equips future engineers with the knowledge, skills, and mindset needed to tackle the challenges of climate change and contribute meaningfully towards communal development.

***Conference Key Areas**: Digital tools and AI in engineering education; Building the capacity and strengthening the educational competences of engineering educators*
***Keywords**: AI; educational innovation; ethics; responsible engineers; learning methodology*

ABSTRACT

In November 2022, the release of ChatGPT to the public challenged the established order of our educational systems. Faced with this disruptive innovation, traditional educational structures were unprepared to handle this complexity and manage its uses. Consequently, the burden of social regulation became the responsibility of individuals and collectives. In this context, students' and teachers' practices adapted

[1] *D. Rodriguez*
david.rodriguez@icam.fr

and evolved to both take advantage of the opportunities offered by this new tool, and/or to establish a regime of "new normal" that would appease tensions and improve learning. This article aims to empirically detail the mechanisms of social reconfiguration deployed to integrate ChatGPT more harmoniously in classrooms. It focuses on initiatives within a French engineering school, on both institutional and individual levels. Firstly, it outlines strategy and actions settled by the "*pedagogical and digital innovation*" team to support and guide teachers in this transition. Secondly, through three case studies, it describes the activities set up by teachers to make ChatGPT an effective resource for diversifying pedagogical practices and questioning students' learning processes. The first case concerns the design of a course aimed at creating a charter for the responsible use of ChatGPT for and by students. The second case covers the adoption of a problem-based learning approach so students can overcome their problematic use of ChatGPT. The last case reports an experiment to help students use ChatGPT more effectively in learning English. With this contribution, the authors hope to inspire similar initiatives and strengthen the existing teaching communities of practice.

1 INTRODUCTION

The introduction of new technologies in society has almost always been followed by waves of "moral panic" (Cohen 1972) in the educational system (Reich 2020). The emergence of Wikipedia and the vast amount of knowledge it shared with everyone (Reagle and Koerner 2020), and the arrival of calculators in mathematics (Ellington 2003), are concrete examples of such a phenomenon. In many cases, these sensationalistic discourses have faded with time, leaving place for a normalization of their uses in teaching practices. The same scenario occurred again after the release of ChatGPT in November 2022 (Fütterer et al. 2023). While the use of ChatGPT is still controversial in education, initiatives are multiplying to make generative AI a useful learning resource. Aiming to nurture this growing "community of practice" (Lave and Wenger 1991) through feedback, this article presents the actions taken within a French engineering school by three teachers and a pedagogical coordinator.

2 GUIDING TEACHERS TO BETTER INTEGRATE CHATGPT: PDI TEAM ACTIONS AND STRATEGY

Several institutional reports have been published on the impacts and potential uses of ChatGPT in education since its release (Romero and Heiser 2023, Sabzalieva and Valentini 2023), but teachers don't always have time to familiarize themselves with this literature. Within our engineering school, teachers' concerns about the use of ChatGPT in classrooms were addressed by the Pedagogical and Digital Innovation team (PDI). The PDI's main mission is to support teachers in the pedagogical innovation process. Through its local coordinators, the PDI team can offer guidance and recommendations across multiple campuses (7 in France, and 2 in Africa).

As part of a proactive approach, an educational half-day was organized by the PDI team in May 2023 to present the possibilities of using LLMs to help design teaching programs. The aim of this initiative was to raise teachers' awareness of the potential of these technologies to enhance their teaching practices. Concrete examples of the use of LLMs in the creation of course materials and the running of practical workshops enable teachers to test and experiment with these tools. The main objective was to provide teachers with the skills they need to: integrate LLMs into their teaching practices in a thoughtful and effective way, design innovative learning situations adapted to students' needs, and support students in the responsible use of these technologies. This first step offered an opportunity for discussion and reflection on the implications of these tools for the various courses.

At the same time, teachers questioned the local PDI coordinator about the challenges posed by the use of LLMs by students in the context of assessments. They particularly shared their fears on three issues.1) **Cheating**: students use LLMs to produce non-personal content without bothering about their learning. 2) **Unequal access**: not all students have the same skills or the same level of access to these technologies. 3) **Loss of meaning**: assessment would no longer focus on students' actual skills but on their ability to use LLMs.

Aware of the importance of this topic, a workshop was organized in February 2024 to gather their views and proposals (several workshops were held in parallel, combining fields and courses). Feedback from the 24 participants (teachers and researchers) highlighted the need to train students in the ethical and responsible use of LLMs, as well as the relevance of identifying options to guarantee the integrity and validity of assessments. Discussions also focused on the need to rethink assessment formats to make them more resilient to students cheating using ChatGPT.

To address these concerns, several initiatives have been implemented. One of the first actions taken was to set up a working group with some of the volunteers present at the workshop. Among other missions, the group will monitor the opportunities offered by LLMs for teachers. A second action currently underway consists of testing the various existing AI-generated text detection software to limit fraudulent use of ChatGPT in exams and reassure teachers. These tools will be used in conjunction with preventive measures such as the introduction of a clear policy on the use of LLMs in assessments. Thirdly, a series of new workshops and training courses have already been scheduled to meet the needs of teachers and students. More globally, the PDI team will continue to follow the development of LLMs, support teachers in their use of these technologies, and stimulate a collective reflection on the appropriate solutions to guarantee the integrity and quality of training.

3 ADAPTING TEACHING PRACTICES TO BETTER INTEGRATE CHATGPT: THREE CASE STUDIES

3.1 ChatGPT and Ethics: a charter for and by students to guide their uses

The following case study reports the implementation of a teaching initiative focused on elaborating a charter for a socially responsible use of ChatGPT by and for students. The main inspiration for designing this teaching was the early feedback from teachers like Ethan and Lilach Mollick. Sharing the principles for successful integration of ChatGPT in education (Mollick and Mollick 2023) they emphasized the crucial role of providing students with a document defining clear guidelines for the use of AI in class. Seeking to reverse this top-down pedagogical approach, this course invited students to build their own AI usage charter.

This course took place in the context of a teaching module entitled "Adopting a Position". In this module, teachers must conceive a series of workshops that immerse students in a project-based teaching approach and seek to actively engage them in a creative process, leading to a production that expresses a real standpoint. After reading a booklet presenting the proposed workshops[2], students chose the project

[2] The presentation of the Chatgpt charter workshop is available at the following link:

they would like to contribute to. Project groups were then set up by teachers. The first 8 sessions were devoted to the group production process, the 9th session was a whole-class presentation of each group's productions, and the last session was a written exam inviting students to individually review their own experience[3].

Fig. 1. Gantt chart of the ChatGPT charter creation project.

In the case depicted here, 5 teachers proposed 6 workshops to a class of 84 students in their second year of preparatory studies for engineering schools. The class was divided into 9 groups of 6 to 12 students. Workshops exceeding 12 students were split into two groups working on the same project. Thus, two parallel projects on ChatGPT were directed. They were managed similarly, resulting in two different but close charters. The class ran from February to May 2023 (Fig. 1).

The first 8 sessions were organized into weekly two-hour classes. They were split into 2 phases. The first phase, from session 1 to session 3, consisted in a series of 3 introductory courses on AI, generative AI, ethics and the basics of charter writing. The purpose of these sessions was to provide a common base from which students could build these charters. Although students had benefited from computer science courses, notably in their first year via a programming project for a low-complexity symbolic AI system, their "digital culture" (Crepel et al. 2018) was strongly disparate and relied mainly on watching YouTube videos.

To address these gaps, the first session traced the history of AI from its founding fathers (McCarthy et al. 2006) to ChatGPT, covering topics such as AI systems functioning and their applications, the paradigmatic separation between symbolic and connectionist AI (Cardon et al. 2018), an overview of language models and chatbots, the Transformer model revolution (Vaswani et al. 2017), and the social actors and stakes behind the release of ChatGPT. To help them self-diagnose their knowledge, students were invited, after the class, to answer a consultation led in Occitania (France) to assess citizens' level of awareness and acceptability of AI[4].

The second session addressed the ethical stakes raised by AI, avoiding speculative debates on the consequences of the emergence of a strong AI (Ganascia 2017). To nurture a reflexive perspective on ChatGPT, chatbots with controversial applications, uses or developments were presented to students, such as HereAfter AI (2022), Xiaoice (Zhou et al. 2020), Tay (Suárez-Gonzalo et al. 2019), Koko (Germain 2023), precarious workers training AI systems (Perrigo 2023), or the prohibition of ChatGPT

[3] The standard exam subject proposed to students for this module is available at the following link: https://drive.google.com/file/d/1M-eLJLDaUyPQ4RQMq7H84wPH31st_zPd/view?usp=sharing

[4] More informations about this consultation are available at the following link: https://aniti.univ-toulouse.fr/en/2023/11/23/consultation-citoyenne-sur-lia-les-resultats-sont-disponibles/

in school (Yang 2023) or workplace (Ray 2023). Several questions from the public consultation presented in CNPEN (French national digital ethics pilot committee) opinion on chatbots were collectively discussed (Devillers et al. 2021).

The third session was split into two parts. During the first hour, students were set in pairs, and each group had to analyze one of the 5 proposed charters: OpenAI charter (2018), Montreal Declaration for a responsible development of AI (Dilhac et al. 2018), guidelines for AI in class (Mollick and Mollick 2023), the Responsible engineer and scientist charter of the association of French Engineers and Scientists (Anstett et al. 2022) and the values charter of our school. To analyze these documents, students were allowed to mobilize all the resources at their disposal: including ChatGPT to translate, summarize, vulgarize, criticize, etc. the text. During the second hour: students presented their text in 5 minutes, followed by a 5-minute discussion with the class on the resources they used to study the text and how they used them, on the relevant points to remember that could provide inspiration for their ChatGPT charter, or bringing further explanations from the teacher on this document.

The second phase, from sessions 4 to 8, consisted in the creation of the charter by students. For this, students could mobilize all possible resources. After discussing the plan of the charter as a group, students divided into pairs to write a first draft of each part for which they were responsible. The writing was done in a shared document on the cloud, from which they were able to exchange ideas in real time. To adopt an iterative logic, encourage debates and make the process more dynamic, several techniques were employed. Firstly, a system of rotating pairs so that each participant could collaborate with different colleagues and bring a fresh perspective to the various written parts. Secondly, close supervision by the teacher to guide them towards questions or resources they might not have considered. Finally, encouraging discussions within the group on best practices for using ChatGPT.

These discussions led to several observations. Firstly, the students' use of ChatGPT remained poor, usually limited to a single iteration, which didn't allow them to meet the requirements of the charter-writing exercise. Secondly, like any other tool, skills development were necessary (notably in prompting) to maximize the effectiveness of ChatGPT's use. Finally, they realized that to really perform in this exercise, the essential points were to understand the methodological expectations, to multiply the confrontations of various points of view (colleagues, ChatGPT, articles, etc.), and to be able to converge all these views in a coherent way in a single document. A long and complex task which cannot be substituted by a superficial use of ChatGPT.

This process led to the production of two 4-page charters[5], both containing: 1) a preamble, providing background information on the implications of these charters and the conditions under which they were produced; 2) definitions, to ensure that these charters are accessible to everyone; 3) a series of articles setting out recommendations and warnings on the use of ChatGPT. These articles include critical analysis on the use of ChatGPT by students to cheat, advice on how to improve the effectiveness of prompts for learning purposes, and the potential "hallucinations" (Alkaissi and McFarlane 2023) of ChatGPT. Are also included the responsibility that students must have when using erroneous information, the importance of critical thinking and comparing different sources without becoming dependent on ChatGPT, the data collection done by OpenAI, or ChatGPT's environmental impact and the

[5] These two charters can be consulted at the following link: https://drive.google.com/file/d/15nWJQeVxaeByheMq1oTOcer8gGY-LY0T/view?usp=sharing

importance of considering the relevance of its usage. This work was then presented to the rest of the class during session 9, in a 15-minute presentation, followed by a discussion with the audience.

Throughout this workshop, using ChatGPT as a starting point and through the creation of a charter, students were able to think critically on innovation, which is essential for any engineer. Beyond nurturing a reflection on the uses of chatgpt, this charter acted as an intermediary for students, to inform, debate, argue and defend their opinions, but also to listen and make concessions, to produce a document that could reach a consensus within the group. This workshop was repeated from February to May 2024, with a single group this time, assigned to synthesize these two charters into a single one and focus solely on the recommendations section in order to simplify the document and encourage its appropriation and discussion in the school. Students will be recontacted, in a few years, in order to evaluate any lasting impacts of this course on their use of ChatGPT.

3.2 ChatGPT and coding: problem-based learning to empower students

Programming is an ever-present subject when learning engineering, be it for specialized fields or generalized tracks (like in our school). Students must and need to learn one or several programming languages. Tools like ChatGPT have become commonplace as they can quite easily, and with very basic prompts, generate functional snippets of code. Positive impacts of using ChatGPT in a classroom setting, when learning to code, have been observed (Yilmaz and Yilmaz 2023). In this study the authors demonstrated that students who used ChatGPT when learning had increased levels of computational thinking and programming skills, as well as programming self-efficacy and motivation. However, AI coding bots do struggle with more complex problems, especially when using badly constructed prompts. We thus must address questions like, how can the students subdivide the problem at hand? How can they plan to reach a useful solution? And most importantly, what process pushes them to learn? In this setting, AI can be a source for co-creation (Jonsson and Tholander 2022) and an agent aiding the students to learn.

To showcase our approach, and attempt to answer these questions, we detail a use case pertaining to two PBL activities (Problem Based Learning) conducted with first year engineering students. Generally speaking, a PBL is any activity centered around a given problem situation where students learn and work in groups in order to find a possible solution. The aim of these two PBLs was to teach students the basics of algorithmic thinking and its applications using Python. In the first PBL, their task was to find a way of converting text into an image containing an encrypted message generated using a simple substitution cipher. In the second, students had to improve a program with a user interface using the tkinter Python library.

The format of PBLs adopted in our institution is as follows: the activity stretches out over two to three weeks and the class is divided into groups of 6 to 8 students (called PBL groups). The PBL is composed of five main phases (Fig. 2). Starting with the "Go Phase" where the problem situation is introduced to students, followed by the "Self-Study" phase where students discover resources (textbooks, technical reports, online articles, etc.). In these two phases, interactions between the tutor and students are limited. Next comes the "Practical Session" which is more classical and can consist of guided exercises and practical work. The activity ends with the "Group Return" phase where each PBL group presents its results. This can be done under a variety of formats depending on the main topic of the PBL. Then comes the "Common Return" phase with the whole class where direct feedback is given to the students. It is also important to highlight that the adopted evaluation method is based on competencies and not grades. This means that the metric used to assess success or failure in learning is the ability of a student to demonstrate specific skills.

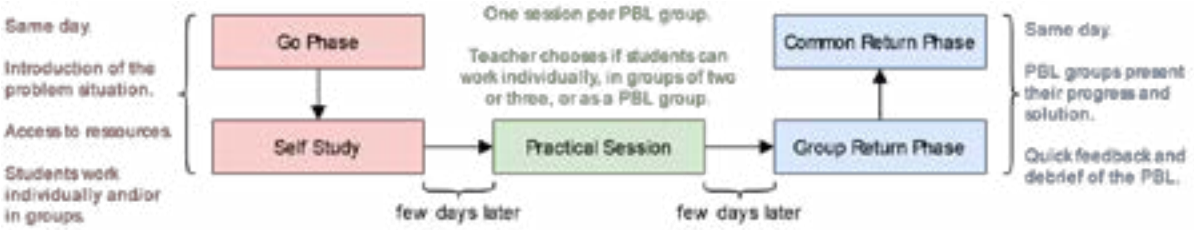

Fig. 2. Diagram representing a typical organisation of a PBL.

In the first PBL, after introducing the problem situation, students were asked to work collaboratively in groups. However, and as anticipated, a good deal of them directly sought refuge in ChatGPT, which started outputting answers that students simply could not comprehend as they lacked the basics that they are supposed to learn throughout this PBL. The more the students went back and forth with ChatGPT, trying to inefficiently modify the increasingly complex generated code, the more they struggled to comprehend it.

This situation should be treated as any other engineering problem. First, the main issue has to be clearly identified. When discussing this topic with students, it became clear that their rush to use ChatGPT was due to three main reasons. First, a lack of confidence in their abilities to tackle new topics. Second, a lack of patience and sometimes, an inability to deal with their frustrations when their solutions “do not work”. Third, the importance they give to obtaining results over the learning process. Student self-efficacy (Zimmerman 2000) is key when studying the implication of students. As they leave high-school and enter higher education, the paradigm shift can be brutal. Not only are the subjects of their courses more complex, but their autonomy becomes crucial for their progress. In this context, ChatGPT became an easy way to face their lack of confidence and patience. Thus, the path towards autonomy and critical thinking is slowed by a growing dependence on ChatGPT.

It has become abundantly clear that ChatGPT is influencing learning both positively and negatively (Bai et al. 2023). Such tools can on the one hand introduce bias, superficial and false information, while on the other hand offer a flexible and creative environment to learn. This is why during the PBL, and in parallel to the technical skills, one of the main goals was to show students how to properly divide and conquer a problem. Instead of jumping steps and expecting to arrive at a solution in one go using ChatGPT, students needed to be explicitly guided through this fundamental approach, which is necessary no matter what tools they might use to find information. However, a new question arises: How can they identify steps to solve a given problem if they haven't faced it before? To solve this issue, the students’ sense of curiosity and desire to understand must be nurtured. Without this, it will become quite impossible to converge towards an impactful and long-lasting solution. Even if the students use tools to generate answers, their new posture will automatically push them to strive to comprehend what they have in hand and to go and seek information at its source, and not only through the filters of AI.

Throughout the practical sessions of the PBL, a plan to solve the main problem situation was iteratively co-constructed with the students (Fig. 3). For each new step, the main objective was recalled, as well as all the steps taken thus far, and the global plan readjusted due to newfound information. A rhythm was imposed where for each new arising question, students had to either go through technical documents, or use AI to help zoom into the issue so they could tune their search. This tempo was heavy on the students, and by the end of the four-hour session most of them felt like they just went through a rigorous class of mental gymnastics. The impact of this approach became quite apparent in the second PBL, as during the practical sessions, students were presented with basic building blocks for adapting a functioning user interface, and were free to explore other existing methods on their own, and they were of course allowed to use AI. However, some wanted to go through the same hard process as the previous PBL. Surprisingly, students seemed more patient and rather eager to show what they are capable of.

Research has shown that students benefiting from using AI to learn can indeed be more creative and propose more original solutions (Urban et al. 2024). Yet, awakening the students' desires to learn is intimately coupled to their confidence and patience. Once the students witnessed that they are indeed capable, they became bolder and more structured in their approach, and their willingness to construct unique solutions to a given problem became much more apparent. Of course, this approach will not totally solve all ChatGPT related issues, but it can certainly nourish reflections that can push students towards becoming responsible future engineers.

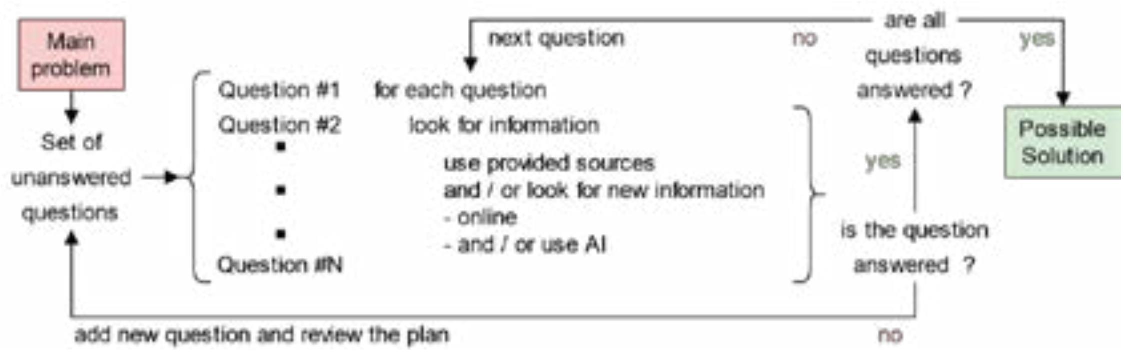

Fig. 3. Flow diagram showing the problem-solving approach shared with students.

3.3 ChatGPT and language courses: AI tutor to improve learning efficiency

The following case study reports an experimentation to help students use ChatGPT more efficiently in learning English. In a very traditional way, we regularly ask our students to read a text and answer comprehension questions. Digital tools are usually forbidden during these courses, in order to particularly avoid the use of automatic translators. But, several considerations led us to make the use of ChatGPT compulsory during one particular course. Firstly, the fact that multiple studies have shown the benefits of chatbots for language learning (Haristiani 2019, Jeon 2021, Godwin-Jones 2022). Secondly, inspired by a questionnaire conducted among students by Czech-Norwegian researchers to assess ChatGPT usefulness and effectiveness for English learning (Shaikh et al. 2023), we decided to conduct our own experiment to analyze student practices and see how ChatGPT could help them improve their English language learning.

As usual, students had a text to read and comprehension questions to answer. They had 10 minutes to read and understand the text, then they could use ChatGPT for 10 minutes. The only instruction was to use ChatGPT to help them understand the text. They were then asked to send their conversations with ChatGPT to the teacher, and we analyzed them. The analysis showed that they mainly used ChatGPT to translate words or sentences, to ask for explanations on specific words, and to summarize the text. One student asked ChatGPT to generate questions on the text and to give the answers to these questions. Another one asked ChatGPT to ask him questions, and give feedback on his answers. Most of the students considered their use of ChatGPT very basic. Then, they were asked to use this prompt:

“Assist a French student with an A2 level in English in text comprehension. Begin by asking 10 easy questions, then gradually increase the difficulty of the comprehension questions. Continue this process until the student says 'Now, move on to questions focusing on vocabulary'. Present one question at a time, each with three possible answers, concerning the meaning of the text and its vocabulary. After the student answers, provide feedback on correctness, offer a brief debriefing, and then present the next question. This is the text: [...]”

They had 10 minutes to chat with ChatGPT, then sent their conversations to the teacher. All students said that this conversation was more interesting than their traditional use of ChatGPT. To get a more objective view of this experience, the 11 present students were asked to complete a questionnaire[6] structured around 4 questions, to which they could respond via a 5-level Lickert scale (1=more negative, 5=more positive), with indications to better situate themselves towards each level. Those questions concerned: 1) relevance of comprehension; 2) relevance of vocabulary; 3) clarity of feedback; 4) activity efficiency for learning. Figure 4 shows the results of this survey. They could finally answer the usual comprehension questions. The success rate was the same as usual, but students felt more confident and said they would use this prompt again. They even asked if we could create another prompt to help them during the other technical project-based courses, as they often feel alone and confused.

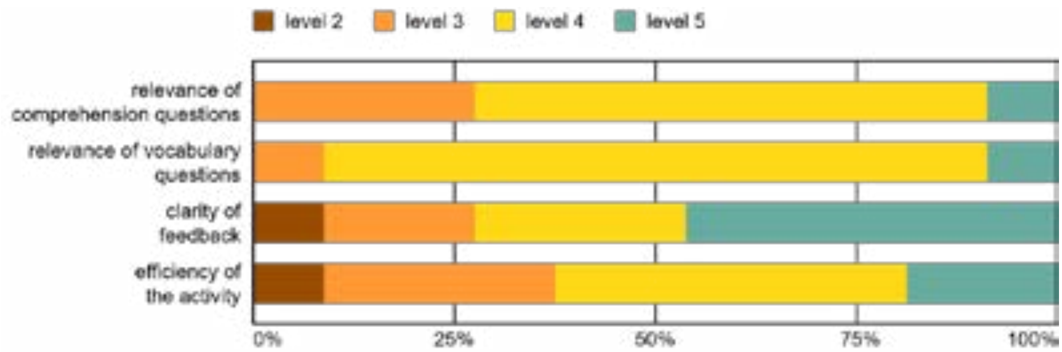

Fig. 4. Chart depicting student satisfaction levels.

Although the small sample size makes it impossible to generalize results, this short experiment has strengthened the trust relationship between teacher and students, and helped students to identify more efficient ways of using ChatGPT for learning. As predicted, their initial use was really basic. They were convinced of the usefulness of writing more complex prompts to help them reflect and check their understanding. This experiment reinforced our belief that students should be taught to use ChatGPT, and that they are willing to use it more as a tutor (Mollick and Mollick 2023) than a simple tool that gives them the correct answer that just has to be copied and pasted. Using ChatGPT in this way, can improve the students’ autonomy and learning experience by giving them personalized feedback, something a teacher cannot easily achieve in large classrooms.

[6] The questionnaire addressed to students is available at the following link: https://drive.google.com/file/d/15atk4Vaak3G5zX8eLlprR54hXVKFxZoL/view?usp=sharing

4 SUMMARY AND ACKNOWLEDGEMENTS

This article explores the potential impacts and uses of LLMs in higher education, by sharing initiatives conducted at institutional and individual levels in a French engineering school. It illustrates the conditions under which students and teachers can appropriate LLMs by sharing the actions led by a pedagogical advisor within the "*Pedagogical and Digital Innovation*" team, and by three teachers through various case studies: 1) the creation of a ChatGPT charter for and by students in an ethics course to help them develop sociotechnical reflexivity on this tool, 2) the adoption of problem-based learning approach in a programming course to emancipate students from ChatGPT dependency, 3) a prompt experiment turning ChatGPT into a tutor to help students become more autonomous and efficient in language learning courses. Far from speculative debates and moral panics, these case studies demonstrate that when ChatGPT is used with creativity while keeping the educational objectives at the heart of the process, it can be a versatile and useful tool for students and teachers. Moreover, enriching the growing corpus of pedagogical experiments conducted since the arrival of ChatGPT, such feedback contributes to paving the way towards a more responsible use of ChatGPT in the learning experience of future engineers.

ABSTRACT

As concerns regarding sustainability and ethical responsibility in engineering practices continue to rise, it becomes imperative for Higher Education Institutions (HEIs) to

[*] V. Rossi
valentina.rossi@epfl.ch

equip future engineers with the necessary knowledge and skills to address these challenges. This practice paper presents the introduction of a mandatory sustainability course for first-year students, designed to foster a deeper understanding of the ethical implications of engineering solutions and promote sustainability in engineering practices. The course is structured to integrate theoretical foundations of sustainability science with practical applications, utilizing innovative pedagogical approaches to engage students in systems thinking group projects and develop critical thinking. Through this course, École Polytechnique Fédérale de Lausanne (EPFL) aims at cultivating a new generation of responsible engineers, architects, chemists, mathematicians and physicists equipped to address complex societal and environmental challenges in their future careers.

1 INTRODUCTION

In recent years, the intersection of technology and sustainability has emerged as a pressing concern highlighting the need for engineers to consider the ethical implications and environmental and societal impacts of their work (Martin, Conlon, and Bowe 2021). The establishment of a first-year mandatory course on sustainability at EPFL reflects a concrete response to this imperative, recognizing the pivotal role of engineering education in ensuring an ethical and sustainable conduct of engineers as responsible citizens. This paper outlines the roots of the sustainability course, including the institutional context, logistical challenges, objectives and pedagogical structure, as well as its significance in cultivating responsible engineering practices and fostering a culture of sustainability within the larger academic community.

1.1 Related work and Benchmarking

Hereunder, we briefly present a non-exhaustive range of initiatives and perspectives on integrating sustainability into engineering education considered for the introduction of a new common sustainability course in the curriculum. (Børsen et al. 2021) presents the efforts of the Social Ecological Responsibility in Science and Engineering Education Network in discussing and promoting social and ecological responsibility teaching practices, while (Guerra and Rodriguez-Mesa 2021) focuses on the future of engineering education, particularly in response to the Sustainable Development Goals (SDGs), through problem and project-based learning. (Mann et al. 2021) proposes a shift from problem-based learning (PBL) to practice-based education (PBE) to address complex challenges, advocating for a holistic approach to engineering education.

Furthermore, the sustainability approaches of engineering Danish students are investigated in (Haase 2014), identifying distinct clusters of attitudes and practices. (Lozano et al. 2017) offers a framework connecting competences and pedagogical approaches for sustainable development education, aiming to enhance the effectiveness of courses in delivering sustainability education. Finally, (Smith, Tran, and Compston 2020) reviews engineering education programs integrating humanitarian action and development principles, emphasizing the need for discussion and collaboration to ensure effective outcomes and ethical practice.

1.2 Why a sustainability course

As a result of a 2022 survey to EPFL's alumni, environmental responsibility emerged as the second most crucial skill for their current jobs. Nonetheless, 60% indicate weaknesses in their environmental skills, and 30% express the absence of sustainability education in their curriculum (Duvilard, 2022). Additionally, companies increasingly seek profiles with sustainable competencies, highlighting a growing demand for sustainability expertise (Engineering Technology 2023).

There is a growing concern among young people about future challenges, particularly regarding climate change, as evidenced by a survey of 10,000 individuals aged 16-25, where 84% expressed worry, and over 50% reported feelings of sadness, anxiety, anger, discouragement, or guilt (Hickman et al. 2021). In light of these trends, universities have a critical role to play in adapting education to the demands of the 21st century, ensuring that students are equipped with the knowledge and skills necessary to address pressing global challenges (Lozano et al. 2013).

The integration of sustainability into the curriculum at EPFL has been a participatory effort driven by both students and institutional leadership. The combination of a bottom-up approach through advocacy from students and student associations prompting calls for sustainability education, and the top-down backing from the direction within our institution provided the groundwork for the realization of the sustainability course.

2 SET UP AND LEVERAGES

2.1 Institutional leverage

Context Efforts to address sustainability within EPFL were primarily coordinated through the Sustainability Task Force, which included a subgroup focused on education. In 2019 and 2020, this task force had been actively engaged in identifying opportunities to enhance sustainability education within the institution. Challenges such as the COVID-19 pandemic, lack of sustainability representative at the direction level, and limited collaborative actions have slowed down these efforts.

In 2021, our institution underwent a significant structural reorganization, establishing novel vice-presidencies to oversee various aspects of the institution's operations. A dedicated vice-presidency was created with a focus on sustainability and equality initiatives on campus. This strategic decision underscored the institution's commitment to integrating sustainability principles into its core mission, operations and academic duty. With the institution of a dedicated vice-presidency, a more centralized approach to sustainability initiatives emerged at our institution.

Teach4Sustainability Working Group Under the guidance of the associate vice-president for education, who maintained a strong link with the institution's leadership, the Teach4Sustainability Working Group (T4S) aimed at integrating sustainability into EPFL's educational offer, with the intention on implementing major actions by the academic year 2024/25. Coordination assistance was provided by project leaders from the sustainability focused vice-presidency, who offered valuable support and ensured that deadlines were met in the process.

T4S created a framework consisting of three parallel action areas, or pillars (see Figure 1): Pillar 1 involves the introduction of a new school-wide first year course providing a foundation in sustainability, Pillar 2 focuses on linking specific study plans with sustainability topics, and Pillar 3 entails integrating sustainability-related content into individual courses.

The new sustainability course, focus of this paper, falls under Pillar 1 and has the objective to align first year bachelor students on a scientific knowledge of sustainability applicable to bachelor students studying at a technical university. The course, currently piloted with 150 students, is slated for implementation in the study plans for the academic year 2024/25.

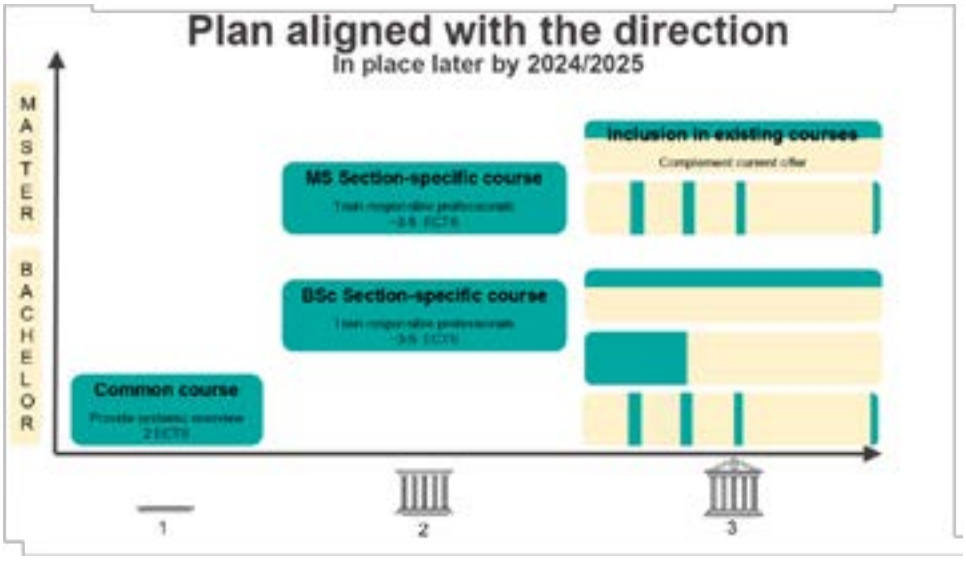

Figure 1: Illustration of the three pillars

Students engagement The collaboration between our institution and students associations, especially the ones advocating for urgent and ambitious action, underscores a unique partnership in addressing sustainability challenges within the academic community.

The participatory approach to integrating sustainability into EPFL's educational offer facilitated the dialogue between different stakeholders and therefore allowed to have a more consistent alignment of goals despite the challenges that such endeavour may entail.

3 PEDAGOGICAL STRUCTURE

3.1 Collaborative course design

In the process of designing of the sustainability course logistical aspects played a crucial role.

Following the joint demand from the education and sustainability focused vice-presidencies, numerous units from our institution were consulted and involved in the setup. These include the Teaching Support Center, which provided pedagogical advice for teachers

and teaching assistants, the Center for Transversal Skills and Career, which supports student learning of transversal skills, and the Center for Digital Education. The sustainability course is furthermore the result of the joint endeavour between the Program of Social

and Human Sciences and the Section of Science and Environmental Engineering, which contributed by facilitating the engagement of teachers from the respective structures in the sustainability course, establishing an interdisciplinary perspective from the inception. This collaborative effort among faculties, units, departments and centers ensured a comprehensive and well-coordinated logistical setup, laying the foundation for a sound and resilient institutional and pedagogical structure.

3.2 Piloting phases

The final format of the course is a 2 ECTS course across two faculties, taught by a teaching team of 14 teachers and lecturers, 6 teaching assistants and one coordinator. Two pilot courses are therefore planned: the first edition in 2024 with approximately 150 students, which we will hereafter refer to as "2024 pilot", followed by a larger pilot in 2025 with approximately 2000+ students, hereafter "2025 pilot". The former is intended to test the scientific content, while the latter to validate the logistics.

It is worth knowing that each bachelor study plan at EPFL demands students to take a 2 ECTS course from the *global issues* program in their first year of bachelor which includes courses on climate, communication, energy, food, health and mobility. Given this context, the pilot 2024 was integrated within this existing framework. However, in order to fit the sustainability course in the study plan for all bachelor students (pilot 2025), *global issues* will shift to the second year, ensuring the space for the sustainability course in the first year of studies at EPFL and guaranteeing a continuity and deepening of the topics related to global issues. This significant restructuring in all study plans at EPFL freed up 2 ECTS in the first year specifically for the sustainability course.

Outline of the course The content of the sustainability course has been defined and divided into three main parts: firstly, students are introduced to the theoretical background of planetary boundaries (Richardson et al. 2023), encompassing climate, biosphere integrity, hydrosphere, and a historical approach to sustainability. This foundational knowledge is complemented by an exploration of social, technological, political, and economic levers, followed by a systems thinking course and a project requiring a systemic approach to case studies (see Table 1).

Table 1: Outline of the course

Crisis, Planetary Boundaries and Social Needs	Week 1: Crises, Climate
	Week 2: External conference
	Week 3: Planetary boundaries, biosphere integrity
	Week 4: Hydrosphere and water cycle
	Week 5: Historical approach to sustainability
Potential Levers and Limits	Week 6: Technological, political and economical levers
	Week 7: 3 horizons and new narratives
	Week 8: Social levers and local transition examples
Intermediate Exam	Week 9: Multiple choice exam
Systems Thinking Study Case	Week 10: Systems thinking, examples of study case
	Week 11: Managing information search + prepare study case
	Week 12: Preparation for study case
	Week 13: Deadline for study case and poster
	Week 14: Poster presentation

In the initial stages of the course, students engage in ex-cathedra lectures followed by workshops to validate their theoretical understanding through experience following an active learning approach. While only three workshops were tested in the 2024 pilot, an additional four new ones will be developed for the 2025 pilot.

3.3 Pedagogical considerations

The pedagogical structure of the sustainability course aims at providing students with an interdisciplinary approach to sustainability science. The course is taught by an academically diverse team of 14 teachers, including experts from University of Lausanne and EPFL, and external professionals from the sustainability office of the city council, offering insights from the local context. The process of the content creation (modules, common thread and approach) has been the result of discussions between an initial group of teachers and students, and subsequently validated by the direction. It is important to note that the initial group of teachers partially differ from the ones involved

in the implementation of the course, demonstrating the non-dependency of the sustainability course to the group who initiated the project. To ensure coherence and avoid overlaps,

the teaching team has met monthly in the six months preceding the start of the semester. During this period, teachers have been supported in familiarizing themselves with the logistical constraints, including the assessment method for the 2024 pilot, in the conception of a concept map of each module and the whole course following (Lanares, Laperrouza, and Sylvestre 2023)'s approach, as well as an offer of pedagogical coaching and individual support when deemed necessary.

The course is supported by five master students working as teaching assistants and one PhD student, who have been following several training sessions (coaching skills, teaching with questions, facilitating group work, dealing with eco-emotions) aimed at providing them with the necessary tools to facilitate students' group work. Their main responsibilities include the facilitation of workshops, providing feedback related to the third part of the course (group projects applying systems thinking to a case study), and help to grade the students projects.

To accommodate the large number of students expected in 2025, the ex-cathedra lectures will transition to a flipped classroom model. This will require students watching a 45' video before attending class, where they meet with the teacher for 45' in large groups to delve deeper into the material by tackling common misconceptions, errors and potential questions arising from the first interaction with the theoretical content. Teachers can also take time to explain their own research work related to sustainability to give students ideas about their different professional futures. In the next period of 45', students will participate in weekly workshops designed to put into practice what they have previously learned in a more interactive setting.

Assessment method The 2024 pilot has taken place within the *global issues* program and consequently respect its evaluation method. It consisted of a 30% individual grade on a multiple choice mid-term to assess students' understanding of the content (first part), and 70% group work report and poster on a case study of their choice related to a sustainability challenge, that they will analyse and illustrate using the systems thinking approach based on (Meadows and Wright 2008). The evaluation criteria have been transparently communicated to the students as follows:

Sustainability	The link between the studied system and sustainability elements
Big picture	The definition, description of the context and limits of the studied system
Inter-dependencies	How the elements are connected to each other, cause-effect chains, feedback loops, etc
Leverage points	An action that would bring about a desirable effect, but can generate both wanted and unwanted consequences
Diagram of the system	Visual representation of the system
Language and structure	Quality of the report
Poster coherence	Logic, common thread with the report
Oral presentation	Vocabulary, time management, logical flow between group members

During the group work, students are requested to fill-in two intermediary reports aimed at scaffolding their analysis via guiding questions, and supporting their group work

While these two assignments are not graded, students are strongly advised to discuss them with the students assistants to receive feedback on the progression of their work.

4 FIRST RESULTS AND FOLLOW-UP

4.1 Preliminary feedback

Students intermediate survey A first feedback obtained after five weeks of course highlights positive aspects as well as areas for improvement. Considering a response rate of 47%, 79% of students *agree* or *strongly agree* that the course allows them to learn in an appropriate class climate [1]. The workshops are generally well-received, with students finding them enjoyable and valuable for their practical understanding. However, some students calls for a greater balance between workshops and ex-cathedra lectures. While the theoretical content is praised for its interesting and diverse nature, concerns are expressed about the depth of information provided and the frequent changes in topics and instructors. Some students suggest focusing more on practical sustainability solutions and reducing repetitions. Regarding organization and logistics, students highlight the need for improved classroom logistics and clearer communication regarding course requirements and evaluation methods. Considering this as a pilot, these observations constitute a valuable learning experience to the team involved in the teaching and design of the course.

Teaching Assistants' feedback The team of five student assistants provides weekly feedback that contribute to the improvement of the content for the 2025 pilot. While much of their feedback pertains to specific classes, several overarching themes emerge. Firstly, they highlight the importance of clarification and good organization of course material, the need for clear definitions and key concepts to guide students' understanding of the learning objectives. They also advocate for the inclusion of more examples illustrating local sustainability solutions to enhance relevance and engagement.

Regarding the workshops, students assistants noticed an active participation from students. We acknowledge nonetheless that the enthusiasm may be biased due to the fact that students who choose to partake in the 2024 pilot did it on a voluntarily basis. As the course expands to accommodate a larger cohort, we anticipate challenges in maintaining engagement and participation, stressing the need for innovative pedagogical approaches and logistical support.

5 CONCLUSION AND FUTURE DEVELOPMENTS

While the preliminary feedback for the 2024 pilot are promising, the limitations and constraints for the 2025 pilot are challenging. Teaching 2000+ students with limited human resources calls the need for innovative pedagogical methods and coordination with several services of our institution. To prepare the 2025 pilot, videos for the flipped classes will be recorded in the following months. We aim to digitalize most of the course's content with help from the Center for Digital Education and other school's services. Finally, a new Master course about teaching sustainability will start in the Fall of 2024. This new course will aim at training the team of teaching assistants to facilitate the workshops of the sustainability course and develop the

[1] Answer to the question "The running of the course enables my learning and an appropriate class climate"

specific skills required by the pedagogy of sustainability education. Once the courses will be running operationally, the goal is to obtain a virtuous cycle, where course Alumni will become assistants, both contributing to the continuous improvement of the course and deepening their sustainability competences by learning **and** teaching them.

ABSTRACT

This practice paper introduces an approach to learning outcomes within the context of the Innovation Space Bachelor End Project (ISBEP), which underscores the transition from traditional outcome-focused education to a process-level learning paradigm at a Technical University in the Netherlands. At the core of ISBEP's methodology is competence development through challenge-based learning, encouraging interdisciplinary collaboration and engagement with societally relevant challenges. The paper discusses the effectiveness of process-level learning outcomes, highlighting the importance of reflection, self-awareness, and iterative learning in fostering a growth mindset among students.

We then outline the application of this process-oriented approach to knowledge-based learning outcomes, an area traditionally dominated by outcome-based

[1] *P.AM. Ruijten-Dodoiu*
p.a.m.ruijten@tue.nl

assessments. By segmenting educational progress into distinct stages—beginning, emerging, proficient, and advanced—this approach facilitates a more engaged and reflective learning process. It encourages students to actively participate in their knowledge acquisition, applying critical thinking and synthesis to complex problems.

The proposed methodology is set to be tested in the "Automotive Societal Factors" course within the Master program in Automotive Technology, a course that focuses on the societal impacts of autonomous driving. This course will assess students' self-reflection on personal development, aiming to foster intrinsic motivation and a growth mindset that may extend to other areas of their education. This exploration into process-level learning outcomes represents a significant shift in educational philosophy, offering a comprehensive framework for enhancing learning engagement and understanding in various settings.

1 DEFINING LEARNING OUTCOMES ON PROCESS LEVEL

The Innovation Space Bachelor End Project (ISBEP) stands at the vanguard of educational innovation, embodying the principles of challenge-based learning (CBL) (Doulougeri et al., 2024). This approach is encapsulated in the course's core characteristics: interdisciplinary collaboration (i.e., different disciplinary backgrounds, such as mechanical engineering and electrical engineering), focus on societally relevant challenges, and partnership with a broad spectrum of stakeholders.

ISBEP promotes both skill and (disciplinary) knowledge development. Assessment of disciplinary knowledge is performed by specialists from each student’s own department. Assessment of skills is performed through a set of individual and team-based learning outcomes. Individually, students strive to understand the nuanced needs of stakeholders, to dissect interdisciplinary problems into manageable components, and to navigate the murky waters of situations with no clear answers while applying or deepening their respective disciplinary knowledge. Collectively, their goal is to synthesize their findings into a cohesive, experiential demonstrator, showcasing their ability to apply knowledge across disciplines and to collaborate effectively.

1.1 Skill-Based Learning Outcomes on Process Level

Central to ISBEP's educational philosophy is the transition from traditional outcome-focused metrics to an approach that emphasizes process-focused metrics. In other words, the focus is less on showcasing abilities at the end of the course, and more on guiding students in the process that leads them to acquire the necessary skills.

This philosophy underlines the understanding that learning is an iterative journey, unfolding over time and across various stages of comprehension and competence (i.e., skills, knowledge, attitudes) development. By articulating these process-level outcomes, ISBEP offers students guidance along their educational journey, enhancing their engagement with the learning activities and facilitating a deeper understanding of the challenges and successes they can expect in the interdisciplinary collaboration. It encourages a growth mindset, which is shown to enhance intrinsic motivation to learn (Ng, 2018). Fostering a growth mindset encourages the development of new talents (Dweck, 2009), and as such empowers students to take charge of their own learning progress. It also encourages students to set goals for themselves, and in the field of academic performance, studies show that self-based goals are associated with higher motivation and engagement (Martin & Elliot, 2016; Yu & Martin, 2014).

This methodology proves particularly effective for several reasons. First, it provides students with clear milestones in their learning progression, helping them identify their current stage in the development of learning outcomes and the steps needed to advance further. This clarity is crucial for fostering awareness among students regarding their learning process, enabling them to seek appropriate support and resources as they progress. Furthermore, by delineating the stages of learning, students are encouraged to engage in reflective practices, (self-)assessing their strengths and areas for improvement in relation to the defined learning outcomes.

The organization of ISBEP thus facilitates a learning environment where reflection (i.e. actively thinking about one's own learning), iterative learning (i.e. continuous improvement through small steps), collaborative learning, and practical application have become the cornerstone of the educational experience. Students are not merely passive recipients of knowledge; they are active participants in a learning journey that emphasizes growth, development, and the practical application of skills.

1.2 The Role of Self-Reflection

Reflection plays a pivotal role in ISBEP, serving as a mirror for students to examine their learning processes, both as individuals and within their teams. Through coaching sessions, guided reflection, and self-assessment, they gain insights into their growth, challenges, and achievements. A digital platform serves as a canvas for their self-reflection, offering graphical overviews of their growth in individual learning outcomes and a holistic view of their competencies through spider diagrams.

ISBEP delineates four stages of process orientation: beginning, emerging, proficient, and advanced. Each stage represents a milestone in the student's journey towards becoming engineers who are more aware of their interdisciplinary competencies. At the start of the course, students carry out a first self-assessment in relation to their overall development and gain awareness of their starting point in the learning journey within ISBEP.

- **Beginning**: This initial stage is characterized by foundational learning, where students are introduced to new concepts and begin to engage with the learning activities and their project. The expectation at this level is foundational knowledge and basic application.
- **Emerging**: At this stage, students start to display an increased understanding of the competencies they are developing, their role within the team, and contribution to the challenge. Moreover, they can apply concepts in more varied contexts. Expected outcomes include a deeper engagement with the project and the beginning of critical thinking regarding the subject matter.
- **Proficient**: Proficiency is marked by a significant level of mastery over the project, with students demonstrating the ability to apply knowledge in complex situations and engage in higher-level thinking and problem-solving.
- **Advanced**: The advanced stage signifies a deep and comprehensive understanding of the subject matter, with the ability to engage in creative problem-solving, contribute original ideas, and synthesize information across various contexts.

ISBEP places a strong emphasis on reflection as a mechanism for learning. Reflection, both guided and self-driven, allows students to internalize their experiences, understand their thought processes, and critically evaluate their own work. This approach is structured in several layers:

- **Team / Individual Work**: Encourages collaborative learning as well as individual study, providing a balanced environment for knowledge acquisition.
- **Coaching Sessions**: These sessions offer personalized guidance, helping students navigate challenges and gain deeper insights into their learning process.
- **Guided Team Reflection**: Facilitated by process coaches, guided reflection helps students identify key learnings, challenges, and areas for improvement.
- **Self-Assessment**: Students engage in a personal review of their learning journey, fostering self-awareness and personal growth.

2 APPLICATION IN AN ENGINEERING COURSE

The process approach to intended learning outcomes has shown to be successful when applied to a course with only skill-based learning outcomes. Most of the courses at our university do not (only) contain skill-based learning outcomes, but are designed to help students obtain knowledge-based learning outcomes. Knowledge-related learning outcomes are those through which knowledge acquisition is being assessed.

2.1 From Skill-based to Knowledge-based

Expanding the principle of process-level learning beyond broader competence (i.e., skills, knowledge, attitudes) development and into the realm of knowledge-related learning outcomes, marks a significant evolution in educational philosophy. This extension involves reimagining traditional content acquisition as an exploratory, iterative process. The segmentation of the educational process into stages would suppose the enhancement of students' ability to engage with complex problems, but knowledge acquisition also becomes an active, engaged process that emphasizes critical thinking, reflection, and synthesis.

Despite the advantages of a process-oriented approach (as experienced in ISBEP), its implementation, particularly within the context of knowledge-based learning outcomes, is met with several challenges. Traditional educational frameworks often prioritize outcome-based assessments and discipline-specific knowledge, presenting obstacles to the adoption of process-oriented strategies.

When relying on self-reports to assess learning gains, there are some limitations to consider. For instance, Rogaten et al. (2019) highlight that students may exhibit overconfidence in their knowledge. This tendency tends to amplify over time (Mathabathe and Potgieter, 2014; Rogaten and Rienties, 2021; Varsavsky et al., 2014). Additionally, scholars emphasize that self-reported measures constantly compare students' perceived learning gains against their subjective "feeling" of learning or "feeling of knowing" (Rogaten and Rienties, 2021). Self-reflections thus are inherently subjective, as they represent individual students' perceptions of their learning experiences and progress. This subjectivity poses a difficulty in evaluating self-reflections against standardized criteria, as interpretations of learning progress can vary widely among students.

One potential solution to this challenge is taking a learning analytics approach, where linguistic indicators of personal development could be examined in reflective writing (Kovanović et al., 2018). Another approach is integrating self-reflections with other types of evidence in course deliverables. By comparing the elaborations in self-reflections to tangible outcomes and artifacts produced during the course, educators can achieve a more comprehensive and objective assessment of student learning. This comparative analysis allows for a triangulation of evidence, wherein self-reflections provide insights into the students' self-perceived growth and learning processes, while course deliverables offer concrete evidence of their skills and knowledge application. This method not only enhances the reliability of assessments but also encourages students to consistently align their reflective practices with their practical work, fostering a holistic approach to learning.

2.2 Context of the Engineering Course

This approach will be put to the test by applying it in an engineering course that has knowledge-based learning outcomes. The course is a core course in the first quartile of the Master program Automotive Technology; Automotive Societal Factors. The course addresses the relation between a car or other vehicle, its human driver, and its dynamic environment. It is especially concerned with technological, social, and legal perspectives of autonomous driving. Apart from lectures students will work in groups on an assignment that incorporates many of the topics of the course: societal dimensions of autonomous driving, future mobility and traffic, user perception, legal issues, and ethics.

2.3 Knowledge-Based Learning Outcomes on Process Level

The intended learning outcomes of the course are based on four levels of Bloom's (1956) taxonomy and are the following:

After completion of the course, students are able to

- **Apply** human-centred design methods and evaluation metrics within an automotive context
- **Analyse** a driving task in terms of perceptual, attentional, environmental and societal processes
- **Analyse** connections between key theories and principles within the automotive context
- **Evaluate** their own personal development on the learnings outcomes throughout the course
- **Create** a (VR) simulation/experience showing automated driving in context

These learning outcomes are then each split into the four process-levels. For the learning outcome "Analyse a driving task in terms of perceptual, attentional, environmental, and societal processes", this leads to the following:

- **Beginning**: Students recognize the components of driving tasks but cannot articulate how perceptual, attentional, environmental, and societal factors influence these tasks.

- **Emerging**: Students can describe how each of the specified factors affects driving tasks but struggle to integrate this understanding into a coherent analysis.
- **Proficient**: Students provide a thorough analysis of driving tasks, clearly explaining the interplay between perceptual, attentional, environmental, and societal factors. They can predict task performance outcomes based on these analyses.
- **Advanced**: Students offer deep insights into the driving task analysis, incorporating cutting-edge research and theoretical frameworks. They are adept at forecasting the implications of these factors on future automotive technologies and societal impacts.

3 IMPLEMENTATION IN THE COURSE

The Automotive Societal Factors course starts in September 2024, and this will be the first rendition in which students' self-reflection on personal development is assessed. The design of the assessment itself (the assessment criteria and descriptors of the different levels) will look as follows: at the end each week, all groups submit a new part of their assignment to Canvas (the Learning Management System used by TU/e). At the same time, students individually complete an assignment in which they reflect on their personal development. They indicate for each ILO which level they have achieved, and elaborate on their choices by answering one open question. Assessment of the reflection will be based on two components. The first is the extent to which the indicated levels on individual level correspond with the quality of the work on group level. The second is the quality of the elaboration on the reflection itself (i.e. showing a deeper understanding of one's own capabilities and what is needed to reach the next step would make a student get a more positive assessment).

Our expectations are that students will become intrinsically motivated to study for the course, as the process focus will nudge them into obtaining a growth mindset. This will be evaluated by measuring students' mindset several times throughout the course (at the start and at the end, and one or two more times in between). We expect that the educational approach of the course will foster more growth mindsets, which ultimately could spill over into other courses in the program, preparing students for a successful educational path.

ABSTRACT

This article deals with research focused on exploring the efficacy of virtual reality (VR) in maintenance training within a large mechanical engineering company. It highlights the research collaboration in pedagogical issues between a technical university of applied sciences (UAS), a pedagogical university, and an industrial company, marking a departure from traditional research topics focused mainly on technical problems and processes. The study involved BSc engineering students from the UAS as participants in an experimental pedagogical research project conducted at the Case Company during academic year 2023-2024, with the primary researcher affiliated with a pedagogical university. Three groups of students were

[1] *V.Shokati*
vida.shokati@abo.fi

trained each with a different instructional method, one being the VR training. Data collection encompassed both qualitative and quantitative methods, with subsequent analysis aimed at assessing the effectiveness of VR in facilitating learning of technical maintenance tasks. The preliminary results of the semi-experimental study at Case Company showed that overall, the VR learning group (8.00 $p \leq 0.05$) had better practical skills learning outcomes in overhauling engine pistons compared to the distance learning group (3.00 $p \leq 0.05$) with the hands-on learning group (13.00 $p \leq 0.05$) getting the best results. Nevertheless, the quantitative data analysis also revealed that the VR group performed equal or worse in some practical skills variables compared to the distance learning group. The qualitative assessment revealed the potential reasons for the underperformance of VR group compared to the other groups, where students' feedback highlighted the strengths and weaknesses of VR complemented by suggestions for improvement.

1 INTRODUCTION

With the continuous development in technology, we are also facing a new era in education. Nowadays, there are different forms of immersive technologies that can make learning more engaging. As shown in Figure 1 on this page, Extended Reality (XR) is a label commonly used to categorize different types of such digital experiences. In this domain, there exists Virtual Reality (VR), a technology generating interactive virtual surroundings, Augmented Reality (AR), a technology overlaying virtual data onto the real world, and Mixed Reality (MR), blending aspects of VR and AR in one interface. Interest in XR has surged in Higher Education (HE) recently. Engineering stands out as the primary area within HE utilizing this technology for research, with 24% of research papers focusing on it. Various disciplines in engineering benefit from XR applications, such as manufacturing training, workshop safety, fluid dynamics, electrical principles, and chemical/biological simulations. XR has gained significant attention in higher education due to the numerous advantages it provides to the learning process, including enabling individuals to explore knowledge and surroundings using unconventional approaches not typically available through traditional means (Bangert et al. 2023).

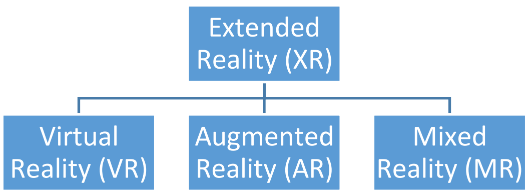

Fig. 1. Immersive technologies

In this study, we are focused on VR and not other forms of similar immersive technologies. VR is a virtual environment that is created using computer technology and is designed to simulate real-world experience. This technology allows users to interact with and explore a 3-dimensional environment, enhancing the learning experience. It has been widely used in a variety of fields including gaming, entertainment, healthcare, and education. VR in engineering education has gained significant attention in recent years due to its potential to improve the teaching and learning experience (Soliman et al. 2021).

VR technology allows students to immerse themselves in realistic and interactive virtual environments, providing them with hands-on experience and practical training (Marougkas et al. 2023). VR offers a dynamic and immersive learning environment for students in engineering education. It enables them to visualize complex concepts, simulate real-world scenarios, and manipulate virtual objects, fostering deeper understanding and problem-solving skills. Additionally, VR can enhance collaboration and communication among students, as they can interact and work together in the virtual environment. Furthermore, VR provides a safe and cost-effective alternative to traditional hands-on training methods.

Instruction with VR lies on various theoretical frameworks, learning theories, and educational approaches (Marougkas et al. 2023) with constructivism learning, experiential learning and gamification of learning being probably the most dominant ones. For instance, constructivism posits that individuals construct their own understanding and knowledge of the world through experiences and interactions with their environment. In the context of VR, this theory suggests that learners can construct their own knowledge and understanding of a subject by interacting with a virtual environment. This type of learning experience can be particularly effective, as it allows learners to engage with the material in a hands-on and immersive way, which can lead to deeper understanding and retention. In addition, experiential learning in VR can provide opportunities for trial and error without the consequences that might be associated with real-world mistakes. This can be especially beneficial in high-stakes or potentially dangerous situations, where the cost of failure is high. As such, this risk-free environment allows individuals to push their boundaries and explore new challenges with confidence. Furthermore, gamification of learning can make the learning process more engaging and enjoyable. It can also promote healthy competition and collaboration among learners. As a result, it can lead to improved knowledge retention and a greater sense of accomplishment.

This study aims to investigate the effectiveness of VR in engineering education, specifically focusing on a semi-experimental study conducted at Case Company. The special training center in the Case Company that conducted the study delivers training to its employees and customers. The Case company produces different types of marine and power plant engines. Two of its engines designed for marine applications called W20 and W25 were used in this study.

More specifically, this research aims to evaluate the effectiveness of VR for learning the technical task of overhauling engine piston. The participants will be taught with the following delivery methods: 1) Instructor-led Distance Learning via Teams 2) Instructor-led Hands-on Learning at Training Center 3) Instructor-led VR Learning at Training Center. The purpose is to see which works best in which areas. The researcher will evaluate students based on the following research questions:

RQ(1): To what extent is virtual reality efficient in terms of transferring theoretical knowledge? (understanding and remembering components, understanding the process of overhauling an engine)
RQ(2): To what extent is virtual reality efficient in terms of transferring practical skills knowledge?
Several other studies (Ma, Zhang, and Wu 2022; Amin et al. 2022; Athik Nagappan and Shobithraj 2022; Mojica-Irigoyen et al. 2023; Taghian et al. 2023; Sánchez-López et al. 2024; Wong and Humayoun 2022; Jalil et al. 2022; Kumar et al. 2021; Bhatia and Hesse 2023; Ivanova, Ivanov, and Zdravkov 2023; Asham, Bakr, and

Emadi 2023; Ghazali et al. 2024; Han 2023) in this area have shown positive outcomes, suggesting the effectiveness of VR in engineering education. However, to the best of our knowledge, no dedicated study has done such a comparative experiment. We aim to fill this research gap by comparing teaching with VR to two other traditional ways of maintenance training. As the results related to the first research question are not ready yet, we are reporting only the results of the second research question in this article.

2 METHODOLOGY

2.1 Study Design

The research uses mixed methods approach. As shown in Figure 2 on this page, the participants answered surveys both before and after the training received in the delivery methods. Some of the participants were also interviewed and qualitative data was collected.

The research has a semi-experimental design. There is no random assignment, or control of other variables that might affect the experiment.

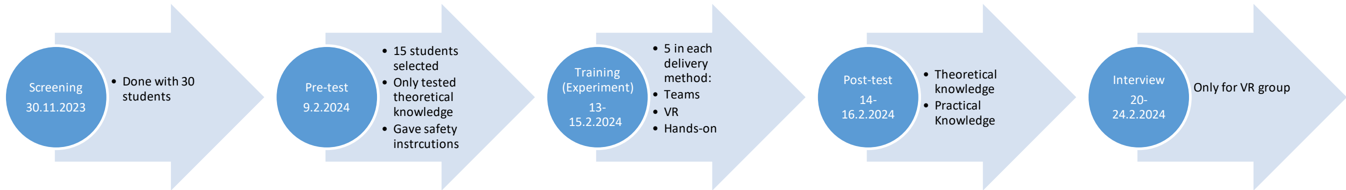

Fig. 2. Five main stages of study

The independent variables in the study are instructional methods: virtual reality (VR), face-to-face and distance teaching mode. The dependent variables are theoretical knowledge and hands-on skills on an engine maintenance task which was chosen to be overhauling the engine piston. The training content was based on the engine W20 for those coming to the hands-on facility for face-to-face session. For the VR group, the engine W25 was the only option for the training as that is the one which has been modelled for the virtual reality. For the distance group, the instructor used the available videos of some older engines from the video database of the Case Company. Still, all the face-to-face activities for the evaluation phase was based on the W20, purely for the safety reasons.

The collecting tools (screening survey and pre/post-test survey) was a researcher-made instrument. The process of designing, developing, and validation was as follow: first, the tools were made with collaboration of a research team consisted of the researcher, the expert/instructor from the company with extensive knowledge and experience about the engine, and an expert in research methods and pedagogical studies. Second, in line with the research questions, the relevant dimensions of practical and theoretical knowledge necessary for the training were identified by the expert of the engine and the researcher. Third, the identified elements were transformed to the tools for collecting data with the collaboration of methodological and pedagogical expert. Fourth, for the content validity of the tools, they were assessed by the exerts from the company to see if the tools measure what (theoretical and practical knowledge about engine) they claim. Fifth, for the face validity, and before the main administration, the tools were given to a few students from the same population (not the same sample) to see if they fully understand the questions in surveys. The final recommendations were integrated into the tools to be used for the study.

As shown in Figure 2, this research has five stages: 1) Screening 2) Pre-test 3) Experiment 4) Post-test 5) Interview.

In screening, measuring the background of students in terms of main dependent variables was necessary. The researcher screened the students with the help of a screening survey and put them in different groups based on their answers. To that end, students answered a survey on Microsoft Forms based on theoretical knowledge and practical skills of overhauling engine piston. The practical skills have only been inquired theoretically and students were not required to perform their skills. The purpose of the screening was to rule out any students who had too much or too little knowledge about the engines. The first phase of data collection (screening data) was completed with thirty BSc engineering students visiting the Case Company on 30.11.2023.

In pre-test phase, students were tested for theoretical knowledge on overhauling engine piston. The post-test was the same as the pre-test and it was given after the training was completed. To that end, they have answered a standardized level test on Microsoft Forms. For testing practical skills knowledge, pre-test could not be used. It was unsafe and would influence the actual test results. The expectation was that there is zero practical skills knowledge as the topic was Case Company specific and the test persons were students.

In the experiment phase, there was training for both theoretical and hands-on skills knowledge on overhauling engine piston.

In the post-test, students were tested for both theoretical and hands-on skills knowledge on overhauling engine piston to see the effect of the training. There was only one instructor to deliver the training. However, for evaluating practical skills knowledge, we had to have at least two mechanical instructors to ensure safety and more valid results. The practical skills knowledge was scored based on a rubric designed within the Case Company. It has gone through validation by at least two mechanical instructors.

In addition, some qualitative test data was also collected when the researcher interviewed the VR group after their training. The interview questions addressed the quality and effectiveness of the VR instructional method.

2.2 Study Population

Thirty students studying BSc degree in Energy Technology at a UAS have participated in this study. They were screened to fifteen students in the screening phase. In the experiment, there were five students per instructional method. The inclusion criterion was that students should not have completed any training related to the engines of the Case Company or worked in the Case Company before. The ideal scenario was that the participants did not have extensive background knowledge or experience about engines or piston overhaul to evaluate the effect of the delivery methods. Similarly, field service workers were not suitable participants either since they had been working already with engines.

Even though students were above eighteen, we had to consider these steps for following research ethics: First, we provided honest information about the purpose of the study; Second, we informed the participants that participation is voluntary; Third, we provided information about anonymity; Finally, we gave information on how we plan to store the data during the study.

2.3 Method

The researcher has evaluated the screening survey results with SPSS. Homogenous sampling was used to attain a sample of similar cases in the screening phase. The screened participants have similar characteristics so that the group that is the representative sample can be researched in depth. The participants were screened based on their average scores for the five theoretical knowledge and two practical skills assessment questions (See Appendix 1 for part of the survey).

After screening the population, the participants have gone through the training as the intervention in this research. This research is semi-experimental since we could obtain post-test results only. The researcher has further analyzed the data set using SPSS. The data set mainly consists of analyzing ten theoretical knowledge questions (See Appendix 2), and eight practical skills knowledge questions (See Appendix 3). The results of the first research question are yet to come and, in this paper, we only report the results of the second research question. Overall, we reported eight variables based on the practical skills knowledge and we also computed a new variable based on their average score. The researcher analyzed the data using the Kruskal-Wallis test. It is a nonparametric (distribution free) test and evaluates data ranks. It is used when the assumptions of one-way ANOVA are not met.

2.4 Procedure

In the pre-test, some students attended in person, while others participated online. The instructor provided safety instructions on the same day. The actual research happened in 2024 (See Figure 2). There was preparation, training and then testing of students. The training sessions for each group, and theoretical and hands-on tests were at least around four hours each including the breaks. The tests happened on one day with the practical test following the theoretical test. The distance learning group followed their training remotely and they only came for the tests to the Case Company.

The instructor from the Case Company gave the technical training using three different delivery methods: 1) Distance Learning via Teams 2) Hands-on Learning at Training Center 3) VR Learning at Training Center. The researcher was not the instructor, but she was present when the instructions were delivered. Students were divided in three different groups, and they were receiving training with these delivery methods. Only one group was trained with VR since we wanted to see the effectiveness of VR compared to other methods.

As shown in Figure 3, after the training, on the next day, there were tests to see how well students performed the tasks which were about overhauling engine piston. The researcher was monitoring the theoretical tests that were given to the students.

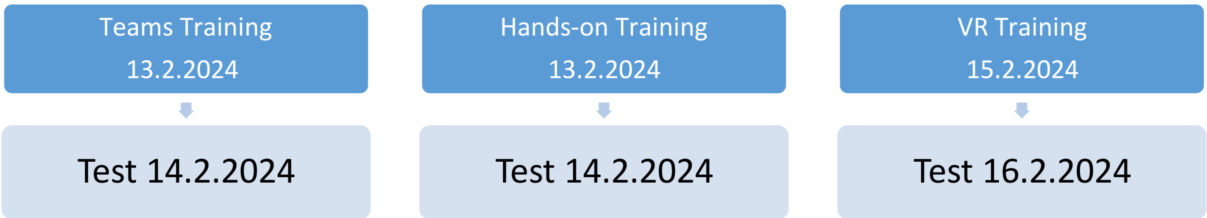

Fig. 3. Training and post-test schedule

The practical skills knowledge test was conducted by the Case Company instructor. Like the instruction phase, the researcher was present in the testing situation.

3 RESULTS

In this chapter, we have analyzed data in line with the second research question we posed. The results are organized in two sections: 1) Inferential Analysis Report 2) Interview Results.

In the inferential analysis, the main goal was to see how effective the intervention, teaching with VR, was in enhancing students' learning about engine overhauling compared to distance and hands-on groups. As such, we analyzed the practical skills knowledge of students after training (post-test).

3.1 Inferential Analysis

Our second research question (RQ2) aimed to evaluate the extent to which virtual reality is efficient in terms of transferring practical skills knowledge.
As shown in Table 1, we have summarized the results based on the nine variables that we had for measuring the effectiveness of instructional methods in terms of transferring practical skills knowledge.

We hypothesized that there were no significant differences among three groups in terms of the nine variables in engine overhauling after experiment (H0). A Kruskal-Walli's test was performed on the scores of the three groups (VR, Teams, Hands-on). The differences between the rank totals of the three groups were statistically significant, H (2, n = 15) = 14.000 p ≤0.05. This means that the null hypothesis was rejected. In other words, there was a significant difference between the three groups in terms of the nine variables in engine overhauling after experiment.

Table 1. Instructors' practical skills knowledge evaluation

Variables	Instructional methods	Mean rank	Sample size (n)
Correct selection of parts	Teams	8.00	5
	VR	3.00	5
	Hands-on	13.00	5
Correct selection of tools	Teams	5.50	5
	VR	5.50	5
	Hands-on	13.00	5

Job safety analysis	Teams	3.00	5
	VR	8.00	5
	Hands-on	13.00	5
Work safety	Teams	5.50	5
	VR	5.50	5
	Hands-on	13.00	5
Process executed in correct order	Teams	3.00	5
	VR	8.00	5
	Hands-on	13.00	5
Applying the use of manual	Teams	8.00	5
	VR	3.00	5
	Hands-on	13.00	5
Work done autonomously	Teams	5.50	5
	VR	5.50	5
	Hands-on	13.00	5
Timing of the work	Teams	3.00	5
	VR	8.00	5
	Hands-on	13.00	5
Practical skills knowledge average score	Teams	3.00	5
	VR	8.00	5
	Hands-on	13.00	5

3.2 Interview Results

We summarized the interview results based on the following five interview questions:

1) What do you think about the quality (effectiveness) of the teaching method you experienced?

2) What were the strengths of the teaching method you experienced? What was good about it?

3) What were the weaknesses of the teaching method you experienced? What were the inefficiencies/problems?

4) Did the training method you experienced meet your expectations?

5) Do you have any suggestions for the improvement of the teaching method you experienced?

Here, we have explored the key takeaways:

- Interviewee one found the visual and interactive nature of VR learning was effective for understanding complex concepts like engine components, although she experienced discomfort after prolonged use. She suggested more training time.
- Interviewee two also had a positive experience with VR, improving awareness of complex systems but faced challenges like headaches. He suggested making the training easier to use and recommended taking regular breaks.
- Interviewee three appreciated the immersive experience of VR training for machine assembly but noted the potential for dizziness with prolonged use. He also suggested more training time.
- Interviewee four praised the interactive learning process with VR but pointed out issues with tool handling, teleporting objects, and connection issues when collaborating with multiple team members in the VR setting.
- Interviewee five highlighted the detailed view and ease of use in VR training and its time-saving benefit. However, he also noted the difficulty translating VR experience to hands-on tasks, especially tool selection, as real-world situations involve more detailed knowledge and complexity. He suggested adding more instruments to simulate specific tools for specific tasks in the program and emphasized the need for pre-training on using VR tools to avoid time constraints during actual sessions.

4 CONCLUSION

This study collected both qualitative and quantitative data to evaluate how effectively VR facilitates learning of technical maintenance tasks. Unlike conventional research, this study emphasized collaboration between a UAS, a pedagogical university, and an industrial company. Based on our experience, we suggest more of these types of collaborations for future studies in similar topics.

The qualitative findings of this study align with previous research in this area, emphasizing the potential of VR to create a dynamic and immersive learning environment for engineering students. The ability to visualize and interact with 3-dimensional models, simulate real-world scenarios, and collaborate with peers in a virtual space has been shown to enhance the overall learning experience.

The quantitative findings of this study, however, showed that the VR group performed the same in practical skills variables like correct selection of tools, work safety, and work done autonomously compared to the Teams group. In some other cases like correct selection of parts and applying the use of manual, the VR group had even a poorer performance compared to the other groups. The hands-on group did the best in all the practical skills variables. Based on these results, we suggest a combination of different instructional methods for better learning results. Future studies could work on finding the optimal combination.

This study had a few limitations that can be a basis for further research and should be considered by other researchers. First, we had limited time to be able to test all the participants for practical skills knowledge and give individual scores, so we could only give group scores. Second, we should point out that the engine type for VR intervention was different from other training types and this could be one possible factor that affects our sample's learning performance. We suggest, for further research, the researcher use the same engine type for all training types to control this issue. More specifically, the only engine type available in the VR was W25. With further development, more engines can be simulated in the VR environment. There is a chance that engine design might affect the difficulty level of maintenance task. The engine type affects the results, but it is hard to tell how much the design for W20 and W25 affects the results since this study was the first one done with the VR in the Case Company. Third, the intervention (the training type administration) was too short, and the sample may not fully have experienced the learning environment of each training type, particularly teaching with VR. A longer intervention is required to scientifically study and compare the learning environment of each training type and its effects on practical knowledge of the students.

For engineering education, our results indicate that both virtual and practical skills training need to be included while virtualizing engineering labs. Laboratory courses can be virtualized, but we still need to keep the hands-on training to some extent. In the higher education, the extent to which laboratory courses can be virtualized should be further researched. In summary, this study has provided us with useful insights into using different types of training in engineering, however we need to be careful about generalizing the results to other contexts because this study relied on one Case Company and its VR technology. More research is required to deal with the above-mentioned limitations.

APPENDIX 1: SCREENING SURVEY

Theoretical Knowledge Assessment

This is added in Microsoft Forms as a subtitle: ***Instruction on the scaling system:*** *On a scale from 1-5, please rate your experience with engines (theoretical knowledge and practical skills) from questions 6 to 13. A score of 1 indicates no experience, while a score of 5 signifies extensive experience as follows:*

1. *I have no knowledge or skills about engines.*
2. *I know a few basic facts or skills about engines.*
3. *I have a fair amount of knowledge or skills about engines, but there's more I could learn.*
4. *I have a strong understanding or skills of engines and how they work.*
5. *I have a comprehensive understanding or skills in engines, including complex concepts and mechanics.*

Q1: How would you rate your theoretical knowledge about engines?

Q2: How would you rate your knowledge of the four-stroke engine working principle?

Q3: How would you rate your knowledge of main engine components?

Q4: How would you rate your knowledge of engine piston function?

Q5: How would you rate your knowledge of the process of engine piston overhauling?

Practical Skills Assessment

Q6: How would you rate your practical skills of assembling engine components?

This is added in Microsoft Forms as a subtitle: On a scale of 1 to 5, a score of 1 indicates no experience, while a score of 5 signifies extensive experience.

Q7: Have you ever fixed or repaired any type of engines?

1. Never
2. I have only seen how it is done or watched videos of it.
3. I have done it only once or twice.
4. I have done it a couple of times.
5. Fixing engines is my hobby/work.

APPENDIX 2: THEORETICAL KNOWLEDGE SURVEY

#	Questions	Answers
1	Identify following main components:	(picture of engine from engine course at Case Company)

		2	What type of an engine Case Company engines are?	Case Company engines are reciprocating (piston) engines.
3	What three things are needed to create a flame/combustion?	Fuel, air (oxygen), heat (spark)
4	What happens inside Case Company diesel engine cylinder?	Fuel is mixed with hot air, fuel and air reacts chemically and due to the presence of high temperature, the mixture ignites creating combustion. Combustion causes heat, exhaust gases and generates pressure, all of which are different form of energies. Piston is being pushed down via the pressure, some of the heat radiates out and most of the heat is delivered out via exhaust gases. Hot exhaust gases are directed (pushed out) and fresh air is taken in to start the combustion process from the beginning.
5	What are the four main events of an 4-stroke engine working cycle?	Intake (stroke) Compression (stroke) Power (stroke) exhaust (stroke)
6	How are Case Company engines named?	Engine name comes from the cylinder bore. Example: W20 engine means cylinder bore/diameter is 20 centimeters.
7	How do you call the side of an engine where flywheel is located?	Driving end (Flywheel end)
8	What is the function of a flywheel in Case Company engine?	Flywheels are used to provide continuous power output in systems where the energy source is not continuous. For example, a flywheel is used to smooth the fast angular velocity fluctuations of the crankshaft in a reciprocating engine. In this case, a crankshaft flywheel stores energy when torque is exerted on it by a firing piston and then returns that energy to the piston to compress a fresh charge of air and fuel.

9	What are the initial steps to start the engine overhaul process (describe as many as you can, and in correct order!):	1) Stop the engine and let it cooldown. Cooldown duration depends totally on the size of the engine. 2) Engage the turning device. => Make sure engine cannot be restarted. (mechanical and electrical safety aspect) 3) Set engine to service mode from automation system. 4) Drain the cooling water line. 5) Block the fuel delivery line (mechanical isolation) 6) Mechanical lever to "stop" position to block the movement of the fuel rack line. 7) Main starting air valve to be blocked and isolated
10	Arrange following items to correct removal order: Cylinder Liner, Cylinder head, piston, Fuel pipes, Hob box cover, Cylinder head hydraulic connections, Connecting rod hydraulic connections,	1) Remove hotbox covers 2) Remove fuel pipes 3) Remove cylinder head hydraulic connections 4) Remove cylinder head 5) Remove connecting rod hydraulic connections 6) Remove piston 7) Remove cylinder liner

APPENDIX 3: PRACTICAL SKILLS KNOWLEDGE SURVEY

	Group	Outcomes not reached	Outcomes partially reached	Outcomes reached	Outcomes reached beyond expectation	Points	Evaluating instructor:

ABSTRACT

While traditional engineering education emphasizes linear problem-solving techniques, this practice piece offers the “writing-to-engage” method for engineering educators to incorporate writing and design instruction to develop students’ creativity, essential for navigating complex engineering situations. This approach to educating the whole engineer integrates writing and creativity into the engineering curriculum to support the teaching of technical content.

1 INTRODUCTION

1.1 Project context and need

This paper presents writing and design instruction in a sustainability-focused 10-week course required for senior environmental engineering majors at California Polytechnic State University, San Luis Obispo (Cal Poly). Engineering students need to develop creative problem-solving skills when linear problem-solving techniques (well-established

[1] *K.S. Sarraf*
ksarraf@calpoly.edu

in Cal Poly students' previous engineering classes) are inadequate for addressing engineering problems. The pedagogical approach shared in this work-in-progress may inspire discussion among engineering educators, as it emphasizes the writing process itself as a problem-solving technique useful for navigating challenging engineering design situations.

Teaching writing as a problem-solving technique aligns with calls to educate the whole engineer. Engineers need to "understand the social, ethical, cultural, political, and environmental contexts of their work" and begin to develop that understanding in context of their engineering classes (Hitt et al. 2023, p. 457). Engineering programs take many approaches to educating the whole engineer, from hosting guest speakers from liberal arts departments, to hiring faculty with interdisciplinary backgrounds, to encouraging engineering majors to pursue liberal arts minors (Hitt et al. 2023, p. 465). These approaches can be resource-intensive, leading the authors to consider ways to educate the whole engineer within the constraints of an engineering course, and teaching writing and creativity in ways that support the learning of technical content. This work-in-progress piece may inspire engineering educators to experiment with pedagogical approaches to integrating engineering, writing, and creativity.

1.2 Defining writing

For our purposes, writing involves the entire process, from idea generation to production. Writing process activities (e.g., conversations, notes, lists, drawings, etc.) count as writing, as do written products (e.g., reports and proposals). This definition reflects a threshold concept in writing studies: writing is a cognitive (thinking) process that "extends before and after the moment of text production " (Dryer et al. 2015, p. 72). This means that writing is more expansive than "transcribing thought while avoiding error " (Dryer et al, 2015, p. 72). Writing is also a metacognitive process, meaning that writers must "think about their mental processes" (Dryer et al. 2015, p. 76). Since writing requires both cognition and metacognition, we designed activities that would develop both areas for students.

1.3 Defining creative thinking

We offer the following definition of creative thinking that aligns with our focus on environmental engineering and sustainability. Creativity is "the ability to generate new or unique and effective ideas in conjunction with other members of a community to challenge unjust status quos and tackle wicked social justice problems" (Sarraf 2023, p. 3). As Caratozzolo et al. (2019) note, creative thinking is a "metacognitive process" that enables "complex problem solving" and facilitates "a high degree of innovation" (p. 2). As such, developing creative thinking skills and writing skills (as defined above) are complementary activities.

1.4 Relationship between writing and creativity in engineering education

The pedagogical approach offered here is inspired by the Writing as Creative Praxis (WaCP) model of writers' creativity, developed by Sarraf (2020) from their study of workplace professionals' use of writing as a tool to move from reflection to action about wicked communication and disciplinary problems. Essentially, WaCP positions writing itself as a tool to move from creative reflection to creative action, deepening interdisciplinary understandings of the relationship between writing and creativity. WaCP adapts the notion of "critical digital praxis [...] as a form of critical reflection and action in digital media" (Vetter & Sarraf, 2020, p. 5). Praxis involves combining reflection and action to intervene in problems in meaningful ways.

In praxis, reflective writing enhances metacognitive awareness. To exercise creativity, engineering students need to have metacognitive awareness about their own creative thinking processes. Several studies have demonstrated that writing activities promote metacognition, enhance creativity, and improve students' engineering skills (Ford et al. 2021; Gardiner 2020; Gorzelsky et al. 2016; Langer and Applebee 1987; McVeigh et al. 2023; VanKooten and Berkley 2016). Foundational texts such as Emig's (1977) article and Langer and Applebee's (1987) book demonstrated that writing helps students to engage with and integrate course information. Born from this research, the writing across the curriculum (WAC) and writing in the disciplines (WID) global movements have led educators to integrate informal and formal writing in engineering classes.

However, it is important to note that the writing across the curriculum (WAC) and writing in the disciplines (WID) movements take three approaches to the writing/disciplinary-knowledge connection. First, the-writing-to-learn approach prioritizes the use of informal, ungraded writing exercises to help students memorize and understand course concepts. Second, the writing-in-the-disciplines approach teaches students to communicate like disciplinary-experts and write clear technical communication (Andrews et al. 2021; Fleming et al. 2023; Jalali et al. 2022; Londner et al. 2023). Unfortunately, writing-in-the-disciplines requires a large investment of instructor time to teach disciplinary-writing practices. Thus, more recently, a third approach has developed called "writing-to-engage." Writing-to-engage uses both informal and formal writing assignments to help students develop their thinking about a discipline.

Writing-to-engage provides a middle way for instructors (Palmquist 2020). It uses a spectrum of formal and informal writing activities to promote students' cognitive development. Importantly, writing-to-engage activities ask students to "draw on critical thinking skills such as reflecting, applying, and analyzing," engaging in "knowledge transforming" (Palmquist 2020, p. 16). Students reflect, apply, and analyze scenarios, using writing to bridge lower-order skills (like remembering/understanding) and higher-order skills (like evaluating and creating) (Palmquist 2020).

Thus, we explored a writing-to-engage approach to enact the Writing as Creative Praxis model, in which writing is a tool to teach creative problem-solving, communication, and engineering design. The potential innovation is our use of writing-to-engage to enhance *creativity* in engineering. Our writing activities include freewriting and brainstorming, which "records" the thinking process and moves it forward, helping students to "discover, develop, and clarify" their ideas (Bean 2011, p. 120). We also used integrated reflective writing prompts, as reflection promotes metacognition and transfer. As Sheppard et al. (2018) wrote, "Reflective practice is essential for the ability of emerging engineering practitioners to nimbly meet the ever-changing needs they encounter while tackling the world's complex problems" (p. 125). Thus, given that reflective practices help engineers address complex problem-solving, we also integrated reflective activities into our writing prompts. The activities presented in the next section draw on the writing-to-engage movement, bringing this pedagogical approach to the engineering classroom. Further, the activities presented may inspire readers seeking to explicitly connect writing-to-engage to creativity in an engineering context.

2 METHODOLOGY

2.1 Section Overview

Here, we offer our experiences developing writing-to-engage activities that aim to promote creative thinking about environmental engineering problems. Specifically, we describe co-author Outlon's implementation of the co-authored pedagogical approach in their sustainability-focused 10-week course. As this paper's goal is to provide inspiration for teaching and directions for future research, we present the teaching activities that occurred over five weeks as a sampling of possible approaches to writing–to-engage methods. The authors plan to develop a mixed-methods study based on this work-in-progress to further examine the efficacy of these pedagogical approaches in comparison to previous years without these activities.

2.2 Assignment and activity overview

The authors first met to adapt the exercises from an assignment Sarraf designed for her technical and professional writing courses, which included both science, technology, engineering, and math (STEM) and liberal arts majors. Then, to help develop students' creative problem-solving skills, Oulton incorporated a series of writing and design exercises into the engineering course.

The engineering course was structured to develop and apply creativity skills, teamwork skills, communication skills, and technical skills simultaneously. In this way, the course epitomizes the goal of "educating the whole engineer." Essential to this goal is reinforcing with students the understanding that engineering is not just a technical profession, but a creative and communicative one as well. At its core, engineering is about creating and communicating solutions, and there may be myriad valid approaches to develop, optimize, and amplify those solutions. Embracing creativity, teamwork, and communication are necessary for developing innovative technical solutions.

With those goals in mind, the culminating experience of the course is preparation of a technical report and presentation for a real world client to provide recommendations to improve an existing process. Students work in groups over the entire ten-week quarter to prepare their project. Creativity exercises were incorporated throughout the quarter to scaffold students' creative thinking processes as they worked on their projects.

While most of the creativity exercises were not explicitly related to the project or engineering, each lab ended with a writing reflection and/or a talk back with the class, to emphasize the relevance of the exercise and its application to students' engineering development and creative thinking skills. Thus, students made explicit connections between creativity, writing, and engineering. The objective was that these individual and/or group metacognitive writing reflections would facilitate skill development through explicit reflection.

The writing-to-engage exercises described below were intended to progressively develop creative thinking and problem-solving skills through group activities and individual or group writing assignments. These initial creativity exercises were conducted during a three-hour laboratory class each week for five weeks. Other creativity exercises were offered throughout the quarter; we limit the present focus to five weeks for illustrative purposes and to meet the constraints of this particular practice piece.

- Week 1: The creativity exercises began with a divergent thinking exercise in which students played improvisational games where they were limited to using only one communication skill: verbal, visual, or body language. This low stakes activity was designed to build teamwork and emphasize the value of combining verbal, visual, and other means to communicate ideas in engineering. Students reflected individually on their experiences with the games to increase their metacognitive awareness. They also reflected via a class talk back about the importance of varied communication skills in engineering.
- Week 2: Students engaged in a series of storytelling activities in which they collaborated in different ways (linear, non-linear, and convergent) to build a story inspired by work of art. The intention of this activity was to develop team cohesion and collaboration skills while using various modes of "design" to create a group outcome. A post-activity reflection focused on the value of storytelling to engage nontechnical audiences when communicating engineering ideas.
- Week 3: This week, exercises started to connect more explicitly to course content: students worked in small groups to develop educational materials to explain an aspect of the wicked problem of climate justice to a group of younger students (first-year college students through elementary/primary students, at the group's choice) and inspire those younger students to engage with and think critically about the issue.
- Week 4: Students worked in small groups to propose conceptual stormwater infrastructure improvements for selected locations on campus. Again, the challenge combined technical considerations with creative thinking to reconceptualize an existing and familiar location to achieve a specific goal, and communication skills to present their conceptual design effectively.
- Week 5: This series of exercises culminated in a Design Charette intended to facilitate creative problem solving focused on their team design project (culminating experience) for the course. The Design Charette is discussed further below.

Similar creative engagement activities continued throughout the course; generally focused on specific class topics. While games and storytelling may at first seem irrelevant to engineering, they help build essential engineering skills such as communication skills and team building while taking minimal time from class. Primarily, these introductory creativity exercises established the class as one that will challenge students to take risks and helped students build comfort with non-traditional approaches to problem solving in a low-stakes environment. Further, each exercise combined creativity with communication and asked students to make explicit connections to engineering practice.

2.3 Activity Spotlight: Design Charette

Here, we highlight the Week 5 activity, a Design Charette, offering it to readers for its integration of writing, design, and creativity skills focused on a specific engineering design challenge.

Design Charrettes are long standing practice in both Architecture and City Planning, though the two fields practice charrettes differently. In City Planning, and increasingly in related fields such as Civil and Environmental Engineering, Design Charrettes are intended to allow for multiple stakeholders from different fields to work together to develop potential project solutions. Design Charrettes typically involve some divergent thinking practices (such as brainstorming) to develop a large number of ideas, followed by convergent thinking practices (such as ranking or grouping ideas from the brainstorming session) to hone the ideas to those most feasible for a solution.

Engineering students completed the Design Charette during Week 5's lab. By this time in the course, students had become familiar with the background of the project and had developed a solid technical understanding of the client's challenges. The goal of the Design Charette was to develop ideas for solutions to those challenges that the student groups would develop for the remainder of the quarter.

The Design Charette for the class followed established Charette practices, though with an accelerated time scale to fit into the class period:

- Divergent Thinking Activity. First, student project teams were directed to spend 30 minutes on a series of visioning or brainstorming activities to generate ideas without judgment. Each team used a white board to record ideas, and they were instructed to rotate recorder responsibilities at least every ten minutes.
- Research Activity. During the second phase (1 hour), students worked in pairs to research the feasibility of the proposed ideas. Groups were tasked to decide collaboratively, while keeping an open mind, which ideas were worth researching. If even one member of the group felt an idea was worth further investigation, the group included the idea in their research activities.
- Convergent Thinking Activity. The final phase was a discussion (45 minutes) for groups to refine their list of ideas to no more than six, with the ultimate goal to include three well-developed proposals in the final report. The Design Charette ended with an individual commitment to "next steps" by each team member.

3 INSTRUCTOR TAKEAWAYS

Here, we share instructor takeaways from implementing these activities, with the goal to provide inspirational value for future project iterations.

3.1 Hold short brainstorming sessions

Time constraints can encourage rapid-fire brainstorming and help reduce inhibitions. During the Design Charrette, the engineering students struggled with the extensive length of time required for continued brainstorming. Several groups were ready to move onto research after approximately ten minutes, when the easy ideas started lagging. They were encouraged to use all thirty minutes and to lean into creative or even ridiculous suggestions, and let that process inspire more reasonable options. All of the groups successfully continued to develop ideas for the requisite time period, though it became a struggle for most groups by the end. Instead of a single, long brainstorming session, instructors can encourage students to engage in short, sprint-like brainstorming sessions to reduce fatigue and enhance ideation.

3.2 Conduct research to move from divergent to convergent thinking

The engineering students were more comfortable with the research phase, as this is familiar territory for senior-level engineering students. The research informed their group convergent thinking as they were able to merge or hone their list. While most student groups focused on honing to those most practical or most feasible, some groups retained at least one “creative” idea that they thought was worth further development.

3.3 Showcase rejected ideas

Convergent thinking necessarily requires students to select the most effective and feasible idea from a list of many possible ideas. However, convergent thinking is limited by students’ notions of effectiveness and feasibility. Incidentally, sometimes students may embrace an idea that is practical but less novel than rejected ideas. Thus, we recommend that instructors give students space to showcase and share the ideas that their teams rejected during the convergent thinking phase. For example, in Oulton’s class, students wrote a Design Report based on the ideas that their team selected from the initial brainstorming and research phases. Oulton asked students to include team-rejected ideas in an appendix to their reports. Interestingly, it was these creative ideas housed in the appendix that the real-world clients were most interested in when students presented their work. Despite the apparent infeasibility of the rejected ideas to the students, the clients drew inspiration from the unique solutions, rather than the more traditional solutions presented by most teams.

4 CONCLUSION

Engineering is a creative and communication-based profession, in addition to being a technical one. Integrating a writing-to-learn approach that uses low-stakes creativity exercises such as the Design Charrette allows students to learn technical material while they develop their communication, creativity, and broader critical thinking skills in the context of their engineering courses. Rather than considering writing and creativity as practices relegated to their GE classes, students may learn to recognize that these are essential skills for their engineering practice as well. Educators may use the ideas presented in this paper to develop their own writing-to-engage activities. Future research will examine the efficacy of these and other writing-to-engage activities in engineering classrooms.

ABSTRACT

In this practice paper, we propose a framework for integrating AI into disciplinary engineering courses and curricula. The use of AI within engineering is an emerging but growing area and the knowledge, skills, and abilities (KSAs) associated with it are novel and dynamic. This makes it challenging for faculty who are looking to incorporate AI within their courses to create a mental map of how to tackle this challenge. In this paper, we advance a role-based conception of competencies to assist disciplinary faculty with identifying and implementing AI competencies within engineering curricula. We draw on prior work related to AI literacy and competencies and on emerging research on the use of AI in engineering. To illustrate the use of the framework, we provide two exemplary cases. We discuss the challenges in implementing the framework and emphasize the need for an embedded approach where AI concerns are integrated across multiple courses throughout the degree program, especially for teaching responsible and ethical AI development and use.

1 INTRODUCTION

Computing and computing education have become an integral component of the engineering profession and engineering education. Topics such as programming, data analysis, and computational sciences are now commonly taught in the engineering curricula (Malmi and Johri 2023; Raj et al. 2019). In recent times, the field of artificial intelligence (AI), encompassing domains like data mining, machine learning, natural language processing, large language models, and transformers, has also begun to impact engineering (Broo, Kaynak, and Sait 2022; Johri 2020; Mustapha, Yap, and Abakr 2024). Consequently, in addition to computing literacy or computational thinking skills, it has become necessary to integrate these topics within engineering curricula and pedagogy (Magana, Falk, and Reese Jr 2013).

Given the expansiveness and ever-evolving nature of AI as a field with diverse applications, comprehending the specifics of AI education, including what and how they should be taught, is a challenging task for educators. Recently, there have been several efforts towards defining AI literacy as a basic set of competencies integral to for acting in an AI-driven professional environment (Long and Magerko 2020; Laupichler et al. 2022). Several studies have proposed generic competencies in AI (Laupichler et al. 2022; Ng et al. 2021) that cut across disciplines but increasingly there is an emphasis towards a more discipline-based approach. For instance, Stolpe and Hallström (2024) proposed AI literacy for technology education, Knoth et al. (2024) outlined an assessment matrix spanning from generic to domain-specific AI literacy and Schleiss et al. (2022) proposed an interdisciplinary competence profile for AI in engineering, that highlights the intersection of disciplinary and AI knowledge and skills.

While several teaching approaches and implementations have been proposed and tested (Isaac Flores-Alonso et al. 2023; Singelmann and Covarrubias 2023; Ng et al. 2023), the adoption of AI literacy in engineering education has not received much focus. Consequently, educators are challenged with identifying relevant competence constructs in the context of their disciplinary domain. Since AI in engineering is largely application-oriented, it is important for educators to understand the disciplinary and interdisciplinary contexts of these applications. At the same time, educators in engineering education do not always have a background in AI and their domain, making it difficult to identify the relevant competencies and building a barrier to integrating AI education into the disciplinary teaching offers.

To address the gap of clarity in relevant AI competencies, we propose a role-based approach that integrates AI literacy and competency to assist disciplinary faculty with identifying and implementing AI competencies within engineering curricula. In particular, we focus on the question of how to identify and select relevant AI competencies for discipline-specific AI education in engineering education. The paper builds on prior work related to AI literacy and competencies within the literature and on emerging research on the use of AI in engineering. To situate prior AI literacy frameworks within an engineering context, we take a roles-based approach. Our framework focuses on the use of AI by a specific actor within the engineering context and how this leads to the need for integration of a distinct AI competency within the curriculum. We inductively analyze case studies of the use of AI in engineering to understand emerging patterns and translate findings from literature into a practical and usable framework for educators.

Overall, this study aims to contribute to integrating AI education in engineering education across disciplines (Laupichler et al. 2022; Schleiss et al. 2023; Patel et al. 2021). In the following, we first introduce related work on AI literacy definitions and competencies and the roles-based approach that provide the base to our framework. Next, we describe the cases and inductively develop the **r**oles-based **c**ompetency for **AI** in **e**ngineering or RCAIE framework. Last, we discuss our findings and provide conclusions.

2 RELATED WORK

2.1 AI Literacy Definitions and Competencies

With the field of AI literacy being a novel and growing research field, there exist many definitions of AI literacy aiming at different target populations, purposes or from different disciplinary perspectives (Long and Magerko 2020; Laupichler et al. 2022; Ng et al. 2021; Stolpe and Hallström 2024; Knoth et al. 2024). Most prominent is the definition of Long and Magerko (2020) who define AI literacy as “a set of competencies that enables individuals to critically evaluate AI technologies, communicate and collaborate effectively with AI, and use AI as a tool online, at home, and in the workplace” (p.2). To bridge the gap between definitions of AI literacy to educating these competencies, several conceptual frameworks exist (Almatrafi, Johri, and Lee 2024). In their literature review, Almatrafi, Johri, and Lee (2024) identified six core constructs that form AI literacy: (1) *Recognize (Be Aware)* different types of AI applications as a basis to enable informed interactions, (2) *Know and Understand* fundamental concepts and techniques of AI, (3) *Use and Apply AI* applications and tools to solve tasks or achieve an objective, (4) *Evaluate* as the “ability to analyze and interpret the outcomes of AI applications critically”, (5) *Create* as the ability to design and code AI applications, (6) *Navigate ethically* refers to understand ethical and social implications and become a responsible user of AI. These categories form an understanding of the core constructs of AI literacy and can be used as an analysis lens as well as to identify disciplinary-specific AI literacy constructs. Given the extensive systematic review on which this list of constructs rests, we utilize them as a core part of our framework but extend them towards domain-specific competencies in the context of roles and use-cases in engineering education.

2.2 Roles-based Approach to Competencies

Roles-based approach, although new to engineering, has widespread acceptance within another professional field – medical education. The approach has been applied both to roles in the profession that students need to be prepared for and for better understanding roles played by faculty as educators. For example, Harden and Crosby (2000) argued that given the changing and complex role of teaching in medical education, it was important to categorize these roles so that teachers or educators could identify what kind of expertise they needed in the medical field and in their roles as teachers. Whitehead et al. (2014), further argue that although more work needs to be done, the use of roles to describe competencies and build competency-based frameworks is now the norm in medical education reflecting “a conceptual shift in understandings of medical education from a process representing one of knowledge acquisition and time-based clinical rotations, to one in which competence can be considered as the adequate performance of a set of professional roles" (pg. 786). Similarly, Cenkner et al. (2017) identify six roles for an educational technology expert and for each role describe the corresponding competencies and give examples of activities that someone playing that role engages in.

In summary, a roles-based approach makes it easier for those who are new to a topic or area to approach it and have a guide or mental model of what it looks like including the responsibilities and objectives. The encapsulation of the knowledge as a role makes it task based and thereby easier for a newcomer to grasp given the alignment with practice. For this paper, we have created roles as group-level constructs meaning that roles define or identify groups of professionals who are "guided in their domain of practice by an established set of heuristics for thought and action (McClarey 2004; pg. 4)."

Professionals performing a certain role require a specific set of knowledge or expertise. The knowledge needed to perform a given role is known as 'role knowledge' (McClarey 2004; pg. 12). We adopt this approach towards examining roles that professionals in the workplace can play in relation to AI and what this means for what students need to be taught to be prepared for the workforce. In this initial mapping, we develop a broad conceptualization that can be expanded and defined more precisely through future work.

Within the literature on AI literacy, a roles-based approach has found resonance. Faruqe, Watkins, and Medsker (2021) distinguish between four groups of users with different depth of contact and competency requirements: (1) consumers, the general public and policymakers, (2) co-workers and users of AI products, (3) Collaborators and AI Implementers, and (4) creators of AI. Similarly, Schüller et al. (2023) distinguish between (1) informed prosumer, (2) skilled user, and (3) expert creator and developer. These roles correspond with different skill profiles within the industry such as AI Management, ML Architect, Data Engineer, Data Governor, Product Owner, Data Analyst, Data Architect, Data Steward, Data Scientist and ML Engineer (Machado and Mynter 2024). Given that this is an emergent area and there has been no rigorous analysis of AI-related roles for engineers, we synthesized three broad roles that we believe can provide guidance for knowledge assessment and skills development: a) consumer; b) user; and c) creator and developer. These roles in conjunction with the AI literacy constructs stated above provide us with a framework to describe the knowledge needed for AI integration within engineering.

3 RCAIE Framework and Case Studies

Overall, the **R**oles-based **C**ompetency in **AI** for **E**ngineering (RCAIE) framework builds on three pillars of use cases, roles and competencies (see Figure 1) and acts as foundation to identify suitable learning experience.

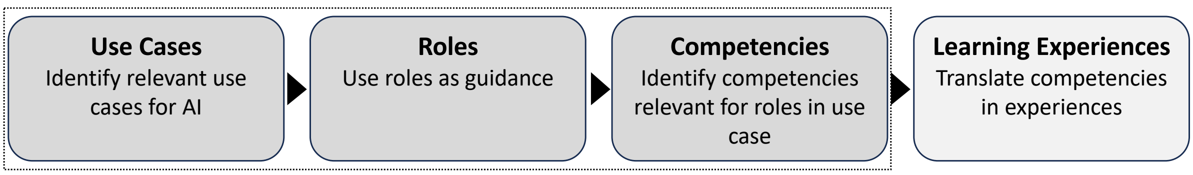

Figure 1: Process to identify competencies with the RCAIE framework

Given the wide application area for AI in engineering, we selected two exemplary case studies that help us explicate and describe the RCAIE framework in use. We have deliberately selected cases that are applied, in the sense that they are relevant to industrial applications, as opposed to AI research.

Case 1: Predictive Maintenance

Predictive Maintenance describes at its core the idea of optimizing the maintenance process by predicting and preventing machine failures proactively (Dalzochio et al. 2020; Lee et al. 2019; Hrnjica and Softic 2020). Found often in manufacturing environments but also in transportation or civil engineering, the goal of predictive maintenance is to minimize unplanned downtime, improve management of spare parts and repairs and enhance the overall equipment effectiveness (Dalzochio et al. 2020).

Different data sources can be used to bring the scenario to life. This can include machine condition data, historical maintenance records, real-time operational data from sensors or environmental factors like temperature or humidity. To use the thought frame introduced earlier, the goal is to infer and monitor the “health condition” of a machine by assessing different sensory inputs and historical data to anticipate and respond to potential problems (Lee et al. 2019). As the name suggests, predictive maintenance moves from reactive maintenance (“fix when it is broken”) and periodic, scheduled maintenance towards using AI capabilities to predict machine failures (Hrnjica and Softic 2020). From a data perspective, the theoretical underlying concepts include time-series data from log-data or even sensory inputs. From an AI perspective, multiple approaches might be useful, from statistical analysis to more advanced models working on time-series data.

Case 2: Quality Control and Testing

Often seen in manufacturing processes, quality control and testing with AI describes the idea of using AI-based solutions to automatically detect defects in an assembly line or inspect quality requirements at a scale. The goal is to increase the overall product quality and reduce defects through higher test coverage. Depending on the product and manufacturing process, various data sources can come into play, mapping to the steps a human inspector would test to ensure quality. Most commonly advanced computer vision algorithms are being used in visual inspection scenarios (Fahle, Prinz, and Kuhlenkötter 2020). Overall, the quality controls can also be embedded into a bigger picture using them as data inputs to predict the overall quality from design factors, manufacturing parameters, sensory data and quality checks (Tercan and Meisen 2022). Thus, the initial goal of quality control is assessing the quality or identifying defects but this can also be used to infer further actions.

RCAIE Framework

Table 1 depicts the elements of the RCAIE framework for both cases introduced above. For each case, it lists how each of the constructs translates into discrete AI knowledge relevant for each of the roles: consumer, user, and creator and developer. The constructs were derived by mapping the relevant knowledge and skills for the use case and the respective role, in consultation with prior work. As presented here, the framework is an initial proposal that can be adapted by educators as needed and further validated by experts trough e.g. a Delphi Study.

Table 1: The filled RCAIE framework with constructs for selected cases

#	Use Case	Roles	AI Literacy Constructs					
			Recognize	**Know/ Understand**	**Use/ Apply**	**Evaluate**	**Create**	**Navigate Ethically**
1	Predictive Maintenance	Consumer	Recognize that prediction relies on sensor data and AI systems	Understand the concept of predictive maintenance and how it supports the maintenance scheduling	Use maintenance recommendations to inform decision-making	Assess and compare predictions to own experiences and traditional approaches	-	Be aware of ethical implications and potential pitfalls in the use case
		User	Recognize different types of sensor signals and predictions	Understand the concept of prediction and its connection to data	Use time series prediction on sensor data	Assess the impact and performance of different prediction algorithms	-	Consider ethical implications in the decision-making
		Creator and Developer	Recognize different types of sensor signals and AI algorithms	Understand different types of sensor data and how they can be processed towards predictions using AI algorithms	Use different signal processing algorithms, build specific models using (physical) domain knowledge and deploy them	Test and validate different modelling approaches using multiple types of metrics	Develop new physical-based modelling approaches	Address and communicate ethical implications in the use case
2	Quality control and testing	Consumer	Recognize that automated quality control relies on sensor data and AI algorithms	Understand the difference between AI-based and traditional quality control	Use insights to make decisions about product rework or acceptance	Assess and compare quality control to own experiences and traditional approaches	-	Be aware of ethical implications and potential pitfalls in the use case
		User	Recognize that AI capabilities useful for quality control	Understand different data sources, algorithm approaches and their limitations	Select and apply AI-based quality control systems for different manufacturing processes	Evaluate the performance in use	-	Ensure ethical and responsible deployment of tools
		Creator and Developer	Recognize data potentials in manufacturing processes useful for quality control	Understand underlying data and model requirements for development and deployment	Use different AI capabilities based on the data requirements	Evaluate the effectiveness of models and overall solution with various metrics	Create new solutions and models for quality control	Advocate for responsible development and deployment

4 DISCUSSION AND CONCLUSION

In this practice paper, we illustrate one approach for disciplinary engineering faculty to understand and integrate AI into their curriculum. As the description for each of the constructs in Table 1 shows, based on the area of application, different levels of knowledge need to be developed. From a basic and generic recognition of AI capabilities to an advanced understanding of models and training for a specific function, a range of options are available for learners. Their inclusion in curriculum depends on instructor expertise and training, as well as the level of course, and critically, students' prior knowledge.

Application of the Framework for Educators

Given the increasingly broad and dynamic developments in AI, we argue that a roles-based approach to competency allows instructors to develop a mental model that provides them with an anchor such that they can start integrating AI aspects in a useful but simple manner. They can then keep building on constructs of competencies while keeping in mind the potential role of how an engineer would use AI and what additional knowledge they would need. Thus, educators can use the RCAIE framework as an approach to define and identify relevant competencies given identified use cases and future roles of their students. Moreover, a collection and synthesis of filled RCAIE frameworks in a domain can inform future development of curricula.

Limitations and Outlook

Although we only use two case studies, it is easy to use the framework we have advanced to look at other disciplines or applications. The developed framework opens new avenues for research and has direct implications for the practice of engineering educators interested in integrating AI competencies in their studies.

We recognize that the framework has certain limitations. First, it is currently inductively developed from case studies only and, thus, not yet validated in use with educators. Second, the selection of case studies might have biased the development of the framework. In the future, these limitations can be overcome through a more thorough analysis of use cases, especially those that build on expert interviews to validate and deepen the insights into the domain-specific AI competencies. This approach can form the basis to identify domain-specific AI competencies and constructs that can be recognized across different engineering disciplines as well as other similarities and differences among the competencies. A collaborative approach with other educators so that they can share their identified competencies through an open repository will also help make this work stronger. Finally, competencies build the base for pedagogical approaches and this work can also be extended towards systemizing and analyzing the effectiveness of pedagogical approaches for different target groups or specific competencies.

Keywords: *Institutional change; Engineering curriculum; Theories of change*

ABSTRACT

Building up competencies in working with data and tools of Artificial Intelligence (AI) is becoming more relevant across disciplinary engineering fields. While the adoption of tools for teaching and learning, such as ChatGPT, is garnering significant attention, integration of AI knowledge, competencies, and skills within engineering education is lacking. Building upon existing curriculum change research, this practice paper introduces a systems perspective on integrating AI education within engineering through the lens of a change model. In particular, it identifies core aspects that shape AI adoption on a program level as well as internal and external influences using existing literature and a practical case study. Overall, the paper provides an analysis frame to enhance the understanding of change initiatives and builds the basis for generalizing insights from different initiatives in the adoption of AI in engineering education.

[1] *J Schleiss*

1 INTRODUCTION

The use of AI has become increasingly relevant across domains (Broo, Kaynak, and Sait 2022; Patel et al. 2021). The rise of generative AI tools in particular is an example of how the use of AI-based tools, such as ChatGPT, has found high use, especially by students, while their conceptual understanding of how these tools work is limited (Weidener and Fischer 2024; Tsoeu et al. 2023). Thus, the digital transformation accelerated by AI increases the need for AI education in the disciplinary context so that students can make responsible judgments about the use of tools, the outputs they get, and so that they are workforce-ready (Dignum 2021; Cevik Onar et al. 2018).

Positioning AI Education

AI education is a complex undertaking as the field can be positioned from multiple perspectives. First, it describes *teaching about AI* rather than the use of AI tools in teaching (Zawacki-Richter et al. 2019). Second, it can address different target groups, distinguishing between *general, (basic) AI literacy* that builds foundations for the broad public, *domain-specific AI literacy* that aims to build competencies in the context of a disciplinary field, and *expert AI literacy*, which might target Computer Science majors (Schleiss, Laupichler, et al. 2023; Long and Magerko 2020; Laupichler et al. 2022). Third, AI education in engineering education can be seen as a subset of Computer Science (CS) education, similar to the role of programming, which is a basic skill but applicable across disciplines, which requires a greater understanding of how it can be integrated into curricula (Malmi and Johri 2023).

Integration of AI Education in Disciplinary Engineering Fields

With the premise that the use of AI tools and applications will become more dominant across different engineering use cases, it is necessary to address the integration of related AI competencies in the engineering curricula and create systematic research-based understanding. This aligns with the call for interdisciplinarity in engineering education aimed at integrating multiple disciplines to solve a problem (Van den Beemt et al. 2020; Spelt et al. 2009) as well as the continuation of efforts towards digital engineering and use of data and computation in engineering (Cevik Onar et al. 2018).

In the context of engineering education, Kolmos, Hadgraft, and Holgaard (2016) advanced three different curriculum change strategies: first, an *add-on strategy*, referring to including additional courses or components in a curriculum but not changing the overall educational paradigm; second, an *integration strategy*, which involves modifications of programs, and third, a *re-build strategy* which refers to a fundamental change of the educational paradigms of the curricula. These can be used as an analysis lens for the type and depth of curricular change.

The applicability of either of these strategies depends on the context as curricular change does not take place in a vacuum and a range of factors shape curricular reform, especially in interdisciplinary efforts (Knight et al. 2013; Klein 2018). One conceptual framework that helps to understand the factors that influence design decisions on curriculum and course planning is the *Academic Plan Model* (Lattuca and Stark 2009). The model proposes that the development of curricula and courses while being conducted by faculty is also influenced by external and internal forces in a sociocultural context.

In this paper we build upon the three curriculum response strategies proposed by Kolmos, Hadgraft, and Holgaard (2016), the *Academic Plan Model* (Lattuca and Stark 2009), and perspectives from change theory to create practical insights for integrating AI in engineering education. Our approach is guided by the question: *what factors – external, internal, and program level – influence the integrating AI knowledge in engineering education?* We combine findings from literature and a case study of curricular development to provide an analytical frame for integrating AI education in disciplinary engineering fields.

We first review prior work relevant to understanding curriculum change in engineering before moving on to a practical case study that will help us exemplify change by integrating theoretical perspectives. Our move from the concrete to the analytical is deliberate so that the practical insights we generate are theoretically grounded in an integrated manner. Overall, this paper contributes to a system perspective on the integration of AI education in the engineering domain and supports educational strategy development in engineering education.

2 RELATED WORK

2.1 Transformation towards AI Education in Education

There already exists some work on transformation processes towards AI education that can be used to identify important drivers. Cantú-Ortiz et al. (2020) described a case study of the AI education strategy and programs at the Tecnologico de Monterrey that builds on five strategic initiatives of (1) developing *academic programs*, (2) building up *research capabilities*, (3) *dissemination* through conferences and training seminars, (4) *outreach* through industry-university collaboration and (5) *internationalization* to enhance the exchange. As influencing factors for the program, the paper mentions internationalization and internships, employability, entrepreneurship, academic competitions, growth plans, funding from industry and public sector, AI conferences, and industry partners. Similarly, Southworth et al. (2023) described the “AI Across the Curriculum” initiative at the University of Florida. The initiative is built on pillars of (1) *investment towards compute* and *adding AI-focused faculty*, (2) *developing AI pedagogy* and including *measures* towards it in the quality enhancement plan, and (3) *developing an understanding of AI literacy* in the university and *targeting curriculum development* and development of new academic programs, pathways, research experiences and career development. The complexity and multidisciplinarity of developing AI programs are also highlighted by the experiences of Utrecht University’s AI master program (Janssen et al. 2020) and the design of AI education offers for K-12 target groups (Chiu and Chai 2020).

2.2 Models for Interdisciplinary Engineering Education

Approaches in interdisciplinary engineering education have the vision to focus on complex real-world problem-solving, the social awareness and entrepreneurial competencies of engineers as well as the improvement of disciplinary programs (Van den Beemt et al. 2020). Thus, related work on change processes and related change efforts do exist, and two recent efforts that can be a good model for AI are the integration of ethics education and sustainability education in engineering curricula. For example, Weiss, Barth, and von Wehrden (2021) analysed 131 case studies of curriculum change towards integrating sustainability and identified six *implementation patterns* ranging from (1) collaborative paradigm change, (2) bottom-up, evolving institutional change, (3) top-down, mandated institutional change, (4) externally driven initiatives, (5) isolated initiatives, and (6) limited institutional change. Also in the context of sustainability, the *curriculum response strategies* of (Kolmos, Hadgraft, and Holgaard 2016) are inspired by responses to sustainable education proposed by (Sterling 2001): making adjustments in the existing system such as improvements or restructuring and changing the educational paradigm as in redesigning the system and institutions. Similarly, Lambrechts (2010) analysed how and to what extent sustainability-related competencies were integrated in Bachelor programs at their university. Next to sustainability, engineering ethics is another topic of curriculum change processes. In this context, Martin, Conlon, and Bowe (2021) analysed literature through four different analytical levels: individual teaching practices, institutional (programs, departments, implementations), policy (accreditation, funding) and culture (paradigms of practice). This suggests that similar to ethics, AI should be integrated across modules, needs to be put into practice and is shaped from different disciplinary domains (Hitt, Holles, and Lefton 2020).

3 Case Study

Next to looking at curriculum change from a theoretical perspective, we describe the case of a curricular development of a Bachelor program of AI engineering to understand practical factors of influence in the context of engineering education. The program (210 ECTS (European Transfer Credit System) credits) at the Otto von Guericke University Magdeburg aims at integrating both disciplines, AI and engineering. The interdisciplinary curriculum, situated between AI and engineering, has been developed in a collaborative and participatory process using the method of curriculum workshops (Schleiss, Manukjan, et al. 2023). As a newly developed curriculum, it follows the re-build strategy and recreates educational experiences on a green field. The purpose of the program and vision is to bridge the gap between engineering and AI and train so-called AI engineers who can develop data-driven solutions for engineering use cases. This interdisciplinary skillset focuses on competencies to responsibly work with data and (AI) models as well as having a domain understanding of underlying engineering processes, data and requirements. Moreover, it requires a high level of systematic problem-solving skills and the ability to communicate effectively across disciplines. As a re-build curriculum, about half of the modules are newly developed targeting different educational experiences, for example, projects, flipped-classroom settings, or hackathons. Additionally, a focus lies on developing and using Open Educational Resources (OER) in teaching and collaboration with industry.

The program structure roughly consists of six different elements: fundamental courses, specialisation courses, projects, electives, internship and thesis. The first semesters target the fundamentals in engineering and computer science with a focus on working with data and AI, and related subjects such as maths or working with sensors. After the fundamentals, students select a specialisation of one engineering application area and focus on working with data and AI solutions in this application context. Throughout the program, students have projects that aim to integrate the different knowledge components and bring them into practice. In the higher semesters, the students have three electives allowing for going deeper in some directions. Moreover, in their last semester, students have a 12-week internship and complete the program with a thesis.

The program development was influenced by multiple internal and external drivers. From the external side, AI education is currently high on the political agenda and funding has been provided to establish the study program. Moreover, the content and implementation are shaped through interactions with industry partners. Internally, the program is influenced mostly by the educators who designed the program and secured the funding for its establishment. While acknowledging the need for such a program on the faculty and institutional level, the development was not driven top-down or part of strategic initiatives for further development. Moreover, the program in its form is only possible through the availability of resources, especially concerning faculty staff (mostly financed by external funding) and existing computing resources for the students. The culture at the institution and faculty was initially resisting change, especially concerning novel approaches to teaching and the structure of the curriculum. At the same time, the external funding and governmental support were perceived as validation of the ideas and acceptance of the proposed curriculum. Next, we use this case to exemplify how AI can be integrated into engineering programs and curricula.

4 INTEGRATED PERSPECTIVES FOR AI EDUCATION IN ENGINEERING FIELDS

4.1 Academic Plan Model for AI Education in Engineering

To move towards a system perspective on integrating AI education in disciplinary engineering fields, we integrate the findings from theory and practice towards a system model that highlights external and internal influences. The abstract model (Figure 1) builds upon the *Academic Plan Model* (Lattuca and Stark 2009) and frames the context that is used to understand and describe how change might occur towards adopting AI education. In the following, we describe the different contexts in more detail and highlight how these behave specific to AI education.

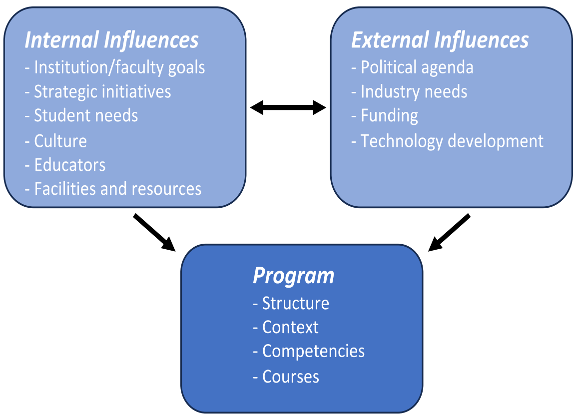

Figure 1. System perspective on influences of curriculum change inspired by (Lattuca and Stark 2009)

4.1.1. Program Level for AI Education in Engineering

Within the context of an educational environment, the central element is the *program* with its structure, context, competencies, and content such as instructional resources, processes and assessment and evaluation. A program includes content aspects (curriculum) and organizational aspects (regulations). A curriculum is usually described through the goal, purpose, content and sequence of how different modules work together. Different modules might consist of one or more courses and include instructional resources, processes, assessment and evaluation, all targeted to build out competencies for learners. As introduced earlier, when looking at changes in curricula, response strategies can be roughly distinguished into an add-on, integration and re-build strategy (Kolmos, Hadgraft, and Holgaard 2016). Thus, we can use these perspectives for integrating AI in engineering education.

Following this structure, it becomes clear that we need to understand how to develop (interdisciplinary) curricula that integrate AI and different engineering domains including aspects of what competencies and content are relevant and in what sequence it should be taught. This can lead to adding new competencies, integrating them into existing curricula and courses or re-building them. More specifically, from a course perspective, there is the need to understand what our learners need in their interaction with AI, what relevant instructional resources are, how we can structure instructional processes and how we can assess and evaluate the learning.

A few curricula and course development efforts exist in the literature. Work in the context of curricula, development has been focused on the idea of multi- and interdisciplinary design highlighting the diverse nature of AI (Janssen et al. 2020; Southworth et al. 2023). The research on understanding relevant AI competencies is still in development (Tenório and Romeike 2024; Almatrafi, Johri, and Lee 2024; Wolters, Arz Von Straussenburg, and Riehle 2024). Regarding course development, there have been efforts to provide structure for educators, e.g. the AI course design planning framework (Schleiss, Laupichler, et al. 2023). Moreover, there have been multiple efforts in the definition of AI literacy assessment instruments (Hornberger, Bewersdorff, and Nerdel 2023; Laupichler, Aster, and Raupach 2023).

Exemplary Core Questions

- What is the purpose of integrating AI in the program?
- What AI competencies are targeted and should be integrated?
- Does the adoption of curricula or courses towards AI follow an add-on, integration and re-build strategy?
- What learning activities and assessment strategies are suitable for AI education?

4.1.2. Internal Influences on AI Education in Engineering

Within the socio-cultural context, we find internal and external forces. Concerning internal influences Lattuca and Stark (2009) distinguish between institutional such as the objectives of the institution, resources or governance, and unit-level influences such as educators in faculty, discipline culture and student characteristics. From the perspective of adopting AI education in engineering education, it is important to understand internal drivers in the institution. These can be roughly distinguished as focusing on people and focusing on organizational structures. People are central to change, especially in education. In adopting AI education, one key challenge is the readiness of faculty for change, be it the level of expertise and skills in AI, the needed support structures, or the potential resistance to change (Stark et al. 1988). Moreover, aspects such as governance structures are important to consider. For example, Knight et al. (2013) highlighted the importance of organizational features, such as the appointment of a program director and faculty appointment within the interdisciplinary field. Additionally, in the context of AI, computational resources are needed for deployment, experiments and teaching. Thus it is important to consider what resources are available on a faculty and institutional level.

Exemplary Core Questions

- Who is driving the integration of AI education? Is it led by leadership (top-down) or by faculty/educators/students (bottom-up)?
- How well embedded is AI education in the faculty goals or strategic initiatives?
- How well-equipped are educators to teach AI topics?
- What governance structures can support the integration of AI in curricula?
- How is the funding and resource situation, e.g. for compute at the institution?

4.1.3. External Influences on AI Education in Engineering

Next to internal influences, the educational environment is influenced by external forces. These can include market forces, political agenda and initiatives, accrediting agencies, disciplinary associations, technology advancements, funding or industry needs. Concerning AI education, we can highlight five major forces from theory and practice. First, AI development has mostly accelerated due to technological advancements in computing and model architectures in recent years, leading to new market forces and industry demand for AI talent. This creates a demand for more AI education at universities. Second, the need for AI talent and research is also picked up by governments and supported through funding or political initiatives, which create an opportunity for universities to create new programs or research initiatives. Third, new competencies are also picked up by accrediting bodies, even though a recent article highlighted that currently AI is not yet broadly integrated into engineering accreditation (Tsoeu et al. 2023). Fourth, the use of AI systems has ethical, legal and social implications and is also a topic of regulatory aspects. Regulations like the EU AI Act influence the possible use of AI systems but in a broader sense also what should be taught in the context of AI education to educate responsible engineers. Fifth, there exists the challenge of a high volatility of skills due to technology advancements. Identifying the relevant skills and adopting courses and curricula at the required speed remains challenging for higher education.

Exemplary Core Questions

- How important is the topic of AI considered on the current political agenda?
- What is the need for AI skills in the industry? Who are potential partners?
- How much funding is available to develop new programs?
- How is the constant technology change in AI influencing relevant skills, adoption in programs and in courses?

4.2 Change Theory Perspective for AI Education in Engineering

Curriculum change can be viewed from three dimensions: (1) *triggers* of change, (2) *drivers and barriers* of change, and (3) the *type and content* of change. *Triggers of change* refer to the impetus of change, from forces within the institution or from external sources (Lattuca and Stark 2009), and it can be normative or goal-oriented

(Fumasoli and Lepori 2011). *Drivers and barriers of change* can again be external or internal influences (Gruba et al. 2004). Internally, questions about the institutional goals, resource availability, governance structures, and readiness of faculty for integrating and changing (Gruba et al. 2004; Roberts 2015). Moreover, student needs and interests as well as their characteristics and abilities might drive or hinder change (Gruba et al. 2004). Externally, the market forces, the political agenda, accreditation agencies or disciplinary associations or change in other institutions might influence the change process (Gruba et al. 2004). Finally, the *type and content of change* vary and can be linked to different response strategies, e.g. adding new degrees or course work, new subjects or integrating aspects in core or electives (Gruba et al. 2004; Kolmos, Hadgraft, and Holgaard 2016). From a content perspective, there is the question of what competencies are relevant and categorizing their integration, e.g. in vertical integration (explicit mentioning of competency), horizontal integration (competency implicitly integrated across the curriculum), and a combination of both (Lambrechts 2010). For an overview, the system and the change perspective are summarized in Table 1.

Table 1. Integrated Systems and Change Perspective towards integrating AI education in EE

Change Dimensions	**System Elements**		**Program Level Changes for integrating AI education in engineering education**
	Internal	*External*	
Trigger	Faculty interests and motivation Strategic initiatives from leadership Student demands for integration of AI	Accreditation processes Funding from industry and government Market demands for AI graduates Risks of the use of AI	Awareness and training in AI for faculty and leadership as well as new faculty hires can trigger change Loop between market demands and student needs for AI related competencies and new learning experiences Responsible and ethical use of AI is key for engineers
Drivers and Barriers	Institutional goals Available resources Governance structure Readiness of faculty	Accreditation processes Funding from industry and government Internationalization Exchange with others Change in other HEIs	Faculty AI skills, motivation and time as well as related governance structures relevant for program level change Funding and accreditation accelerates the change process towards integrating AI in EE AI technology advancement driven through industry - Industry collaboration more important Student demands accelerates AI adoption
Type and Content	Curricular regulations Agility of faculty administration	Availability of competence frameworks Accreditation	Identification of relevant competencies and their integration across curricula as main challenge Selecting adequate change response strategy and integration strategy and related teaching approaches

5. DISCUSSION AND IMPLICATIONS

We have introduced a system perspective on integrating AI education in disciplinary engineering fields building upon literature and a practical case study. Connecting to other transformation processes, this work contributes towards an improved understanding of the required change processes for integrating AI competencies in disciplinary engineering fields. It can serve as a thinking frame for educators and faculty leaders to see where they stand and how to develop a change strategy towards integrating AI into their educational offers. We recognize that the paper has certain limitations. First, the system perspective as an analysis frame is inductively developed from a case study and literature only and not yet validated in use. Moreover, the selection of the case might have biased the development. These limitations can be overcome in future through analysis of further use cases and integration of expert feedback, in particular with comparison to previous integration efforts of other cross-ranging aspects such as sustainability and ethics. From the analysis frame, we can also identify implications for further research. First, more case studies should be collected and analysed within the analysis frame to build a foundation for transferring local best practices to more general contexts. Second, more research is needed to understand program structures and ways to integrate AI competencies in engineering education in a disciplinary and interdisciplinary way. Third, internal and external drivers of AI education can benefit from more research, in particular to map change theories to the drivers (Reinholz and Andrews 2020). Fourth, the analysis frame could be further enhanced with metrics, e.g. a readiness scale, to support the change processes at universities and allow for comparisons on a faculty, institutional, national or international level.

ABSTRACT

This empirical study explores the effectiveness of the Flipped Classroom (FC) model combined with blended learning in the context of Electrotechnical Bachelor of Engineering education in a digital electronics and programming course on 2nd semester. It particularly focuses on the use of a Learning Management System (LMS) to facilitate pre-class, in-class, and post-class activities, emphasizing the role of quizzes, video materials, and slide presentations in enhancing student engagement and preparation. The research was conducted over several semesters, comparing student engagement metrics and assignment quality before and after the implementation of rule-based access to learning materials. Data were gathered from the LMS, including quiz participation rates and access to pre-class slide presentations and correlated with the quality of students' assignment submissions.

The findings indicate a mixed impact of rule-based access on student preparation, with some improvement in quiz participation and slide access but less engagement with video materials. However, the quality of assignment submissions did not significantly correlate with the enforced pre-class activities, suggesting that motivation and engagement might be influenced by factors beyond the structured access to learning materials. The study also highlights the challenges of encouraging consistent student preparation and the potential of LMS tools to tailor the learning experience to individual needs.

The research contributes to the ongoing discussion about the flipped classroom (FC) model's effectiveness, offering insights into how digital tools and structured access rules can enhance or hinder student learning in programming courses. It calls for further investigation into the motivational factors driving student engagement in blended learning environments.

1 INTRODUCTION

In this empirical work, we will study and analyze if students uses of materials reflects the quality of assignment and if a rule based setup in the learning management system improves the uses of material compared to year without any rule set. The rule-based access to the lesson slide presentations was introduced in fall 2023 and also used in spring 2024. The rule is: The quiz must be scored before getting access to the in-class slide presentations. The paper introduces the concept of the flipped class, drawing from relevant literature and providing motivation for the research questions. The course used is introduced. Details about data collection and results are presented. The paper concludes with a discussion and conclusion.

1.1 Introduction flipped classroom

Programming involves various skills to learn. The Flipped Classroom (FC) creates a new learning environment with practical programming sessions and enhances

students' learning experiences (Siripongdee, Pimdee, & Tuntiwongwanich, 2020).

The main advantages of FC are providing students with knowledge before class and preparing them to spend extra time in class for active and collaborative learning (Eusoff, Salleh, Mohd, 2021). The FC principle typically covers 3 parts of activity: pre-class, in-class, and post-class. Our course Digital electronics and Programming (62734) on 2nd semester electro technology Bachelor of Engineering used for research here uses pre-class activity: video, slides, quiz and in class activity use slides and assignment programming as well as post-class work on the assignment and report for documentation.

This paper written by Eusoff, Zin, Salleh(2022) shows literature review and it reveals in-class activity hands-on experiences are most used, whereas only 21% use assignments. Moreover, they find mostly pre-class videos to convey knowledge and quizzes. When using FC, learning is individualized, and students must be able to learn at their own pace and ask questions to the facilitators in the class. (Rasheed A. et al. 2020). The teacher's role is changed to support, guide, and facilitate the students towards learning from different perspectives.

The teacher is responsible for materials available online due to the FC being a 24/7 classroom. The FC model also effectively enhances students' engagement, interaction, self-efficacy, and attitudes (Eusoff, Zin, Salleh, 2022), But in practice, one of the challenges educators face is ensuring students' participation in learning activities in pre-class (Eusoff, Salleh, Zin, 2021). Our previous work (Schultz, & Blaszczyk, 2023).) reveals that 25 – 30% percent of the students don't use the pre-class materials.

Motivation is the most important element when using the FC method. In addition, Lopes et al. (2019) have analyzed data regarding students' affective perception of flipped classrooms and write that the statistical analysis indicates, especially in the 3rd and 4th semesters, semesters in e-learning and classroom classes present a significantly higher affective perception. A motivation factor for the students could be quizzes - a kind of gamification, a competition. Many research articles ex (Eusoff, Zin, Salleh, 2022)(Baig, Yadegaridehkordi 2023)(Sobral, 2021) present data from research and literature reviews. The course (62734) activity in-class programming could also motivate the students as the program can do specific tasks in a microcontroller with a visible result. Lio (2024) has done an evaluation of the flipped classroom used in programming and one of the findings is “the motivated students aggressively accessed the course materials and obtained a better score”. Founded on above studies and own experiences it is relevant to raise these two research questions: **1st research question:** Does a rule-based setup in the LMS system for access to in class slide-materials improve the amount of students answering the quizzes before class as well as uses of the pre class video and pre-class slides?

2nd research question: Is the solution to assignments dependent on the students' engagement with the in-class materials in the LMS?

In the next section the course in the LMS delivering data is described

1.2 The course Digital Electronics and Programming for research

As in general, programming learning software-development for embedded platforms (microcontroller) is pretty much the same. The main difference is the program runs in a small processor (microcontroller), not a PC. The course has been taught, during the last 8 years, as FC or semi-flipped. The course content is both about understanding the hardware and in parallel programming/configuring the controller to perform different tasks on the input-output, serial ports, etc. We use a Learning Management System (LMS), Learn, developed by Brightspace. At Learn the materials are sorted in different folders.

Preparation materials are available in a subfolder to the specific lesson folder and contain a slide series, a video presentation of the slide series, and a quiz and sometimes a demo to exemplify how to write a small program. The quiz questions are questions in the digital electronic, but there are also programming questions ex. true/false or select a correct program-statement among four opportunities about a program statement ex. read a signal level on a physical port or turn on a Light Emitting Diode (LED).

The quiz(es) results are used as an introduction to the lesson where we go through some of the answers at the beginning of the lesson. The video length is between 10 and 15 minutes as suggested in the literature (Baig, Yadegaridehkordi, 2023). Due to the time limitation, there are sometimes 2 or 3 videos for preparation.

We use Discord as a 24/7 online communication tool therefore students can always reach out for help or use it for internal discussion.

Students work in pairs-groups up to three students on four different assignments. The groups hand in a small report documentation for the program and a program. The teacher/supervisor correct each assignment report and the program. Moreover, an example solution will be available for students who have handed in the assignment. The course is evaluated through an oral individual exam. Students answer six general questions related to the curriculum, with 5 minutes to explain a randomly drawn topic. Afterward, additional questions assess program knowledge and understanding. The grade reflects documentation quality, program proficiency, and demonstrated understanding during the exam

2 METHOD AND DATA

For answering the questions raised above, we use empirical data from the LMS system and evaluation of two assignments. We extract a record of data for each student enrolled in the course. The record includes access/clicks on all topics, encompassing access/clicks to the lesson slides, pre-class slides, quiz scores, hand-ins of assignments.

The Table 1, next page, shows year, semester and number of students enrolled and groups in spring semesters. In principle, all enrolled students should access all materials. From the LMS we use the records of data for answering the first question: Does a rule-based setup in the LMS system for access to in class slide-materials improve the amount of students answering the quizzes before Class, as well as uses of the pre class video and pre-class slides? The students in the fall semester are from a winter intake by February and are more diverse, and not everyone is just coming from high school but have been in work before the study started.

Table 1: Data size 2nd semester students enrolled into course 62734

Year	Fall - enrolled	Spring - enrolled	Groups of students
2022	28 students		
2023	29 students	48 students	21 with 43 stud.
2024		68 students	25 with 63 stud.

Whereas the spring semester students are from a fall intake by September and most students are continuing from their high school. In spring 2024, there are 68 students (IT-electronics students together with electro technology students).

The second question: Is the solution to assignments dependent on the students' engagement with the in-class materials in the LMS? This question is answered using two assignments (Assignment 2 and Assignment 3) handed in in week 4 and 6 respectively in spring 2023 and spring 2024. Fulfillment of an assignment requires having a program running on the microcontroller and acceptable quality of documentation. Evaluation data is created as: The quality of documentation is given a rating from 2 for good, 1 for poor, and 0 for not handed in. The program is rated -1 for not running, 0 for not handed in, and 1 for running. As data is not Gaussian distributed, Spearman’s correlation coefficient (named for Charles Spearman) summarizes the strength between the two data samples. For kind of falsification of correlation, data used in this analysis is only from students in groups either lacking a working program or adequate documentation, and those with satisfactory documentation but no working program, as well as groups that have not handed in a program, documentation, or both. Nevertheless, all students access data to in-class slide presentations is correlated with completed hand-in of report and program.

In the following result section, we conduct the data analyses and later in the discussion section we discuss the results.

3 RESULTS

Here, data records extracted from the LMS and data from correcting the tasks are analyzed.

3.1 Preparation by pre-class activity

For answering the first question, we use plots of students’ completeness to pre-class materials in histograms for the first 8 lessons.

Figure 1 on next page shows students' pre-class activity during week 1 to week 8.

On the X-axis, the Module is the lesson in week 1 to 8. The Y scale is the percentage of students who have completeness/accessed the materials listed in the categories shown by the legends.

The legends shown by color for each bar. The color changes for each legend and the first two colored bars are the video, the next two are the quiz, and the last two are the pre-class slide presentation.

- The figure to the left is for fall 2022 (F22) and fall 2023 (F23) covering: video_F23, quiz_F23, and sl_pr_F23 (pre-class slide presentation).
- The figure to the right is for the years: spring 2023 (S23) and spring 2024 (S24).

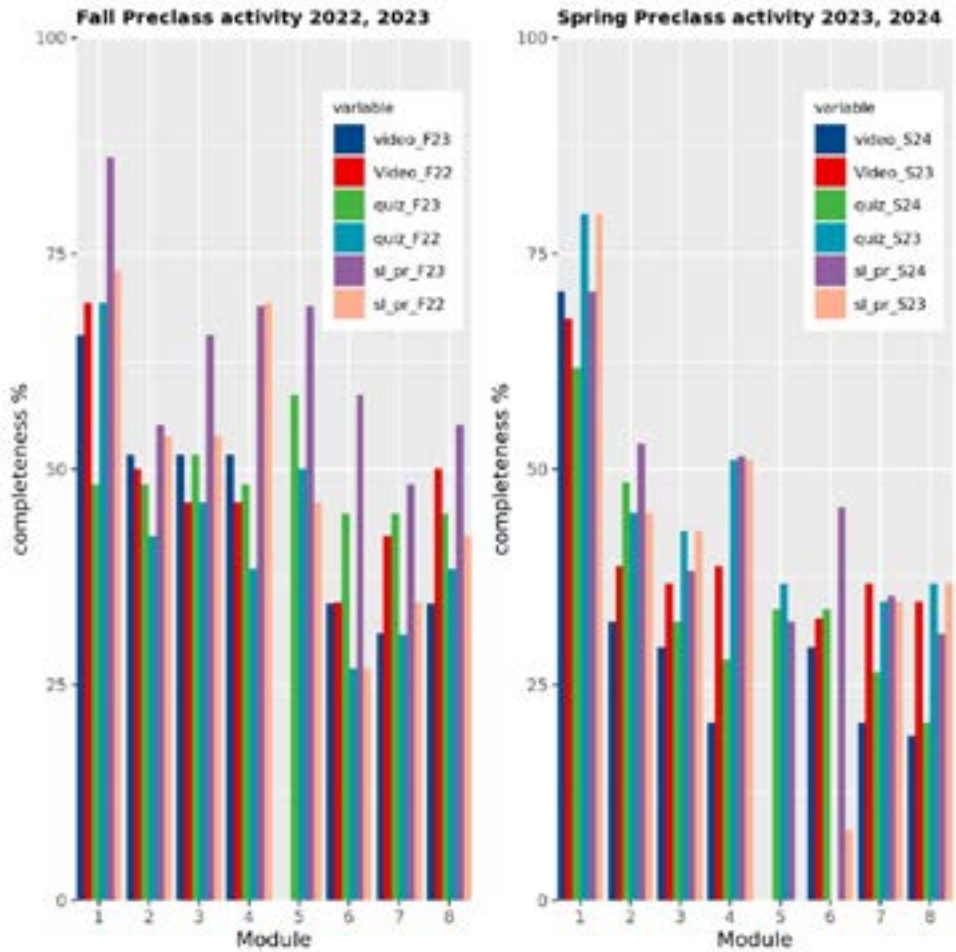

Figure 1: Pre-class activity in fall 2022, 2023, spring 2023, 2024.

The Average value for access for each kind of material is:

- **Video**: video_S24 2024: 29.14 % and for 2023: 38.78% so a decrease by 10%.
- **Quiz**: quiz_S24 2024: 31.25 % and for 2023: 36.36 % a decrease by 5%
- **Pre-class slide series**: sl_pr_S24 2024: 39.81% and for 2023 36.36% an increase by 3%.

Overall, students accessed the pre-class slide presentations improved from S23 to S24 except for lessons: 1,3,8. While video access and quiz scores for all semesters have mixed results depending on the module.

Looking at the left figure for fall 2023 compared to fall 2022; the same picture pre-class slides are used more in 2023 than the previous year. The pre class slide series is together with the video mend as the foundation for the quiz. This is also confirmed by the figure both quiz and pre class slides is accessed more in fall 2023. But in the spring 2024, with some exceptions, it is the opposite picture. Students in 2024 are not complete the quizzes as much as in spring 2023. Looking on the video access, the students in spring 2024 use the video more for preparing than in spring 2023. That could of course be the reasons for not accessing the pre-class slides. Exactly opposite to spring 2023, where the students access the video less. The rule about the quiz to be completed seems not to motivate the students to do more quizzes in spring 2024 compared to spring 2023 where there was no rule. However, in fall 2023 the rule could have an impact on the uses of the materials compared to fall 2022, where there were no rules applied.

3.2 The Slide materials

The figure 2 shows how the students access the in class slides (sl_les22/23/24) and pre class slides (sl_pre22/23/24) in years: 2022, 2023, and 2024. Again, a pair of colors address the two types of slides and the related semesters. The semester term and year is headline for each sub-figure in figure 2. In addition, on the x-axes Module is the lesson from 1 to 8. The slides used in the lesson are used most which also is found by (O. Schultz and T. 2023).For Spring 2024 there is small difference between the slides for preparation (sl_pre24) and slide ls_les24 used in the lesson. Whereas in spring 2023 the difference between access in class and pre class slides, is more than 10%

On average, 42% have accessed the preparations slide presentations in spring 2024, and in spring 2023 only 31% accessed, so an increase of 11%, and for the slide presentations used in the lesson, the average access is 57% in spring 2024 and in spring 2023 78.6%, so a decrease of 21% - reflected in the outstanding purple bars in figure 2 to the right. So, with the rule use less access to the slide presentations and less quiz completed.

Therefore, the rule about the quiz must be done, does not in 2024 motivate students to take the quiz and watch the pre-class slide presentations nor the in-class slide presentations, but in Fall 2023 with the rule used, it results in higher completeness. It could be explained with rules that motivates students.

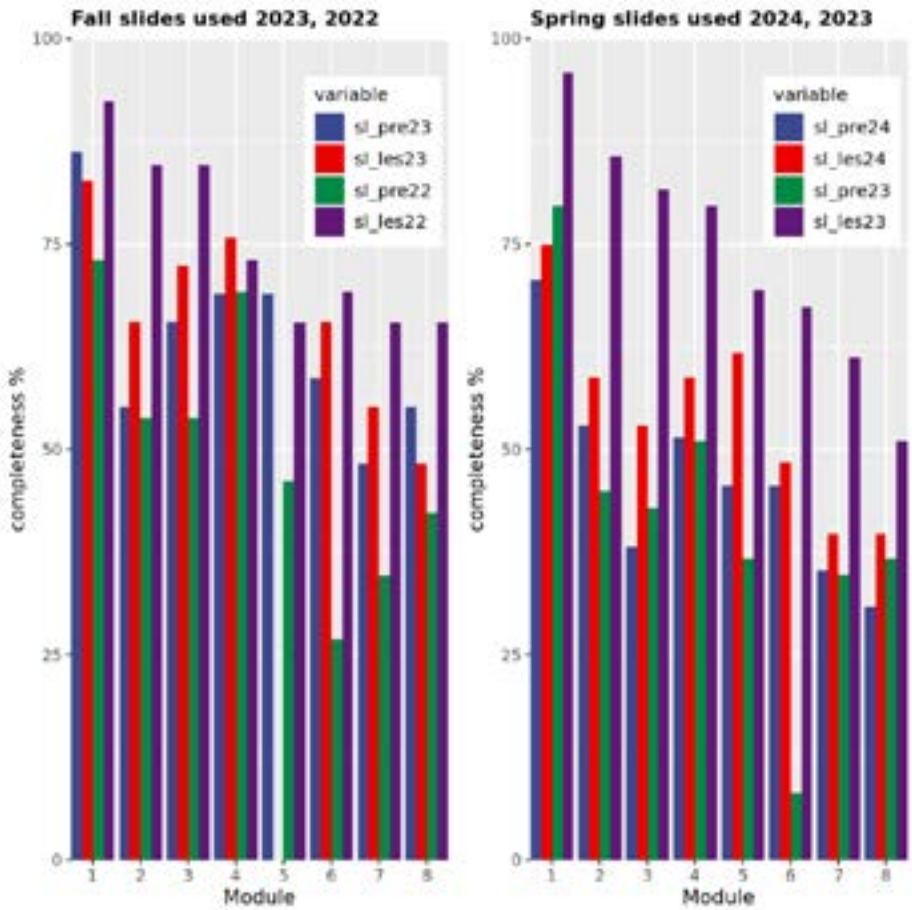

Figure 2: In-class and pre-class slide activity in fall 2022, 2023, spring 2023, 2024.

3.3 Quality of assignment work

Table 2 shows the documentation evaluation data correlated to slide presentations (doc_sl) for lessons, and slide presentations for preparation (doc_psl) and quizzes before class (doc_q). And the program evaluation-data correlation to slides used in class (pro_sl) and slide presentations for preparation (pro_psl). Data is from students not completely full fill assignments as explained in section 2. Spring 2023 no rule for getting access to in class slide presentations. Spring 2024 we use the rule: quiz must be scored before access to in class slide presentations.

Table 2. Correlation coefficients scoring assignments in relation to activity

year	assign	doc_sl	doc_psl	doc_q	pro_sl	pro_psl
Spring 2023	2	0.58	0.51	0.23	-0.27	-0.26
Spring 2024	2	-0.47	-0.16	0.12	0.33	0,21
Spring 2023	3	0.44	0,22	0,36	0,19	-0,36
Spring 2024	3	-0,22	0,073	-0,045	0,015	-0.13

Assign column is referring to assignment 2 and 3 by number.

- Rows spring 2023 -in blue:, there seems to be a weak correlation between the use of slides (doc_sl for lessons, doc_psl slides for pre-class) and the quality of documentation. But the program and slides (columns: pr_sl, pro_psl) does correlate weak negative – confirming programs quality is poor due to not using the hints in the slides.

- Rows spring 2024 – in black, with the rule for accessing slides introduced, there is a weak to none and negative correlation for the quality of documentation. Whereas for the program quality there is a weak correlation 0.33 to the slides for assignment 3 and for assignment 2 correlation of 0.33, which contradicts with the results in spring 2023.In spring 2024 Quality of documentation for assignments has a weak negative correlation to the slide presentations, that can be explained by less uses of the slides confirmed by figure1 and 2.

When using all students' **access data (slide presentations in-class and preparation slide presentation) for spring 2024** correlated to the hand-in of program and journal (for assignment 2) in correlation to the slides used in class it shows correlation by 0.40 and for assignment 3 hand-in correlated to in class slides by 0.28. In addition, **data for spring 2023** for assignment 2 close to zero correlation 0.060 whereas assignment 3 has a correlation to slides in class by 0.35. This confirms using the materials helps students to fulfill hand-in of assignments.

4 Discussion

The results shown in Figures 1 and 2, where we compare two different semesters in fall 2023 and 2022, and spring 2023 and 2024, indicate that, in general, there is less activity in 2024 compared to 2023, particularly for pre-class material in Figure

1. The rule setting, where a quiz must be scored before access to the lesson slides, does not seem to have any significant effect on activity in the Spring semester.

However, in the fall, there are up to 20% more students scoring on quizzes, and the pre-class slides series is more frequently visited. However, in spring 2024, where the rule is active, even the quiz scores are less than in spring 2023, except for lesson 2.

Figure 2 illustrates the difference between slides used for preparation and those used in the lesson. The rule for accessing the lesson slide series in spring 2024 does not motivate the students to do the quiz before class. However, opposite in the fall 2023 where activity was 10 to 20% higher compared to fall 2022 without any rule. Therefore, perhaps there is a motivation factor by the rule. That could lead to the conclusion on first question: "Does a rule-based setup in the LMS system for access to in class slide-materials improve the amount of students answering the quizzes before class as well as uses of the pre class video and pre-class slides". For the fall 2023, rule-based access improves the access to quizzes and materials, whereas in 2024 it seems not to have much influence. Conclusion on the points to the rule based assess can have an impact for some kind of students.

The other question: "Is the solution to assignments dependent on the students' engagement with the in-class materials in the LMS?". From table 2 we find there is in the positive correlation between the documentation quality and slides used in class for the spring 2023 and for spring 2024 a negative correlation between documentation quality and access to the slides used in class. In addition, the program quality has a positive correlation to the slides used in class for spring 2024 and opposite for the spring 2023.

When we look at completeness of assignment 2, 3 spring 2024, and correlated with completeness/access for slide presentations used in class there is a positive correlation between hand-in of the assignment and access to slide presentations.

When relate that to the first question then we must conclude the rule does not help all students, but the more students use the slide presentations, the better quality of the assignments and completeness.

Regarding these results, one challenge with the pre-class activity and the programming assignment is that students are evaluated on the assignment report and the program running in the microcontroller, and there is not any tight coupling with the content on Learn. Ex. the material mainly for pre-class activity is about the digital electronics part and the general concept of the microcontroller not about programming. The assignment can be completed using resources like ChatGPT, which are accessible without login. This allows students to get immediate assistance with their tasks. The quizzes mirror the oral exam's theoretical questions, making them good practice. However, Schultz & Blaszczyk (2023) found no link between quiz performance and final grades. Similarly, quiz usage did not correlate with the quality of programming or documentation in the evaluated tasks (see table 2).

5. Conclusions

The research questions regarding whether a rule setup can motivate students to be more prepared by doing quizzes and thereby using the supplied materials are addressed in the work presented here, drawing on data from the LMS system. There is a tendency to suggest that the rule could motivate to do the quiz before class; however, it also presents challenges for students who haven't scored on the quiz and are thereby unable to access the slides for hints, consequently affecting their ability to fulfill the assignment. A correlation analysis between individual students' data from the LMS and the scores of assignments shows a weak correlation between the program running in the microcontroller and the use of slide presentation in the lesson. Students can complete the quiz by using the pre-class slide presentations, but the videos are not utilized as much. Nonetheless, the changes observed are minor. Therefore, other ways to motivate the students should in the future be tried in this course.

ABSTRACT

Gamification in a learning environment can positively impact student engagement, commitment, motivation, and deep learning. Conventional teaching methods have shown a deficiency in actively engaging students with their learning and helping them gain a profound and lasting understanding of the contents. This practice paper introduces a learning innovation framework for implementing point-based gaming (PBG) to improve student engagement and learning in the apprenticeship advanced mechanical engineering modules. The effectiveness of this pedagogy is evaluated based on the mark of their final individual assessment compared to the outcome achieved through the traditional teaching method. Previous evaluations have shown that more than 90% of students actively engage with the activities and find them fun and engaging. Based on the results, an increase in academic performance was observed compared to the previous delivery model, which did not incorporate these active methods, with the fail rate reduced by 28% and the number of students achieving a first-class mark increased by over 35%. Implementing PBG also helped achieve a high-quality education based on the Ofsted lesson observation model. This approach can be applied to other engineering courses, empowering instructors to enhance students' experiences by engaging them to think, feel, and act.

1 INTRODUCTION

Conventional lectures in higher education are based on a teacher-centred approach, with the lecturer primarily responsible for delivering and transmitting knowledge to students. The large cohort sizes (100+ students) typical of Science, Technology, Engineering and Mathematics (STEM) courses often mean that teaching sessions are heavily reliant on a lecture-based format (Cho et al. 2021). In this traditional classroom setting, students play a passive role in their learning, where limited opportunities exist for students to ask questions (van Alten et al. 2019) or to interact with the lecturer or their peers, thus hindering opportunities to develop higher-order critical thinking and transferable skills. Moreover, lectures are considered ineffective in catering to different student needs and learning styles (Howell 2021; Lax et al. 2017).

The lack of motivation and engagement from students has been linked to poor academic achievement, demonstrating the crucial roles that engagement plays in student learning (Metzger and Langley 2020). The lack of social and intellectual stimulation within the traditional classroom setting can result in academic boredom (Sharp et al. 2020). It leads students to believe the topic is tedious and challenging. Students can quickly become disengaged in the class and lose interest in the subject matter entirely.

Various works have explored a shift from this teacher-centred approach to student-centred learning over the last decade to overcome these challenges. (Freeman et al. 2014). Using student-centred strategies such as *Active learning* has reported increased academic performance, particularly within the engineering field, where hands-on activities are crucial in applying theoretical concepts to real scenarios and developing the soft skills required by graduates (Garcia et al. 2020).

However, transitioning to a student-centred approach requires an initial time investment from the lecturer. The amount of work needed to plan and design such activities is more significant than traditional approaches (Howell 2021), and lecturers are required to develop the technical and pedagogical competencies needed to implement such learning environments effectively (Das Neves et al. 2021).

1.1 Active Learning

In active learning (AL) approaches, the student takes a proactive role in their learning, and the teacher now acts as a facilitator rather than the sole transmitter of knowledge. AL activities promote higher-order thinking, student interaction with their peers, creativity and reflection. These activities include case studies, team-based exercises, simulations, games, practical labs and flipped classrooms. Engaging students in these cognitive activities allows them to retain at a higher level (Savin et al. 2023) and to develop other transferable skills.

The use of active learning in higher education has been widely explored in several disciplines, with an increase in student achievement observed as a result of implementing active learning strategies despite the field of study (Sumanasekera et al. 2020; Kozanitis and Nenciovici 2022; Ting et al. 2023).

Practical labs, problem-based learning (PBL), and project-based learning (PBL) are some of the most commonly used active learning activities in engineering education. These activities are well suited to exploring scenarios found in real-life engineering projects (Das Neves et al. 2021). For example, López-Fernández et al.

demonstrated a positive impact on student motivation in an Aerospace postgraduate module through the use of PBL (López-Fernández et al. 2019).

The use of these active learning strategies has also been linked to the development of professional competencies (Hernández-de-Menéndez et al. 2019). Gómez-del-Rio et al. used a combination of lab sessions and PBL in a Mechanical Design undergraduate module, enabling students to improve their skills and competencies as part of the learning outcomes (Gomez-del Rio and Rodriguez 2022).Other active learning strategies, however, such as game-based learning, are less popular when teaching advanced engineering subjects.

1.2 Game-based Learning

Games are a powerful platform for change, increasing productivity, optimism, social connections, and the desire for an epic win (McGonigal 2011). Using games in the classroom can spark friendly competition and cooperation among peers, creating an engaging environment that supports students' learning (Plump and LaRosa 2017). This active learning approach of embedding games as part of the learning process is known as game-based learning (GBL). Games in educational settings can range from traditional board games such as puzzles, crosswords, quizzes, etc. (digital or non-digital) to computer-based or video games designed to meet specific course learning outcomes.

For the implementation of digital-based games, readily available platforms exist, a popular one being Kahoot (Mohammad Zadeh et al. 2024; Knight et al. 2022), which allows for game-based quizzes to be created by the teacher and deployed and answered by students through their mobile phones, with scores and leaderboards presented. Plump and LaRosa reported on the use of this platform in undergraduate business courses, noting an increase in student engagement and willingness to ask follow-up questions (Plump and LaRosa 2017).

It is important to note that these games must be accompanied by appropriate training and reflection. Bado emphasises that pre-game and post-game stages are needed for these tools to be practical. Students should be briefed on how to use the technologies and their purpose before using them, and debriefings should follow to discuss, clarify, and reflect on them (Bado 2022).

1.3 Aims and Objectives

Engineering Degree Apprenticeships (DAs) are transformative courses that combine working in industry (on-the-job learning) while studying for an academic degree at university. The development of knowledge, skills, and behaviours (KSBs) required for occupational competence in a job role is at the core of the course. Therefore, active learning approaches can be more beneficial in these courses to ensure effective learning. This work aims to introduce point-based gaming (PBG) through the implementation of a gamification approach in engineering degree apprenticeship modules for enhancing student engagement and deep learning, and comparison with conventional teaching methods. To evaluate the effectiveness of this method, we considered the mark of the final assessment for both PBG and traditional methods in delivering an advanced mechanical engineering module as a success criterion for students achieving the ILOs.

2 METHODOLOGY

Gamification is the application of game principles in a non-gaming context to enhance engagement (Deterding et al. 2011; Huotari and Hamari 2017). Game characteristics can help us achieve an effective learning environment (Sandford et al. 2006).We developed a point-based gaming (PBG) model that utilises the specifics of gamification that contribute to learning, such as low-stakes opportunities to practice, rapid disconfirmatory feedback, and support for cooperative social learning.

The PBG means students play as part of the team and anonymous characters, achieving points for different levels. Ultimately, the ones at the top of the leaderboard gain the trophy. As the levels progress, the points increase exponentially so that the students who could not achieve the points in the first activities do not lose hope, keep their engagement, and try for the epic win. Figure 1 illustrates the student-centred learning innovation flowchart and the four main stages of the PBG. This strategy is helpful for block delivery of modules (modules that are delivered in five full teaching days), a common delivery model in apprenticeship courses.

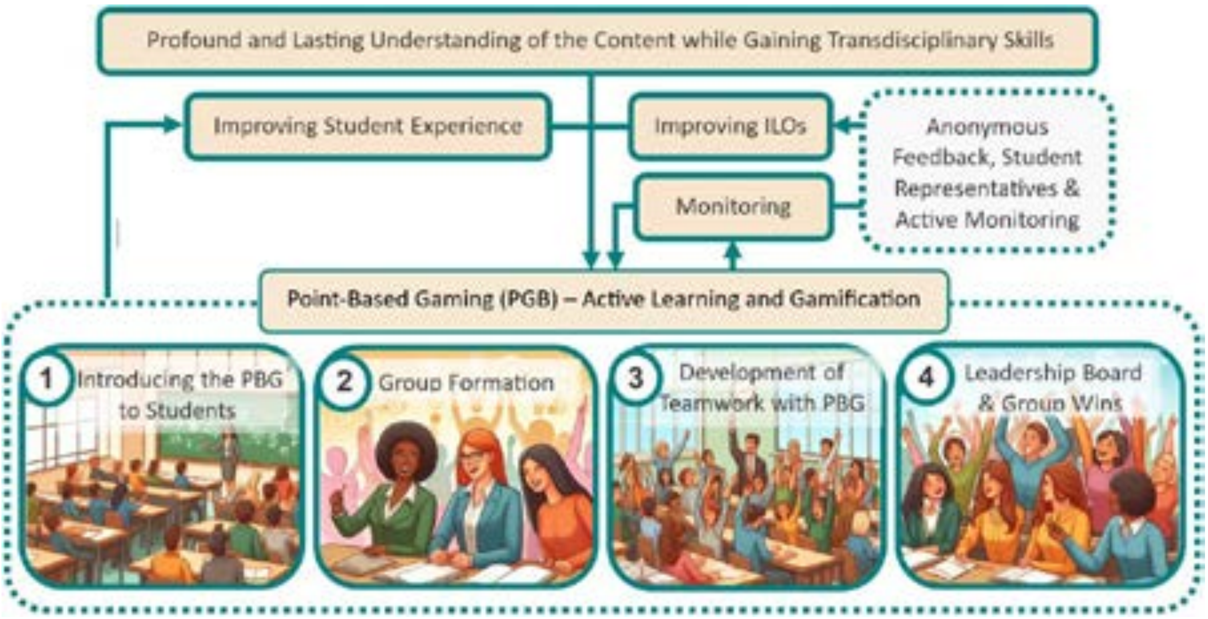

Figure 1. The flow chart of the student-centred learning innovation PBG pedagogy applied in this study, including setting a proper objective, improving the intended learning outcomes (ILOs) and student learning experience, implementing PBG, active learning and game-based learning, and monitoring and applying the changes—the arts in the flow chart are AI-generated using Microsoft Copilot.

This framework is an adaptation of the learning innovation operation, which consists of three main phases: designing, implementation and monitoring (Sancassani et al. 2018). This design aims to give the students a more profound and lasting understanding of the content by providing proper activities (point-based prizes), media, and resources. In this framework, the lecturer's focus is not just on selecting the content but also on designing the entire learning experience so that the students improve their transversal competencies: collaboration, creativity, communication, critical thinking, and a transdisciplinary mindset (Akimov et al. 2023), the ability to find connections among disciplines to solve current challenges or to provide new solutions (McLay et al. 2023). One important goal is to ensure that attending class can be more fun, engaging, and motivating for students and lecturers.

As presented in Figure 1, the PBG consists of four steps. First, the lecturer must introduce the PBG and the importance of having fun while learning to achieve a lasting understanding of the content to the students (Mayer et al. 2013). Students need to be reminded that these points are not marks and will not affect their marking and assignments. In the second step, students are asked to form groups and participate in the PBG activities. They may resist forming a functional group for the first activity, but step three usually resolves this issue.

In step 3, it is essential to motivate teamwork by introducing game rules that dedicate triple points for a team with all active members (interactions within each group) and times 100 points for them if they present their solution to the class (group interactions). As a result, students start forming a functional group. In step 4, it is time to introduce the leadership board, which records the student points throughout the day. The group with the highest number of points wins. The monitoring phase and confirmation are done with the help of student representatives, an anonymous feedback platform and active monitoring of students' reactions and engagement during the class. It is fundamental for the learning process.

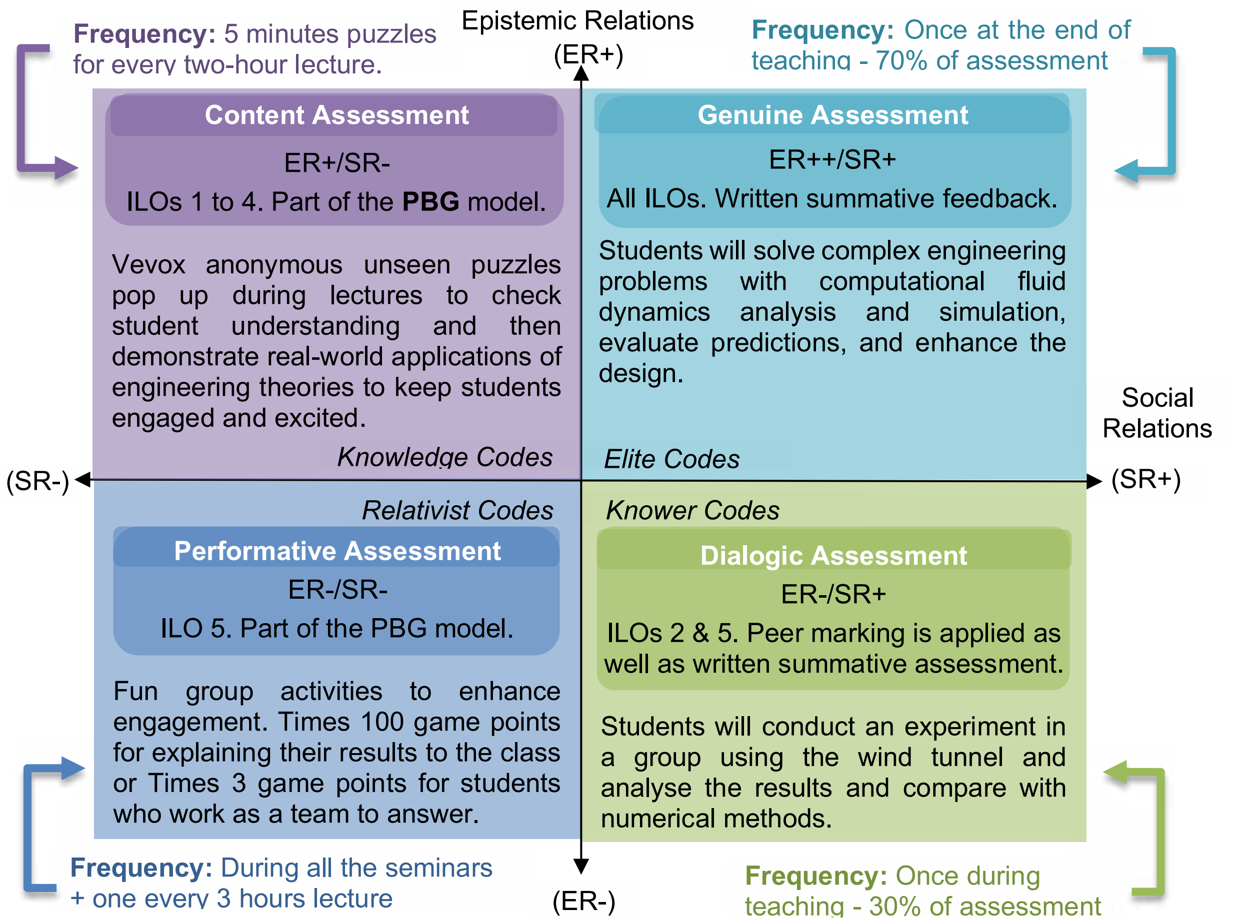

Figure 2. A framework of assessment inquiry specialisation plane was adapted from Maton (Maton 2013; Forde-Leaves et al. 2023) *and they are applied to the case study of this paper for the advanced engineering module. The ILOs for this module are to solve complex engineering problems and optimise design parameters (ILO1), critically examine different experimental and numerical data (ILO2), examine different assumptions for simplifying complex engineering problems (ILO3), apply innovative ideas into designs and examine their efficiency (ILO4), and demonstrate the ability to function effectively as an individual or as a member or leader of a team (ILO5).*

The content of PBG depends on the module and can be applied to different fields. The activities must include active learning, short anonymous quizzes, industry-related and real-life applications, theories, and calculations. Hence, they solve the activities using different tools, from the traditional paper and whiteboard to the Vevox platform and Engineering software packages. During the PGB activities, it is important that the focus is on deep learning, and they can link theories to real-life problems. Figure 2 presents the assessment inquiry specialisation plane adapted from Maton (Forde-Leaves et al. 2023; Maton 2013; Kukuczka 2024) for the case study of this practice paper. This plan includes the summative assessments, the PGB activities, their link to the ILOs, and their focus and frequency.

3 Results and Discussion

To evaluate the effect of PBG on student learning, the mark of the final assessment is considered for two types of assessment: type 1 is a closed book exam, and type 2 is a project-based assessment. For each type, the results are shown for two cohorts, one after conventional teaching and another after teaching based on the learning innovation method, including PGB. The content, level, and student entrance criteria to the degree are similar. Figure 3 presents the final assessment grade distribution results for the case studies.

	1st	2.1	2.2	3rd	Fail
Conventional	4%	32%	8%	28%	28%
Student-Centred with PBG	41%	44%	11%	4%	0%

	1st	2.1	2.2	3rd	Fail
Conventional	7%	43%	43%	7%	0%
Student-Centred with PBG	38%	52%	10%	0%	0%

Figure 3. Grade distribution differences of the final exam of an apprentice cohort with a conventional teaching method versus a cohort with a learning innovation method, which includes the PBG, for two assessment types: (a) closed book exam as the final assessment (70%), (b) project-based assignment as the final assessment (70%). These cohorts are skilled and well-experienced, which led them to achieve such an impressive performance.

It is important to point out that various factors of the learning innovation method influenced this change in learning performance, with PGB playing an effective part in it as well. The innovative learning method helped improve students' performance significantly for both closed-book and project-based final assessments. The number of students attending the class is 25 for both cases in the type 1 assessment. The results show a 37% increase in the 1st grade and a 12% increase in 2.1. The second assessment type also follows a similar trend: a 31% increase in the number of students in the 1st grade and a 9% increase in 2.2.

As expected, gamification incorporates essential components that are effective for learning and addresses the teacher's concerns regarding motivating students, their participation, and voluntary commitments.(Paciarotti et al. 2021). This framework also helps to achieve a high-quality education based on Ofsted criteria in-class observation (Ofsted 2019) especially in three key areas, by providing consistent opportunities to practice previously learned skills and knowledge, using appropriate technology and resources to clarify the meanings, and effectively checking for understanding through anonymous quizzes.

To ensure the success of this strategy, two factors must be considered while designing the core activities. First, the topics should be linked to engineering design practice and natural occurrences of relevant phenomena. Second, they apply to real-world challenges, active learning, and engagement. In the PBG activities, students were encouraged to answer the class activities in groups of three. These points were not related to any of the module's formal marks and were only defined to motivate students to participate in the game, which led to high engagement of the attendees for each day. It had previously been observed that following a conventional approach, only a few students would volunteer to participate in the activities or present their answers. Usually, only a few specific students participated in the conventional method.

PBG was incorporated into another module and had a similar response. Based on the module feedback, 91% to 95% of students found the subject exciting and intellectually stimulating and gained interdisciplinary skills to bring information and ideas together from different topics. Student achievement of the learning outcomes was evaluated using two assessments, including a group project assignment and an exam.

4 CONCLUSION

Creating an environment that promotes engaging and innovative learning experiences enhances students' interactions with the teacher and course materials, leading to better academic outcomes. This work presented a learning innovation framework for the point-based gaming (PBG) method in an advanced mechanical engineering course. The effects of PGB activities on academic performance were investigated by comparing the final assessment marks for two types of teaching: conventional and learning innovation-based with PBG. Apart from the enhanced student engagement and motivation, a significant increase in academic performance was achieved, with over 30% in the number of students achieving the 1st grade and a 10% increase in 2.1. This framework also helps to achieve a high-quality education based on the Ofsted criteria in-class observation. Another advantage of PBG is cost and time efficiency; it does not require high game design quality or support. This practice demonstrates the impact of incorporating PBG in delivering advanced engineering subjects.

ABSTRACT

We are developing a new approach to leverage Mixed Reality (MR) affordances for teaching microfabrication processes, such as performed in a cleanroom. Our goal is to design interactive MR content to improve microfabrication and cleanroom training practices. MR presents a promising avenue as it allows hands-free interaction with the system and diminishes cognitive load when learning complex content. We

[1] *Q. Shan*
qinglan.shan@epfl.ch

incorporate diverse learning techniques such as real-time feedback, scaffolding, simulations, inquiries, and multimodal interactions to enhance the efficacy and feasibility of educational practices in the design of applications. In a course about microfabrication in bachelor curriculum, we carried out hands-on training sessions in a real cleanroom environment. By the end of the course, five students completed their experiments. We observed that MR was effective in customizing learning experiences and increasing student engagement. Additionally, MR proved helpful for teaching assistants in clarifying complex concepts and phenomena related to the fabrication tools during practical sessions. Although the small sample size limits our ability to draw definitive conclusions, initial qualitative assessments and post-training evaluations suggest that integrating MR into practical engineering education holds great promise.

1 INTRODUCTION

1.1 Background

Learning microtechnology/nanotechnology (Micro/Nano-tech) can be difficult because of its multi- and interdisciplinary nature (i.e., a mixture of biology, physics, math, chemistry, and engineering). Microfabrication faces complicated teaching and learning problems. There is a significant demand in well-trained workforce, yet educational institutions often lack the necessary infrastructure. Students find it difficult to integrate knowledge from these diverse fields and to apply it to the 'invisible' micro-scale. Many are hesitant to operate in laboratory settings due to the intricacies involved. Microfabrication not only demands a grasp of these foundational concepts but also the development of practical skills through hands-on laboratory experiences. However, equipping a lab with the required facilities, including a cleanroom, alongside ensuring safety training and the availability of skilled personnel, poses its own set of challenges.

1.2 Literature Review

Extended reality (XR) is growing rapidly in a range of industries and education (Fortman and Quintana 2023). XR is the overarching term that encapsulates current and future development in virtual reality (VR), augmented reality (AR), and mixed reality (MR) (Logeswaran et al. 2021). The application of XR in engineering and STEM education is increasingly diverse and impactful. For instance, AR has been effectively utilized in chemistry lab experiments to enhance learning and training (Chen and Liu 2020), (Dinc et al. 2021), (Domínguez Alfaro et al. 2022). Besides, AR also has the potential to make abstract concepts more tangible, as demonstrated in physics (Radu et al. 2023), (Radu and Schneider 2019), or bioscience education (Reeves et al. 2021). In the context of VR education, VR supports mathematics education through embodied learning mechanisms, enhancing students' engagement and understanding (Chatain et al. 2023), problem-solving skills (Halabi 2020), etc. MR has been shown to improve learning outcomes across various STEM subjects, offering interactive and immersive experiences. In the field of microfabrication specifically, research is currently more limited but still noteworthy. For example, an accessible VR ecosystem provides immersive education in nanotechnology (Kamali-Sarvestani et al. 2020), and a recent MR application has been developed for microfluidics courses (De Micheli et al. 2022). The complex and interdisciplinary nature of microfabrication, which integrates elements of physics, chemistry, and mathematics, presents unique challenges in translating theoretical concepts into practical applications for students. XR technologies, therefore, offer promising solutions to these educational challenges by making intricate and often invisible aspects of microfabrication more accessible and understandable.

As for the pedagogical methods, mixed-method combines the qualitative and quantitative approaches to provide a comprehensive understanding (Borrego, Douglas, and Amelink 2009), which has been applied associated with XR studies (Johnson-Glenberg and Megowan-Romanowicz 2017). Additionally, core theories in learning sciences, such as Kolb's Experiential Learning Theory, emphasize the importance of hands-on training, enabling students to benefit from concrete experiences (Kolb 2014). The concept of scaffolding, introduced by Bruner, involves providing essential instructional support that gradually decreases as learners become more proficient (Bruner 2009). The use of interactive media in XR is particularly intriguing because it can dynamically and personally adjust this scaffolding. The idea of productive failure is activating the prior knowledge and attention to a hidden efficacy through the designed failures (Kapur 2008). These educational foundations have been widely applied across various topics((Fleischer et al. 2023), (Hou and Keng 2020), (Quintana et al. 2004), demonstrating their effectiveness in enhancing learning outcomes through XR technologies.

2 METHOD – APPLICATION DESIGN AND MODULES

In this practice paper, we introduce *MixedLAB*, an MR application designed to blend virtual and real environments for microfabrication learning. Unlike fully virtual simulations, *MixedLAB* complements physical experiments by bridging the gap between theory and hands-on practice. This tool allows students to visualize and understand complex processes before performing actual experiments, thereby boosting their confidence and competence.

By integrating MR tools like MixedLAB into our teaching, we preserve the irreplaceable value of tactile, hands-on learning while enhancing it with digital technology. This innovative approach promises to equip future engineers and scientists with the knowledge and skills needed to excel in an increasingly complex and interdisciplinary field.

Many MR and AR applications focus on replicating real-world interactions with high-fidelity and immersive environments. However, they often fall into the trap of emphasizing technological affordances over the student’s learning experience. To avoid this, we began our project design by conducting interviews and semi-structured investigations among students learning microfabrication. This helped us ensure that our design meets the real needs of students.

MixedLAB, designed for MR headsets like the HoloLens (Microsoft), utilizes the Microsoft Mixed Reality Toolkit (MRTK) to support specific learning scenarios in microfabrication. It offers a set of experiences that supplement the practical modules assigned by educators, with each module focusing on a specific skill or knowledge area in microfabrication. Additionally, the system's content can be customized for other subjects, making it versatile for broader educational applications. To address the high development costs of AR within Unity, we created an administrative platform that allows teachers to modify content, significantly reducing future development time and costs.

2.1 Description of *MixedLAB*

The present study applies a co-design methodology (Sanders and Stappers 2008), which invites the stakeholders into the design process, including teachers, researchers, and students.

The iterative process began with the definition of the educational need, which is to better teach students experimental knowledge with a deeper understanding. Besides, after the co-design process, we selected several topics that are fundamental and challenging since they require both theoretical knowledge and experimental experience. Subsequently, a low-fidelity prototype was created and evaluated. For this process, 8 students and researchers in engineering participated in a think-out-loud study and completed usability questionnaires. The think-out-loud process helped define problems in the first version such as no direct feedback and response after interacting with buttons, voice inputs are not intuitive, etc.

It is worth noting that after the first pilot study, we found that several topics such as photolithography in microfabrication are suitable for MR learning. This topic was chosen in the case study as it is one of the typical and fundamental experiments done repeatedly in introductory courses of both undergraduate and graduate curricula. Furthermore, students struggle to understand the phenomena and reactions during the fabrication process while operating advanced equipment because of the lack of visibility.

2.2 Application Design Principles

Figure 1 displays different screenshots from *MixedLAB's* learning modules. These codes, integral to physical, real-world scenarios, allow for an overlay of digital information, like visualizations and auditory feedback, directly onto actual experiences. When participants scan a placed QR code, *MixedLAB* guides them through relevant learning modules, such as substrate pre-treatment steps. The subsequent paragraphs will delve into how the application, adhering to essential learning science principles, was developed:

Scaffolding: The term “scaffolding” is used in learning science to refer to support designed to help participants learn productively in problem-solving contexts (Fischer 2018). We designed virtual representations that gradually display and support participants from different perspectives. For example, to help students understand why Hexamethyldisilane (HMDS) treatment does not work on chromium surfaces, we start by zooming in to show 3D structures of molecules at the nanoscopic level. Finally, we conclude and guide them through the experimental processes (Figure 1. a, b).

Real-time feedback: In practices, it is common that one teaching assistant (TA) needs to coach students in a group, which results in neglecting individual students’ needs and questions. However, the idea of *MixedLAB* is as participants engage in tasks, they receive immediate, contextual information about their actions. For instance, if a student makes a mistake, the system guides him/her to understand and correct it. This instantaneous feedback ensures that all the participants are engaged and learn through the interactive representations (Figure 1. c).

Personalized learning trajectory: In *MixedLAB*, personalized learning trajectory tailors the educational experience to each participant’s unique needs and learning speed in the MR affordances. It accommodates different learning styles and speeds, making the study of experimental practices more efficient and effective, as students can better focus on what they need for their improvement. At the same time, the system tracks students’ performance data such as their attempts on questions, time spent on the single questions, etc. Researchers can analyze students’ log data to adapt to the level of difficulties and problems students mostly struggle with (Figure 1. d).

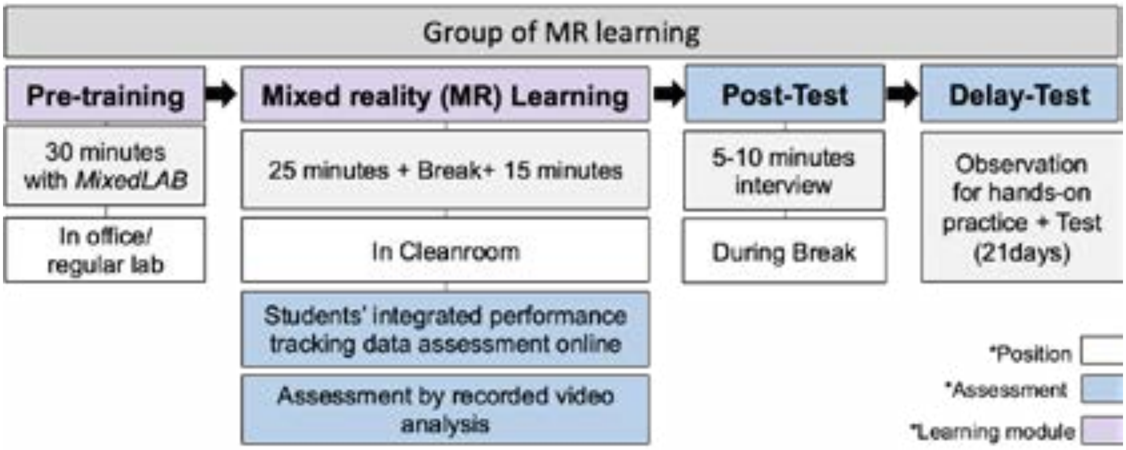
Reward system of gamification: Incorporating a rewarding system of gamification into the application enhances engagement and motivation in learning and has been used a lot in XR educational applications (Díaz et al. 2019). We applied a reward system to the questions to encourage students to answer the questions quickly and correctly. The participants' initial attempts at the task will be recorded. If they answer correctly within the allotted time, they will earn a golden coin. However, if they answer after the time limit, they will receive a silver coin instead. In this case, students are still allowed to explore different options but still get rewards for performances. This gamified approach makes the learning process more enjoyable and stimulating, encouraging continuous participation and effort (Figure 1. c).

Figure 1. First-person engagement with different design functionalities inside the MixedLAB application: (a) While learning pre-treatment in photolithography, it provides 3D model representations to display the reactions behind the theory. (b) A screenshot of the spin coating module process flows to finish the steps, which reminds participants to check their process and “check” virtually on the button. (c) A screenshot of real-time feedback and reward coins from the integrated quizzes. (d) A screenshot after selecting wrongly in the previous quiz step, a further explanation with simultaneous graphics and text are displayed.

3 METHOD – APPLICATION DESIGN AND MODULES

3.1 Participants and Curriculum

Once the Human Research Ethics Committee approved our proposed experiment (No: HREC000439), we invited undergraduate students to enrol in the practical course for microfabrication. Eight of the twelve undergraduate students participated



in the experiment voluntarily ($N_{class}=12$, $N_{MR}=8$). The students were invited to take part in the pre-training for HoloLens one week before the experiment. Each participant spent around 30 minutes on the 'playground' designed for them in the same *MixedLAB* application to get familiar with the basic functions. No participant reported their discomfort during the pre-training. Ultimately, five students were able to conduct the experiments due to scheduling conflicts. We obtained their consent before participation and assigned each a code to anonymously track their performance via the application. It is important to note that this performance tracking did not affect their official course grades, and no personal information was required to ensure anonymity. The entire process is illustrated in Figure 2.

Figure 2. Process flow of participation

3.2 Results and Discussion

Because of the low number targeted participants, we did not take the between-subjects comparison to split the volunteers into two conditions. Instead, we

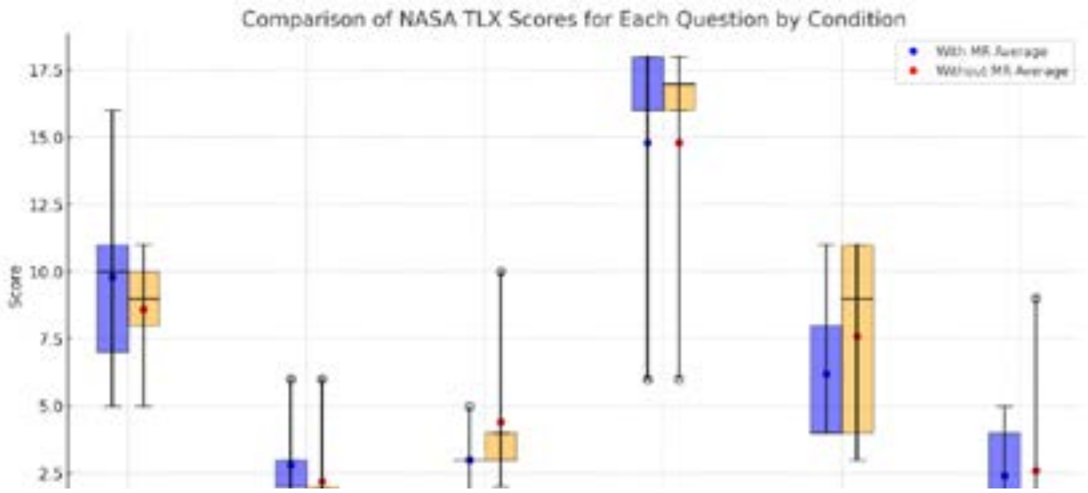


Figure 3. NASA TLS comparison between two conditions: students performed experiment with MR and then tested their knowledge without MR in the same environment after 21 days

calculated the NASA Task Load Index (TLX) (Hart and Staveland 1988) cognitive load of MR condition and Non-MR condition by within-group comparison in Figure 3. Although the result is not significant, we can still extract that it is slightly more physically demanding, and mentally demanding in MR condition. On the other hand, it is less temporal demanding, less frustrating, less stressful, and requires less effort but with higher successful performance.

In Table 1, We conducted semi-structured interviews with the students (see Table 1) to help researchers better understand which features of MR in engineering education students enjoyed. And those quotes are selected removing "no comments" and redundant feedback. From the table, we could interpret that students benefit from practical learning, personalized learning, interactions, etc. Also, we could see that experimenting with MR is unexpectedly natural and presenting differently compared with the classroom. As Figure 4 and Figure 5 depict that students are working individually with virtual guidance, this also coincides with their qualitative feedback (as P4 says).

Table 1. Feedback from students with semi-structure interview

Questions	Code	Voice answers transcripts
How do you feel after a mixed reality experience?	P3	"It is fun, it is really good, and it **changes from the classroom**."
	P1	"It is **natural**, actually I **can't really feel it**, I know where is dangerous and this makes me **feel safe**."
	P2	"In general, I am feeling good and it's **really fun**…"
What is the good part of the *MixedLAB* application for you?	P2	"I like it when you have the video **presenting something wrong** with sound effects that is bad (subsequence)."
	P3	"You can **see the stuff you have to do at the same time** as what you (are) do, if you are confused at something the instructions just by your side, you don't have to do in new place, a lot of paper of stuff."
	P4	"The best thing for me is I can **learn on my own pace**, I feel comfortable when I am learning. Sometimes when I feel it is fast, I am a little bit scary to say this is too fast so I missed a bit of something. But with HoloLens (*MixedLAB*), I wouldn't be because it was so interesting and I would like to know all the details provided…… I was swimming in it."
	P5	"At first, **I didn't expect this work well on me**… But, I can really learn practices that is not included in the classroom through this … I want to learn something practical, this could be good."
What do you think of the system embedded in practical teaching?	T1	"For me, it **saves a lot of energy and time**, I also joined the design so I know for those procedures I just need to observe the students' performances and focusing more on answering their creative questions, and check if they are making any serious mistakes…"

4 SUMMARY AND OUTLOOK

In this paper, we introduced MR in engineering education, specifically microfabrication, and conducted a practice course with a small group of students. Due to the limited number of participants, we cannot state any certain conclusion. However, this practice paper allows us to explore more on the affordances provided by MR and conclude the efficient design principles and learning science principles that are aligned with them. Specifically, students enjoyed the personalized learning trajectory, the multi-media scaffolding compared to how they learn in class. The MR seems to work well if designed properly to guide them with scaffolds and experimental knowledge such as potential risks and failure, correct process, and various TA's experience. We can also conclude that students feel engaged with the MR tool while doing their experiment and it is a unique opportunity for students to bridge practical and theory simultaneously. We encourage to apply MR-assisted learning in practical experiments when students know they are safe in the environment and the instructions can be designed to distinguish virtualism and reality. Through qualitative analysis, it is worth knowing that for some subjects personalized MR-assisted learning could trigger higher confidence and achievement.

Besides, by reducing the time and effort required for TAs to provide individualized support, MR allows for more efficient and effective instructional practices. It would be promising to see whether MR enables TAs to focus more on direct interaction with students, offering timely feedback and guidance. Additionally, it is worth examining if students receive better support and personalized attention, enhancing their understanding and engagement.

Inspired by this study, we will follow up with a subsequent phase study focusing on how embodiment affects students' learning outcomes with MR, especially for conceptual understanding. Also, we will focus more on TAs' responses and tiredness while collaborating with MR tools. Ultimately, we aim to apply our concept to different experimental knowledge learning scenarios, which may lead to more efficient engineering education and science education.

5 ACKNOWLEDGEMENT

This research is financially by DRIL funds at EPFL. We thank afca.ag company for its contribution to development. We thank our teaching assistants in the microsystem laboratory for assisting with the experiments. We also thank our participants for spending time and sharing their experiences.

ABSTRACT

Computational modelling is important in the life sciences, but students may not be greatly exposed to it in typical curricula. This paper describes an innovative, one-semester Master's level course in cell biology that uses computer simulations as the primary learning tool. The course originated in the idea that performing simulations can increase students' biological insight by animating static textbook/blackboard images into dynamical life. The students identify a cellular behaviour and carry out simulation-based exercises, culminating in a semester project. In addition to mastering the course material, the students develop proficiency in transversal skills: they learn to disassemble the complexity of a living cell, and recreate it in a model; they use computers to probe biological questions, thereby developing their computational thinking; and they become aware of the computational resources and data management issues necessary to manage large data sets. Working in teams on a project helps improve their scientific collaboration and communication skills. These skills are highly transferable to other domains of research and industry. This course provides evidence that simulation-based teaching can enhance students' learning, and prepare them for careers in subjects such as cell biology that might not be obvious candidates for simulation-based learning.

1 INTRODUCTION

In creative writing, a good novel delivers more than you might expect. A good course in science or engineering can do the same. Cell biology is an experiment-heavy discipline that generates large amounts of data, and it requires experience to manage both theory and data efficiently. However, within life science lecture courses, students are often exposed only to the static pictures that appear in textbooks or light and electron microscopy images. Because the world outside the classroom is more dynamic and complex than textbook images, how can students learn the core subject matter of cellular biology, and acquire proficiency in transversal skills such as model abstraction, data management, and hypothesis generation and testing?

This paper describes an innovative course in cellular biophysics — Computational Cell Biology that uses computer simulations as the main learning tool. A recent highly-cited meta-analysis of simulation-based learning has shown it to be beneficial in engineering curricula (Chernikova et al. 2020). Simulation-based learning in general may include role-playing scenarios, such as medical interventions, expertise development (Jossberger et al. 2022) as well as computer-based simulations. In the present paper, I restrict the discussion here to computer simulations carried out on digital computers, for which the students are required to set up, run, and analyse the results of the simulations.

Computer simulations have been used for many years to study complex dynamical systems, and this has led to the idea of Systems Dynamics Modelling (https://systemdynamics.org). This discipline focuses on quantitatively capturing the interactions, feedback, and evolution of complex systems in computer models. Although this perspective provides a more complete understanding of dynamical systems, it is not necessarily simple to persuade people of this (Senge 2020). In specific fields, simulations have been used to present introductory biology to non-biology students in STEM subjects (Kohn et al. 2018); to simulate processing of stone in mining (Akkoyun 2017); and econometric modelling (Fu et al. 2022). Training engineers in modelling and simulations is increasingly recognised as important (Magana 2017). These studies demonstrated the benefits for students of manipulating and analysing large datasets. Fu et al. (2022) showed that both high-achieving and lower-achieving students benefit from the transversal skills acquired in using simulations. Student motivation also increases when they are able to select and carry out their own simulation projects (Datta et al. 2010). In the course described in the present work, the core biological subject matter is encountered by the students through modelling and simulations. They acquire a range of transferable skills that are applicable to many data-heavy subjects. Funding agencies including the EU and Swiss National Science Foundation require applicants to prepare Data Management Plans before giving funding, and acquiring skills in data handling has become essential in laboratory work, industry, and large collaborative projects.

2 METHODOLOGY

2.1 Aims in setting up the course

I created the course Computational Cell Biology (CCB) in 2018 because I believe that computer simulations can be an effective tool for students in life sciences to gain insight into cellular dynamics by constructing a model and exploring its behaviour.

This active use of modelling provides opportunities for greater skill development and understanding than lectures alone. An innovative aspect of the CCB course is that it utilises three disparate components: 1) blackboard presentation of the core cell biology; 2) a quantitative study of mathematical models of typical cell biological dynamics, e.g., diffusion as a random walk; 3) a semester-long use of computer simulations, including the need to manage the large amounts of data produced. The students use the provided simulation tool to generate data on a cell biological model they construct. They analyse their data, and write up the work as a scientific paper which they present to the class at the end of the semester.

One challenge of this approach is revealed by the background quiz given in the first lecture. This samples what they already know about the biology, chemistry, mathematics, and numerical analysis that form the theoretical content of the course. The class is usually small (10 - 25 students, Fig. 1), and although the majority of the students are in the Faculty of Life Sciences, there are usually 1-2 from other faculties, such as mathematics, physics or materials science. At least half the students are female. One of the background questions is: *I prefer to think of biological questions in terms of a) equations, or b) experiments that reveal their behaviour*. Routinely, fewer than half the responses select a), showing that mathematical modelling of cell biology is not a common way of thinking for Master's students in the subject. I have observed that for many students it is the first time they have set up and run a simulation. For a sizeable minority, it is the first time they execute a programme from the command line of their laptop.

The teaching elements of the course are selected to help students develop transversal skills in abstraction, simulations, and managing large amounts of data, all while learning the core material. Active learning techniques are used in the lectures to help the students surmount their unfamiliarity with simulations. The need to work in groups to complete the project promotes a sense of engagement during the course. Students' progress is assessed in several ways: in class tests reveal how well students assimilate the core biology; but a greater weight is given to the homework exercises and project, which measure their learning in areas which I believe are more useful for their subsequent careers.

3 RESULTS

3.1 How has the course evolved?

Learning to use a complex software tool is difficult, and the learning curve is lowered when student share their knowledge with each other as they progress. The lectures and exercise periods have a dual use — presentation of the core cell biology, and preparing students for their project. Active learning opportunities have been increased over the years, and ideas on research data management incorporated. These have increased the students' transversal skills. Think-Pair-Share (TPS) opportunities allow the students to connect an abstract theoretical idea to concrete examples. This often reveals that although students may be able to describe a concept (e.g., diffusion), they have difficulty in generalising it beyond the cartoon picture in a textbook. TPS appears to enhance students' ability to *translate* a theoretical picture of cell biology into a working model.

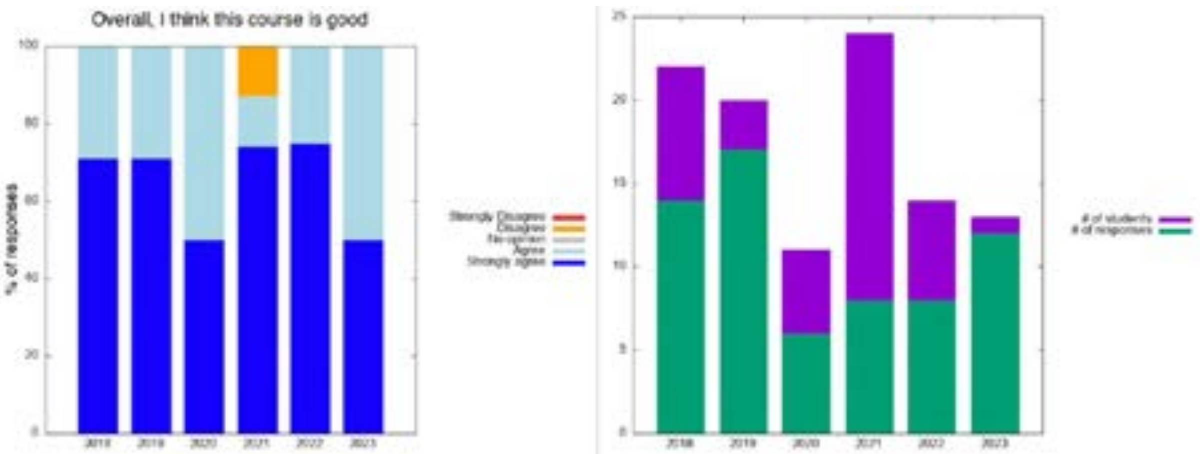

Figure 1. a) Overall student satisfaction with the course is high, and b) student feedback response rate is typically above 50%, indicating a high motivation level for the teaching style.

Feedback from the students consistently shows that they value this style of learning (Fig. 1a), and more than 50% of the students usually participate in the course evaluation, which also indicates their commitment (Fig. 1b). During the covid period (2020/21), another active feedback element was added to the course. After each (online) lecture, I asked the students to send me an email containing what they thought were the “Important Points” of the lecture. I would start the following lecture by presenting what I believe to be the Core Concepts, and we would discuss the similarity/differences between their views and mine. Now that the course is in person, I have retained the core concepts because students indicated that it helped them better assimilate the theoretical material.

During the exercise period, scaffolding exercises in the first 2-3 weeks lead students into the first homework exercise in which they perform simulations in their own time. The simulation tool is provided to the students, and is available on github (https://github.com/Osprey-DPD/osprey-dpd). Each year, one or two students download it and explore it further themselves. Because the codebase is around 500,000 lines of C++, they typically do not modify it, but they gain an appreciation for the complexity of simulation codes. Homework exercises, which usually require tens of simulations, prepare the students to manage their projects, which are 50% of the final grade. An additional benefit of the homework simulations is that students learn to anticipate the volume of data their project will generate. Even creating a naming scheme for the hundreds of files produced by their simulations can be overwhelming as well as tedious, and data management is a key transversal skill in research. Data Management Plans (DMP) are becoming a requirement of the Swiss National Science Foundation and the European Commission’s funding programmes. I introduce the concept of a DMP and the FAIR principles for managing research data: data should be annotated so that it is Findable, Accessible, Interoperable, and Reusable (see, for example, https://dmptool.org/general_guidance).

The students report in the annual course evaluation that the mixed nature of the teaching elements stimulates their interest in the material (Fig. 2a), although the workload is found to be challenging (Fig. 2b). The transversal skills are assessed as important for their future careers in academic and industrial research. This is supported by student comments (some text has been removed for brevity):

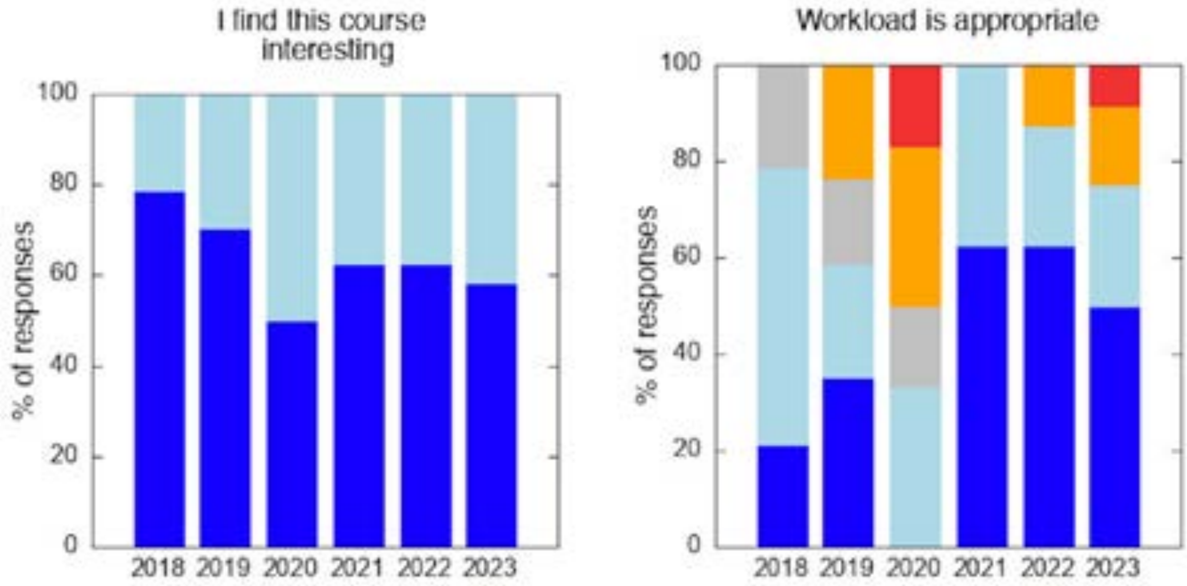

Figure 2. a) The course is consistently found to be interesting. This is attributed by the students to the mix of exercises, theory, and class discussions. b) The workload is found to be challenging, but overall manageable. (Color coded responses as in Figure 1.)

2023 I found this course interesting since we had exams to assess what we saw in the lectures, and projects to work on the computational side. I learned a lot about computational cell biology and biophysics and I am interested in learning more.

2020 Great course to give intuition about the concepts governing behaviour at the cellular scale. One of the only courses trying to bring together different disciplines in such a useful, applied, understandable manner. Course makes me feel more ready for handling this kind of problem and data in a professional setting later on.

2018 The course is very interesting. The practical component of the course is very useful to learn more about each topic in the theoretic part of the lesson.

Finally, the distinctive structure of the course has not affected the students' grades, as almost all students pass each year (Fig. 3). Interestingly, the variance in the marks increased during the covid period (2020). NB. The number of students indicated in Figure 3 is less than that in Figure 1b because not all students who initially register for the course go on to take it for credit.

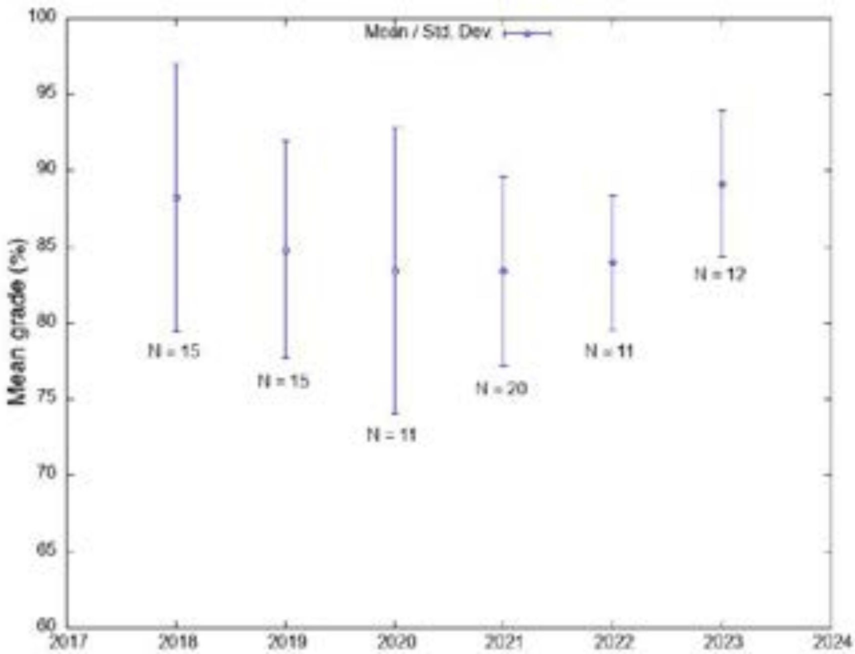

Figure 3. Mean percentage grade of the students taking the course for credit for the years in which the course has been taught. The grade is accumulated from the course assessment elements as described in Section 2 Methodology. Error bars are the standard deviation of the distribution.

4 SUMMARY

Cell biology involves dynamic phenomena in living cells, a perspective that lectures alone cannot convey. This Master's level course uses computational modelling to help the students acquire a better appreciation of the dynamics inside cells. They also gain important transversal skills relating to open-source software and the FAIR principles of research data management. Active learning techniques promote student engagement in the class, and group problem solving allows them to explore larger cell biology problems than they could manage individually. Course evaluation feedback (Figures 1, 2) reveals that the students find this mix of theoretical and practical exploration encourages them to learn. The concept of exploring a subject using computational modelling could be applied to many engineering disciplines provided certain criteria are met. Primary among these is that a suitable simulation tool must be available (preferably open source to allow students to examine its structure); students must be able to master the simulations in the time available; and relevant and interesting problems in the field should be amenable to simulation. Practically, it is crucial that sufficient exercise time be allocated to bring the students up to speed with running simulations, which might limit this approach to smaller class sizes (< 25), unless the students are already familiar with the technique or trained assistants are available. Finally, the combination of traditional lectures with simulations creates a demanding workload (Figure 2b), which is here alleviated by encouraging the students to send questions by email, and discussing them at the beginning of each class.

My goal with the course is to have the students leave with the attitude of "always be asking questions." Translating complex dynamical phenomena into a set of simulations reveals what is important in a problem, and what is ignorable. These are important conceptual skills that can be applied in their subsequent careers.

ORCID 0000-0003-3435-3202

Conference Key Areas: *Teaching the knowledge, skills and attitudes of sustainable engineering, Curriculum development and emerging curriculum models in engineering.*
Keywords: *Life Cycle Assessment (LCA), Sustainability, Project-Based Learning, Excel-based Tool, Multidisciplinary*

ABSTRACT

Amidst the escalating urgency to address environmental degradation and sustainability challenges, there exists a critical gap in engineering education: the inadequate integration of Education for Sustainable Development (ESD). In response to this challenge, this paper presents an innovative Excel-based tool tailored for multidisciplinary engineering programs. This tool aims to seamlessly integrate Life Cycle Assessments (LCA) into engineering curricula, fostering project-based learning. Developed for undergraduate students, the tool uses a T-shaped teaching approach providing engineering training across breadth of disciplines, while emphasizing an in-depth training of fundamental engineering skills as well. The tool is developed in a user-friendly format, with step-by-step guidance, and focused on adaptability for interdisciplinary collaboration. Through iterative development and feedback, the paper discusses challenges, strategies, and the potential impact of this tool on engineering education, ultimately contributing to the cultivation of socially and environmentally responsible engineers.

1 INTRODUCTION

With the increasing need for solutions for climate crisis, there is an increasing demand for including Education for Sustainable Development (ESD) across different engineering disciplines and institutes (UNESCO 2020). ESD when integrated with engineering, encompasses teaching principles and practices that equip students with the knowledge and skills to develop solutions that balance environmental, social, and economic considerations, aiming to address global challenges (Huntzinger et al. 2007). It covers various methods, including life cycle assessment (LCA), green design and technology, renewable energy systems, waste management strategies, eco-efficient manufacturing processes, sustainable infrastructure development, and environmental impact assessment techniques(Byrne et al. 2010; Kamp 2006).

LCA, especially, is important for holistic teaching of sustainability in engineering as it provides comprehensive insights into environmental impacts across the entire lifecycle of sustainable solutions, thus aiding informed decision-making (Mälkki and Alanne 2017). LCA is a method used to evaluate the environmental impacts of a product or process throughout its entire life cycle, i.e. from raw material extraction, manufacturing, transportation to the usage and disposal (Hauschild et al. 2018).

Multiple efforts have been made to use LCA in different curricula all around the world (Piekarski et al. 2019; Cosme et al. 2019; Hauschild, Rosenbaum, and Olsen 2018; Bevilacqua et al. 2015). All these studies show that the tools which are deployed to teach LCA are proprietary tool and need licensing rights on either the software or the databases, e.g. Simapro[i], GaBi[ii], Umberto[iii], OpenLCA[iv], etc. Thus, it limits many universities and institutes to teach LCA in an effective manner without being dependent on a hefty cost or licensing limitations (Viere et al. 2021). At the same time, LCA is a very applicative skill and thus for teaching LCA and other sustainable engineering education methods, project-based setup is ideal. Project-based approach involves students to learn through hands-on, real-world projects that foster inquiry, collaboration, and critical thinking (Uziak 2016; Frank et al. 2003). With given complexity of the project-based approaches, the tools need to be easy to use and open for students to be used.

Noticing the lack of any LCA open tools which can be easily used in project-based environment, a tool was developed, and this paper introduces this innovative Excel-based tool designed to integrate LCA into the engineering curriculum. The tool aims at addressing the scarcity of open tools and data for teaching LCA at the undergraduate level. Developed for the "Ecological Design" course at The Engineering and Design Institute-London (TEDI-London), the tool guides second-year undergraduate students through a project-based learning approach cantered on the sustainable renovation of a large building renovation project in London. The purpose of the tool is to be further adapted and developed iteratively and used for other courses and institutes as well.

The paper progresses as follows: Section 2 discusses the method employed for tool development, followed by Section 3 which provides reflection and outlook on challenges & successes of the tool, and Section 4 concludes the paper.

2 METHOD

The LCA excel-based tool was specifically crafted for a 2nd year undergraduate course “Ecological Design” at The Engineering and Design Institute-London (TEDI-London). It is important to reflect on the institute (TEDI-London) and the module (Ecological Design) itself before looking into the tool itself, as the author developed this module and tool to fit in perfectly within the module learning outcomes/objectives (“Apply ecological considerations and assess the environmental impact of the design of an a complex eco-product, process or construction”) and the ethos of institute (“world-conscious global engineering"). Figure 1 shows how the tool was developed as a subobjective of the module, which is further a key objective module of the institute itself. It is important to note here that though this tool was developed for the institute and the module with a project case study in mind, this paper attempts to support adaptation of the tool for different project case studies (in different institutes and modules) as well.

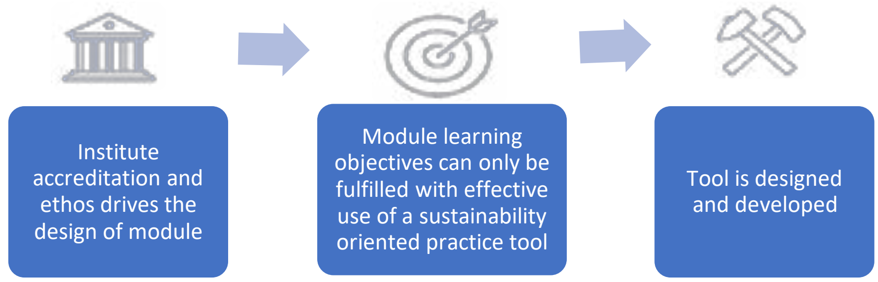

Figure 1: Steps towards development of tool: alignment with institute and module objectives

2.1 Introduction to the institute

TEDI-London, a specialist institute, uses two main approaches for setting up any curriculum. First, nearly all modules follow a project-based learning approach for teaching design and engineering. Secondly, there is always an emphasis on global design approach, focused on responsible engineering i.e. integrating ethical considerations, sustainability principles, and cultural perspectives into the design process to address global challenges. In simple words, each module is developed with consideration of two main steps: (i) a well-organized blend of theoretical instruction, applied tasks, and active engagement with topic-related case studies, and (ii) the execution of authentic case studies in partnership with businesses or other entities.

2.2 Module development

The module on ecological design adopted a consistent approach in teaching LCA, applied within the context of a sustainable renovation project focusing on a building in London.

Project and module objectives: This project focused on the transition of a building from an event venue to a large commercial office space. Students in the ecological design module developed a concept design considering environmental and societal impacts, including energy consumption and end-of-life aspects. They also communicated their engineering processes, assumptions, calculations, and models to the client and stakeholders. All these module objectives were derived from the “Accreditation of Higher Education Programmes” or AHEP in engineering, matched to this module, in line with the UK Standard for Professional Engineering Competence (UK-SPEC)[v].

<u>*Step-by-step synced learning process*</u>**:** The module follows a step-by-step process that mirrors the sequential stages of LCA, which is shown in Figure 2 below (distributed over 10-week module).

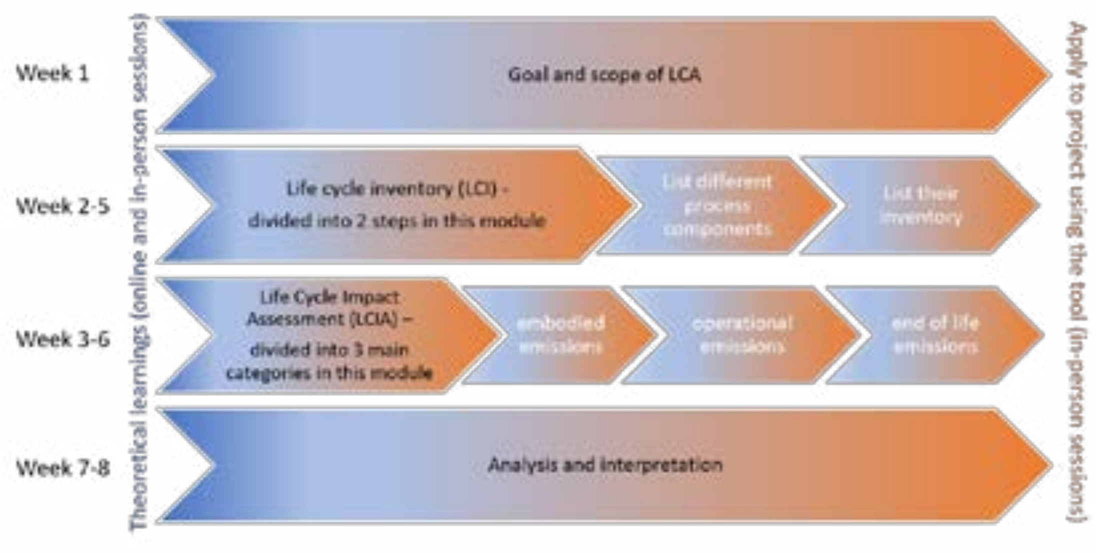

Figure 2: Steps of LCA and syncing with the learning process over the module

Simultaneously, students apply the theories they've learned in the module to a project using an Excel-based tool, ensuring a smooth project-based learning approach.

<u>*Emphasis on fundamental skills*</u>**:** In the module, the main goal was to ensure that students understood the basic principles of LCA and could apply their engineering knowledge to carry out assessments and calculations. Instead of relying solely on software, which often simplifies the process, students were encouraged to think critically and perform calculations themselves.

<u>*T-shaped teaching/learning approach*</u>: The module focused on developing "T-shaped" professionalism, where students gain deep expertise in one area (the vertical stroke of the "T") and broad interdisciplinary skills (the horizontal stroke) (Heinemann, 2009; Elmquist & Johansson, 2011). Mechanical engineering provided vertical expertise on operational emissions (case of a heat pump mechanical design to reduce the operational emissions), while environmental engineering offered horizontal knowledge on building related LCA for sustainable renovations (covering the different emission types across the entire life cycle of a building, e.g. construction/ embodied emissions, operational emissions, etc.). This T-shaped teaching approach, as shown in Figure 3, ensured students acquired specialized skills and a holistic understanding of LCA, aligning with global engineering challenges.

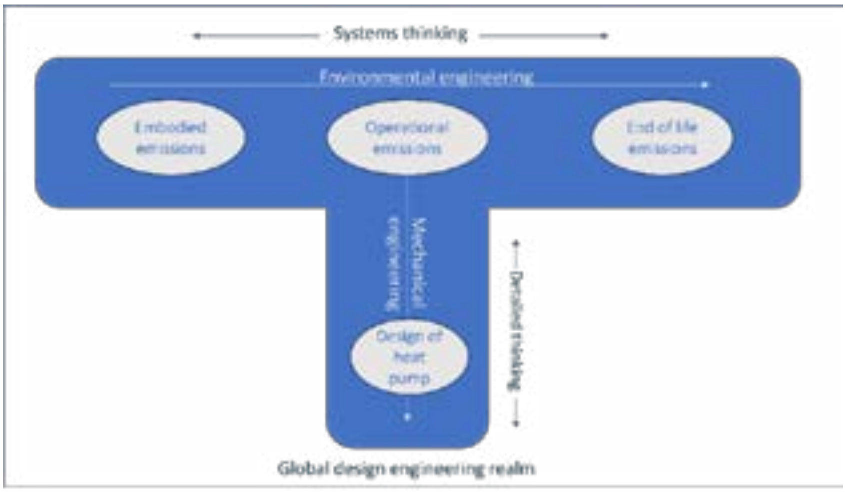

Figure 3: T-shaped teaching/learning approach used for teaching the module

2.3 Tool development

The methodology draws insights from an existing paper and PhD thesis of the author, which was focused on development of a tool for conducting LCA of buildings (Shinde et al. 2024). Similar structure of database and in-built calculations was set up with different data parameters to compute the final total emissions contributed by a building. This tool, consisting of 9 distinct sheets and 3 example sheets, serves as a structured framework guiding students through the multifaceted process of conducting a thorough LCA analysis (in this context, especially for a building construction and renovation process). Figure 4, aligned with steps listed in Figure 3 shows the synchronisation of the tool development with the different stages of LCA. The following subsections discuss each stage, and the including sheets in the tool briefly.

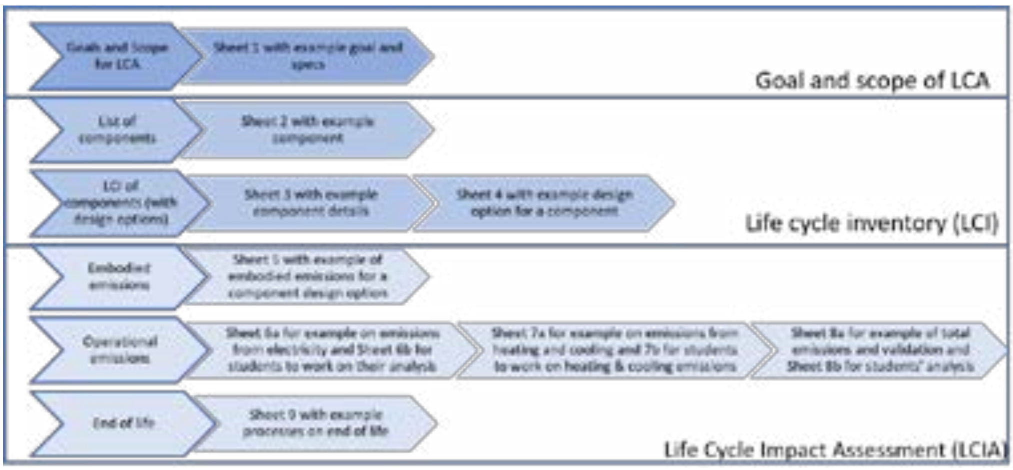

Figure 4: Steps for setting up the excel-based LCA tool

<u>*Goals and Scope for LCA*</u>

The cornerstone of any LCA endeavour lies in setting clear goals and defining the scope of the assessment. Sheet 1 (screenshot in Figure 5) provides a platform for students to articulate these critical elements, establishing the parameters within which the analysis will operate. An example goal, such as reducing greenhouse gas emissions by 20% over the product's lifecycle, along with accompanying specifications, sets the stage for subsequent analysis.

Figure 5: Screenshot of Sheet 1 (goal and scope) in the excel based LCA tool

List of Components

Sheet 2 fosters the systematic compilation of all pertinent components relevant to the product or process under assessment. Students utilize this sheet to identify and categorize components, ensuring a comprehensive evaluation of the entire system. Example of components include roofs, walls, windows, etc.

Life Cycle Inventory (LCI) of Components

Detailing the life cycle inventory of each component, Sheet 3 offers a nuanced understanding of its journey from extraction to disposal. Students delve into the intricacies of raw material extraction, manufacturing processes, transportation logistics, and disposal methods. An example component, such as the steps and processes in designing a roof is accompanied by multiple design options, allowing students to compare various environmental impacts associated with each choice.

Embodied Emissions

Sheet 4 and 5 (screenshot in Figure 6) zooms in on the calculation of embodied emissions incurred during the production and assembly of components. Students grapple with the upstream impacts inherent in manufacturing processes, recognizing the significance of early-stage decisions in minimizing environmental footprints. An example scenario elucidates the embodied emissions linked to a specific design option, underscoring the necessity of holistic consideration in LCA analyses.

Figure 6: Screenshot of Sheet 5 (embodied emissions) in the excel based LCA tool

Operational Emissions and validation

Dedicated to operational emissions, Sheets 6a, 6b, 7a, and 7b shed light on energy consumption throughout the life cycle, stemming from electricity consumption, heating, and cooling processes. Sheet 8a (screenshot in Figure 7) and 8b provides students with a structured template to validate total emissions within the context of their individual projects, reinforcing the importance of meticulous scrutiny in LCA practices.

Building info		building area (approx. gross internal area for operational use, sq.m)	40000
		building lifetime (years)	60
1. Appliances and lighting	Source and emissions	electricity source	UK electricity grid + smart b
		emissions per kWh of electricity source (kgCO_2-eq/kWh)	0.15
	Electricity demands	building electricity demand per square meter (kWh/sq.m./year)	100
		total electricity related operational emissions (kgCO_2-eq/sq.m./yea	15
2. Heating and hot water (+ cooling, as the same system is used)	Source and emissions	heating (and cooling) system energy source	UK electricity grid
		emissions per kWh of heating system energy source (kgCO_2-eq/kW	0.09
	Systems and demands	Heating (and cooling) system	3 Air source heat pump
		Heating system heating capacity (kW)	1028
		Coefficient of performance for heat pumps	3
		Electricity needed per square meter (kWh/sq.m./year)	75.044
		total heating related operational emissions (kgCO_2-eq/sq.m./year)	6.75
3. (Additional) Cooling system	Source and emissions	Additional cooling system cooling energy source	UK electricity grid
		emissions per kWh of cooling system energy source (kgCO_2-eq/kWh	0.15
	Systems and demands	Additional cooling system	radiant chilled panels
		Cooling system energy requirements (kWh/sq.m./year)	38.24
		total chilled panels related operational emissions (kgCO_2-eq/sq.m./	5.74
		Total operational emissions (kgCO_2-eq/sq.m./year)	**27.49**
		Validation data from BI	**26.57**

Figure 7: Screenshot of Sheet 8a in the excel based LCA tool

End of life

Concluding the LCA journey, Sheet 9 contemplates the end-of-life stage, exploring disposal, recycling, and reuse options for components. Through an example scenario, students evaluate the environmental impacts of various end-of-life strategies.

3 REFLECTION AND OUTLOOK

In the following section, personal reflections from the author and informal student feedback are discussed which reflects on the methodology, offering insights into challenges faced, successful strategies employed, and the overall evolution of the curriculum over successive iterations.

Successes

- One notable success in integrating the tool into teaching LCA was students' thorough understanding of the method and its effective stepwise application in large projects.
- Additionally, students showed keen interest in further developing the tool for group assessments, recognizing its value for ease of sharing and collaboration among group members.
- The tool allowed students to grab the fundamental principles of engineering better than introducing a pre-existing tool. For instance, if they used a tool like Simapro to assess the LCA of a product, they wouldn't manually calculate emissions associated with manufacturing because the software provides pre-existing data. However, in the module, students were prompted to conduct these assessments using provided data, matching it appropriately and then making their own estimations. This approach aimed to deepen their

understanding and analytical skills rather than relying on automated processes.

Challenges and Iterations

- Informal feedback collected from students regarding the tool's efficacy and areas for improvement has been integrated into the methodology. This qualitative data helped in understanding user experience, addressing challenges, and refining the tool to better meet student needs and expectations. For instance, the addition of example sheets for operational emissions was implemented based on student feedback, leading to increased comfort and proficiency in using the tool.
- Challenges arose regarding accessing the right information and sources due to the vast array of available data, such as emissions factors associated with concrete. Students found it time-consuming to navigate multiple sources. To address this for the next year's adaptation of the module, the tool will be coupled with either free/ licensed database(s) or project-specific databases through stakeholder engagement would be obtained.

Broader Insights

Beyond its immediate functionalities, the tool's broader outlook reveals significant insights. The scarcity of open software and data for teaching LCA underscores the need for accessible resources in the education sector. Additionally, the consideration of regional aspects in LCA projects emphasizes the importance of tailoring curricula to local contexts, ensuring relevance and applicability. Aligning with environmental engineering principles, the tool fosters a holistic understanding of LCA, bridging mechanical and environmental perspectives. Furthermore, its potential impact on professional accreditation suggests that integrating LCA into engineering education could better prepare future engineers for industry standards.

4 CONCLUSION

The development and implementation of the updated Excel-based tool for integrating LCA into the engineering curriculum have provided valuable insights into its effectiveness and broader implications. The tool's efficacy stems from several key features: it is based on existing researched tools, offers easy-to-understand guidance with stepwise instructions, is well-suited to project-based learning, aligns with the institute's multidisciplinary Design Engineering Program, emphasizes fundamental engineering skills, and aligns with Engineering for Sustainable Development (ESD) education goals.

The initial acceptance of the tool has been positive for the module, but further surveys, student feedback, and implementation of additional project case studies will provide insight into its long-term effectiveness. The tool has potential applicability across various engineering disciplines, fostering sustainability education in diverse fields e.g. it can be integrated in a civil or mechanical engineering project looking at a specific (construction or manufacturing) process or product in any institute keen on integrating sustainability education. Moreover, its relevance aligns with initiatives such as the Engineering Professors Council (EPC) Sustainability Toolkit[vi] and Engineers Without Borders (EWB)'s Competency Compass[vii], providing avenues for collaboration and resource-sharing within the wider engineering education community. Potential integration with would highlight its potential role in advancing sustainability education beyond institutional boundaries, supporting global engineering initiatives.

In essence, this paper not only presents a practical tool for LCA integration but also encourages reflection on the broader implications for engineering education, emphasizing collaboration, adaptability, and the shared responsibility of preparing future engineers for sustainable practice.

ABSTRACT

The framework of primary and secondary STEM education has given engineering education an unprecedented role until now. However, this centrality is not supported by a solid framework from a didactic point of view, resulting in superfluous and lacking proposals. This communication addresses three questions that point to the future of engineering teaching in school: What literacy in engineering should be promoted? What engineering practices should school develop among students? What are the central ideas that should be taught in schools? Taking as a reference the more consolidated and well-founded field of research on science education, we propose a list of engineering practices and a first approximation of engineering core ideas in order to bring an engineering epistemological perspective in school STEM education.

cristina.simarro@upc.edu

1 INTRODUCTION

Giving relevance to Science, Technology, Engineering and Mathematics, whether integrated or not, has marked the direction of many educational policies and has been pervasive in current educational debates, resulting a topic of interest in the field of education research (Bybee 2013; Johnson et al. 2020). Within this STEM education approach, and influenced among others, by the perspective of design as a new twenty-first century literacy (Pacione 2010; Blikstein 2013), the role of engineering education has been modified, gaining more prominence and centrality in pre-college education (Li et al. 2019; Pleasants and Olson 2019). This new engineering education perspective seeks to promote both an engineering literacy for all and to meet the forecasted demand for skilled engineers in the years to come. However, critical voices have denounced the existence of a gap between these intentions and the real presence of engineering education in compulsory education, especially in primary and lower secondary education (Bagiati et al. 2015). In this paper, we consider an epistemological perspective for engineering education as a basis for defining what engineering practices and which engineering core ideas should be developed among primary and secondary school students in order to promote a sound engineering education in compulsory education.

1.1 Engineering in school STEM education: what are we talking about?

In our opinion, some of the motivations and potential benefits of enhancing the presence of engineering in pre-college education somewhat undermine the true *raison d'être* of what engineering education should be, which would, in turn, explain the shortcomings pointed out when it comes to engineering school education. For instance, the perspective of engineering as a context that can improve students' learning in science and mathematics is fundamentally based on an idea of education focused on the products of engineering -technology- (e.g.: energy and power technologies) instead of on the idea of developing among students the understanding of engineering as a standalone discipline. In fact, engineering contents are commonly taught not as a specific subject but within other more general subjects commonly related to science or technology (Bonsall, Bianchi, and Hanson 2022).

At this regard, we agree with McComas and Burgin (2020) who point to the lack of entity of technology compared to engineering and propose the acronym of SEM education instead of STEM, to avoid redundancies. While discussions regarding differences between engineering and technology from areas such as philosophy are still unresolved (Krupczak et al. 2012; Norström 2014; Smit 2016) our vision is that technology is the product of the activity carried out by engineers, that is, the product of engineering practice and we propose this perspective for enhancing engineering education at school. In contrast with educational references that use engineering and technology as synonyms, arguing that both engineering and technology have as their philosophical core the resolution of practical problems(Varnado and Pendleton 2004), or that engineering education is a content already included in technology education (Williams 2010) we claim that shift -giving engineering its own entity in education- would be aligned with claims of authors like Lewis (2005) or Rogers (2006) that point to the need to propose changes in technological education so that the field reaches an agreement with engineering as content.

Hence, from a STEM education perspective that seeks to educate students so that they are able to “identify, apply and reflect upon the way we think, do and talk in Science, Engineering and Mathematics (in a more or less integrated fashion) to understand, decide and act on complex problems and to build creative solutions, using the appropriate technologies and collaborating with others in a critical, reflective and value-driven way, through the enactment of the own agency and the authoring of the contribution of diverse people to minimize the inequalities in the STEM field” (Couso, Grimalt-Álvaro, and Simarro 2022) we see engineering literacy as the one that entails both knowledge of the technologies themselves, to be able to use them and to make decisions about them in an informed manner, as well as of the nature of the process that leads to their design and development (ITEEA & CTETE 2020). A quality engineering education must focus not only on the results of engineering as a discipline (technology) but also in the participation in what we call practices, those cognitive, social and discursive activities that characterize the discipline (Peters-Burton 2014; Gattie and Wicklein 2007).

1.2 Engineering practices: an epistemic view of engineering in school

There is a growing consensus that engineering education should place disciplinary practices as a central focus (Cunningham and Carlsen 2014a; National Research Council 2012) in the same way that scientific practices are for science education (Duschl and Grandy 2013; Osborne 2014). Recognizing engineering as a cognitive, social and cultural activity (Bucciarelli 2003) implies recognizing that it encompasses specific ways of doing, talking, thinking, valuing and being (Couso and Simarro 2020a). From this sociocultural perspective of education, the participation of students in school-based engineering practices analogous to those of the professional engineering world becomes a central element of 21st engineering education. However, while in science teaching the relevance of practices and an epistemic view of school science have already transformed most educational proposals, in the case of engineering education the focus on technology is still ubiquitous and the idea of engineering practices is still scarcely developed.

An example can be found in the eight engineering practices proposed by the National Research Council (National Research Council 2012) which presents engineering as the participation in a set of practices that require the simultaneous coordination of both knowledge and skills. Despite the crucial paradigm shift that entails viewing the teaching and learning of engineering not as the mastery of a generic problem-solving approach but as the promotion of active student participation in engineering practices, we consider the NRC engineering framework insufficient. The main reason is that the list of practices is too dependent on and interlinked with the list for scientific practices: only two practices are specific to engineering (defining problems and designing solutions) while the rest are exactly the same for both science and engineering. In this regard, and from an epistemic viewpoint, we strongly disagree with authors, such as Bybee (2011), who claim that with the exception of their goals, science and engineering practices are parallel and complementary. As Cunningham and Carlsen (2014b) argue, we believe that a subtle differentiation between science and engineering does not capture the epistemic differences between the two disciplines, and thus does not reflect certain salient engineering values that are essential to the engineering discipline and, at the same time, differentiate it from other (Couso and Simarro 2020a). The NRC curriculum framework do not sufficiently emphasize the important differences between both disciplines, science and engineering (Cunningham and Carlsen 2014a), and their statements, built in the image and likeness of scientific practices, do not encapsulate key elements of the nature of the engineering activity. Given the relevance that the list of eight engineering practices has on educational standards and curriculum designs, we consider the need for a new conceptualization of engineering practices in which the idiosyncratic differences between science and engineering are reflected. This is not to avoid an interdisciplinary STEM teaching approach where both science and engineering are considered, but to help teachers to improve students' understanding and knowledge both *of* and *about* engineering either in disciplinary or interdisciplinary oriented curricula.

1.3 Engineering core concepts

Following with the NRC framework, the imbalance between science and engineering is also evident for the so-called core concepts that, together with the idea of scientific and engineering practices and the crosscutting concepts, represent one of the three dimensions of this curricular framework. The perspective of focusing science teaching towards the construction of core ideas or "big ideas" (Harlen 2010) has been fundamental in science teaching for decades. From this perspective, these core ideas are understood as those structuring ideas that have the potential to explain a large number of different phenomena, offering coherence between them and allowing their development throughout schooling.

In front of the eleven core ideas for science, only two central ideas are listed for engineering, being their nature very different from the idea of core concepts. As Cunningham and Carlsen (2014b) point out with respect to the first engineering core concept (ETS1: Engineering Design), its definition is more linked to the idea of activity (defining and delimiting an engineering problem, developing possible solutions and optimizing the design solution) but not to concepts, ideas or theories that must be the conceptual basis of engineering practice. Similarly, the second core idea (ETS2: Links among engineering, technology, science, and society) is far from being a central idea of engineering and is more a reflection on the relationship between science and engineering that: 1) is not included in the central ideas of science, and 2) gives an idea, as specified, of engineering and technology as a mere application of science (Ortiz-Revilla, Adúriz-Bravo, and Greca 2020). Once again, the effort to equate engineering content with scientific content is limited by the lack of an epistemic vision that exalts the idiosyncrasy of each discipline without denying the interrelationships between them.

Evidently, the core concepts included in the NRC framework are not the only ones proposed in the literature as engineering core ideas. In the review by Silk and Schunn (2008), the following are identified as specific engineering concepts: structure-behavior-function, trade-offs, constraints, optimization and systems, subsystems and control. Although relevant, these ideas are somewhere between crosscutting concepts, understood as those that are useful for both science and engineering and that are associated with a scientific-technological way of thinking (National Research Council 2012) and the practices discussed above but they do not represent a way of structuring knowledge in engineering. More recently, the new standards for technological and engineering literacy (ITEEA & CTETE 2020) also include the idea of central engineering concepts but, again, it does so in an inconsistent way when defining operational categories, mixing elements of diverse nature (some related to practices (resources, requirements, trade-offs, optimization), others related to transversal concepts (system and process) and others more related to specific technologies (control)).

Be that as it may, the great diversity that exists and the lack of agreement between all the proposals show that there is still no broad agreement on the complete set of central ideas in engineering on which to base its practices. From a competence point of view, however, it is necessary to establish what this knowledge is, which are these key ideas that must serve as a basis for participating in engineering practices (assessing, for example, whether a solution is optimal or not, may require knowing the resources available and their long-term availability). There is no doubt, therefore, that engineering education requires these specific ways of looking at the world created by and for humans, thus establishing some central ideas of engineering that, as in the case of science, help to propose the curricula and educational approaches of the discipline.

2 METHODOLOGY

In order to give answer to the purposes of our work, we conducted a literature review addressing the following questions: 1) *Which should be the epistemic characteristics of engineering practices in comparison to the scientific and engineering practices proposed by the NRC framework?* and 2) *Which are the engineering concepts that are more commonly presented in engineering and technology primary and secondary curricula or standards?*

Regarding the first question, our search strategy was carried out following the PRISMA Protocol (Page et al. 2021) as data selection strategy. This review involved the identification of key words and the selection of peer review journals in the fields of engineering education, STEM education and philosophy. The key words that guided the review were: nature of technology, nature of engineering, engineering practices, technology practices, STEM practices, engineering education and technology education. Identified publications were screened in order to exclude those that could fall out of the scope of our work. Specifically, we exclude those publications that restricted the meaning of technology to that of computer science and those that treated STEM as a metadiscipline, without distinguishing engineering specific practices. As reported in the results sections, the salient characteristics of engineering were identified within this literature review by contrasting them with the scientific ones using the Family Resemblance Approach (FRA) to NOS (Erduran and Dagher 2014).

A second rapid literature review (Cirkony et al. 2022) was carried out also with grey literature. In particular, official technology and engineering curricula and standards - for primary and secondary education levels- were selected and compared, using the NRC engineering practices as a guiding dimension for the comparative grid. The combination of both comparatives resulted in a first set of eight practices based on the NRC engineering practices but nuanced by both the engineering epistemic characteristics as well as the practices highlighted in other curricula proposals. In parallel, and following a Grounded Theory approach (Glaser and Strauss 1967) the first draft of these practices where applied as categories for analysing primary school student's activity in a particular educational engineering context (in this case, a Tinkering activity in an informal education setting, (Simarro 2019). The aim was to analyse the validity of these categories to analyse students' participation in engineering practices and to identify emerging categories that could enrich the theoretical proposal. As a result, changes to the initial proposal were made, with the addition of new practices and with the inclusion of nuances to the existing ones. On the other hand, the answer to the second question was addressed also by the rapid literature review of the same official technology and engineering curricula and standards. A second grid was generated, grouping the contents presented in each curricula and standards by topic, resulting in a proposal of dimensions that encapsulate the essence of the contents: technologies' development, nature and application. Inspired by the 10 big ideas of Harlen (2010), a set of 10 core engineering concepts covering these three dimensions was proposed.

3 RESULTS

3.1 School engineering practices from an epistemic view

A review from an epistemic point of view of the differences between the aim, spheres of activity, forms of knowledge, values and quality criteria and methodological rules of science and engineering (Couso and Simarro 2020b) can serve as a starting point to qualify the engineering practices proposed by the NRC. Thus, recognizing that the main objective of science and engineering is different (building reliable explanations of natural phenomena and optimal solutions created by humans, respectively) can help to understand when a classroom proposal is promoting certain scientific practices or, on the other hand, it focuses on the development of other practices linked to engineering. Aspects such as the nature of the products of each discipline (theories, laws, models vs. technologies, processes, etc.), the quality criteria and methodological rules (more or less linked to idealization) and, especially, the dimensions that characterize the respective practices (inquiry, modelling and arguing vs. creating, testing and arguing) have served us to propose a first list of engineering practices that, inspired by the list proposed by the NRC, seeks to capture the essence of engineering as single discipline (Table 1) (Simarro and Couso 2021)

Table 1. Alternative proposal to the NRC Engineering Practices

NRC 2012 practices definition	**Alternative proposal[1]**
Defining problems	Defining **and delimiting** engineering problems
Developing and using models	Developing and using **prototypes and simulations**
Planning and carrying out investigations	Planning and carrying out **tests**
Analyzing and interpreting data	Analyzing and interpreting data **to identify points for improvement**
Using mathematics and computational thinking	Using mathematics and computational thinking, **scientific models and available technologies**
Designing solutions	**Identifying and/or developing multiple solutions and selecting the optimal one**

---	**Materializing the solution**
Engaging in argument from evidence	Engaging in argument from evidence
Obtaining, evaluating, and communicating information	Obtaining, evaluating, and communicating information

[1] Changes highlighted in bold.

3.2 Towards the construction of engineering core concepts

Inspired by key scientific ideas and based on a review of various current technology curricula or standards (e.g.: ITEA (2007)) we present a first proposal for the central ideas of engineering by classifying them according to: how technologies are developed (including the exploitation of natural resources), what their nature is (what they are and how they are used) and what their applications are (in what contexts they are used and what particularities characterize each context). Although preliminary, these ways of structuring knowledge in engineering could be the pillars to structure a solid framework that allows defining these central ideas so necessary for engineering education.

Table 2. Proposal for key engineering Ideas

Key Idea	Example
1. The Earth has resources that are useful to respond to the needs of human beings.	On Earth we find minerals that are used as a base to make objects such as kitchen utensils.
2. The natural resources that we take advantage of to obtain energy and materials are limited.	Fossil fuels serve society as a source of energy for many processes. However, these resources are limited and shortages are expected in the future.
3. Depending on the characteristics and properties of the materials, they will have some applications or others.	Given its lightness and easy processing, cardboard is a good alternative for packaging design.
4. There are many ways, some more efficient than others, to transfer, store and distribute energy and transform materials so that it is more usable for human beings.	In a hydroelectric plant, the potential energy of water is used to produce part of the electrical energy necessary for humanity.
5. Technologies make it possible to take advantage of materials and energy to: facilitate processes, obtain and exploit resources and produce new technologies.	Simple machines are a basic example of how to facilitate a process by transforming energy into work...
6. Technologies are designed to provide an optimal response to certain needs, taking into account available resources and considering existing limitations.	In the case of home construction, you can seek to minimize the cost by disregarding aspects such as space (smaller rooms) without the home ceasing to fulfill its basic function.

7. The functions of each technology depend on the parts of which they are composed.	When analyzing a technology such as a manufacturing robot, we must identify the parts that make it up and that allow it to carry out its task: mechanical elements such as gears, electronic components such as position sensors and microprocessors, etc.
8. Technologies combine to result in new, more complex technologies.	Current vehicles include both simple machines such as the wheel and more cutting-edge technologies such as artificial intelligence in the case of autonomous cars.
9. Changes in human needs, as well as the availability of new technologies and new scientific knowledge, result in an evolution of technologies.	The evolution of communication systems has been clearly influenced by scientific and technological advances. The knowledge and exploitation of electromagnetic signals, as well as the appearance of electronics, explains the information and communication society in which we currently live.
10. The basic needs of human beings to which technology responds are: food, housing, health, transportation, communication and production.	Recent technological developments such as production automation or the Internet are explained by humanity's need to respond to its basic needs.

4 SUMMARY AND ACKNOWLEDGEMENTS

The role that engineering plays, and should play, in primary and secondary education is still limited and often misinterpreted (ITEEA & CTETE 2020). In this sense, engineering education is still a growing field if we compare it with a consolidated field such as science education (Bonsall, Bianchi, and Hanson 2022). In this communication, we advocate for including an explicit epistemological perspective for improving STEM education, whether it is integrative or not. Our aim has been to discuss the main areas of potential development of engineering education and to make a first proposal for what we consider the corpus of this discipline should entail: an epistemic view on engineering education resulting in a proposal of engineering practices based on it and a first approach for addressing the core ideas of engineering.

There is no doubt that in our proposal there are still certain aspects that require a higher level of specificity. On the one hand, the engineering practices we have proposed have been based primarily on the current NRC list of practices. There are, however, other perspectives that seem equally or more suggestive to us, such as the idea of engineering habits of mind (Lucas, Hanson, and Claxton 2014) or the perspective that is framed in the contexts of use proposed by the ITEEA (ITEEA & CTETE 2020). These frameworks can enrich our proposal and serve as inspiration to define other more useful approaches to be brought to the classroom. Moreover, our proposal does not gather the NRC idea that engineers not only design new technologies, but are also responsible for manufacturing, operating, inspecting and maintaining them. From this perspective, one might ask whether, beyond engineering practices linked to design, other practices linked to the use and maintenance of technology should be considered. Although some authors have tried to define “technology practices” (Vasquez, Comer, and Sneider 2013) these are far from what we understand as practice, resulting in a list of generic competences and not ways of doing, speaking and thinking.

In parallel, we have also highlighted the urgency of having central engineering ideas that allow for greater structuring of learning, focusing the curricular design on a brief set of ideas in which to deepen this learning. Having a more systematized way of understanding the world created by humans, in the same way that the central ideas in science allow us to understand the natural world, is an essential requirement to help teachers to improve their educational proposals, guiding engineering learning progressions (Bonsall, Bianchi, and Hanson 2022). Our proposal of ten key ideas for engineering is transversal to all branches of engineering to be appropriate for what we could call “school engineering”: the engineering knowledge and competence necessary within a view of engineering for all or engineeringliteracy. This first proposal, however, requires a collective effort to better define these central ideas of engineering, also contemplating engineering ideas that take into consideration the concepts or theories of different areas of knowledge of engineering (e.g.: how in simple machines the increase in distance leads to a decrease in the force to be exerted (idea 7 applied to the field of mechanics) or how the development of semiconductors represented a revolution for the field of electronics (idea 8 applied to the field of electronics)). In turn, the proposal of key ideas for engineering must be enriched with ideas about engineering based on existing knowledge about the nature of engineering. This work, which should be the result of a debate between the educational community and the professional field in engineering and technology, can result in a very useful tool for the advancement of engineering education.

Finally, beyond these three pillars (epistemic view, engineering practices and core ideas), we believe it is necessary to highlight another dimension that should become relevant, not only in the field of engineering teaching, but also in the rest of the STEM disciplines. A quality STEM education, and engineering education in particular, must encourage critical and reflective thinking among students, which allows them to act in accordance with certain values. As Hansson (2007) points out, engineering already operates with certain concepts loaded with values such as justice, well-being or environmental risk. Defining which engineering values should be developed among students and how is also an objective that should guide engineering teaching. Works such as that of McGowan and Bell (2020) and their proposal for critical sociotechnical literacy seem to point the way towards this update of engineering education.

ABSTRACT

The World Economic Forum emphasises the importance of developing individual skills, as part of a "Skills Economy," and that not developing skills within a workforce is an operational and business risk. Within a multi-generational workforce, this places great emphasis on workforce development, including up- and re-skilling for older generations, and also providing targeted development of younger generations (as part of retaining capable graduates within organisations). This will require capable and effective Continuing Engineering Education (CEE) Educators to design and provide these learning activities (courses) in engineering disciplines. Whilst greater emphasis is now placed on educator training and development in Universities, this training is typically focused on students who have recently left school. It does not necessarily prepare staff to design and deliver training activities for professional engineers. Currently, there is a lack of an outline of key considerations to include in a development course for CEE Educators, and it is this gap that this paper addresses.

This paper will explore the different educational paradigms/frameworks suitable for CEE educators to facilitate the effective learning of practising engineers. Firstly, a review of literature relating to principles and considerations for the education of professional learners, particularly in the area of engineering, was carried out to create a proposed model that would be required in a CEE Educator training programme. A set of recommendations for developing CEE Educator training is proposed.

1 INTRODUCTION

1.1 Skills economy and importance of Continuing Engineering Education courses

Recent changes in society and technology - Industry 4.0, Industry 5.0, and Society 5.0 (Huang et al. 2022) - have highlighted the need for practising engineers to continue developing themselves and the importance of lifelong learning and ongoing professional development. As such, there is an up-and-re-skilling need to meet society's and communities' emergent and future needs. Additionally, in many countries registered, professional engineers have a requirement to engage in Continuing Professional Development (CPD) every year to maintain their currency (ENGINEERS EUROPE 2024; International Engineering Alliance 2013). So, there is a clear demand for impactful CPD courses.

Whilst many universities have long-standing engagement with industry in the provision of CPD and Continuing Engineering Education (CEE) courses, these courses were not always a core strategic focus of universities and departments. In many cases they were individual initiatives of faculty members with close ties to the industry, and personal interest in CEE. Consequently, educators are often not given specific support to prepare them to deal with professional, practising engineers with potentially different motivations and differing personal and professional circumstances.

1.2 Current approaches to educator development

Most current approaches for supporting lifelong educator development, both general and more engineering-specific, exhibit a lack of a systematic approach. Many previous works focus their efforts on identifying the necessary competencies and skills of such educators (Van den Broeck et al. 2022; Bernhardsson and Lattke 2011). These can be very broad, ranging from teachers shifting to facilitators while being leading experts in their field, all the way to being able to act as psychologists when necessary (Chakrabarti et al. 2021). Other works focus on how the institutions hosting CEE educators must develop to support them regarding equipment and policies, create learning communities, and offer incentives for their development (Miranda et al. 2021). The common denominator here is that in both levels, the focus is on "what" needs to be done, yet the "how" is still not well discussed. Besides the case of the AGADE and the EMAE projects that created a training course and a Master’s programme, respectively, for educators, most approaches seen in the literature on education professionalization do not offer a clear professionalization path (Bernhardsson and Lattke 2011). They suggest, among other things, that teachers should develop through experiencing being a CEE educator, try to be the leading expert in their field, perform relevant research, individually invest time for their own development (Collins 2009), and seek the help of AI and technology (Diaz Lantada 2020). Therefore, the lack of organized knowledge and models ("how") that can bridge the competencies required from CEE educators ("what") is already identified as a core issue, and this paper will aim to address it (Ioannou 2023).

1.3 Aim/Focus

Consequently, this research aimed to create a development framework for CEE Educators that drew together factors relevant to support efficacy of practice and excellent learning by CEE Educators. Moreover, recommendations are made to those responsible for supporting faculty in delivering effective CEE learning activities.

2 METHODOLOGY

A sequential, multi-qualitative method was used to create the CEE Educator Development Framework. Firstly, a review of the literature was undertaken to understand a) existing practices in preparing engineering educators to work with professional and practising learners (as outlined above) and b) educational models and factors that are similar and different when considering professional learners, and what this means for preparing educators to support these learners.

Secondly, these factors were synthesised into a CEE Educator Development Framework highlighting the specific areas required to improve CEE course development and delivery. Illeris' learning model provides a helpful framework to scaffold these factors, as this model focuses on the presence and interaction of two different processes – learner and their environment; and cognitive process of acquisition (Illeris 2018).

In terms of limitations, this exploratory study uses a non-systematic literature review to determine the model factors, so future work will look to enhance this model with an evidence synthesis method. After this, the validation and utility of the model will need to be evaluated against a broader range of institutional practices and contexts.

3 DEVELOPING A CONTINUING ENGINEERING EDUCATOR DEVELOPMENT MODEL

Professionals need continuous engineering education to meet current and future societal challenges, but professional learning occurs differently than in universities. These professional learners, often with several years of working experience already, have different mindsets and needs regarding content and skills acquisition. Additionally, appropriate forms of delivery of information are essential to meet engineers' needs. Professionals frequently seek just-in-time information to meet acute gaps in knowledge due to the rapid development of technology and interdisciplinary challenges. Moreover, the context and motivation for learning are notably different, so any development of a CEE Educator framework needs to incorporate these critical aspects.

For professional learners, theories such as Andragogy and Heutagogy are highly relevant (Chacko 2018). Knowles' andragogical principles highlight personal factors, such as being intrinsically motivated to learn, knowing why they are studying and taking responsibility for their decisions, and contextual, in that they want to draw on experiences and that the learning is applicable (Youde 2018). Heutagogy is linked with a self-directed learning (and a learner-centric) model, where the learner wants agency in how they study, and the CEE educators act as "activators, deliberate change agents and as directors of learning" (Hattie 2010, 25). Moreover, CEE educators actively use a combination of "reciprocal teaching, feedback, teaching students self-verbalization, meta-cognition strategies, direct instruction, mastery learning" (ibid 2010, 243). These approaches may not always be evident in standard educator preparation but are essential for understanding motivation, learning, and teaching approaches suitable for a CEE context.

Context is essential in the context of professional learning, as professional learning can take place both in formal and informal settings. Hence, educational theories such as *Situated Learning (SL)* theory and *Cognitive Apprenticeship* (Collins et al. 1989; 2009) that focus on the interaction between learning and the social situation in which the learning of a skill occurs are relevant (Julien 2021). In situated learning, social co-participation activities in which social engagements occur are favourable elements to provide a context and facilitate learning (e.g. creating learning experiences in which real-life activities resembling and taking place in practical work environments are suitable contexts that promote deep learning and develop skills). SL theory links with experiential and workplace learning (Helyer et al. 2020), which are relevant in engineering contexts (Rouvrais, Remaud, and Saveuse 2020), and to a*ctive learning* methods (Kolb and Kolb 2020). Problem-based and similar inquiry and critical thinking methods encourage problem-solving and meta-cognitive learning that stimulates skills development. Moreover, constructivist approaches (Woozley 2020) are relevant in stimulating collaborative and reflection settings.

Exploring the different learning contexts further, Fink refers to company-oriented methods, such as just-in-time or on-demand targeting defined topics/goals, and university-oriented methods, which are already made *and target a group of companies or individuals* (Fink 2001). Additionally, competency-based education and its application in engineering continuing education programs (Chappell, Gonczi, and Hager 2020) are critical as they align with industry requirements and to impactful (lifelong) learning amongst professionals (Pichette and Watkins 2018). Workplace learning, such as on-the-job learning that takes place in the professional environment, can be an effective focus company learning approach and can take the form of courses (formal teaching or training), research-oriented in which professionals work in a project within the working context), or on-the-job training where employees learn in the workplace (Nørgaard et al. 2024). Furthermore, collaboration models between academia and industry in delivering continuing engineering education and discussed strategies for fostering partnerships, identifying industry needs, and co-designing educational programs (Bikard, Vakili, and Teodoridis 2019) are pertinent to consider, particularly how this impacts the competences that a CEE Educator will need to possess to deliver collaborative courses effectively.

Consideration is also needed in how best to deliver the education, considering learners want agency and flexibility. Flexible learning provides opportunities for gaining the necessary knowledge and skills regardless of time, location, and level (Mathou, Sarazin, and Dumay 2023). Flexibilization, enabled by digital tools and systems, brings training for professionals close to their reality. In this regard, modularization (Nielsen et al. 2021) is frequently used to provide individual, functional units of knowledge that can be tailored to the professional learners' level. Modules, commonly offered digitally in Learning Management Systems, provide independent pieces of information accompanied, in most cases, by feedback and self-assessment exercises. Modules also include simulations of production systems (Svetlik 2020) to enable engineers to manage their own learning process and monitor progress. Furthermore, the self-contained modules represent tasks that, in the form of building blocks, can also be aligned to other modules or can be offered as just-in-time components; these modules are a functional resource to provide information when needed, to refresh knowledge, to engage in tasks by following pre-knowledge modules on the knowledge they miss, and alike, for specific tasks.

Interestingly, flexibilization and modularization can bring efficiency as individual learning takes place, and educators and companies can reduce manual efforts as if the simulation can resemble scenarios that serve as effective use cases.

The above review of educational theories is summarised in Table 1 below, where the considerations above have been mapped to one of the two dimensions of Illeris' model (Illeris 2018). The synthesised model for CEE Educator Development is presented in Figure 2. The factors identified resonate with the co-researchers (experienced CEE practitioners and educators), so they are credible (within the limitation of these educators' current experiences and practices).

Table 1: Summary of educational concepts relevant to developing the CEE Educator framework (mapped to whether they relate mainly to the incentive or interaction dimensions of Illeris's (2018) learning model).

Educational theory/approach	**Characteristics**
Andragogy (Knowles, Holton & Swanson, 2014; Youde 2018; Chacko 2018)	**Incentive**: 1) Intrinsic motivation; 2) Know why they are learning; 3) Take responsibility for their decisions.
	Interaction: 4) Apply experiences.
Situated Learning Theory (Julien 2021)	Content;
	Incentive & Interaction: 1) Context; 2) Community Participation.
Cognitive Apprenticeship (Collins, Brown & Newman 2009)	**Incentive:** Social interaction.
	Interaction: 1) Modelling; 2) Coaching; 3) Scaffolding; 4) Skill development.
Constructivism (Piaget 1971; Rannikmäe, Holbrook, and Soobard 2020)	**Incentive:** 1) Knowledge is socially constructed; 2) Knowledge is personal; 3) Motivation drives learning
	Interaction: 4) Knowledge is constructed actively (rather than passively absorbed); 5) Learning is an active process;
Experiential and active learning methods (Kolb and Kolb 2020)	**Interaction:** 1) Learning by doing; 2) Learning through reflection on doing; 3) Concrete experience, reflective observation, abstract conceptualization, active experimentation
Company-oriented methods (Nørgaard et al. 2024)	**Incentive:** 1) On-demand targeting defined topic/goals; 2) real-life and authentic learning.
	Interaction: 3) Project-oriented activities; 4) Workplace learning; 5) Collaborative/co-creation; 6) Interdisciplinary learning.
Flexibilization/blended learning (Mathou, Sarazin, and Dumay 2023)	**Incentive:** 1) Self-directed learning.
	Interaction: 2) Modularization; 3) Tailor-made; 4) Use of simulation.

Competency-based education (Chappell, Gonczi, and Hager 2020)	**Incentive:** 1) Competency orientation.
	Interaction: 2) Focus On Mastery; 3) Integrated Development; 4) Relevance To Real-World; 5) Learner-Centric; 6) Outcome-Based; 7) Differentiated.

Figure 1: CEE Educator Framework, structured after Illeris (Illeris 2018) .

4 FIVE RECOMMENDATIONS FOR ADOPTING THIS CONTINUING ENGINEERING EDUCATION FRAMEWORK

The CEE Educator Framework above recognises that CEE training and education come from various providers and will involve both formal and informal development methods (whether separately or as part of an integrated approach). This model seeks to be sufficiently general, so it has consciously not examined content (that may be either leading-edge knowledge, for example, driven by AI and latest technology advances, or around inter- and trans-disciplinary approaches that seek to equip practising engineers with more advanced or new skills to tackle emerging challenges in society and within their workplaces). Recognising the importance of the learner's motivation (incentive), a learner-centric model was used to construct the CEE Educator Framework. A set of recommendations based on this framework are outlined below (in no particular order of importance):

1) A learner-centric model is essential within the framework, and any CEE Educator course needs to equip the educator with theories, concepts, and practical tools to understand the motivations of their learners. Moreover, making this explicit in marketing materials and highlighting these motivations within the course (for both learner and educator) is essential.

2) Related to this first point is the create CEE Educator courses that respond to motivations (whether shaping to match the intrinsic motivation or through formal recognition and reward – external motivation – within their organisational contexts);
3) Understanding the motivations and the nature of the content will influence how best to deliver any CEE Educator course, so a critical learning outcome for any CEE Educator course will be that the educator understands how incentive and interaction need to be aligned. Therefore, courses for CEE Educators need to introduce them to different modalities of CEE courses:
    a. Leading-edge technical courses where the CEE educator will likely be the expert. Within the CEE Educator courses, then education models need to consider how best to share this content whilst engaging the reasons why these professional learners (and their organisations) can benefit from this new knowledge; this could include clear examples;
    b. Transversal skills courses are where you try to develop professional competences. There is a need within the CEE Educator courses to introduce how best to link the intended skills back to the individual in their professional context, whether from modeling, role-playing, or through workplace learning and reflective practice;
    c. "Organisational change" courses are where learners seek to understand how to best support change, such as diversification or responding to technological disruption. Ensuring learners can critically recognise how best to adopt this into their practice is vital within CEE educator courses. Facilitating and encouraging critical reflection in learners will be more important in these instances.
4) The CEE Educator courses around assessment practices (if these are formal courses leading to credits) need to introduce authentic and aligned strategies to the motivational aspects. As such, emphasis on workplace, work-based, and reflective assessments and simulations will need further exploration; this may require collaboration between educators and employers;
5) In the development of any CEE Educator course, then recognition needs to be given that these courses must model best practice, such as flexibility, allowing self-directed and personalised navigation and pace of study, as well as encouraging educator competences (such as being comfortable to facilitate and encourage co-discovery).

5 SUMMARY AND FUTURE WORK

This paper has synthesised a CEE Educator framework from various educational theories relevant to professional learning within a learner-centric model. Illeris' model was adopted to structure this model, highlighting the interdependency between the learners' motivation and how any CEE course should be delivered.

Recognising the limitations of this current research, then future research needs to focus on: a) a more systemic review of educational factors, using evidence synthesis methods; b) conducting a survey of current CEE providers to understand how they currently support their educators, to test and refine the current framework; c) to evaluate the current model against current practices more rigorously; d) to develop accompanying guidance notes and case studies to support those who want to create CEE Educator courses; and e) to explore more fully around the acquisition (content –

incentive) dimension, as professional learners may be experts in the practice where the educator has less expertise, so the educator may feel challenged in how best to adapt their teaching practices to make the most of this rich learning environment that allows learners and educator to co-discover and learn from each other.

ABSTRACT

Engineers can play a significant role in addressing the current and future global challenges, but such an approach will require innovative educational approaches to nurture the required competences. The Engineering for People Design Challenge (EfPDC) from Engineers with Borders (EWB) is one such innovative approach for engineers to develop a better understanding of sustainable development and their place as an engineer to impact positively on people and planet. EWB provide an annual design brief that requires students to develop human-centred solutions to a complex, community-based challenge. Whilst some evaluation of the adoption of this programme within engineering programmes exists, currently there is limited evaluation in the UK of the EfPDC. This research aims to determine what competences are developed, using the competency frameworks of UNESCO and EWB to structure the findings. Key findings highlight that a range of skills relevant to nurturing responsible engineers are developed through the EfPDC, including greater empathy for communities (end-users), ethical decision making and collaboration.

[1] *Christopher Smith;*
Email: Christopher.Smith@gcu.ac.uk

Also, the UNESCO and EWB competency frameworks help to determine what is being developed already and provide a frame for how to enhance future deliveries.

1 INTRODUCTION

1.1 Engineering for Sustainable Development

It is recognised that engineering can play a significant role achieving the UN Sustainable Development Goals (UNESCO 2021). So, unsurprisingly these requirements are being reflected in requirements for professional registration as an engineer (Taylor 2018; WFEO 2018), including in the accreditation of engineering education programmes (ENAEE 2022; Engineering Council UK 2020). Moreover, it is acknowledged that innovative approaches are required to facilitate the development of the required sustainable engineering competences (UNESCO 2021) and to make engineering a more inclusive profession (NEPC 2024). However, this requires a shift in how engineering programmes are delivered to create the changemakers of the future (Hitt et al. 2023; EWB 2024).

One such approach to nurture these future changemakers is the Engineering for People Design Challenge (EfPDC), organised by Engineers Without Borders (EWB, 2023a). This Design Challenge is an annual competition where EWB provide a rich, high-quality, community-based design brief. The location of the community is different each year, and in recent years has included Cambodia, Glasgow (Scotland), Johannesburg amongst others. Participation in EfPDC is voluntary, with universities signing up to this challenge, and national competitions are held in a range of countries, e.g., in UK, Australia, USA, South Africa. In the EfPDC student teams tackle this open, community-focused design brief to design human-centred, engineering solutions. These solutions respond to the needs and desires of that community, with creating relevant long-term solutions of benefit to the community being a key success criterion of the competition.

Some evaluation of the EfPDC has taken place already, with many studies in the USA and Australia (e.g., Brodie et al, 2013), but some of these studies being over 10 years ago. There is one study in the UK (Poursharif et al., 2021) that examined the implementation of the EfPDC at one UK university, using a one-week intensive delivery with students across different year groups and from different disciplines volunteering to participate; outcomes showed improvement in a range of importance skills (ethical decision making; problem solving; creative thinking and communication). Of note, how each university embeds the EfPDC challenge within their context varies – from voluntary to embedded within a module or course; from single programme to multi-disciplinary; from single year to across year groups. Therefore, with only one published UK evaluation then there is clearly a gap of evaluation of EfPDC in UK universities and to reflect the diverse ways in which EfPDC can be implemented. Moreover, there is a need for further contemporary evaluation of EfPDC, and one that reflects current thinking around Education for Sustainable Development and development of relevant skills as competences. This study has chosen the UNESCO (2018) Competences and Global Competency Compass from EWB (2023) frameworks to consider which competences are developed within the EfPDC.

1.2 Context of this research and research question

Glasgow Caledonian University (GCU) in Scotland offers the EfPDC within a credit-bearing module that is a mandatory part of the students' first semester of their programme of study. Students engage with the challenge over one semester (12 weeks) in multi-disciplinary teams; students from three different programmes take this module and were mixed as equitably as possible within timetabling constraints. A Design Thinking approach is used throughout to introduce students to human-centric and user-specific design (Figure 1), with encouragement to empathise (McDonagh and Thomas, 2010). Students engage in two-hour workshops each week with their team supplemented by self-study time where teams complete follow-up creative, research and design activities; workshop activities are supported by tutors and facilitators. Assessment is based on producing a team outcome report (week 12), team presentation (week 6) and an individual reflective essay about the experience (week 12).

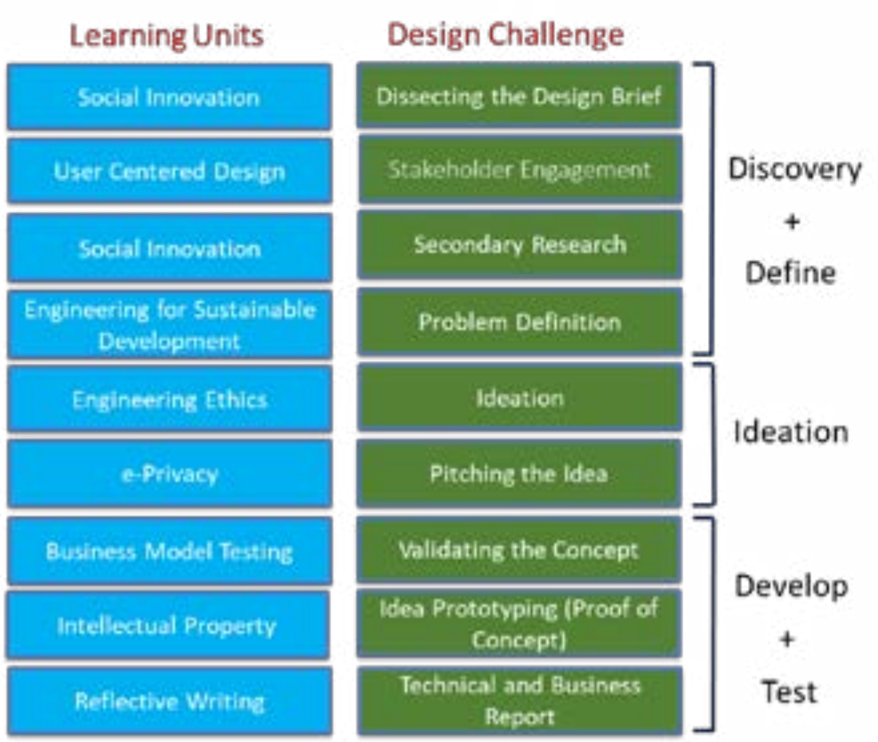

Figure 1: overview of topics covered (learning units), relationship to the Engineering for People Design Challenge and to Design Thinking

Therefore, the research question for this research is "Which sustainable development competences do students participating in the Engineering for People Design Challenge gain?"

1.3 Engineering for Sustainable Development and Global Responsibility competences

Particular competences are required for engineers to engage successfully within sustainable development projects, particularly those that seek to also develop global and socially responsible competences. For this research two relevant competency frameworks have been adopted: 1) the UNESCO (2018) model of competences for sustainable development, and 2) the EWB (2023) Global Competency Compass. The competences outlined in these frameworks are summarised in table 1. There are overlaps in these – such as in systems thinking, collaboration, anticipatory (purposeful).

Table 1: competences for sustainable development (UNESCO, 2018) and global responsibility (EWB, 2023).

Sustainable Development Competences	**Global Responsibility Competences**
- Systems thinking - Anticipatory - Normative - Strategic - Collaboration - Critical thinking - Self-awareness - Integrating problem-solving	- Responsible - Professional value; Sound reasoning; Technology stewards - Purposeful - Life-centred design; Building resilience; Advocate - Inclusive - Diversity, equity and social justice; Facilitates; Creative collaborator - Regenerative - Social and ecological well-being; Mitigating and adapting; Systems thinker

2 METHODOLOGY

A survey method was used to evaluate the competences developed during the Engineering for People Design Challenge. As this research is based on a continuation of previous research around this module before EfPDC challenge was implemented (Nesbitt and Smith 2022), as well as reflecting future comparative research with another UK university that has embedded the EfPDC in a different manner, then the existing questionnaire was refined based on discussions, as well as to align with the existing ethical approval (approval of 7th September 2023). The areas addressed by the questionnaires were around identity, sustainability and sustainable development, and skills and competences. The questionnaire had a set of Likert-style responses, as well as more open questions for students to complete.

Pre and post-surveys at GCU were administered via MS Forms. Students were given time in scheduled classes to complete the survey, but voluntarily participation was emphasised. A “pre” survey was conducted in week 2 of the semester and asked students to consider previous team working (before university) and the level of confidence and skills that they possessed. The “post” survey being conducted in the last two weeks of the semester, and asked students to self-evaluate on the skills that they possessed after the EfPDC. The list of skills was the same for both pre- and post-surveys and focused around a) the nature of the previous group work, such as how open-ended and society-focused the project was, as well as how much the project related to what the respondent cared about [7 aspects]; b) a range of skills across team-working, futures-thinking skills, responsible engineering skills [17 skills]; and c) confidence in some key skills – making ethical decisions, problem solving, creative thinking and in communicating [4 skills]. In the analysis then the 5-point Likert-style responses (strongly agree to strongly disagree for a) nature of project and c) confidence; and not at all to all the time for b) skills use) were translated to a 1 to 5 numeric scale (1 for strongly agree/all the time, and 5 for strongly disagree/not at all). Subsequently, means were calculated for the pre- and post-surveys and deltas analysed.

Qualitative responses (Table 2) were deductively coded against the competency frameworks above to seek greater insights; multiple codes were found in some of the richer qualitative responses. Through this coding by the researchers, then it was determined whether students had commented on a specific competency.

Table 2: Open-ended questions from post-survey that were coded

Question	Question
Q8	Has your perspective changed as to what an engineer does and can do based on this experience (participation in the Engineering for People Design Challenge)?
Q9	What does the term sustainable development mean to you?
Q10	How do you think the term sustainable development relates to the work of engineers and scientists?
Q13	What do you think that you have gained (personally, professionally, and socially) from this learning activity (Engineering for People Design Challenge)?

3 RESULTS

A response rate for the pre-survey was 81.3% (83 respondents from 102 students registered for the class) for the pre-survey, with 68 respondents indicating that they had previous team experiences (so 66.7% of respondents). The response rate was 61.8% (63 respondents) for the post-survey; 1 response from the post-survey was excluded as all answers were empty.

3.1 DOMINANT SHIFTS IN RELEVANT SKILLS AFTER EWB DESIGN CHALLENGE

For all bar one of the 28 questions, then there was a positive shift in the mean, with the one question ("the problem was given to us to solve") that showed a negative shift having a delta of 0.025 (so interpreted as no change). Positive shift means that students self-assessed that their agreement, utilisation of skills and confidence had increased. The positive deltas ranged from 0.045 to 0.914.

Figure 2 below shows most significant changes (delta >0.25) in skills (relating to 10 of the 17 skills). Students have viewed they have enhanced skills relating to responsibility, purpose, awareness of communities (inclusive), as well as developing regenerative solutions. These responses were supported in other questions (nature of project work with delta of 0.65 for "our solution would help a particular group of people in society" and 0.423 delta for "problem required us to generate a solution for end-user." Additionally, skills such as futures thinking (anticipatory), self-awareness, problem solving, and collaboration were identified by students as having changed through this experience. Again, these aspects were supported by the questions around confidence (Figure 3).

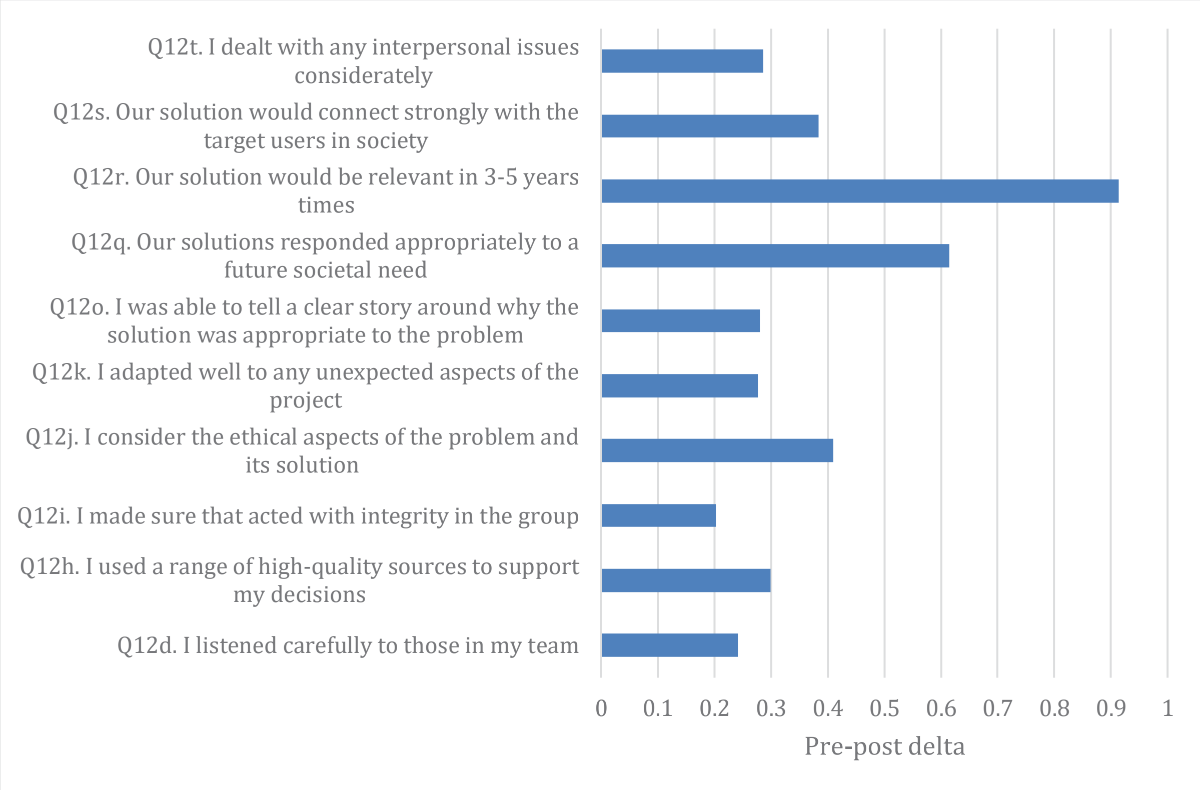

Figure 2: deltas in means between pre- and post-surveys

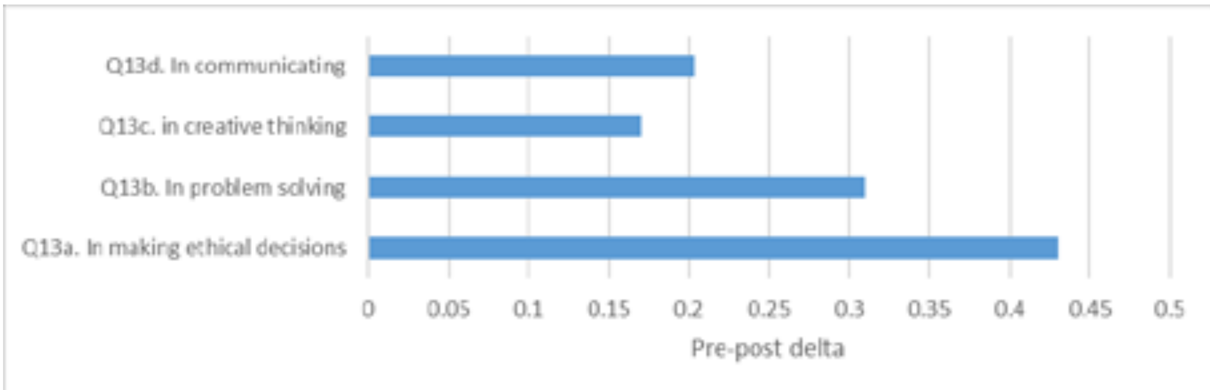

Figure 3: deltas in means between pre- and post-surveys around self-assessed confidence.

3.2 MAPPING AGAINST UNESCO ESD COMPETENCES

Table 3 highlights the count of competences from coding of four qualitative questions and demonstrates a broad coverage against the UNESCO ESD competences, particularly around collaboration:

> *"I gained a better understanding as to how to work in a team when personalities and ideas clash.*" (R13)

> *"I gained a better understanding as to how to work in a team when personalities and ideas clash.*" (R14)

Moreover, self-awareness around sustainable development was evident in responses, such as "*an engineer to me now is someone who has the ability to impact anyone or anything through their designs and initiative.*" (R15)

Also, integrated problem solving features in many responses of students:

"I have realised there is a much more thought-out process before you start tackling a problem." (R27)

"Learned how to assess design challenges from the ground up and ways in which I could improve my ideas." (R29)

It was also reassuring to see that some respondents appreciated the futures-focused competences that they were developing, although some responses appeared close to the Brundtland (1987) definition, so this requires further investigation.

Table 3: coding of qualitative responses from four questions against UNESCO ESD Competences

Competence	Q8	Q9	Q10	Q13
Systems Thinking	-	-	1	1
Anticipatory	-	11	5	1
Normative	2	-	7	3
Strategic	-	-	-	-
Collaboration	4	10	4	36
Critical Thinking	-	1	4	4
Self-awareness	17	31	27	6
Integrated Problem Solving	1	10	10	3
Not coded	49	16	13	14

The not-coded responses here related to one-word response (such as 'yes' or 'no'); short phrases (such as 'not too sure') as well as responses that could not be coded against the frameworks (such as referring to progress generally). There was also the isolated response that did not understand that developing competences around human-centred design was part of being an engineer:

"I feel like my perspective on University has changed rather than engineering due to the fact that I just feel like there is little to no aspect of engineering being introduced within this design part other than the socialising within the class but that can be said for any type of study/occupation." (R37)

This is an aspect that requires further investigation.

3.3 MAPPING AGAINST EWB GLOBAL COMPASS COMPETENCES

Table 4 below shows the count of mapping of the four open questions against the EWB Global Compass Competences (GCC). It is evident that responsibility, particularly professional value, is strongly reflected in responses:

They are here to make a better place for people who cannot do it themselves, they bear the responsibility of providing for the greater good of the world. (R35)

Engineers and scientists must take careful and thoughtful consideration to a number of factors when creating solution such as environmental factors, sustainability, human rights, future proofing, etc. (R36)

Also, it is clear that teamwork (mapped to Creative Collaborator) is a skill that students have developed during the EfPDC. Additionally, students have gained an understanding of socio-ecological systems, the UN SDGs and appreciate the long-term wellbeing of communities with many responses being similar to this response, "*Trying to develop economies and find solutions to problems without further harming environment*" (R53).

Table 4: coding of qualitative responses from four questions against EWB Global Compass Competences.

Dimension	Competence	Q8	Q9	Q10	Q13
Responsible	Professional Value	15	16	36	9
	Sound Reasoning	2	1	2	9
	Technology Steward	-	3	1	-
Purposeful	Life-Centred Design	1	2	2	2
	Building Resilience	-	-	-	-
	Advocate	-	-	1	-
Inclusive	Diversity, Equity & Social Justice	-	6	4	3
	Facilitation	-	-	-	-
	Creative Collaborator	2	-	-	28
Regenerative	Social & Ecological Wellbeing	2	27	23	1
	Mitigating & Adapting	-	1	1	-
	Systems Thinker	-	-	-	-
Not coded	Not coded	41	16	12	15

4 CONCLUSIONS AND NEXT STEPS

In conclusion, this research has identified that the Engineering for People Design Challenge embedded into a first-year, semester-long, credit-bearing module does indeed develop important competences and skills that are relevant to nurturing responsible engineers. With regards to the research question, which sought to understand which competences are developed, then the most frequently identified ones (Tables 3 and 4) relate to 1) anticipatory thinking, 2) collaboration, 3) self-awareness, 4) integrated problem solving, 5) professional value, 6) sound reasoning, 7) diversity, equity and social justice, 8) creative collaborator, and 9 social and ecological wellbeing.

Also, the competency frameworks used allow a clearer mapping of what skills the students perceive as having developed during the challenge. However, there is the odd voice that does not yet appreciate that engineering is a profession that addresses societal and human needs, and this requires further investigation.

Future work will be to move beyond cohort averages, to consider shifts in individual student's perceptions. Moreover, running focus groups to better explore these findings is planned. Furthermore, using the competency frameworks to explicitly discuss with students the skills that they have developed to support careers through workshops is planned. Finally, reviewing the teaching, learning and assessment approach through the lenses of the competency frameworks will seek to evaluate how the Design Challenge can be enhanced further, including how to assess these competences directly within the delivery by the tutors.

ABSTRACT

The paper discusses a project focused on the future of the engineering profession and the emerging requirements for developing appropriate professional competencies. The aim of the project is to bridge the gap between society's needs for engineering performance and the provision of suitable education and training. It is structured into four chapters. The first chapter outlines the inception of the initiative,

[1] *A. Soeiro*
aecef@fe.up.pt

the formation of the consortium, and the operational methods during the funding period. The second chapter addresses the assessment phase, evaluating both current and future training needs for graduating and practicing engineers by offering relevant online courses. The third chapter details the design and preparation of the training courses for testing and validation. Finally, the fourth chapter explores potential scenarios and advancements for the engineering profession, considering adaptations to evolving societal needs for development and progress. Conclusions to define the strategy for the future of engineers and diagnostics of engineering training needed will be produced at the end of the project E4E.

1. INTRODUCTION

1.1. E4E Introduction and Description

The aim of the E4E project is to enhance understanding and insight into the engineering profession in Europe. The subsequent actions are geared towards enhancing the quality of engineering education and continuous training, fostering innovative capacity, and improving the effectiveness of the engineering workforce. Proposed methods include the establishment of an online training platform, the creation of strategic and benchmarking reports, conducting dedicated stakeholder surveys, and launching extensive dissemination campaigns to share produced outputs. The project also aims to develop digital bridging tools to facilitate seamless connections between training and practical application for active engineering professionals and between academia and engineering companies.

One of the key challenges to address within the E4E project is the information gap concerning the collection and accessibility of relevant data for stakeholders. Certain consortium partners, such as national professional engineering associations, can systematically contribute by conducting surveys among their members and maintaining ongoing dialogues with engineering companies and government agencies. These associations can offer comprehensive insights into member engineers' backgrounds, education, ongoing professional development, career paths, training needs, and labor conditions. Such data is crucial for informing effective policy-making and implementing reliable actions to support the education, training, and personal development of engineers and their respective businesses.

Another significant challenge tackled by the E4E project is the human resources aspect of the engineering landscape. There is a widespread shortage of engineers across most economies worldwide, and in Europe, this shortage underscores the need to promote and nurture the engineering profession to inspire current professionals and prospective students alike. Shifting demographics and changing perceptions of the engineering field have further exacerbated the scarcity of engineering talent. This situation raises pertinent questions about training programs, recruitment strategies, working conditions, salary structures, mobility opportunities, career advancement, and potential career setbacks.

1.2. Partners of E4E

The project brings together partners representing various sectors, including professional engineering organizations, academia, vocational education and training (VET) institutions, and companies. On the academic side, partners include universities of applied sciences, research universities, and European associations. In the business sector, partners consist of national engineering associations, supplemented by organizations such as engineering student associations, young engineers' groups, the council of engineering chambers and the association of the HVAC industry and professionals. Academic and vocational training partners play a crucial role in providing stakeholders involved in initial education and lifelong learning opportunities for engineers. Additionally, the consortium includes a quality accreditation agency for higher education programs like engineering.

Partnership comprises thirteen organizations from eight European Union countries, the project spans a duration of thirty-six months and receives a public grant of approximately EUR 1.5 million from the European Union Commission's Erasmus+ program. Coordination of the project is done by an European professional engineering organization with members that are national professional engineering organizations from 33 different countries (Engineers Europe, 1951). The project aims to establish a European Engineering Professional Skills Council, identify and define new trends in engineering education, and develop innovative training programs for the engineering profession. It's worth noting that the E4E project aligns with the objectives of current European policies in education and training, particularly in addressing future skills mismatches and promoting excellence in competence development for engineers. The project seeks to facilitate proactive dialogue between the engineering industry and the education and training sector, focusing on continuing professional development.

Among the project's outputs are the establishment of a permanent observatory of the engineering profession, the definition of entrepreneurial competencies for engineers, the creation of four online training courses tailored to emerging needs in the engineering field, and the proposal of an Engineering Skills Passport aligned with current European Union frameworks. Additionally, the project aims to develop an Engineers Europe Skills Compass to update the competencies required for the engineering profession. Task management within the consortium is divided among vertical and horizontal working groups dedicated to the six working packages. All Engineering stakeholders can participate in the project activities at any time since the significance of the work done will be more valuable with increased participation and diversified contribution.

2. METHOD FOR OVERVIEW OF COMPETENCES NEEDED

2.1. Description of Survey

The "Engineers for Europe" (E4E) project seeks to narrow the gaps between education, training, and industry while operationalizing EU competence frameworks. At the core of the E4E project lies the challenge of how educational innovations and curricula can align systematically and proactively with the evolving needs of industry and the increasingly dynamic and diverse roles that engineers play. As underlined in literature (Aljohani et al, 2022), there is a need to strike a balance between providing education that encourages the skills, values, and attitudes required by society at large and meeting the expectations of the market. The industries of the future require engineers who, as representatives of their technological domains, can leverage innovation and leadership to integrate specialized expertise with the ability to navigate creatively across boundaries in complex environments (Taylor, 2019). Project is coordinated by an European

Within the E4E project's second work package (WP2), there is a focus on skills monitoring and anticipation tools. WP2 aims to develop a sustainable and effective framework and systemic approach for identifying the skills and competences needed to address societal challenges. This framework entails assessing the current situation regarding the demand and supply of skills and competences for the engineering profession, with particular emphasis on non-technical aspects such as digital skills, green skills, and resilience through transversal, professional, and entrepreneurial skills. Additionally, it involves anticipating future needs, while the third work package considers strategic considerations regarding the evolution of skills demand and supply for the engineering profession.

The framework/methodology underscores an operational approach to analyzing the engineering profession, combining primary and secondary research methods to gather relevant data and identify opportunities and challenges. Primary research involves utilizing focus groups, interviews, and questionnaire-based surveys with representatives across the entire education, training, and industry spectrum. Secondary research relies on desktop analysis to capture specific trends in the engineering profession. The methodology aims to offer actionable insights to stakeholders in the profession on addressing skills shortages and mismatches and promoting the acquisition of digital, green, resilience, and entrepreneurial skills among engineers.

Over a period of two months, from May 15 to July 15, 2023, the project partners issued a survey to various stakeholders, comprising 33 closed questions. A total of 3045 fully completed responses were received. Responses from the seven countries' engineering professional organizations represented in the E4E consortium (Belgium, Germany, Greece, Spain, Ireland, Portugal and Slovakia) were isolated, resulting in 802 applicable responses. The survey covered topics such as sustainability, engineering education, stakeholder policies, and entrepreneurship. The majority (about 88%) of respondents were professionally active, with about 65% having more than 10 years of professional experience in either industry or the educational sector. The survey findings offer insights into the issues that the E4E project should prioritize to support European policy development through independent study and engagement as an impartial advisor. Concerning validation of the first survey, this phase is not addressed in the project during the first year of the project. The second survey is ongoing in the second year of the project and will be analysed in the next phase of the project.

2.2. Main Outcomes of Enquiry

The survey results provided fourteen insights relevant to the development of a Skills Strategy (E4E, 2023), which can be categorized into four overarching themes:

1. Role of Education Providers:

Engineers benefit most from competency-based learning, with critical thinking, collaboration, and communication skills identified as crucial professional requirements. Specific policy measures are needed to foster diversity and inclusion by encouraging experimental and problem-based learning opportunities that cultivate ethical decision-making skills. Additionally, attracting a more diverse talent pool to the engineering profession necessitates mentorship programs and diversity/inclusion training for professionals and organizations. Finally, universities/technical schools should collaborate with industry to develop formal or informal curricula aligned with job market needs.

2. Emphasizing Sustainability:

Increasing emphasis on sustainability and environmental concerns, alongside greater utilization of automation and AI in engineering processes, emerged as priorities for the engineering profession in the next five years (2023-2027). This requires innovation and technological advancement in renewable energy and green infrastructure, emphasizing sustainability principles in formal engineering education and training. Engineers play a crucial role in promoting green energy and efficiency by implementing new technologies and providing technical expertise and guidance to businesses, particularly SMEs, to encourage sustainable practices.

3. Employment Opportunities:

There is widespread agreement that the majority of new job opportunities will arise in completely new occupations or existing ones undergoing significant transformations in content and skill requirements. Concerns are raised about shortages of engineers in fields such as electrical/electronic, ICT, and agronomic/environmental engineering to support these growth areas. Additionally, respondents view skills gaps in the local labor market as a greater obstacle to business transformation (60%) than a shortage of investment capital (37%) across various industries.

4. Partnership:

Collaboration between industry and educational institutions, alongside investments and increased funding in research and development (R&D) for emerging technologies, are deemed the most effective tools for addressing skill shortages in digital, green, resilience, and entrepreneurship within the engineering profession. Entrepreneurship is recognized as a key competence for enhancing European competitiveness, with R&D efforts focusing on developing a social and green economy. Professional engineering organizations have a role in fostering an entrepreneurial mindset among engineers and promoting interdisciplinary collaboration among their members.

It is underlined that the project is ongoing until September 2025 and the results presented correspond to the first half of the project. These observations are preliminary in terms of the analysis of the engineering needs and will be complemented by the ensuing questionnaire that is more focused and concise.

3. Online Training Courses

3.1. Tailoring and Design

The E4E courses are carefully crafted to empower engineers, equipping them with advanced competencies (knowledge, attitudes, and skills) to augment their professional prowess. As such, the intended beneficiaries encompass engineers at qualification levels 5, 6 (technician and first-cycle degree – bachelor level), and 7 (second-cycle degree – master level). Drawing from the findings of research conducted to monitor trends in the engineering profession, project established clear objectives for developing courses aimed at fostering competencies deemed essential for all engineers, irrespective of their area of specialization. These competencies, defined according to the European Commission frameworks (EQF), are pivotal for the engineering profession.

Transversal skills pertinent to the engineering profession encompass green skills (sustainability), digital skills, entrepreneurship skills, and life skills, sometimes defined as soft skills. These four groups of skills (may also be designated as competencies) derive from the existing European Frameworks: GreenComp, DigComp, Entrecomp and Lifecomp (European Education Area, 2023) . The significance of green skills, including political agency, is increasingly pronounced (Atkisson et al., 2018), with engineers expected to address sustainability challenges set forth by the European Union, such as the transition to a circular economy and decarbonization.

Digital skills, such as information and data literacy, hold crucial importance in the contemporary engineering landscape (Van Den Bossche et al., 2019). Proficiency in digital tools and platforms enables engineers to streamline processes, boost productivity, and deliver innovative solutions with greater efficiency, thereby positioning them as catalysts for progress and agents of sustainable development across various sectors.

Entrepreneurship skills, such as opportunity recognition, empower engineers to innovate and commercialize solutions, thereby augmenting their technical prowess with invaluable competencies essential across diverse functions and roles within the profession (Fayolle et al., 2015). Engineers equipped with entrepreneurship skills not only spearhead technological advancements but also foster economic growth, job creation, and societal advancement by translating ideas into impactful solutions and ventures.

Soft skills, such as communication and teamwork, are indispensable for fostering effective collaboration and project management in engineering endeavors (Murthy et al, 2021). These skills are fundamentally linked to adaptability, change management, and societal engagement, encompassing principles of resilience. Professionals endowed with these transferable competencies enable companies and industries to address complex challenges, drive innovation, and make meaningful contributions to sustainable development.

These competencies, also called transversal and transferable skills, are essential for the engineering profession, as these are learned and proven abilities which are commonly seen as necessary or valuable for effective action in virtually any kind of work, learning or life activity. These competencies are 'transversal' because these are not exclusively related to any particular context (job, occupation, academic discipline, civic or community engagement, occupational sector, group of occupational sectors, etc.). (Cedefop, 2021).

3.2. Courses Composition

Each of these skill groups has been structured into individual courses. The intended learning outcomes/competencies for the E4E courses were selected from four frameworks: DigiComp (Vuorikari et al., 2022), GreenComp (Bianchi, 2022), EntreComp (Bacigalupo, 2016), and LifeComp (Sala, 2020). This resulted in a 'constructive alignment' (Biggs, 1996), (Biggs et al, 2011), (Loughlin et al, 2020) of the competencies/learning outcomes, with the learning objectives derived from these frameworks. The methodology employed for creating the E4E courses adopted a modular approach, ensuring that each of the four courses comprised at least three modules (EQF levels ranging from 4 to 7), each focusing on the development of competencies within the respective skill groups outlined in the mentioned frameworks.

All modules will be made available online without access restrictions, utilizing Open Educational Resources (OERs) such as micro-videos, papers, other documents, practical activities, tests, etc. The necessity for courses grounded in academia-industry collaboration was emphasized by the primary research survey results. A teaching manual will be provided for the local piloting of these courses.

Regarding assessment, the consortium will develop a Self-Assessment Tool (E4E SAT) for users to evaluate their level of readiness, understanding, and competence in transversal skills. As for certification, each course will be equivalent to 0.5 to 1.5 ECTS credit points in terms of workload, with a total duration of 12.5 to 45 hours, inclusive of synchronous hours, in-person training, and autonomous work conducted by the trainees. Certificates of participation will be issued by the partners delivering the courses. Additionally, participants will receive micro-credentials, operationalizing the "European Approach to Micro-Credentials" (European Commission, 2022).

4. CONCLUSIONS AND RECOMMENDATIONS

Surveys provide valuable insights into the literature concerning future engineering requirements, including professional demands and the competences graduates need for their future careers. These careers often lack clear identification at the outset of their educational journeys. However, as discussed by Fleming et al. (2024) in their analysis of the technical and professional skills essential in the engineering profession, it is also crucial to focus on the preferences of employers. This study, unlike prior studies that relied on disparate methods to aggregate multiple previous studies, analyzed a single sample of 26,103 job advertisements for engineering positions. This approach enabled them to identify a broader range of more specific professional and technical skills than previous studies conducted on a national scale, capturing the pulse of the engineering profession and offering a more refined understanding for the future.

Future surveys conducted by E4E might also consider evaluating engineering programs and the perceived alignment or misalignment between education and the competences required in the engineering sector. By adopting frameworks like the Systems Approach for Better Education Results in Workforce Development (World Bank, 2013) framework and utilized by Fleming et al. (2024), the project can gain insights into the gaps between educational offerings and the profession's requirements. Additionally, utilizing databases related to the engineering profession can provide further understanding of prevailing input/output synergies and factors facilitating them.

The contemporary engineering landscape necessitates a multifaceted skill set beyond technical expertise, encompassing green skills, digital proficiency, entrepreneurship, and soft skills. The E4E project aims to equip engineers with new competencies covering transversal knowledge, attitudes, and skills, with a focus on innovative entrepreneurship, digital, green, and life skills as part of Continuing Professional Development (CPD). CPD plays a pivotal role in enhancing transversal skills for engineers, preparing them to excel not only as technical specialists but also as versatile professionals capable of driving impactful change in a rapidly evolving world. By investing in CPD, engineers can cultivate skills vital for collaborating across disciplines, fostering innovation, and embracing emerging technologies confidently.

As for future actions, defining stakeholders with justification for their status and communication outreach is essential. These stakeholders may have national, regional, European, or global areas of influence, and relevant contacts should be collected and stored in the project Observatory. Engineers Europe should manage these active stakeholders during and after the project conclusion. Passive future activities should focus on providing information to all stakeholders, including data about the engineering profession, its academic, professional, social, or regulatory aspects. This information could be centralized in a platform like an observatory, addressing issues such as CPD provision for engineers, engineer salaries, qualification frameworks, current engineering trends, international agreements, relevant events, mobility schemes/tools, and potential future scenarios for the engineering profession.

Looking ahead, the observatory could assist in defining priorities for actions, such as the sustainability response of engineers as outlined in the UNESCO II Engineering report (Engineering for Sustainable Development). It could also compile examples of potential training opportunities for engineers, including additional competences that may become mandatory for active engineers. Moreover, the observatory could collect concrete data and training opportunities for engineers to promote sustainability in their actions and assess the influence of Artificial Intelligence (or Machine Learning) in the engineering profession.

5. ACKNOWLEDGEMENTS

ABSTRACT

We are living in extraordinary times as citizens of the world. Digital transformation is affecting everyone and everything we do, globalization is a disruptive force to our business, industry and our societal structures, and climate change is an existential threat to humanity. In the U.S., racial inequities are finally being recognized by many and we are beginning to seek solutions that will finally lead to a nation that practices the idea that all are created equal. These issues are not unique to the U.S.; mass disruptions are occurring across the globe.

Engineering education is not immune to these changes. How many creative problem-solvers, who would have become excellent engineers, have we driven from our programs or never given an opportunity over the years? How many inventors and entrepreneurs have we failed to inspire to join our ranks? How many out-of-the-box thinkers have we lost from engineering due to the rigidity of our curriculum? For at least 50 years, we have endeavored to diversify the engineering profession with marginal success. Deficit-based efforts have attempted to “fix” underrepresented groups so that they could fit into the white male culture of engineering, but the systemic challenges facing diverse, aspiring engineers runs much deeper.

[1] *S. A. Sorby,*
sheryl.sorby@uc.edu

In June of 2020, a Task Force of the American Society for Engineering Education was challenged to review the current state of engineering and engineering technology education in preparing engineers in the U.S. The Task Force was charged with taking a fresh look at the preparation of engineers and ways to fundamentally improve the access, diversity, success, and preparation of undergraduate engineering students. Their efforts built upon the foundational work of the 1955 Grinter Report, which still has a significant influence on today's engineering curricula and culture. This paper describes the work of the Task Force to date and outlines future plans for affecting real change in engineering education in the U.S. and briefly outlines similar efforts occurring across the globe.

1. BACKGROUND

1.1 Grinter Report

In May of 1952, in response to the Cold War and growing scientific and technological achievements of the Soviet Union, the president of the American Society for Engineering Education (ASEE) appointed a committee to look at the current state of engineering education in the U.S. The 1955 report, now commonly referred to as the Grinter Report (Grinter et al, 1955), brought about a sea change in the preparation of engineers and became a foundational document for engineering education that still has a significant influence on the engineering curricula today. The Grinter Report also likely impacted engineering on a global scale. In large part, theory replaced practical hands-on work. We have done some tinkering around the edges, added in a capstone design project, but the basic structure of our curricula remains unchanged since ~1955. We have added a few topics as they became relevant and replaced Fortran with various other languages along the way, but we were mostly adding and hardly ever subtracting. We live in a digital world where students can instantaneously look things up on their phones that might have taken us hours to track down in the library. Yet, our curriculum has not fully embraced these changes. We are stuck in 1955. Although changes have been made to reflect today's digital, inclusive, global, and rapidly changing society, these changes have not gone far enough.

One driving motivation for the current ASEE Task Force is that we believe our curriculum is unattractive to under-represented groups when selecting careers and is not optimally preparing *all* students for their future careers. As Richard Riley stated: **"**We are currently preparing students for jobs that don't yet exist, using technologies that haven't been invented, in order to solve problems we don't even know are problems yet".

We have designed a system that is inflexible, uninspiring, and unattractive to the vast majority of our population. We do not take full advantage of all we have learned about the science of learning since 1955 to improve teaching and learning and increase student success (Nyamapfene, 2021). In reality, the engineering curriculum has long-lasting impacts on the engineering culture. This is our "all hands-on deck" moment and we cannot afford to continue along the path that is dominated by a report from nearly 70 years ago. With the rapidly rising cost of a university education, expanding opportunities, including online, for education at all levels, and the changing demographics of the U.S. and other countries, if we do not transform our programs, we will become outmoded and may cease to be relevant.

1.2 The Post-Grinter Era

The preparation of engineers has been operating under the influence of the Grinter Report for nearly 70 years even though its stated purpose was to provide direction for the "next quarter century." The Grinter Report moved the pendulum to the side of theoretical and science-based engineering. It is time to move the pendulum toward a more humanistic approach to engineering in the preparation of engineers, improve accessibility, and be more student focused to prepare a more balanced graduate for the world as it is today and as it will be in the future. Two important U.S. reports since the Grinter Report was released have both advocated for engineers to have both technical and social proficiency: the NAE's 1985 "Engineering Education and Practice in the United States, and "The Engineer of 2020" (NAE, 2004; NRC, 1985). These reports introduced a tension between an engineer's technical preparation and social elements but did not affect *real*, long-lasting change in engineering education.

It is obvious that the world has significantly changed technologically since 1955, which has resulted in significant societal changes. It is also obvious that the preparation of engineers has advanced and made changes since the Grinter Report; but have the changes been enough? The question to consider is whether it is time for the foundational recommendations from the Grinter Report to be reviewed and challenged if, for no other reason, than the world has advanced significantly since the report was released.

Societal changes have also played a major role since 1955 as the civil rights movement, women rights, and changing demographics transformed the world. The Grinter report was written by white men for white men. The very first sentence of the Grinter report summary states, "Engineering Education must contribute to the development of men who can face new and difficult engineering situations with imagination and competence" (Grinter, 1955). Although only limited by gender, it provides critical insight into the authors' narrow world view of an engineer. A report with a broader perspective is vital, leading to the development of an engineering curriculum that attracts a more diverse and inclusive population by broadening the appeal and success of students of colour, women, and with other life experiences.

1.3 Other Global Efforts

The structure and adequacy of engineering education has also recently been examined in other countries and contexts. In Australia, a report was commissioned by the Council of Engineering Deans to examine the changing nature of engineering practice and its implications for engineering education. The report, titled "Engineering Change: the future of engineering education in Australia," (https://www.aced.edu.au/downloads/2021 Engineering Change - The future of engineering education in Australia.pdf) outlines the direction needed for the future of engineering education in the country. The themes that emerged in this report are similar to those that emerged from the ASEE effort (described subsequently) and are:

1. The need to produce a sufficient number of graduates to meet the needs of the country without over-reliance on foreign-born workers.

2. An insufficient number of women and first-nation individuals to engineering represents a massive loss of potential for the nation.

3. There is a need to re-balance the theory/practice components of the curriculum, to include more practice-related experiences for students.

4. Students are motivated by real-world problems that solve societal needs

5. The diversity of engineering career options needs better promotion, particularly at the pre-college level.

6. Exemplars of best practices in pedagogies and experiential learning should be adopted as appropriate.

7. Due to the rapid transition to online instruction in March 2020, the engineering faculty have demonstrated that they are ready and willing to make changes.

In addition to the work conducted in Australia, The global Engineers Without Borders movement is a community of engineers that believes they can be doing more to address global inequity and injustice (EWB, 2024). They have been working for over 40 years to contribute to communities in need. The UK Engineers Without Borders organization in recent years is focused on engineering education and practice reform. They have worked with educators and others in the UK to develop a tool that assists educators navigate changing their curricula: both content and pedagogies. The goal is to help educators embed global responsibility within courses, moving beyond the typically ad hoc approach commonly used. It is a guide rather than a prescriptive approach, since each university will have its own context in which it works. The Reimagined Degree Map, launched in March 2024, supports engineering programs to navigate the decisions that are required to prepare students for 21st-century challenges. The map was co-developed by Engineers Without Borders UK and the Royal Academy of Engineering and is designed in such a way that it could be adopted for non-UK universities, with appropriate care. The tool can be combined with another - the Competency Compass, which provides a basis for developing educators' (and others') skills in support of the curriculum change that the Map supports.

The Map was developed with input from hundreds of educators, students, professionals, deans, accrediting bodies and professional engineering institutions. The Reimagined Degree Map empowers decision-makers with the tools to facilitate real change and is based on the premise that engineers need to be equipped to act sustainably, ethically, and equitably. Global responsibility in engineering recognizes the need to consider all three aspects together in decision making. Students addressing real-world problems in their studies prepares engineers to improve the consequences of their decisions in their careers.

Other countries are also examining engineering education with an eye towards boldly changing the way engineers are educated. For example, the REEdI (Rethinking Engineering Education in Ireland) was sponsored by the Higher Education Authority to design an agile and innovative engineering degree programme in consultation with industry, research centers, and partner universities (https://hea.ie/skills-engagement/reedi-rethinking-engineering-education-in-ireland/). In fact, the theme of the 2022 SEFI conference was “Towards a new future in engineering education,” indicating a recognition of the need for change in engineering education across the EU.

2. THE WORK OF THE ASEE TASK FORCE

2.1 Engineering Mindset

Early in the work of the Task Force, the team decided to focus on the Engineering Mindset in order to anchor the efforts of the full task force to take a fresh look at engineering education. Mindset is simply the established patterns someone uses in thinking. Mindset includes things such as attention, interpreting, feeling, and reasoning, all that lead to actions people take (Dweck, 2006). Carol Dweck, who studies why people succeed, states that she “examines the self-conceptions (or mindsets) people use to structure the self and guide their behavior”. She focuses on a dimension of mindset that range from ‘fixed’ to ‘growth’ (Table 1 adapted from *Mindset: The New Psychology of Success (Dweck, 2006)*).

Table 1. Fixed vs. Growth Mindset

	Fixed Mindset	Growth Mindset
	Intelligence is Fixed	Intelligence can be Developed
	DESIRES TO LOOK SMART	DESIRES TO LEARN
CHALLENGES	Avoids	Embraces
OBSTACLES	Gives up early	Persists
EFFORT	Sees as fruitless	Sees as part of mastery
CRITICISM	Ignores useful feedback if negative	Learns from
SUCCESS OF OTHERS	Feels threatened	Learns from their success

The Task Force, throughout their deliberation, focused on two key questions.

(1) *What needs to happen, system-wide, to attract and retain a more diverse population of engineering students?* For most women and underrepresented groups, as stated by Ilene Busch-Vishniac and Jeffrey Jarosz, “the engineering curriculum is downright unattractive, uninformative, and uninviting”(2004).

(2) *How can we overcome the challenge of faculty adoption?* For students to achieve a growth mindset, faculty must as well. Through this initiative, it will be a priority to promote efforts that incentivize faculty and entire engineering departments to embrace the growth mindset in their thinking and actions. As part of this effort, faculty must flip from the mindset of “sage on the stage” to be coaches and mentors of students and the integration of active learning.

2.2 Working Groups

The Task Force established six working groups that examined various aspects of engineering education and made a series of recommendations in line with the focus of the working group. The six working groups and their charges were:

1. Engineering Fundamentals and Values. *Develop a new canon for the preparation of engineers that will redefine fundamentals and values that are*

equally motivated and culturally relevant to students from under-represented groups, with a specific focus upon mathematics (since mathematics is often viewed as the gatekeeper into engineering success).

2. Antiracism. *Address racial inequities and racial injustice in the preparation of engineers with recommendations on how to eliminate it from the discipline through antiracism education and asset-based approaches.*
3. Inequities. *Address all historical (both well-known and lesser-known) inequities through measured accountability, climate, and equity recommendations.*
4. Learning Experience. *Develop recommendations for curricular and learning experiences that better integrate the cognitive, physical, and affective domains.*
5. Technical-Socio. *Develop recommendations that result in a better balance between engineering science/fundamentals and social skills, ethical reasoning, perseverance, ambiguity, creative thinking, and inter- and cross-cultural competencies*.
6. Pathways. *Develop recommendations for more flexible ecosystems and pathways into and among engineering, engineering technology, community colleges, K-12 and emerging STEM professions through an examination of traditional curricular barriers.*

3. PROCESS

3.1 Virtual Convenings

In the spring of 2023, the Task Force, consisting of ~120 faculty, industry leaders, and members of accrediting agencies, met virtually over four sessions of 5-6 hours each. The virtual meetings were facilitated by KnowInnovation (https://knowinnovation.com/), a consulting firm that specializes in working with scientific teams to engage in deliberate creativity to solve the world's most complex problems. Approximately one month after the last virtual session, select members of the Working Groups met for a two-day, in-person writing session. The recommendations from the Working Groups were organized in themes (there were several overlapping recommendations that emerged from the separate Working Groups) and a draft report was created. The writing team continued to edit and revise the draft report and has recently distributed it to the larger engineering education community for comment.

3.2 Mindset Report

The current version of the draft report includes 32 specific recommendations arranged in the following themes (for each theme, an example recommendation is provided):

- Create flexible program structures to remove barriers
    - Example: Instead of a one-size-fits-all all-math requirement in the expected level of incoming math preparation, incorporate in-context mathematics across the introductory curriculum to help alleviate student inequities due to pre-college, economic, first-generation, and other differences
- Evidence-based pedagogy: Creating a student-centred engineering education

    - Example: Integrate hands-on and collaborative learning pedagogies that balance student ownership and choice and effectively working with others.
- An inclusive and diverse engineering education learning environment
    - Example: Provide professional development for faculty and staff to foster development of a mindset that centres on lifelong learning to support faculty's understanding of inclusive and equitable teaching practices.
- Preparing campuses for a student-centred engineering education
    - Example: Revise tenure and promotion processes at the department, college and university levels to reward effort, innovation, and risk-taking in teaching.
- Leveraging strategic partnerships
    - Example: Foster partnerships among accreditation agencies, academia, and industry councils that focus on engineering in a societal context.

In addition to the recommendations in support of these themes, there are two overarching recommendations that the Task Force presented:

- Change the perception of engineering by promoting the idea that engineering is for everyone who wants to be a problem solver, not just those who excel in mathematics through the following strategies.
- Remove artificial barriers to the engineering profession through a design-by-choice flexible engineering curriculum.

3.3 Future Plans

The project team is in the process of developing a tactical plan for implementing the recommendations of the Task Force on a national scale. The project team has met with experts on strategic planning and accreditation thus far. Future convenings are planned for meeting with experts in change at the university level and professional development. This work to date has been funded by the National Science Foundation in the U.S. and plans are to seek additional funding for implementation of the tactical plan.

4. Conclusions

To transform engineering education across the globe, it is essential to shift from an exclusive "survival of the fittest" mentality to a growth or "gain the skill" mentality. This can be achieved by offering opportunities for mentorship, internships, and project-based learning, all of which enable students to develop practical skills and gain real-world experience. Emphasizing the importance of continuous learning, growth, and skill development, beyond academic performance, and providing opportunities for students to engage in interactive learning, such as real-world problem-solving exercises, can make engineering more interesting and enjoyable. Reframing the role of mathematics as a tool for solving engineering problems with interactive learning can also help students develop critical thinking and practical problem-solving skills and demonstrate the relevance of engineering to their career aspirations. All of these steps can help promote engineering as a career for problem solvers from all backgrounds and foster inclusivity in engineering education.

As engineering educators, it is vital that we examine **the root causes** of the challenges we face in creating the roadmap for an inclusive growth mindset. Research shows that we have designed a curriculum that is meant to keep people out. We force all of our students to take several semesters of calculus—even though the vast majority don't really need that to work effectively in industry. We have a rigid curricular structure, with long prerequisite chains and few free electives. We subject students to one- to two years of academic hazing before they are allowed into "the club." We promote competition at all levels, even though social scientists tell us that it doesn't motivate everyone. We design projects and exams that are so hard that many students fail, and we call it "character-building,"— and we justify it by claiming that everyone should experience failure of some sort as university students. We also use "rigor" as a means to continue to use our curriculum as a cudgel and keep people out. We say that we don't have a weed-out mentality, but we certainly perpetuate a weed-out system.

Change is never easy, especially on a global scale. Transformational change can be accomplished through thoughtful use of successful change models and evaluating best practices. Incremental change over a short period of time will lead to transformational change. Organizational change, especially when involving large groups of people, often requires a systematic and pragmatic approach to ensure successful implementation.

ABSTRACT

This study employs thematic analysis to delve into the experiences of 12 alumni engineering students who participated in the elective course "Collective Creation: Improvised Arts and Engineering" at the Swiss Federal Institute of Technology of Lausanne (EPFL) since 2017. Focusing on the lasting impressions left on alumni, the research investigates retained knowledge and skills, their impact on educational journeys, and relevance to professional development. Furthermore, it explores barriers hindering the transferability of acquired skills and knowledge to diverse contexts. The findings underscore the enduring emotional resonance of the course experience for alumni, emphasizing feelings over measurable cognitive knowledge retention. While alumni express gratitude for the course, they encounter challenges

[1] *M. Studer,*
Studer.melanie@gmail.com

in articulating its direct contributions to their professional lives, suggesting a gap between experiential learning outcomes and traditional measures of educational and career success.

1 INTRODUCTION

The course "Collective Creation: Improvised Arts and Engineering," abbreviated as *Improgineering*, has been taught annually since its inception in 2017, apart from the academic year 2021-2022, at the Ecole Polytechnique Fédérale de Lausanne (EPFL). Situated within the university's Social Sciences and Humanities (SHS) program, this 6 ECTS elective course leads students into improvisation techniques developed in the performing arts (theatre, music, dance, performance) and questions their possible transposition to engineering design practices. The course spans a full academic year and comprises three hours of weekly classes conducted in a nearby theater. Each year, a cohort of first-year Master students from various disciplines follow this course, taught by an Engineering Professor who is also a dancer and complemented by teachers from diverse backgrounds such as theater, music, dance, neuroscience, and sociology. The first semester encompasses theoretical courses on improvisation as well as several practical workshops. The second semester encompasses further practical workshops, including workshops designed by student groups preparing themselves for the final public performance of the course. At the end of the academic year, students stage a public performance in front of an evaluating jury in a theater where they perform two 12-minute improvisations, one in a small group (3 to 5 people) and another with the whole class. [2]

Each year, the students assign high evaluations to the course. But what remains unknown is what sticks with the alumni after the course: What have they learned and how has it contributed to their education and professional life? Is it possible to articulate anything that may have impeded a transfer of the knowledge and skills learned to other settings?

2 THEORETICAL GROUNDING

This study is grounded in theories on embodied learning. According to Nguyen and Larson (2015, p.2) embodied learning consist in “joining body and mind in a physical and mental act of knowledge construction”. This integrative and holistic approach to education nurtures the learner's physical, emotional, mental, and spiritual development (Freiler, 2008).

Researchers have outlined numerous benefits associated with bringing back the body into the classroom. Firstly, embodied learning has been shown to enhance retention and foster deeper engagement and enjoyment among students (Macedonia 2019; Lipson Lawrence 2012; Strean 2011). Shared embodied experiences also cultivate bonds among students and between students and teachers, fostering belonging and inclusion (Doshi and Osborne 2023; Garrett and MacGill 2021; Solomon et al. 2022). Additionally, participation in embodied activities enhances self-awareness and sensitivity to others, nurturing improved collaborative relationships

[2] More information about the course can be found in the book *Barefoot Academic Teaching* (Tau et al. 2024), the website https://www.epfl.ch/labs/instantlab/improgineering/ and the video https://vimeo.com/281099868.

(Lipson Lawrence 2012). Finally, embodied learning has been found to benefit wellbeing (Rodríguez-Jiménez et al. 2022) and creativity (Dawson 2018).

Despite a growing number of initiatives and studies exploring embodied learning, most efforts are concentrated at the elementary levels of education, as well as within informal learning settings. In contrast, there remains a significant gap in research concerning the integration of embodied learning methodologies into higher education (Clughen 2023). As such, only two empirical studies on the use of embodied learning in engineering education could be found in literature.

In Spain at the Department of Science, Technology and Design, at the Universidad Europea de Madrid, Rodríguez-Jiménez et al. (2022) have used embodied learning with engineering students as a strategy for increasing wellbeing. At the Royal Institute of Technology in Sweden, Brandimarte, Funk, and Richter (2024) have experimented with mixing mechanical engineering and circus students to enhance learning. To the best of our knowledge no course like “Improgineering”, which proposes to use embodied and improvisation practice to teach engineering students collective creativity, exists in other engineering education institutions in the world.

3 METHODOLOGY

This research employs a qualitative methodology, utilizing semi-structured interviews to gather data from alumni of the Improgineering course who volunteered to participate in the study. Participants were recruited via an invitation email sent to 111 out of 119 alumni who had provided an alumni email address. Additionally, a WhatsApp message was sent to a WhatsApp group composed of 31 alumni, who had provided their phone numbers to the teacher after completing the course. Eventually, a total of 12 individuals volunteered for an interview, representing approximately 10% of the students who have followed this course since its launch.

The interviews were conducted remotely over Zoom, with each session lasting approximately 30 minutes. Following the interviews, transcripts were generated and anonymized to protect participants' identities. The data analysis followed a thematic analysis approach according to Braun and Clarke (2021), whereby transcripts were systematically examined to identify recurring themes and patterns within the responses provided by participants. This process involved coding the data based on emergent themes and sub-themes, allowing for a comprehensive understanding of the experiences and perceptions of alumni regarding their participation in the Improgineering course.

The demographics of the participants of the study are summarized in Table 1.

Table 1. Demographics of participants of the study

		Frequency	**Percentage**
Gender	Female	10	83%
	Male	2	17%
Year of course	2017-2018	2	17%
	2018-2019	1	8%

	2021-2022	5	42%
	2022-2023	4	33%
Background	Robotics	1	8%
	Computer science	1	8%
	Computational science	1	8%
	Microengineering	2	17%
	Environmental Science and Engineering	3	25%
	Architecture	4	33%

4.1 Theme 1: Impact of the course

Teamwork

Participants emphasized that improvisation served as an effective vehicle for learning teamwork skills, fostering the ability to listen, collaborate, and build on each other's ideas. The absence of pressure on the outcome of the course project further contributed to teamwork dynamics. Interviewee D articulated this sentiment, stating, *"Working without a specific goal was really interesting to be able to work better as a group, because then there wasn't the pressure you usually have with a project where you have to turn in your work on time, with lots of objectives set by the teacher. I think that's what made it so easy to get along in your group."*

Learning effective teamwork was particularly valued, with some interviewees highlighting the lack of emphasis on teamwork skills in traditional engineering courses. Interviewee A expressed the opinion that such a course should be made available to all students, emphasizing its relevance not only in engineering but also in various professional contexts. They stated, *"if everyone followed that [this course], we'd be so much better off in the projects. So in my opinion, this course should be available to everyone. These are things [group work, listening to each other] we don't develop at all, yet it's super necessary for me, in any profession in general and of course in engineering too."*

Sense of belonging and trust

Interacting extensively, including through touch, and engaging in experiential activities together fostered deep bonds among students, creating a sense of belonging, trust, and ease within the group. Descriptions such as feeling like a cohesive unit or a tightly knit troupe were common among interviewees. Interviewee F described the atmosphere as unique, stating, "*it created an atmosphere that I've never found in any other course. It was really a team and that was special*." This safety, felt within the group, allowed participants to engage in activities they might not have otherwise felt comfortable doing. Interviewee L noted, "*everyone felt very comfortable and allowed themselves to do things that perhaps even in other groups, be they friends or associations, they wouldn't have allowed themselves to do*."

Wellbeing & positive affect

Despite not being explicitly designed as a wellbeing program, the course had significant positive effects on participants' wellbeing. Many interviewees reported feeling relaxed and in the present moment during the course, likening the experience to a sense of "*breathing*" or to a session of meditation or sports. Terms like "*soft bubble*", "*oasis*" or "*break*" were also used to characterize the course. This positive affect was linked to feeling amused, free, connected to others, engaged physically but also to the novelty of the experience, as expressed by Interviewee D, who stated, "*It felt good also to just do something completely different*."

Sense of freedom

Participants described feeling "liberated" in multiple senses within the course environment: free to be themselves, express themselves, explore, experiment, create, imagine, play, let go, and follow their intuition. This sense of freedom was fostered by the safe space created and the absence of rigid expectations regarding specific outcomes. Participants contrasted this freedom with the often restrictive nature of engineering curricula, where solutions are predefined, and answers are either right or wrong. Interviewee E highlighted this contrast, stating, "*we could test just about anything and everything. As a result, we were much freer in our creation*." This freedom was perceived as both rare and beneficial for creativity within the context of their studies.

4.2 Theme 2: the perks and downsides of doing something unusual

Participants frequently characterized the Improgineering course as "*atypical*", "*completely different*", "*astonishing*", "*hyper*-special", "*extra-ordinary*", "*unusual*". While this distinctiveness contributes to the course's memorability, it also introduces challenges.

Many participants cited the course as one of the most memorable experiences during their studies due to its pedagogical approach, which diverged significantly from other courses. Interviewee E reflected, "*At every class, I'd come out surprised by what had happened. So I think that's why it had a big impact on me*." The interactive and embodied nature of the course, combined with its demand for engagement in unfamiliar activities, fostered a lasting bodily memory and prevented any possibility of escaping behind screens.

However, the unconventional nature of the course also led some participants to perceive it as less serious compared to traditional courses. Interviewee E contemplated the impact of pedagogical norms however, stating, *"I think it gives the impression that it's not so serious when it's an exception among all our other courses. But if all our courses were like that, it becomes a bit of a norm and we get used to learning that way.*"

Moreover, some participants found difficult to relate the course to their engineering work. Interviewee H articulated this struggle, noting, "*it's both super interesting to do it [the course], but also super difficult to relate it to reality, to our daily life."*

4.3 Theme 3: A complex contribution to professional life and studies

Interviewees mentioned feeling enriched by the Improgineering course and grateful for it. For a few recent alumni, the course fostered professional reflections. For example, Interviewee F thought "*I should never have studied something like* *engineering, but something else that's more fun*" or Interviewee K reflected that the course reinforced "*the idea I already had that a job where you're creative is something I'd really like to do".* While other interviewees felt the course contributed especially to their personal lives, art and creativity practice.

In general, the interviewees acknowledged the acquisition of a wide array of transversal skills, spanning creativity, reflexivity, daring, risk-taking, self-confidence, public speaking, intuition, adaptability, and imagination. Despite this recognition, articulating specific examples or quantifying the course's impact on their professional lives proved challenging for participants. Interviewee H candidly expressed this difficulty, stating, "*I can't really measure the influence it's had on my life, but it's certainly had an impact, but in my everyday life, I couldn't say that it's helped me."* This sentiment resonated with other participants, who described the effects as "*subtle*," "*indirect*," or "*unconscious*."

Participants acknowledged also the complexity of evaluating the course's effects within the broader context of their professional and personal experiences. Interviewee B captured this sentiment, likening the course's impact to "*one brick in an accumulation of bricks.*" They elaborated, "*I don't know if it's enriched things a little, but in any case, it hasn't metamorphosed my way of thinking, and I don't actively think about it again*." This perspective underscores the gradual and integrated nature of learning, suggesting that the effects of the course may manifest over time and in conjunction with other experiences.

4.4 Theme 4: Barriers to transfer

Interviewees identified several barriers hindering the seamless transfer of skills and knowledge acquired in the Improgineering course to their professional lives.

A prominent barrier highlighted by Interviewee I is the stark misalignment between the sedentary nature of their engineering work and the movement aspect emphasized in the course. Interviewee I admitted, "*I must confess that anything to do with movement, unfortunately, I don't really have many opportunities to apply it because in computer science, well, you're sitting behind a computer half the time.*"

Moreover, participants lamented the structured and often non-cocreative nature of their engineering work, which limits opportunities for creative expression. Interviewee H articulated this sentiment, reflecting, "*It's never very creative or it's called brainstorming when you're working. I admit I allow myself to be creative more alone than collectively*."

Additionally, participants identified a lack of familiarity among their peers and colleagues with the co-creative methodologies taught in the course as a significant barrier to implementation. Interviewee A observed, "*The majority of people in this school (...) haven't had that kind of training. (...) And as a result, it's extremely difficult to implement. Because if I listen but they don't listen to me, it doesn't work either*."

5 LIMITATIONS OF THE STUDY

The study is subject to several limitations, each of which bears implications for the interpretation and generalizability of the findings.

The first set of limitations pertains to the characteristics of the research sample. Notably, the self-selection bias among alumni who volunteered for interviews may lean towards individuals with a more positive perception of the course, potentially skewing the representation of its effects. Secondly, the predominance of recent graduates among interviewees limits insights into the long-term professional impact of the course. Lastly, female alumnae are overrepresented in the research sample as the course has about 50% female students, while this study sample is 83% female. Conducting additional interviews with male alumni could help elucidate any gender disparities and provide a more balanced understanding of the course's effects across gender.

The second set of limitations concerns the data collection method employed in the study. While interviews offer valuable insights into participants' experiences, perceptions, and reflections, they may not fully capture the nuanced and often subconscious impacts of experiences. Participants may struggle to articulate or recognize changes resulting from the course, potentially leading to an underestimation of its contribution to their professional life. However, it is essential to recognize that the absence of overtly expressed impacts does not necessarily negate the existence of subtle or indirect influences.

6 DISCUSSION AND CONCLUSION

This study illuminates the impact of the course "Collective Creation: Improvised Arts and Engineering" on alumni students, who consistently express deep appreciation for their experiences and emphasize the unique atmosphere and distinctiveness of the course. Remarkably, alumni predominantly recall the emotional and experiential dimensions of their participation, highlighting the course's holistic approach that goes beyond mere cognitive knowledge acquisition.

Surprisingly, the course emerges as a catalyst for student wellbeing, despite this not being its primary objective. This positive impact can be attributed to several factors. Within EPFL's academic environment, characterized by high levels of stress and pressure as reported by the Mental Health and Well-Being Survey of the EPFL community (Courvoisier et al. 2023), the Improgineering course seems to provide a liberating experience by providing students carte blanche, with no right or wrong answers and no pressure related to academic performance on standard test. Additionally, research suggests that activities promoting movement and creativity, central components of the Improgineering course, can alleviate stress and enhance wellbeing (Rodríguez-Jiménez et al. 2022; Tan et al. 2021; Tait et al. 2024). Moreover, the course facilitates social connectedness, a sense of belonging, trust and freedom, all of which contribute not only to student wellbeing but also to student retention, engagement and motivation (Pedler, Willis, and Nieuwoudt 2022; Strayhorn 2018; Allen et al. 2018).

The study also sheds light on the potential of improvisation and embodied practices for student engagement and transversal skills teaching. Indeed, the course, in alignment with embodied learning theories (see section 2 Theoretical groundings) fosters deep engagement and enhances memorability by involving the whole person. The integration of improvisation and embodied practices also nurtures essential skills, such as collaboration, active listening, and creativity, which are often overlooked in traditional engineering courses (Daly, Mosyjowski, and Seifert 2014; Kovacs et al. 2020; Kazerounian and Foley 2007; Zhou 2012).

However, the study also underlines challenges in articulating the course's professional benefits. Participants cite barriers such as a lack of training in teamwork among other peers and colleagues, limited opportunities for application in professional settings, and discrepancies between the course content and the demands of engineering work.

The question thus arises as to whether a course, whose direct contribution to engineering education and one’s later profession is unclear, has a place in the engineering curriculum. One can first note that the unclear direct contribution of the course to engineering may be related to engineering students lacking training in articulating what they have learned. Moreover, dismissing the value of the course solely based on its transferability overlooks its intrinsic benefits. The immediate impact and value students experience during the course are significant in themselves, reflecting a broader philosophy of education that transcends mere instrumental outcomes. Furthermore, challenges in transferring learning to other contexts may reflect systemic issues, such as a lack of environments and safe spaces conducive to deep listening and effective teamwork.

Additionally, while the course offers unique and enriching experiences, it is perceived by some participants as less “serious”. This raises questions about what is considered serious in academia. In this case, it seems that less seriousness is in opposition to a certain rigidity of traditional courses since the course attendance is at about 80% which is relatively high, given the late timetable (16:30-19:00) and the remote location of the course (in a theater off campus site). Thus, we can wonder whether presenting the course as less serious is a way for certain participants of resolving the tension produced by the unconventional nature of the course, without questioning the rest of their studies.

More generally, an important secondary effect of the Improgineering course seems to be making students critically reflect on their engineering studies and work. It raises their awareness of how much they remain within an individualistic, cognitive, and rigid education system, both in terms of the work's format and the objectives to be achieved. The realization that none of this is necessary could be a major contribution of an unconventional course such as Improgineering in engineering education.

In conclusion, this study prompts a re-evaluation of conventional educational paradigms within engineering. It challenges us to consider the potential of integrating improvisation and embodied practices into engineering education. Rather than viewing the Improgineering course solely through the lens of its immediate applicability to professional settings, we must recognize its profound influence on student wellbeing, sense of belonging, creativity, and collaboration. As we contemplate the future of engineering education, we are compelled to ask: What if courses such as Improgineering were no longer the odd ones out but more mainstreamed in engineering education? How might this shift impact the way we engineer solutions to the complex challenges of our time? Would students become better engineers?

Keywords: *tacit knowledge, life-long learning, skills training*

ABSTRACT

The "Manufacturing Academy 2.0" project, co-funded by the European Social Fund Plus, addresses the challenge of an aging workforce and declining birth rates in Finland’s manufacturing industry. It focuses on developing training modules to preserve and transfer tacit knowledge from retiring experts to new employees in manufacturing industry. The education institutions involved in this project represent both higher education (Tampere University of Applied Sciences, Finland) and vocational secondary education (SASKY, Finland). This partnership ensures that the training programs are not only grounded in theoretical knowledge but are also directly relevant to the current and future needs of the manufacturing industry at various levels. Through structured interviews at the "Konepajamessut" Manufacturing Expo, the project gathered data to tailor training topics to industry needs. Results indicate a significant recognition of importance of tacit knowledge and a varied readiness to collaborate on training development. The responses also highlighted an overall positive disposition towards continuing education initiatives. This indicates a growing recognition of the value of life-long learning and upskilling opportunities, particularly through university and vocational school courses or training facilitated by them, to maintain a competitive and proficient workforce.

1 INTRODUCTION

In recent years, Europe has been experiencing a consistent decrease in birth rates, leading to an increasingly aging workforce. Lower birth rates mean a gradual decline in the young, working-age population that is the backbone of labour market. Therefore, there are fewer entrants into the workforce, which can lead to a shortage of labour. Manufacturing companies across Europe are responding to these challenges in various ways, including automation, to reduce dependency on human labour, and enhancing training programs to transfer knowledge from retiring experts to the newer workforce. There is also a growing trend towards encouraging later retirement to retain older workers' expertise and experience within the industry. As the workforce in manufacturing industries ages, there is a risk that not enough new skilled workers will be attracted to the field to compensate for the shortfall, and companies are responding to this by moving their production abroad. When older workers retire, they take with them tacit knowledge, which is often quite significant for performing certain work phases or procedures.

Tacit knowledge refers to the knowledge that a person possesses but which is difficult to convey to others through words or writing. It can include personal experiences, intuitive insights, implicit skills, and practices that have been acquired over a long period and in a certain context. One of the most famous definitions comes from the philosopher Michael Polanyi (Polanyi 1966), who emphasized that we know more than we can tell. This suggests that a large part of human knowledge is internal and subjective and cannot be easily or completely articulated. Tacit knowledge encompasses a wide spectrum of insights, from intuitive judgments and implicit skills to nuanced practices honed over years of hands-on experience. The complexity of defining and encapsulating this knowledge has led to a variety of interpretations across academic and practical fields, underscoring the rich diversity yet elusive nature of tacit understanding.

Within the manufacturing sector, the transfer of tacit knowledge is a significant factor. Experienced workers possess an invaluable ability to detect subtle cues—be it minor alterations in machinery sounds or operational shifts—that pre-emptively signal potential issues. Their decision-making ability, refined through years of observation and engagement, often operates beneath the surface of formal recognition or documentation. Mohajan (Mohajan 2016) emphasizes that tacit knowledge is a crucial, yet often overlooked, component of an organization's knowledge base that plays a vital role in innovation and the successful implementation of knowledge management strategies. While tacit knowledge is inherently personal and context-specific, certain technologies can aid in its transfer. For instance, virtual reality (VR) and augmented reality (AR) can simulate real-world scenarios for training purposes, making it easier for workers to gain insights into tacit knowledge without the direct intervention of a human instructor. Also, AR/VR technologies can be used to capture and digitize the expertise of skilled workers (Sarhan et al. 2022).

2 MANUFACTURING ACADEMY 2.0 -PROJECT

Tampere University of Applied Sciences (TAMK) and SASKY education association, collaboratively initiated a "Manufacturing academy 2.0" project, which is co-funded by the European Social Fund Plus (ESF+). The aim of this MA 2.0 project is to find methods to identify, collect, and train tacit knowledge to bolster the manufacturing sector in Pirkanmaa region in Finland. At the heart of MA 2.0 project's approach is the development of a pedagogical model or education concept that aligns with the needs of the manufacturing industry. The project also aims to modernize the training in the manufacturing industry so that tacit knowledge can be better transferred to new employees and that the training in general would better meet the demands of the modern age, which are related to the needs of the digital and green transition. The long-term goals of the MA 2.0 project are related to the establishment of the training model and increasing the attractiveness of the field, especially among young people. Additionally, the project offers opportunities for cooperation between different actors, both domestically and internationally, which strengthens networks and promotes the sharing of expertise.

A pivotal aspect of the MA 2.0 project is its collaborative framework, involving key stakeholders from both the education and industrial sectors. The education institutions involved in this project represent both higher education (TAMK) and vocational secondary education (SASKY). This partnership ensures that the training programs are not only grounded in theoretical knowledge but are also directly relevant to the current and future needs of the manufacturing industry at various levels. By fostering a strong link between education and industry, the project aims to ensure that the tacit knowledge transferred through its programs directly contributes to enhancing the competitiveness and innovation capacity of the manufacturing sector.

To be well aligned with the skill needs of the industry, companies were surveyed during “Konepajamessut”, a national Manufacturing Expo, that took place March 17-19, 2024, in Tampere, Finland. The expo spotlights advanced machinery, modern workshops, and smart investments. It's tailored for decision-makers in the metal industry, featuring machine tools, welding and joining tools, automation, robotics, maintenance, and industrial services. Alongside the Manufacturing Expo, also the Nordic Welding Expo and the 3D & New Materials Fair took place, making it a comprehensive event for industry professionals. The participating companies at the Manufacturing Expo span across various sectors of the manufacturing industry and other sectors, offering a diverse array of products and services. There were over 200 participating companies of which 78 were interviewed for this project. This manufacturing expo is one of the largest in Finland and companies all over the country participate. The companies interviewed range from medium-sized national to large international companies. Therefore, the results are expected to rather reflect rough average across companies operating in manufacturing sector in Finland, than only small regional companies.

3 SURVEYING COMPANIES THROUGH STRUCTURED INTERVIEWS

In the structured interviews aimed at manufacturing companies, the focus was on identifying the sector's near-future skill needs and whether companies have models for transferring tacit knowledge. The information obtained enables the project to direct its efforts so that training modules can be tailored to meet the skills the industry most urgently requires. The interviews also revealed which topics interest which companies, allowing for targeted training for different companies later on. The MA 2.0 project aimed to identify not only current but also future skill gaps, to proactively address labour market changes through education. The interviews sought to find out which topics companies' current or future employees need concrete skills in and whether there are existing methods and models for transferring tacit knowledge to new employees. The questions and the response distributions are presented in the next chapter.

A key focus of the survey was to gauge the perceived magnitude of the problem posed by the loss of tacit knowledge. By employing a 6-point Likert scale, companies were queried on the extent to which they view this loss as a challenge, thereby quantifying the urgency and importance of devising effective transfer mechanisms. This quantitative assessment is complemented by inquiries into the existence of current practices or training models aimed at facilitating the inter-employee transfer of tacit knowledge, offering a snapshot of the industry's readiness to tackle this issue. In the beginning of the interview, the respondent was briefly informed about the survey and also about the tacit knowledge transfer and its' definition.

The survey further investigates the willingness of companies to participate in the development of tacit knowledge training programs in collaboration with Tampere University of Applied Sciences (TAMK). This partnership underscores the project's commitment to creating a synergistic relationship between academia and industry, ensuring that the developed educational models are not only theoretically sound but also practically relevant and directly applicable to the manufacturing context.

One component of the survey centers on identifying the specific areas of manufacturing where companies foresee imminent workforce needs, attributable to retirement or other factors. By soliciting input on the significance of new workforce competencies across various domains, the survey aims to tailor the educational concept to address these emerging requirements effectively. Additionally, companies' preferences for the modality of training delivery—ranging from VR and AR simulations to online and in-person formats and workshops—are explored to design programs that align with organizational needs and learning cultures.

4 RESULTS

Figure 1 shows the answer distribution to the question of the importance of tacit knowledge loss in the company. The companies were also asked if they had methods or training models for transferring tacit knowledge from one employee to another and if they were willing to co-develop the transfer methods together with the education institution (TAMK). The answers are shown with different colours for different responses as indicated in the figure. Majority of the respondents (45 companies, 58 %) considered this to be a problem for them (scores 3-5). Altogether 18 companies expressed their interest to participate in developing tacit knowledge transfer methods. This is a very good starting point for planning the next actions and workshops in the MA 2.0 project.

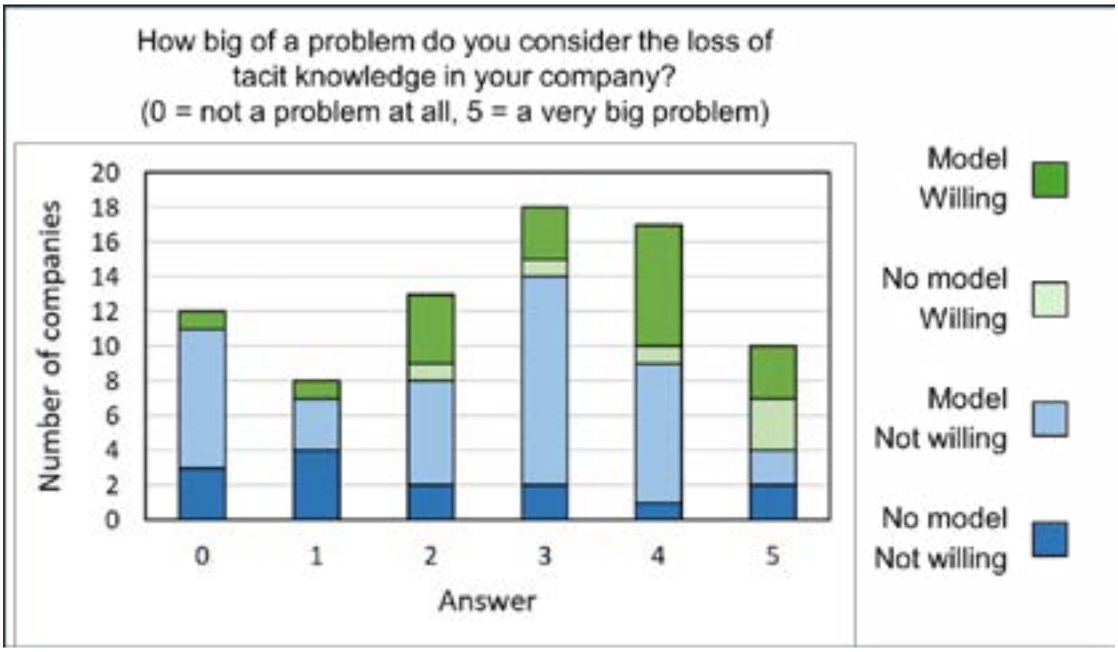

Fig. 1. The answer distribution to the question of the importance of tacit knowledge loss in the company. The companies were asked if they had a model for transferring tacit knowledge and if they were willing to co-develop it with TAMK. N = 78.

The survey results in Fig 1. indicate a substantial recognition among companies of the importance of transferring tacit knowledge, with a significant majority affirming the existence of practices or training models dedicated to this end (58 companies, 74%). This demonstrates a widespread acknowledgment of the risks associated with the loss of tacit knowledge, especially as a skilled workforce approaches retirement. However, it also highlights that a notable proportion of companies have yet to implement systematic approaches to address this issue.

Responses regarding the interest in collaborating on the development of tacit knowledge training with Tampere University of Applied Sciences (TAMK) showcased a divide. While some companies expressed interest (25 companies 32 %), a larger portion appeared reluctant. This hesitancy could be attributed to various factors such as resource constraints, satisfaction with existing training mechanisms, or possible uncertainty about the efficacy of new educational initiatives.

Figure 2 presents a bar graph illustrating the perceived significance of different skill areas for the new workforce. Almost identical results were obtained for the question about the training needs within a company for the near future (1-3 years). Due to the similarity of the results, only this first one is presented here.

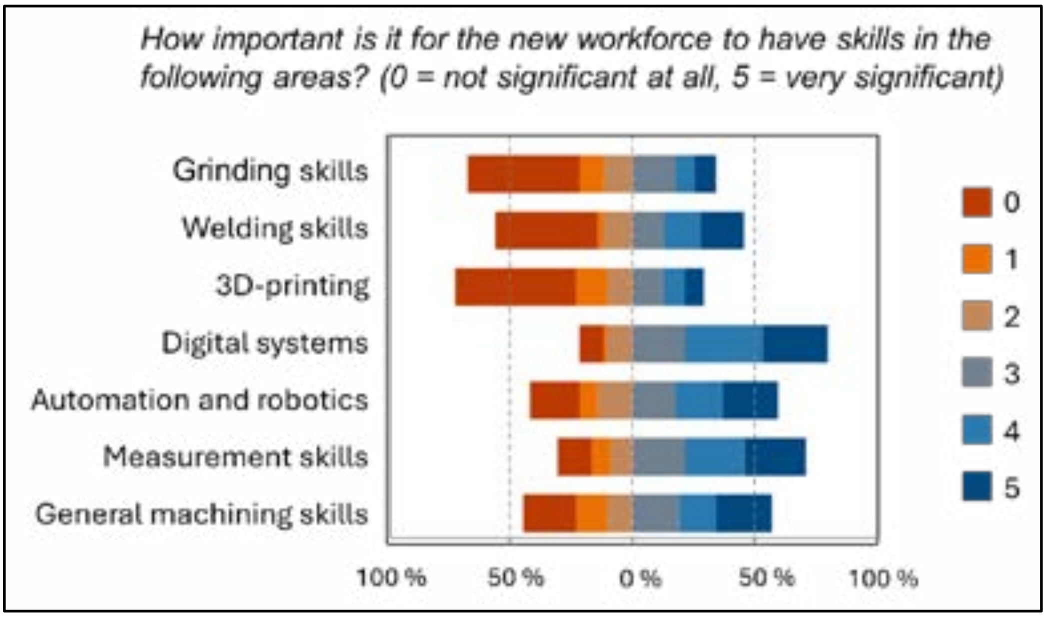

Fig. 2. The answer distribution of the importance of different skills that the new workforce should have. Similar results were obtained also for in-company training needs. N = 78.

Each topic was rated on a 6-point Likert scale from 0 (not significant at all) to 5 (very significant). The data points to a recognition that there is a varying need for training across different technical skills. All topics received answers ranging from 0 to 5. This was to be expected, as the sectors in which the companies operate varied, and thus the needs for skills also varied between companies. On average, companies rated skills such as digital systems and measurement skills as significant for their staff and for new employees, to mention a few. The results help the MA 2.0 project to contact right companies with certain training topics but also tell about which aspects to take into consideration in formal higher education programmes in general.

The companies were also asked about which training delivery methods would suit them. The answers are shown in the figure 3. This horizontal bar graph shows the number of responses for different types of training preferences. The respondents were encouraged to choose all possibly suitable training methods. According to the results in figure 3, online courses are the most preferred training type among the respondents, with supported self-learning as the second. The preference for online courses and supported self-learning among companies likely reflects a broader trend towards flexible and accessible forms of professional development. Online courses offer the convenience of anytime, anywhere learning, which aligns with the busy schedules of working professionals. Supported self-learning, being the second preference, indicates a desire for autonomy in learning, yet with a structure that provides guidance and support when needed. These preferences suggest companies value both the adaptability of online learning environments and the effectiveness of personalized learning pathways in meeting their workforce's ongoing skill development needs.

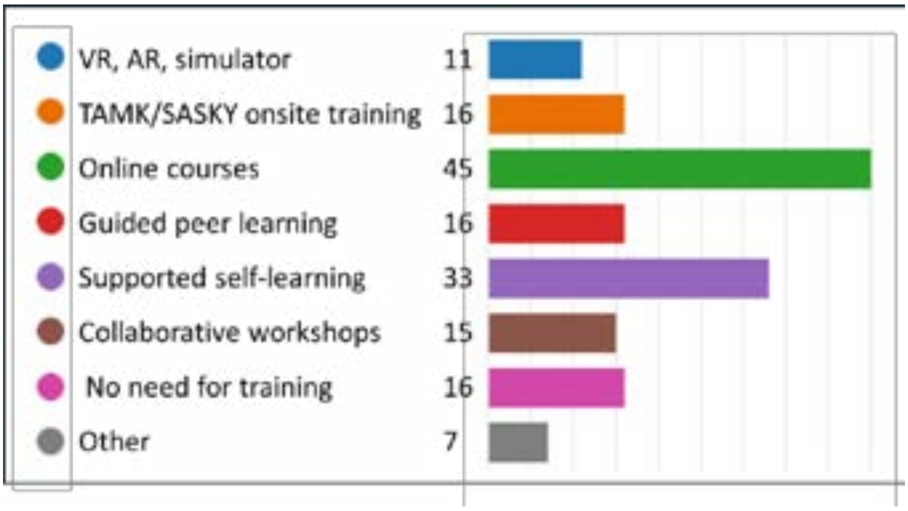

Fig. 3. The preferred training methods.

The traditional training delivery methods, like onsite training (TAMK/SASKY), guided peer learning and collaborative workshops received roughly similar response rates, but they were not as popular as the self-spaced learning options. VR, AR, and simulator trainings, on the other hand, are not considered as so good options. These are of course the state-of-the-art training methods and the reluctance to use them is a bit surprising. The hesitance towards VR, AR, and simulator training might stem from several factors, including the initial high costs and resource requirements for setup and implementation. Additionally, there could be a lack of familiarity or comfort with these advanced technologies within the company's current training ecosystem. This reluctance may also reflect a perceived complexity in integrating such state-of-the-art methods into existing training programs or uncertainty about their effectiveness and return on investment compared to more traditional, less technologically advanced training methods.

5 CONCLUSION

While the readiness to engage with TAMK in developing tacit knowledge training programs varied, the responses highlighted an overall positive disposition towards continuing education initiatives. This indicates a growing recognition of the value of life-long learning and upskilling opportunities, particularly through university and vocational school courses, to maintain a competitive and proficient workforce.

Survey results highlight the importance of retaining valuable tacit knowledge within the industry as technology evolves. The findings indicate varying needs for skills and training across different areas. Self-directed and flexible study methods, such as online learning and guided self-study, seem to best suit the industry's needs. However, there's hesitation in adopting new technologies like VR and AR. The project emphasizes the importance of collaboration between the education and industrial sectors to adapt to labor market changes. More dialogue and cooperation between educational institutions and the industry are needed. As the manufacturing sector progresses, these insights will inform the development of training models that aim to meet both current and future skill needs.

Although these findings were gathered in Finland, the issues of aging and retirement are widespread across the European manufacturing workforce. Consequently, there is a need for upskilling and reskilling initiatives to preserve critical knowledge and maintain industry competitiveness beyond Finland. By customizing training modules to local industry needs, this approach can be adapted to various contexts, promoting tacit knowledge retention and enhancing competitiveness in companies across Europe.

ABSTRACT

The study explores the integration and perceptions of AI in ICT engineering education, highlighting both the current utilization and future expectations among teachers. With the advent of generative AI applications, there is increased pressure and awareness for higher education institutions to incorporate AI into their curricula. The paper discusses the necessity for faculty in ICT engineering to stay updated with AI developments, ensuring relevant and innovative instruction for students. It also examines the use of AI in various educational facets, such as assessment, prediction, assistance, and learning management, based on systematic reviews and empirical research. The findings reveal a mix of enthusiasm and caution among teachers, with a clear recognition of AI's potential benefits in enhancing teaching efficiency and student learning, alongside concerns about ethical, safety, and cost implications. The study advocates for comprehensive training and institutional support to effectively integrate AI in teaching, emphasizing the need for ongoing development to align with the rapidly evolving technological environment.

1 NTRODUCTION

The explosive spread of artificial intelligence (AI) usage also puts pressure on universities to educate personnel on AI-related matters. In ICT (Information and Communication Technology) engineering education, this also means developing expertise in development principles and necessary technologies. However, Bates et al. (2020) state that AI has had little impact on teaching and learning in higher education so far. This perspective prevailed four years ago. The 2023 launch of OpenAI's ChatGPT marks a significant milestone in generative AI's penetration into various sectors, intensifying the push for its integration into daily operations and support systems. Integrating AI into higher education is nowadays seen as inevitable (Hodges and Ocak 2023; Mallik and Gangopadhyay 2023). Universities must adapt and prepare teaching staff for an AI-driven future (Hodges and Ocak 2023).

Historically, the introduction of Virtual Learning environments (VLE) marked a significant shift in educational paradigms, offering new modalities for content delivery and student engagement. This mirrors the current evolution we're seeing with AI applications in education, which similarly aim to revolutionize teaching methodologies and learning outcomes (Azmi et al. 2022). For instance, earlier research has highlighted how VLEs improved accessibility and personalized learning paths, aspects that are increasingly relevant as AI tools begin to offer similar advantages in educational settings (Cellini 2021). Moreover, studies on VLEs have also discussed challenges such as the digital divide and the need for robust faculty training—issues that are paralleled in the current discourse on AI in education. By comparing these scenarios, we can better anticipate potential barriers to AI adoption and develop more effective strategies for integration (Torres 2021).

Personnel must keep abreast of these changes to deliver current and relevant instruction, thereby preparing students effectively for the workforce. Incorporating sensible content into the curriculum that also promotes students' creativity and innovative thinking is essential. The industry demands that students possess knowledge of the latest technologies, including AI and its applications. Understanding ethical and societal issues helps teaching staff to transfer perspectives of responsibility to students as well. Staying current with new technologies also addresses the challenges of continuous learning, where ongoing development requires continuous learning and adaptation. Therefore, to provide high-quality and up-to-date ICT engineering education, teaching staff must stay abreast of the latest developments.

Research related to the subject has been conducted under the concept of AIEd (AI in Education), which is one of the categories of AI usage and focuses specifically on the use of AI in higher education institutions (Compton and Burke 2023). Cropton and Burke (2023), in their systematic review on the utilization of AI in higher education conducted between 2016 and 2022, have observed that AI is primarily used for five different purposes: Assessment/Evaluation, Predicting, AI Assistant, Intelligent Tutoring System, and Managing Student Learning, with AI Assistant being specifically mentioned as utilized by students. According to a study conducted by Pisica et al. (2023), most views on the benefits of AI in higher education focus on its impact on the teaching-learning process, research, and the development of new skills, while the most significant concerns relate to fears of socio-psychological impacts, loss of ‘humanity’, and safety and ethical considerations. The costs of using AIEd tools can also widen the gap in education availability, including from the perspective of equitable access (Mallik and Gangopadhyay 2023). It is noteworthy that actors must prepare for the adoption of AI and pave the way in the field of education (Lampou 2023), including in the case of the strongly technically oriented staff of ICT engineering education.

The ICT Engineering degree program at Lapland University of Applied Sciences (Lapland UAS) adheres to the Conceive, Design, Implement, and Operate (CDIO) framework. It includes routine self-assessment against the twelve standards of CDIO, currently at version 3.0, as outlined by Malmqvist et al. (2020). In the self-assessment, standard 9 ‘Enhancement of Faculty Competence’ and standard 10 ‘Enhancement of Faculty Teaching Competence’ were identified as areas for improvement. In the refinement phase, the staff identified competence development in the field of AI as particularly important, leading the faculty unit to plan a competence development roadmap accordingly. The research described in this paper contributes to this development work.

Núñez and Lantada (2020) explore AI's role in enhancing engineering education in their study, presenting a roadmap that begins with an analysis of the current state and identifies key themes to reach the desired state. They investigate AI's impact on technical systems and its potential to enhance higher education's teaching-learning processes, particularly in scientific and technical fields. The authors discuss AI's role in supporting educational technology and detail strategies for its rapid integration into educational programs. The roadmap encompasses themes such as AI's utility in educational practices, the trends and best practices in AI-based teaching-learning experiences, the concept of intelligent universities, and the challenges and proposals for integrating AI in engineering education.

This research aims to assess the present and future use of AI in ICT engineering education, focusing on how educational staff employ AI in teaching and guidance. It also examines their expectations for future AI utilization. The study addresses two main research questions: How do ICT engineering education personnel use AI in their teaching and guidance activities, and what are their future expectations for AI use?

In addition, this study's insights into teachers' experiences with the systems and their considerations for its implementation can serve as a foundation for developing guidelines to integrate AI into school curricula, particularly in STEM education, as suggested by Kim and Kim (2020).

2 METHODOLOGY

2.1 Data collection methods

The data collection for this study was conducted as a web survey. The thoughts, experiences, and expectations of the participants, namely the ICT engineering education teachers (N=18), were surveyed through a questionnaire. The survey aimed to get in-depth information about the respondents' perspectives and motivations. Its purpose was to understand the topic and problems from the perspective of individuals. Validated questionnaire instruments appropriate for this recent research topic and research questions were not readily available in the literature. A mandatory preliminary ethical review was not needed, because the study did not meet the criteria required for ethical evaluation defined by TENK (2019), such as participants being underage or exposure to security risk.

The survey was administered using Webropol 3.0, a robust online survey and reporting platform. At the outset, respondents were provided with a comprehensive definition of AI, encompassing all its sub-areas such as machine learning, computational environments, ethics, and user interaction. This was to ensure a uniform understanding and to mitigate variations in responses due to differing interpretations of AI. In the same context, respondents were also informed that participation in the survey was voluntary and were provided with information on handling the data and reporting results. Respondents answered the survey anonymously.

The first multiple-choice question aimed to determine if the teacher felt they belonged to any of the following categories: STEM (science, technology, engineering, and mathematics) subjects, languages and communication, software development, cyber-physical systems (including robotics), and other professional subjects. The remaining 8 questions were open-ended:

Q1: Describe how you use AI in your course planning.

Q2: Describe freely how you utilize AI in the implementation and guidance of teaching.

Q3: What kind of AI solutions do you utilize in assessment?

Q4: What obstacles and challenges have you encountered in integrating AI into the planning, implementation, guidance, or evaluation of teaching?

Q5: Based on your observations, how has AI affected students' learning outcomes and motivation?

Q6: What expectations or suggestions do you have for better integrating AI into the planning, implementation, and evaluation of teaching?

Q7: How do you assess the significance of AI for the future of engineering education? Justify your thoughts.

Q8: What kind of AI-related training would you like to be organized for teaching staff?

One week was given for response time, and the responses were collected anonymously. There were 12 responses to the survey, making the response rate 67 percent.

2.2 Data analysis

Initially, the results, including interpretations of tone, were examined based on the taught major for the utilization of AI, experiences, and the attitude toward its use. The results were analyzed by different groups of people by calculating frequencies. For question Q2, the response determined whether it was categorized as ‘Utilising’ or ‘Not utilizing.’ The responses to question Q4, in turn, were divided into two categories: has challenges and no challenges, and for Q3 into ‘Positive’, ‘Negative’, and ‘No effect’. The responses to question Q5 were classified into four groups: ‘Positive’, ‘Negative’, ‘Both’, and ‘No Observations’. In question, Q7, the tone of the responses regarding the direction of engineering education development was interpreted as either ‘Negative’ or ‘Positive’.

The contents of the responses to open-ended questions were also analyzed thematically, iterating in a way that general concepts and meanings were extracted through inductive reasoning. Using content analysis of open coding, the units of analysis were classified and grouped inductively by aggregating individual observations into general themes. Hits were calculated for the themes to determine their frequency of occurrence.

3 RESULTS

Half of the respondents (N=8) taught vocational subjects, such as software development or cyber-physical systems. Nearly a third (N=5) worked as teachers in subjects other than vocational or STEM fields, and two respondents represented language or communication teachers.

In question Q2, the majority of respondents utilized AI in the implementation and guidance of teaching (N=10), 5 respondents did not utilize it, and 1 response was left blank. The responses to question Q2 reveal that artificial intelligence was primarily understood as based on language models, with Chat GPT being mentioned seven times. Three respondents reported that they have not used AI in teaching or guidance, and AI was most commonly utilized in the planning of tasks. In Figure 1, the proportion of respondents facing challenges or not facing challenges is depicted in the subject taught. Out of 16 respondents, 13 (81 %) had encountered challenges, while 3 respondents had not faced any challenges. Specific barriers to the use of AI included mandatory registration and costs in Q4.

Figure 1. The proportion of those facing challenges per subject taught.

In Figure 2, the impact of AI on students' motivation and learning outcomes is analyzed, segmented by the subjects taught as specified in Question 5 (Q5). Of all respondents, half (N=8) reported observing no significant effects of AI on motivation or learning outcomes. However, the responses varied: three respondents noted both negative and positive impacts. These mixed observations were reported by teachers from various professional subjects, including software development.

Interestingly, while only one respondent noted purely positive effects, three others — teachers in software development and language and communication — reported exclusively negative impacts. The distribution of responses was generally even across different teaching subjects. Notably, some respondents observed improvements in the quality of task responses, though two expressed concerns about potential deterioration in learning outcomes. For student groups with diverse backgrounds, one respondent highlighted a possible improvement in motivation.

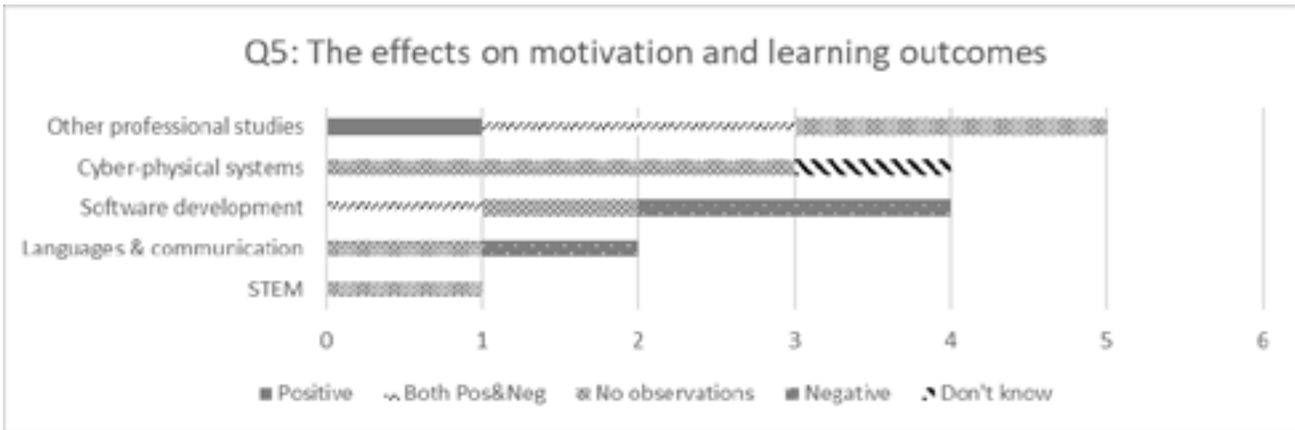

Figure 2. The proportion of the observations of the effects on motivation and learning outcomes.

In Q8, respondents expected additional training for staff and general guidelines on the use of AI in teaching. Specifically, a solution to the issue of costs at the organizational level was desired, and the initiation of a project or development initiative utilizing AI to integrate into the planning, implementation, and evaluation of teaching was suggested. Concerning the theme of sustainable development, the weakest responses were received, with ten being either blank or of the 'I don't know' type. In some responses, collaboration with companies to develop AI-supported solutions was proposed.

Twelve respondents evaluated the development direction of AI for engineering education (Q7) positively. Only four respondents saw the impact as negative. Both language teachers and teachers of other subjects saw the future positively. In contrast, responses from vocational subject teachers, such as software development and cyber-physical systems, included both positive (N=5) and negatively interpreted responses (N=3). Respondents emphasized that engineering education must keep pace with technological development and that AI tools will be central in planning and implementation in the future. Furthermore, it was seen that AI plays a role in the design and execution of teaching as well. In Q6 respondents were looking for ideas and tips for utilizing AI in education, with specific challenges related to machine vision and the cybersecurity of AI being highlighted.

4 SUMMARY AND ACKNOWLEDGMENTS

This study clearly demonstrates an increasing integration of AI within ICT engineering education, as evidenced by widespread use among educators. The proactive adoption of AI tools across various teaching domains reflects a significant shift towards technologically enhanced educational. Most teachers have already started using AI tools in their teaching and guidance processes. This indicates a proactive approach towards embedding AI into the curriculum, aligning with the necessity for educational institutions to evolve with technological advancements. However, the data also reveals a substantial number of teachers facing challenges in AI integration, primarily due to cost and mandatory registration barriers. These hurdles underscore the need for institutional support in facilitating access to AI resources and training, to ensure that the benefits of AI can be fully leveraged in education.

While the research by Pisica et al. (2023) provided valuable insights into the adoption of AI, it did not address critical factors such as the time and financial investments required, which are essential for understanding the full scope of AI integration challenges. In contrast, our study identifies these investments as significant barriers, emphasizing the need for detailed planning and resource allocation in future AI adoption strategies. However, these factors emerged in the case of teachers in the ICT field as described in this article.

Pisica et al. (2023) point out that contemplating restrictions on the use of artificial intelligence partly reflects a narrow perspective and a lack of understanding of the true potential of AI. The mixed observations on AI's impact on students' learning outcomes and motivation suggest a nuanced interaction between AI and educational processes. While some teachers noticed improvements in task quality and potential boosts in student motivation, concerns about the negative effects on learning outcomes were also reported. This dichotomy highlights the complexity of AI's role in education, necessitating further research to understand its effects comprehensively and to develop strategies that optimize its benefits while mitigating potential drawbacks.

Teachers' positive outlook on the future role of AI in engineering education, coupled with the call for additional training and guidelines, reflects a strong belief in AI's potential to enhance teaching and learning. The desire for organizational support in overcoming financial barriers and the initiative for AI integration projects indicates a proactive stance toward embracing AI in education. Moreover, the specific interest in training on machine vision and AI cybersecurity points to a keen awareness of the emerging areas within AI that are relevant to ICT engineering.

The relatively weaker responses concerning sustainable development suggest a gap in the current discourse on AI's role in fostering sustainability in education. This gap presents an opportunity for future research and development efforts to explore how AI can contribute to sustainable educational practices. The proposal for collaboration with companies to develop AI-supported solutions reflects an acknowledgment of the potential synergies between educational institutions and the tech industry in advancing AI in education.

The findings from this study underscore the significance of AI in the evolution of ICT engineering education. While there is evident enthusiasm and acknowledgment of AI's potential, the challenges faced by teachers highlight the need for comprehensive institutional support and training programs. Addressing these challenges and leveraging collaborations with the tech industry can pave the way for a more integrated and effective use of AI in education, ultimately enriching the learning experience and ensuring that students are well-equipped for the AI-driven future. Additionally, the experiences and perspectives of teachers obtained from this study on the needs for competence development and student motivations can serve as a basis for developing guidelines for the advancement of AI expertise from the perspective of engineering education faculty, especially those in ICT engineering education.

In conclusion, the feedback from ICT engineering educators at Lapland UAS underscores a critical need for robust institutional support and strategic planning. These elements are essential to effectively integrate AI into higher education curricula, ensuring that educators are well-equipped to navigate the evolving technological landscape. Other institutions can learn from these findings by actively seeking ways to incorporate AI into their curricula, addressing potential challenges proactively, and fostering collaborations with industry to enhance the relevance and effectiveness of AI in education.

In almost all changes related to teaching in higher education institutions, the conclusions and recommendations can be considered as general instructions on how to respond to these changes. Caution in introducing artificial intelligence, as well as courage, curiosity, and promotion of new methods, may present conflicting goals. Based on the responses in this study, it can be assumed that the latter perspective—a bold approach—is recommended in higher education.

This study also has some limitations. For example, the sample size is small, which can affect the generalizability (Ercikan & Roth 2014). Out of 18 surveyed, 12 answered. The survey was sent to the entire population, so the coverage of the survey is sufficient. Negative perspectives have also been brought up in the study, which enhanced the reliability of the study (Creswell 2014, pp. 251-252). The disruptive effect of artificial intelligence is a global phenomenon that has appeared simultaneously everywhere, and it can be assumed that the challenges it brings to higher education are universal.

ABSTRACT

Engineering students must be able to generate diverse, creative solutions to problems as a key skill for their future careers, as industry and the environment requires innovative solutions to complex problems. This paper reviews some current best practice in ideation and problem framing that are taught in engineering programmes and surrounding education. Frameworks include morphology analysis, design heuristics, SIT tools and generative-AI. Each framework aims to present problems in different perspectives and encourage students to solve them creatively, with each demonstrating an improvement in student creativity and diversity of thought when they are taught in project-based activities. Following this review, two case studies from The Engineering & Design Institute London (TEDI-London) are presented, illustrating how students utilised various ideation tools during an engineering product design module. The paper concludes with key lessons for educators interested in incorporating such tools into their teaching. Overall, the paper highlights innovative methods to foster creative problem-solving skills among engineering students.

1 INTRODUCTION

Engineering education needs to consistently innovate so that engineers entering the workforce are better equipped to tackle industrial, societal and environmental problems (Nordin and Norman 2018). Courses on user-centred design, and teaching where students tackle open-ended projects are seen as an emerging part of innovative engineering education (Graham 2018), and ideation (forming ideas or concepts) is a key stage in problem solving (McGlashan 2018).

Ideation and problem framing are key to better develop problem solvers, with project-based learning (PBL) offering a practical, hands-on approach to training engineers in ideating and in improving creativity (Chang et al. 2022). PBL courses have become increasingly popular in engineering education. For example, University College London have adopted PBL modules within the integrated engineering programme (Hailes et al. 2021) and newer providers such as the New Model Institute for Technology and Engineering (NMITE) or The Engineering & Design Institute London (TEDI-London) have emerged, and primarily teach using PBL.

There are several widely used frameworks and concepts for ideation, including group brainstorming and the ‘theory of inventive problem solving’ (TRIZ). Group brainstorming, has been shown to significantly reduce the productivity of ideation (Mullen, Johnson, and Salas 1991). TRIZ (originally derived from the study of inventive patterns in patents), meanwhile has been shown to improve the novelty and variety of ideas, compared with ad-hoc ideation (Hernandez, Schmidt, and Okudan 2013). TRIZ can be challenging for newcomers with 40 different inventive principles (Ilevbare, Probert, and Phaal 2013), however, through simplifications, and derived techniques such as ‘systematic inventive thinking’, these can be potentially fruitful alternative ideation techniques for engineering students.

Accordingly, in this paper, we (i) present an overview of emerging methods for ideation and (ii) present two short case studies from our institution where example tools have been used in diversifying potential solutions. Finally we highlight key take-aways for educators looking to implement such techniques in their programmes.

2 IDEATION METHODS

2.1 Morphological analysis

The process of morphological analysis is defined by breaking a problem down into its constituent parts, subcomponents and functions, and ideating for each individually, resulting in a morphology chart. In this different combinations of solutions are selected together to design products. There is little academic literature to define how to select different solutions, as the number of total solutions may be unreasonable to consider, e.g. a chart with 6 functions and 7 different solutions per function yields over 117,000 solutions. Approaches may include systematic combinations of all functions, intelligent combinations or random combinations. In any case, this is often seen a vague to students and can be challenging to apply if a student is not comfortable the procedure.

There are few recent academic studies on the use of morphology charts in design thinking. One study (Daly et al. 2016) compared creation ideation techniques with beginning designers investigating the use of morphological analysis, design heuristics and individual brainstorming. This found individual brainstorming to be the simplest method of idea generation, producing the most concepts. Alternatively, with appropriate teaching, morphological analysis resulted in more elaborate concepts than individual brainstorming. An additional study of 54 mechanical engineering students (Smith et al. 2012) lead to the development of guidelines for the use of morphology charts in design thinking. This stated that designers should explore and expand the design space through the use of additional solutions, rather than functions, and that primary and critical functions should be focused on.

2.2 Design heuristics

Design heuristics are design strategies that can be employed in ideation, and may be considered 'rules of thumb' (Yilmaz et al. 2016) to apply in the design process, to aid in generating a wide range of concepts and, to help designers avoid becoming 'fixated' on early ideas. There are many design heuristics, often tailored to different fields. For example, Yilmaz (Yilmaz et al. 2016) analysed key features and functional elements of 400 award-winning products, from different designers, and from this extracted 40 design heuristics. They extracted well-specified heuristics that other designers could clearly identify with and apply to their own designs. The heuristics included principles such as "implement characteristics from nature within the product", "allow user to reorient" and "use the inner surface space of the product for different functions". They went on to study how the heuristics aided undergraduate industrial designers during ideation, and found that, on average, concepts that showed evidence of using the heuristics were more creative, and also more diverse.

In recent progress, authors from ETH Zurich (Blösch-Paidosh and Shea 2021, 2022) summarised a set of design heuristics for design for additive manufacturing. This set of 25 design principles included "consolidate parts to reduce assembly time" and "create multi-functional artifact with reconfigurable structures".

Heuristics are helpful "quick and dirty" tools that can help spark ideas for a wide range of design scenarios. As there are plentiful resources of design heuristics for many highly specific areas, teaching these to undergraduate students can pay dividends in (i) increasing creativity (ii) increasing diversity of concepts and (iii) increasing productivity of designers by ensuring they build on others' findings.

2.3 AI-Assisted techniques

With recent advances in AI technology, in-particular Generative AI (Gen-AI) and Large Language Models (LLMs), studies have attempted to decipher the usefulness and drawbacks of this technology in design thinking, innovation and creativity. Gen-AI has made rapid advances typified by Open AI's ChatGPT chatbot which is able to match or improve on human performance in examinations and, Microsoft Co-Pilot able to aid in writing and debugging code. Furthermore, Midjourney and Microsoft Designer, based on DALL-E 3, are able to produce images from text. Various sectors have begun utilising the use of Gen-AI including in healthcare, business and design (Chong et al. 2022) with the benefits of Gen-AI being extensively researched for their use in design, ideation and in co-design (Kim, Maher, and Siddiqui 2021; Chiou et al. 2023).

Prior to the release of this software, a studied showed innovation managers regarded idea generation and idea evaluation as the least important areas for AI application within the design process (Füller et al. 2022). Since then studies have shown a remarkable increase in the use of Gen-AI in design thinking. Students from engineering and design courses used a range of tools including ChatGPT and Midjourney during both the research and empathy phases and the ideation and prototyping phases of a makeathon (David, Krebs, and Rosenbaum 2023). Within the study, 82% of engineering, and 76% of design students used Gen-AI tools to aid in the creation of their solutions. During the research and empath stages 67% of students used textual only tools (ChatGPT) and 19% used visual only Gen-AI tools (Midjourney). This significantly increased to 30% using visual only in the ideation and prototyping phases with students using visual Gen-AI tools to visually validate and develop their solutions. This approach is supported by a number of other studies, suggesting that Gen-AI can work with human designers rather than replace them (Esling and Devis 2020; Bilgram and Laarmann 2023).

Bilgram (Bilgram and Laarmann 2023) showcased the use of Gen-AI in accelerating the digital prototyping and innovation phases of design, through the production of an app. In this, discussions with ChatGPT were used to create HTML/CSS prototype at an accelerated rate through aiding the user in debugging the software, providing instructions and code snippets, however limitations were reached due to extensive conversations leading to content being ‘too for back’ for the AI to remember features and requirements.

It is seen that Gen-AI may be a game changer in early prototyping as the delegation of tasks can lead to faster iterations and reduced costs. Numerous studies have shown the positive impact on the early stages of design (Tholander and Jonsson 2023; Chiou et al. 2023; Girotra et al. 2023). However, this is often reliant on two factors. (i) the quality of the prompt used for generation and (ii) the input of the designer to co-create with Gen-AI rather than replacing the designer. Although studies have shown that Gen-AI is capable of matching or surpassing professional designers in idea generation judged on novelty, customer benefit and feasibility in some scenarios (Joosten et al. 2024), often designers find the tools to be useful for ‘going wide’ on a topic rather than ‘digging deep’.

This is a rapidly changing landscape with new tools and capabilities of LLMs and Gen-AI being developed at unprecedented rates creating new scope for idea generation and development.

2.4 Systematic inventive thinking

Systematic inventive thinking (SIT) is a derivative of TRIZ (Boyd and Goldenberg 2013), and as well as being a thinking method, is also the name of an innovation consulting company (SIT 2024). In SIT, designers implement five different “thinking tools” to generate new ideas. Initially, designers create an inventory of the components in the product, then apply one or more of the thinking tools, which are:

1. **Task unification**. Each component is converted to a resource to be used in another way. The tool then assigns a new task to the existing component.
2. **Multiplication**. One component of the inventory is multiplied, whilst giving it a qualitative change that makes it different from the original in some way.
3. **Division**. The components are divided up, physically or as a function of time.
4. **Subtraction**. Components are divided up, then one or more are removed.
5. **Attribute dependency**. Internal variables are corresponded to external variables to check if there is an attribute dependency on the internal variable to the external variable, then imagines that there is one, or vice versa.

The new ideas are then generally reflected on to evaluate whether the new ideas align with design principles. Designers ask the questions “what are the potential benefits”, “who may find this change valuable?” and “how may this help to address a problem” in response to the change made to the product.

(Barak and Bedianashvili 2021) showed several examples SIT for ideating and problem solving, for example the innovation of a spirit level to measure the specific slope of a surface. The authors described how, when a set of 110 engineering experts were given a 30-hour workshop on problem solving, including the SIT method, the engineers were able to show a marked increase in the number of inventive solutions (from 0.65 up to 4.84 solutions) in an exam, after the workshop.

3 CONTEXT: THE ENGINEERING & DESIGN INSTITUTE LONDON

3.1 Education Setting

In this paper, two case studies were examined using different ideation techniques by 2nd year Global Design Engineering students at TEDI-London . The degree programme primarily focuses on educating students through project-based learning. The case studies presented are indicative of the concepts and frameworks taught a module titled “User Centred Product Design” (UCPD). In this module students are required to define their own problem statement, ideate potential solutions and present their developed idea in a final assessment. The project theme was “design and prototype wearable technologies”. The final assessment is a design history file with physical prototype. Some of the learning outcomes of the module include (i) the ability to research and evaluate user needs as applied to the design of a product (ii) establish and apply aesthetic and ergonomic design and (iii) generate concepts and evaluate, iterate, and develop them.

Students are introduced to frameworks and tools through a blended approach. Background theory and formative tasks are delivered through online learning, allowing students to work at their own pace and become familiar with the tools by completing tasks adjacent to their main project. Some of the design tools include the use of journey maps, ethnographic tools and ideation techniques, including theory on how these help to overcome cognitive fixedness.

During in-person classes, theories and frameworks are presented and discussed in greater detail, often with workshops to practice using them. Students learn how to apply the tools to the situations they are solving, providing them with the opportunity to explore the possibilities. Students are given a range of frameworks to choose from, enabling them to select the tools and methods that best suit their situation and timeframe within the product development cycle.

3.2 Case Study 1: Systematic inventive thinking

During UCPD, 35 students took part in the module. Over ten weeks, students engaged in user research, and were required to produce material highlighting user pain points (both explicit and, latent pain points) and, from this, elicit design principles, that is, the characteristics (or “attributes”) that ideas must have in order to successfully overcome the identified pain points. Students initially worked in groups of three to four and gave an assessed interim presentation of their research and initial ideas. After the presentation, students worked independently on one selected idea. Whilst students were free to research any area, they were required to find problem areas that may be conceivably aided using wearable technologies.

Beyond the more obvious example (around ergonomics and battery life etc.) the type of design principles that students uncovered were varied, but some representative examples included: “Doesn’t add stress to the user’s life.” and “encourage conversation also … encompass immersivity”. The 5 SIT tools were applied to existing wearable technologies, to see if ideas could be sparked to create helpful innovations. The results were, very varied, but in some cases, laid the foundation for some innovative concepts. Some examples included:

- Division of a smartwatch into small modules, so a user could physically ‘leave’ a certain function at home, to reduce distraction or anxiety, initial sketches shown in Figure 1.
- Using the task attribution tool to assign the task of monitoring and calculating UV exposure and dosage, to a hair clip.

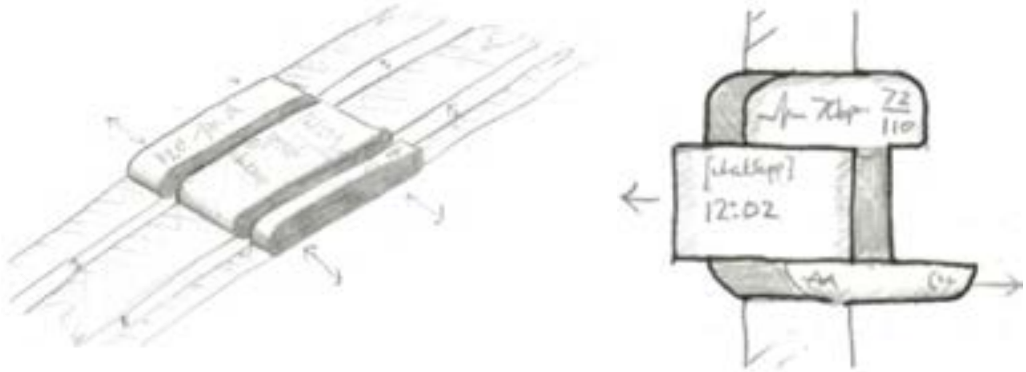

Figure 1: Examples of using the SIT ‘division’ tool for a modular smart watch design.

Out of a class of 35 students, anecdotally, nearly all engaged with, and were able to use the SIT tools. Students were generally able to generate a wide range of ideas using the framework. Of the 16 students that recorded ideas using a ‘creative matrix’ (a matrix with design principles as columns and ideation techniques as rows, with ideas in the cells), the average number of ideas in the creative matrix as generated from SIT was 15.4 ideas (minimum 4, maximum 51).

Students appeared to find the ‘attribute dependency’ tool relatively difficult to implement, whilst others were generally seen as simple and helpful. However, after the completion of the UCPD module only a handful (3 or 4 students) had continued to develop ideas that had originally been generated by SIT.

3.3 Case Study 2: Alternative worlds and visual Gen-AI

This second case study includes findings from the same cohort and module. Beyond SIT, two further frameworks were employed during UCDP to build inspiration and creativity in the product designs: ‘alternative worlds’ and visual Gen-AI. Students were encouraged to use Gen-AI throughout the design process with the majority using visual tools during the second phase: product development.

Using the ‘alternative worlds’ framework, students were asked to imagine how different brands may design their wearable products. For example, what if ‘Starbucks’ made smart glasses or ‘Beats headphones’ made VR glasses. Students selected an existing brand and identified the brand guidelines and design language used in their products to influence their own product development. Using these brand guidelines, concept images were generated using Microsoft Image Generation tools, powered by DALL-E. The results of this process can be seen in Figure 2 with examples of smart watches and ski goggles.

Figure 2: Examples of AI-Generated designs following brand guidelines established by students (a) a smart pill watch using Lemsip branding and (b) smart ski goggles using Garmin branding and design language.

Following the generation of images, students were asked to complete group design critiques of the images and designs. In this, they were required to highlight elements of the design they liked, or thought suitably matched the design language, and what elements they would change in future iterations. Students identified details of designs they wanted to progress through to final design, and further inspirations for their designs. Colorations between images critiqued and the final designs of students can be seen, with Figure 3 showing initial images generated and final renders of their products. Clear links and inspiration can be seen through the strap connectors, side buttons, shape and screen with refinements made to the designs generated by the student. These frameworks exposed students to a wider range of ideas and concepts during the development phase which enhances their creativity and diversity in idea development and ideation.

Figure 3: (a) Gen-AI images using design language from Canon products and (b) final student renders of smart watch produced by students.

4 CONCLUSIONS

Ideation and creative design are key tools for graduate engineering students starting their careers, hoping to produce innovative solutions to complex problems. This paper presented a range of tools taught across engineering design thinking programmes to increase the creativity and diversity of thought in solutions.

Traditional lecture-based programmes often struggle to engage students with key frameworks due to lack of practice and integration. Project-Based Learning, and user centred design courses are alternative education styles, allowing students to engage with tools and frameworks, as well as traditional engineering practices, whilst developing their own ideas and products.

Through presenting two case studies at TEDI-London , this paper has discussed the value of two frameworks, SIT and Generative-AI in fostering creative ideas in student projects. SIT was shown to aid nearly all students (in our cohort) in the generation of a wide range of initial ideas and concepts. A smaller number of students developed these concepts to a working prototype solution. This suggests that SIT may best be taught amongst a range of other tools, rather than a sole method.

Secondly, students used Microsoft Image Generator to create concept images of a range of designs for wearable products. This process was seen aid in the generation of diverse ideas, allowing students to imagine different products being produced in distinct design language or company. Rather than students using these designs as their products, a group design critique was conducted to encourage students to evaluate the designs. Final output from the project can be seen to contain inspiration from the generated images, combining different aspects together.

4.1 Key Takeaway for Educators

The pedagogy at TEDI-London primarily utilises PBL and online learning to teach fundamental principles and the application to real-world problems. There is a growing trend in engineering education programmes towards this methodology and this paper aims to enable other institutions to learn and implement the experience gained in their own programmes. Subsequently, the key takeaway points from this experience are summarised here:

1. Frameworks such as brainstorming and morphology analysis are traditionally taught in engineering undergraduate programmes but may reduce the productivity of ideation. Students who were taught methods such as SIT, and alternative worlds tended to favour their use in the product development cycle.
2. These frameworks are suitable for undergraduate engineering courses, and do not take up too much time to introduce, but considerable time to perfect.
3. Structuring PBL courses with significant tutor lead activities for new frameworks and tools is required for student engagement with such tools.
4. Introducing students to a wide range of frameworks and tools enables them to interact with methods they find useful and creative, leading to a diverse output from the cohort. Students value the access to a wide range of these tools.
5. Students were keen to engage in new technologies such as Gen-AI during projects but educators should work with students to help develop prompts and co-create through critiquing designs produced to influence their own designs.

Acknowledgements

The authors would like to thank all second year “Global Design Engineering” students at TEDI-London for their hard work in the modules based in this study. All data was collected in accordance with all TEDI-London Ethics Policies and Regulations.

Conference Key Areas: *1. Teaching the knowledge, skills and attitudes of sustainable engineering, 11. Engineering skills, professional skills, and transversal skills.*
Keywords: *Project-Based Learning, Multidisciplinary, Transferable Skills, Inclusivity, Sustainability*

ABSTRACT

All accredited engineering programmes in the UK need to meet learning outcomes set out in 'Accreditation of Higher Education Programmes' (AHEP 4) requirements. First and second year multidisciplinary project weeks have been developed to meet

[1] *R Toqeer*
r.toqeer@sheffield.ac.uk

some of these requirements at a large scale. They focus on teaching transferable skills, with a particular focus on ethics, inclusivity, and sustainability. The project weeks were first delivered in 2012 and have been running consecutively for 13 years. An optimisation algorithm is used to create diverse groups of 5-6 students, considering gender, disability, programme of study and international status. Groups are clustered into “hubs”, which are organised and run by graduate student facilitators. Students produce design solutions to complex, real-world problems, using innovative thinking and teamwork. Consideration needs to be given to stakeholder and student outputs are required to be inclusive and sustainable. Each hub is supported and assessed by industry and faculty staff mentors. The project weeks are cost effective, delivering a 35-hour week of education for less than £60 GBP per student, including staff time. Additional features of the project week approach include equipping graduate students with experiences of using transferable skills, as a recruitment tool to attract prospective students to study engineering, the opportunity to innovate solutions without risk of failure and providing opportunities for facilitators to develop as teachers. The project week are generally well received by staff, students and industrial mentors.

1 INTRODUCTION

In addition to their technical knowledge, engineers require a variety of more general skills to function effectively in the workplace. Accreditation bodies recognize this necessity and incorporate requirements for such skills in their documentation. In the UK, these are specified in the 'Accreditation of Higher Education Programmes (AHEP 4),' which includes ethics, group working, multidisciplinary working, inclusivity, sustainability and presentation skills. Engineering courses have adopted to address these requirements with, for example, directly teaching these skills and integrating them into practical work. For this learning to be meaningful, it must be authentic. Many new engineering students envision their careers as focused solely on technical projects, where design, modelling, and analysis are the only necessary skills. However, experienced engineers understand that a broader set of strategies and experience is essential for effective performance. These transferable, non-technical skills become increasingly important as one advances in their career.

The development of transferable skills in higher education remains a central concern particularly in aligning these skills with employer expectations in a dynamic job market (Ehlers and Eigbrecht 2024). The engineering industry fuelled by technological innovation, demanding graduates equipped to navigate an uncertain future and potentially fill roles that have not been created yet. In response, project work emerges as an efficient pedagogical approach for fostering these future-critical skills through large-scale multidisciplinary learning experiences. Project-based learning is often lauded for its efficacy in fostering diverse skill sets within a multidisciplinary or interdisciplinary framework in engineering education (Kolmos et al. 2024). However, research suggests that existing applied projects in this field tend to be confined to a single discipline (Santana and de Deus Lopes 2024). Project weeks in contrast champion a multidisciplinary approach, featuring cross-disciplinary teams collaborating on complex problems. When tackling such challenges, incorporating diverse perspectives and technical expertise becomes crucial to identifying solutions with broad applicability. The project-week structure allows students to design solutions that are not only relevant and viable, but also feasible and desirable (Dennehy et al. 2019). Consequently, engineering students gain a heightened understanding of user needs and the significance of problem selection within complex projects. Additionally, interactions with industry mentors foster a "big picture" perspective enhancing their ability to conceive disruptive and impactful solutions (Charosky et al. 2018).

The Faculty of Engineering at the University of Sheffield, which teaches approximately 6,000 undergraduate students, across 10 broad engineering programme areas, has developed a project-based learning initiative. This is designed to cultivate transferable skills to a whole year group of about 1,500 students. This initiative ensures graduates are not only technically proficient but also have a strong foundation in ethical considerations, social impact, and environmental responsibility. The faculty integrates these elements to meet accreditation requirements and to produce well-rounded engineers equipped with multidisciplinary skills in a cost-effective and efficient manner. Emphasising inclusivity and sustainability, this approach aims to foster a generation of engineers who can make positive contributions to society.

This paper outlines the 'project weeks'. All engineering and computer science students participate in a full week of project-based learning in both their first and second years. The first year's project week, known as the 'Global Engineering Challenge' (GEC), focuses on cultural awareness and global agility. The second year's project week, 'Engineering You're Hired' (EYH), builds on the GEC and concentrates more on employability. They immerse undergraduate students in real-world problem-solving, including critical skills such as sustainable design, inclusive engineering design and practice, ethical decision-making, risk management, and multidisciplinary collaboration. The projects are designed to address complex issues that lack definitive solutions, mirroring the realities of professional practice.

The GEC and EYH project weeks have been running for 13 consecutive years, taking place in January during the three-week period of winter examinations. Engineering students have their exams scheduled over two of these weeks, providing an additional week free of other commitments. Finding a week without academic commitments across all 10 engineering programmes is a challenge, but scheduling the project weeks during the exam period allows them to proceed without disrupting other timetabled teaching.

2 METHODOLOGY

All first-year and second-year students are enrolled in one of two project week modules. Students are allocated into teams of 5-6 members, and each team collaboratively works on a project. Six teams are grouped together into a 'hub.' In 2012 the project weeks were run for the first time to a cohort size of 750 students, in 125 teams and 21 hubs (Murray and Horn 2012). In 2024, 1,440 students participated in the GEC, forming 240 teams and 40 hubs.

Each hub is provided with two rooms: a 'hub room' for project work and a 'boardroom' for presentations during the week. Hubs are managed and organised throughout the week by 'facilitators,' who are postgraduate students working as teaching assistants. Additionally, one faculty staff member is assigned to each hub to offer periodic mentorship and evaluation.

Teaching materials and activity planning are coordinated and led by a small group of academic project leads. Throughout the week, all students follow a guided programme of tasks to achieve a project conclusion. However, facilitators have the authority to adjust the delivery for their context, ensuring academic ownership of the teaching and maintaining the flexibility to adapt to unexpected circumstances.

2.1 The projects

Projects are selected to correspond with global challenges, especially those identified by the United Nations Sustainable Development Goals (SDGs). This strategic alignment ensures that students confront issues of paramount importance, utilising their engineering prowess to devise sustainable and inclusive solutions.

The first-year Global Engineering Challenge (GEC) projects are aligned with the design challenges presented by Engineering Without Borders (EWB). The academic leads of the project week then tailor the provided information to suit the GEC. This pedagogical approach to project selection is one of a number used by different institutions (Truslove 2022).

Typically, GEC projects are situated in rural, international settings that are unfamiliar to most engineering undergraduates. For instance, the 2024 project took place in Pu Ngaol, a community in Cambodia. Such projects necessitate that students work inclusively by:

- Collaborating with local stakeholders,
- Understanding the unique cultural, social, and environmental context,
- Developing solutions that empower the local community by involving them in the problem-solving process and utilising their knowledge and expertise,
- Adopting a “designing with” rather than a “designing for” approach.

Inclusive design requires students to devise solutions mindful of the significant resource constraints of the project communities, which often have limited access to essential services, expertise, and infrastructure. Students must creatively apply their engineering skills to discover innovative and practical solutions that are sensitive to the cultural and environmental sustainability of the area.

The second-year Engineering You're Hired (EYH) projects are conceptualised by the academic project leads and are rooted in the global challenges targeted by the Faculty’s research strengths or come from engaged industrialists. These multidisciplinary design projects maintain a focus on sustainability and inclusivity, developed during the first year, while escalating the demand for the technical engineering acumen necessary to produce a feasible engineering product. Students are expected to address considerations such as cybersecurity, intellectual property, risk, cost, timeline, and presentation of their solutions to various stakeholders. Example projects include electric aircraft, deconstruction robots, and ocean debris.

2.2 Team allocation

Multidisciplinary team are created so that projects are narrow-interdisciplinary systems projects, as defined by Kolmos et al (2024). Considerable effort is dedicated to team formation to ensure an equitable experience and the chance for students to work with a diverse range of peers. Before the project weeks start, students rank their project title preferences. An algorithm is utilised to optimise several considerations:

- Teams comprise members from different degree programmes (e.g., an aerospace engineer, a civil engineer, an electrical engineer, a computer scientist).
- The variance between home and international students in all teams is minimised, aiming for 1 to 2 international students per team.
- The distribution of team members with 'learning support plans' (declared disabilities or additional educational support needs) is considered.
- No team includes a single female engineer; all teams have either no female members or two or more.
- As many students as possible are allocated their highest project title preference.

In 2024, approximately 90% of students were assigned to their preferred projects, with the majority working on their first choice. However, this process faces contemporary challenges. First, forming multidisciplinary groups becomes more challenging with the fluctuating cohort sizes of different programmes. Notably, there has been a significant increase in students opting for Aerospace Engineering and Computer Science, with a decline in those selecting Bioengineering, Chemical Engineering, and Materials Science. Second, an increasing number of students choose not to declare their gender, potentially leading to a situation where a student identifying as female might be the only female in a team, though manual intervention has prevented this so far.

Efforts to engineer team formation aim to mirror the diverse dynamics of modern professional engineering environments. This process not only encourages collaboration and innovation but also prepares students for the realities of working in multidisciplinary teams. It provides an invaluable opportunity to recognize the importance of inclusivity in teamwork. The project weeks are deliberately designed to teach students the value of others' knowledge and expertise, fostering solutions that would be unattainable within the confines of a single disciplinary boundary. The international setting can also empower students from less traditional and overseas backgrounds as they may have had a wider experience of diverse cultures.

2.3 Facilitators

Facilitators play a crucial role in delivering content and guiding students throughout the project weeks. Each hub, comprising approximately 36 students, is overseen by a facilitator. These facilitators are graduate students employed on fixed-term contracts as teaching assistants. A number of 'flexi' facilitators are also recruited to cover absences and undertake other necessary reactive duties.

Selection of facilitators is conducted through interviews. Those chosen receive 10 hours of comprehensive training, which includes basic pedagogical training, in-depth orientation on the project weeks teaching and assessment, guidance on working with students with disabilities, and an introduction to digital learning tools. This training establishes the cultural tone for the initiatives and guarantees that all students are supported consistently and effectively.

During their training, facilitators are encouraged to take ownership of their teaching delivery. While the academic leads of the project week supply the overall structure and materials, facilitators are empowered to tailor the content and approach, making autonomous decisions and applying their unique teaching styles. This offers two main benefits. First, it enables facilitators to address hub-specific challenges or make decisions independently, without the need for intervention from the academic leads, who cannot be present at all hubs simultaneously. Secondly, it provided the facilitators with career development experience of leading.

Scheduled debriefs between facilitators and academic leads are incorporated into the week's structure. In addition, a set of digital tools allows continuous communication across all hubs.

2.4 Staff and industry mentors

Each hub receives support from a member of the academic staff within the faculty and an industrial mentor who is currently practising as an engineer. These mentors play a crucial role during the project week, offering insights to assist teams with their design solutions. They provide the perspective of experienced engineers, introducing considerations students might not have encountered, and they evaluate the students' work during boardroom-style presentations.

For faculty staff, contributing their time as part of their teaching responsibilities. Industrial mentors, many of whom are alumni, from approximately 100 Global Engineering companies, volunteer their time as philanthropy. Throughout the project weeks, students have opportunities to interact with these industrial mentors through activities such as panel sessions. These engagements are strategically organised to emphasise and enhance the focus on employability, ensuring students gain valuable insights into the engineering profession directly from experts in the field.

3 LEARNING, TEACHING AND ASSESSMENT

To replicate a work environment, students work in their hubs from 9am until 5pm, Monday to Friday. They participate in a mixture of facilitated sessions and group work time, receiving feedback and support at key points. Facilitated sessions cover topics such as presentation skills, team behaviours, ethics, and sustainability. There are fewer organised sessions in the second of the years, reflecting the students' improved experience and autonomy. Several milestones, reflections, and assessment points are set to allow students to understand their progress. The final activity is a presentation of their proposed solution, watched and assessed by the facilitator, staff member, mentor, and other hub members.

Information is provided to students through a website and VLE course sites. Facilitators are then permitted to adapt their version of the VLE site as appropriate. The assessment strategy for the project weeks is designed to holistically evaluate the students' integration of technical knowledge with transferable skills, to meet the AHEP 4 requirements.

The project weeks are zero credit, must-pass modules. The programme regulations require students to pass the modules to obtain an accredited degree, but the marks do not contribute to their final grade. The numerical outcome from the modules translates into a pass, fail, or distinction. Recognizing the importance of perseverance and continuous improvement, resit opportunities are provided for students who may not meet the passing criteria initially.

3.1 Alignment with AHEP4 and SDGs.

The rationale behind the creation of the project weeks was to address, on a large scale, the necessity of meeting the learning outcomes required by accrediting bodies. In the UK, all engineering accrediting bodies adhere to a uniform set of standards known as 'Accreditation of Higher Education Programmes' (AHEP 4). Given that these standards are consistent across all engineering and computer science programmes, it is feasible to efficiently meet them through faculty-wide project week modules.

Of the 18 learning outcomes specified in AHEP 4, the two project week modules meet or contribute to 11 (60%), including C4, C5, C7, C8, C9, C10, C11, C13, C15, C17, and C18. The project weeks are particularly adept at teaching and assessing outcomes related to ethics (C8), inclusivity (C11) in both design and teamwork within diverse groups, reflection (C18), and sustainability. These outcomes are specifically targeted in the assessment design.

Sustainability serves as a foundational theme of both project weeks. The activities and assessments focus on incorporating sustainability into the design process (C4) and evaluating the environmental and societal impacts of solutions (C7). Instruction is centred around the Sustainable Development Goals (SDGs) as defined by UNESCO, enabling students to comprehend the extensive sustainable impacts of their engineering work. It has been found that the participatory to sustainability education benefits the students in terms of academic, professional and personal growth (Cornet et al 2024).

4 EVALUATION

A stated rationale for introducing the project weeks was to deliver the experience to students in a cost-efficient manner. Table 1 provides information on the costs associated with delivering the project weeks. Fixed costs are those incurred regardless of the number of students participating, while variable costs are calculated per student (based on the number of hubs and 36 students per hub). Direct costs are those requiring payment from the faculty budget, and indirect costs account for staff time (approximated at the median senior lecturer grade).

Table 1. Costings for project weeks

Indirect Fixed Costs				
	Yearly (GBP)	*Fraction*	*Total (GBP)*	*Cost per student (GBP)*
Project Manager	48,000	20%	9,600	
Academic Leads	72,000	20%	21,600	
			31,200

Facilitator Marking	23	4	92	25
Industry mentor expenses			50	1
			947	**26**

The fixed costs for running the project weeks amount to 31,200 GBP for staff and 4,500 GBP for Engineering Without Borders. With 3,000 students participating, this equates to approximately 12 GBP per student. The variable cost includes 20 GBP for staff time and 26 GBP for direct costs.

For 3,000 students, the total cost is 57 GBP per student, including staff time, and 28 GBP as a direct cost excluding staff time. For this investment, students receive a full week (35 hours) of education. In comparison, providing practical lab-based education in the faculty of engineering costs approximately 20 GBP per hour.

Details here

4.1 Advantages of the project week approach

Beyond cost efficiency, there are additional advantages of the multidisciplinary project weeks approach:

Employability and transferable skills: Graduating students can cite experience of the skills that are critical for career progression. The project weeks embed non-technical skill development sought by employers, such as team working, inclusive thinking, creative problem-solving, and communication.

Unique experience for student recruitment: The project weeks are used as a tool to recruit students to study engineering at the institution.

Consistency in educational: The project weeks offer a consistent educational experience across various engineering disciplines. By standardizing the approach to teaching transferable skills and professional competencies, the project weeks ensure all students, regardless of their specific discipline, have a foundation of knowledge in areas such as ethics and sustainability.

Freedom to innovate and fail: The zero-credit basis of the project weeks allows students to be liberated from the constraints of traditional grading, encouraging bold, innovative solutions to complex problems. This freedom fosters a safe environment for creative experimentation and learning through failure.

Developing the facilitators as future academics: The flexibility afforded to the facilitators allows them to gain valuable teaching experience and develop skills essential for an academic career. This experience is particularly beneficial for those pursuing education fellowships, as it provides a real-world case study. Developing early-career academics is beneficial for the higher education sector to ensure a rich pipeline of talent.

5 DISCUSSION

The importance of planning and preparation for large-scale teaching should not be underestimated. When teaching small class sizes, it is common for educators to quickly develop material by taking shortcuts or creating processes that require manual or ad hoc intervention to function. In software engineering, the decision to quickly implement solutions that work but are not robust is referred to as “technical debt”. On a small scale, imperfections are manageable. However, when scaled up, as in the example of project week teaching being scaled to 40 simultaneous teaching sessions across many physical locations, small imperfections are amplified to a critical extent. Having to reactively cascade and communicate errata or misunderstandings on a large scale is extremely demanding.

To mitigate the potential for disruption, training and setting expectations with facilitators is key. Empowering facilitators to make decisions about how teaching is delivered and adapt this to the circumstances of their delivery allows each hub to operate autonomously. Facilitators should be equipped with knowledge of what is and is not important, what can be changed, and what outcomes are critical for the students to achieve, to allow those decisions to be made. Ensuring facilitators know who to find support from among the academic leads, and when not to seek that support, is a worthwhile investment of effort. A staff mentor sent the following comment about their facilitator to the academic project leads:

“*She's been exemplary this week in ensuring everyone has the correct information (myself and the industrial mentors), ensuring we know what we need to do and keeping us organised and on time. Her communication skills via email, Blackboard and Collaborate have been excellent and she's provided a supportive, yet constructively critical, environment for the students!*”

The project weeks were run online during the pandemic. A certain degree of hybrid teaching has been retained since, with the rationale that having experience of remote interactions is a valuable skill to develop for future employment, although the proportions have reduced. Feedback from students, staff, and industrial mentors is extremely divided about hybrid working. Some find the ability to work remotely valuable, while others feel it is determined by the experience of teamwork.

Prior to the week starting, some students are reluctant to engage. Many new engineering students envision their careers as focused solely on technical projects, and the value of transferable skills is not immediately apparent. To incentivise engagement, opening lectures are given by senior members of staff. These include personal anecdotes about how transferable skills have benefited their careers, and videos featuring previous students explaining how they have utilized the skills gained from the project weeks. It is worth noting that over 10000 students have

completed each of the 2 project weeks since their inception.

Following the project weeks, feedback indicates they are generally well-received by both staff and students. They are particularly enjoyed and valued by the industrial mentors, who offer significant praise. Survey respondents indicate:

- 100% of alumni stated they wanted to volunteer at the University because they wanted to support students.
- 96% of alumni felt their time was well spent.
- 100% believe the students benefited from participating in the activity.

Free text comments were also received, including the following from the head of software engineering at a major UK retail chain:

"*The challenges they've had are consistent with what engineers [sic] face in their careers. That's what's so great about EYH, it gives some real-world feedback on the softer skills of the industry that are just as important as the technical knowledge, and that's not something you learn about in a lecture theatre, you learn by doing it.*"

The final reflection concerns the sense of achievement felt upon completion of the weeks. Although there is little measurable evidence, it becomes immediately apparent to all involved that by the end of the week, students, staff, facilitators, and mentors genuinely feel that something substantial has been accomplished.

ABSTRACT

This article discusses the basic exercises taught as part of a course on Critical Thinking (CT) aimed at undergraduate engineering students (Torres et al. 2021). It is presented as an innovative tool to increase students' awareness of how cognitive biases can affect the decision-making process. When students are confronted with some of the classic examples of cognitive bias through Google Forms surveys, as conceived by Nobel laureate of economic sciences Daniel Kahneman, most fall into these cognitive errors. These surveys, originally intended for the general public, show engineering students that even individuals with a good understanding of basic probability theory (and well aware that they were going to be deceived) are prone to these cognitive biases. This approach has also shown that students who experience these cognitive errors first-hand become more involved, first, in developing the

[1] *F. Torres*
francesc.torres@upc.edu

underlying concepts and, finally, in discussing debiasing techniques for better decision-making outcomes.

1 INTRODUCTION

1.1 Context and motivation

The emphasis of traditional STEM student education has been almost exclusively on acquiring technical and scientific knowledge, leaving a gap in terms of their preparation for the labour market. However, the need for continuous innovation, the increasing acceleration of change, or the reduction in the useful life of products and services, requires a new brand of STEM graduates able to cope with increasingly challenging tech market demands. In this sense, surveys addressing future labor market demands give growing importance to social, emotional and higher cognitive skills, such as Critical Thinking, as key transversal competences (Bughin et al.2018), (Dondi et al. 2021), and cognitive bias is receiving increasing interest in engineering education (Chattopadhyay et al. 2022) (McDermott et al. 2020). Within this context, a series of elective subjects developed at the Universitat Politècnica de Catalunya (UPC) aims to provide engineering students with a grasp on critical thinking basics. The examples presented in this paper are included in four 2-hour sessions titled "Perception and Deception" that has been taught since 2021 (Torres et al 2021) within a CT course. They are devoted to exposing common biases when probability and risk are involved in intuitive estimations.

1.2 Critical thinking for improved decision-making outcomes

Critical thinking has emerged as a crucial skill in improved decision-making processes to manage the overwhelming amount of information to deal with. It is becoming increasingly clear that the information we perceive may be tainted with intentional or unintentional biases intended to influence our behaviour. As a fundamental step in the decision-making process, young STEM graduates must develop a sceptical attitude toward the information they receive and also improve their awareness of the main sources of cognitive deception. (Kahneman 2011) showed that, in general, intuition has little capacity to face choices that involve estimating probabilities, which are very common in problems related to social and economic issues. Developing strategies to address this type of potential source of flawed decisions is a key competency for STEM students to develop.

2 METHODOLOGY

2.1 Cognitive bias

The course begins with a brief introduction to the work of Nobel Prize Winner Daniel. Kanheman, who unveiled ground-breaking findings in the field of behavioral economics and cognitive psychology (Kahneman 2011). As summarised in Table1, Kahneman states that people have two ways of thinking when making decisions. He called them System 1 and System 2 modes:

- System 1 (intuition), which is fast, automatic, frequent, effortless, emotional, stereotyped and subconscious. It generates intuitions that serve us most of the time, but not always.

- System 2 (reason), which is slow, effortful, logical, infrequent, calculating and conscious. It makes final decisions, based on system 1 intuitions, expanding them with more information and rational processes.

Table 1. Kahneman's System1 and System 2 main features

System 1: Fast, Intuitive, and Automatic	System 2: Slow, Analytical, and Deliberate
➢ Fast Processing	➢ Slow Processing
➢ Automatic Responses (efficient)	➢ Effortful and Controlled
➢ Heuristic-Based (rules of thumb)	➢ Rule-Based Decision Making
➢ Associative Thinking	➢ Calculative Thinking
➢ Energy-Efficient (effortless)	➢ Needed to Overcoming Biases

People mainly rely on their intuition (System 1) to deal with the bulk of daily activities. They use heuristics, mental shortcuts derived from past experiences, that facilitate fast problem-solving and probability judgments. These strategies are generalizations, or rules-of-thumb, that reduce cognitive load (System 2). Although they are useful in many everyday activities, heuristics can lead to misjudgements and errors. Particularly, Kahneman made a list of several systematic cognitive biases, that are quite widespread and that are very prone to produce flawed decisions. To improve students' awareness of this problem and motivate them further, as developed in the following sections, some surveys based on Kahneman's work have been prepared to show them that they also suffer from these misperceptions.

2.2 Surveys on cognitive biases in the classroom

As an introduction to the main concepts of cognitive biases, students are asked to provide answers in the classroom, using Google Forms, to a set of classical problems of choices and judgments thoroughly described in (Kahneman 2011):

- **Representativeness**
- **Base rate**
- **Availability**
- **Gain/loss asymmetry**
- **Framing effect**

Once students realize first-hand that they are not free from cognitive biases they are much more engaged in discussion about this topic. The following section presents these specific examples, as developed in the classroom.

3 DISCUSSION ON COGNITIVE BIAS SURVEYS

3.1 Representativeness bias

This bias is introduced to the class using the so-called Linda's survey, where students are asked to estimate the plausibility of several statements about the job a graduate in philosophy is performing several years after graduation. Figure 1 shows these statements and the answers given by the students.

Linda is 31 years old, single, open-minded and very bright. At university, she graduated in philosophy. As a student, she was deeply concerned about issues of discrimination and social justice. At that time, she participated in the organization of student demonstrations against the use of nuclear energy. About Linda's activity *today, 8 years after her graduation, estimate from 1 to 10 the degree of plausibility of several statements:*

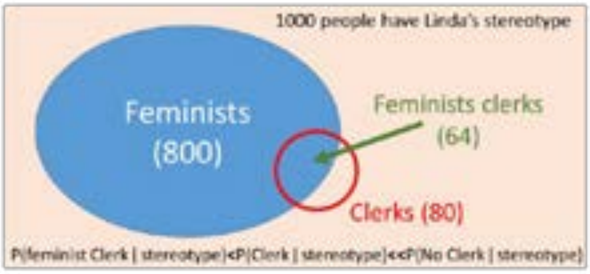
(1 Completely unlikely, 2.5 unlikely 5 plausible, 7.5 likely 10 very likely)

Fig. 1. Linda's survey illustrates the conjunction fallacy: assuming that a specific situation (office worker at a bank and active in the feminist movement) is more probable than the general situation (office worker at a bank).

In the set of questions in Figure 1, only numbers 4 and 8 are relevant to the conclusions. They both apply to the plausibility that Linda is a bank teller. Students fall (statistically) into the representative cognitive bias. They assign a larger probability to the fact that Linda is a bank teller involved in the feminist movement than she simply is a bank teller. But this goes against elementary probability theory which states that a subset cannot be more probable than the entire set. Linda is an individual representative of a class that readily comes to the minds of the students. They unconsciously answer to a different fact: if Linda is a bank teller (a rare event) then she probably is involved in a feminist movement with a high degree of probability. Once the survey has been completed Figure 2 (left) is shown to the students, where a probability of 80% has been assigned to the main assumptions. This cognitive bias, also known as the conjunction fallacy, appears when it is assumed that a specific situation is more probable than the general situation. It is motivated by the representative bias that leads us to answer a different question that comes to our mind more easily, mistaking plausibility for probability. In this case, students have mistakenly jumped to provide an answer to the questions in Figure 2 (right): In both cases, the answer is "very high" given the "feminist" stereotype, but the real question was the other way around:

- **What is the probability that Linda is a bank teller and a feminist?**

The probability that Linda is a bank teller with no adjectives is very low (80/100), but larger than being a bank teller and a feminist (64/1000), in this example.



- **What is the probability that Linda is a feminist?**
- **If Linda is an office worker at a bank, what is the probability that she is also a feminist?**

Fig. 2. Plausible distribution of Linda's stereotype (left). This bias occurs when students answer a different question that comes more easily to their minds (right)

3.2 Base rate fallacy

Joaquin's Survey in Figure 3 shows that even engineering students can make a common mistake called the base rate fallacy. This happens when they miss important information in an open problem, usually due to the representativeness bias. In this case, 95,7% of students, 31 over 32, have estimated option A (engineering student) as the most probable. However, the real world is not so straightforward. They have missed that there are a lot more humanities students than engineering students (base rate bias). This mistake is driven by a tendency to rely on stereotypes rather than facts. Instead of answering the right question—***'What's the chance Joaquin is an engineering student given certain facts?***'—again, they end up answering a question that unconsciously comes more easily to their minds, ***'If Joaquin is an engineering student, how likely is he to fit the stereotype?***' This mix-up shows they're not using Bayes' Theorem correctly, where the probabilities should be seen differently depending on the question. Once the survey has been completed Figure 3 is shown to the students to illustrate their misperception. It has been assumed that, over a population of 300.000 students in Catalonia, 66,7% are enrolled in humanities studies and 6,7% in engineering. For the sake of discussion, it has been assumed that 10% of humanities students match the stereotype whereas this figure grows to 75% in the case of engineering students. With the number given in Figure 3, conditional probabilities can readily be computed:

$$P(Engineering|Stereoptype) \neq P(Stereoptype|Engineering)$$
$$\frac{15.000}{35.000}(42{,}9\%) \neq \frac{15.000}{20.000}(75\%) \quad (1).$$

$$P(Humanities|Stereoptype) \neq P(Stereoptype|Humanities)$$
$$\frac{20.000}{35.000}(57\%) \neq \frac{20.000}{200.000}(10\%) \quad (2).$$

The right-hand part of these equations shows the direct probability computation leading to the bias: students correctly assume that engineers match the stereotype much better than humanity students, but, like in the Linda Survey, that was not the original question. By comparison of the two results, with the population numbers in Figure 3, we can see that the probability that Joaquin is an engineering student is 42.9%, lower than the probability that he is a humanities student (57%). This misuse of Bayes' theorem, which assumes that the exchanged conditional probabilities are equal, is the main source of representative bias errors. In fact, this cognitive bias is one of the main sources of prejudice (e.g. most street thieves are poor, so most of the poor people are thieves). It should be noted that engineering students are quite proficient at calculating probabilities when given all the relevant information. However, in real life, this relevant information can be easily overlooked and suffer from the base rate fallacy. This is the case, for example, when testing for infection with procedures that have a low but significant failure rate (e.g. COVID testing), incriminating evidence in trials (e.g. prosecutor's fallacy) or drug tests, among others.

Joaquín is a 20-year-old guy who lives in Catalonia. He is methodical and his fundamental fun is everything related to computers. Which of the two options do you think is more likely?

A) Joaquín is an engineering student

B) Joaquín is a humanities student

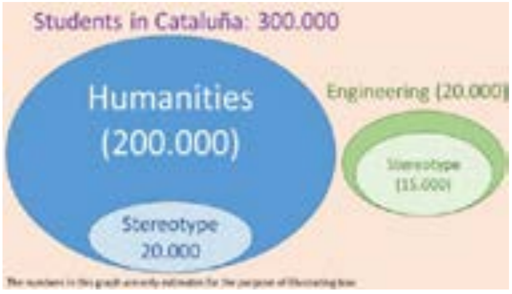


Fig. 3. Statement for the Joaquín's survey (top) and approximate classification of HE students in Catalonia (bottom). It has been assumed that 10% of humanities students match the stereotype and 75% in the case of engineering students

3.3 Availability bias

Here, students are asked to answer several questions of this kind:

What should you be most afraid of?	What causes more deaths per year?
A) A Plane crash	A) Sharks
B) Struck by lightning	B) Hippos

The majority of the students answer A) in both cases because plane crashes and sharks come more easily to their minds. However, the real numbers are the following: sharks, 7 deaths/year; hippos, 500 deaths/year; planes, 400 to 1000 deaths/year and lightning, 6.000 to 24.000 deaths/year. Availability bias is a well-known cognitive bias that benefits insurance companies: people tend to overestimate the probability of events that they remember more easily and are willing to pay overpriced policies for overestimated risks.

3.4 Gain/loss asymmetry

In this survey, students are asked about their willingness to accept a coin-tossing bet. This test is intended to show them that individuals tend to perceive losses more intensely than gains of equal magnitude. This means that the emotional impact of losing 10€ is typically felt more strongly than the pleasure derived from gaining 10€. To overcome this risk-aversion bias and make the bulk of students accept the bet, the expected gain must be significantly larger than the expected losses (usually a factor 2 to 3 larger) as shown in Figure 4. This asymmetry in emotional response can influence various aspects of decision-making, including financial choices, investment strategies, and everyday judgments. Understanding this phenomenon is crucial for comprehending why individuals may exhibit risk-averse behaviour in certain situations, even if potential gains are substantial (e.g. resistance to change).

A. If HEADS comes up you win **10€**, if TAILS you lose **10€**
B. No bet

A. If HEADS comes up you win **15€**, if TAILS you lose **10€**
B. No bet

A. If HEADS comes up you win **20€**, if TAILS you lose **10€**
B. No bet

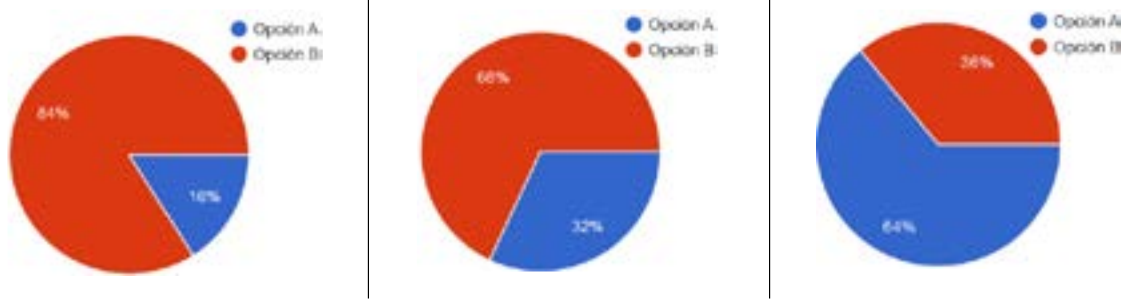

Fig. 4. "Tossing-a-coin". Expected gains must be significantly higher than expected losses to make students accept the bet. 25 bachelor engineering students answered the survey.

3.5 Framing

Framing, as defined by Kahneman, refers to the way information is presented or framed, which can significantly influence people's perceptions and decisions. That is, the same information presented in different ways can lead to different judgments and choices despite the same objective information content. In particular, in this exercise, two different groups of students are faced with a survey to show them that individuals tend to be risk-averse when faced with decisions framed in terms of potential gains (positive framing), but to risks-seeking when the same decisions are formulated in terms of potential losses (negative frame). The results in Figure 5, related to the "Rare disease problem" (Kahneman 2011), illustrate how the framing of information can shape people's attitudes toward risk and their subsequent choices, even in sensitive matters such as life and death decisions.

4 DEBIASING

The exercises developed in the previous section convince students that important decisions require special attention to avoid flawed decisions and misjudgements. Once the main sources of cognitive biases have been presented, the course ends with a discussion on the main techniques that can improve decision-making by preventing this kind of error, the so-called debiasing techniques:

- Develop awareness of the bias
- Improve how information is presented
- Create psychological self-distance
- Consider alternatives
- Change incentives
- Increase accountability
- Make the reasoning process explicit
- Slow down the reasoning process
- Elicit external feedback
- Reduce reliance on subjective memory

The United States is bracing for an outbreak of a rare disease, which is expected to kill 600 people. Two alternative programs have been proposed to combat the disease. Choose one of the two possible alternatives if the exact scientific estimates of the consequences of these programs are as follows:

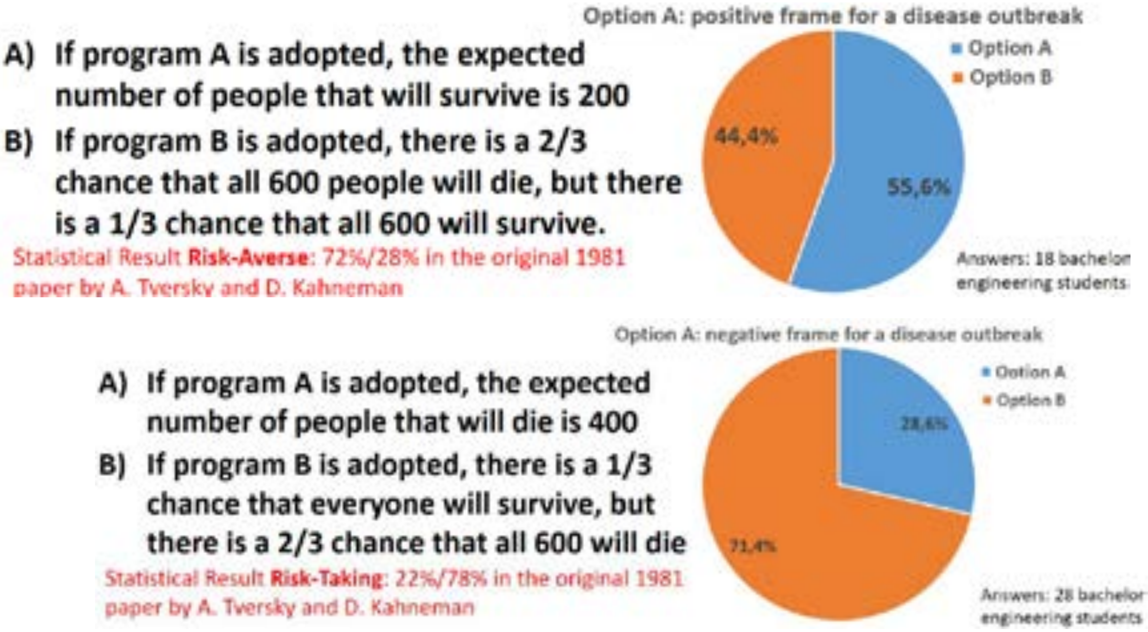

Fig. 5. Framing of a choice as positive or negative changes the decisions people make, even in sensitive matters, despite the objective information being the same

.

5 SUMMARY

This paper takes a closer look at how our decisions can be influenced by cognitive biases, especially when people are trying to estimate probabilities by intuition. It is part of a course on Critical Thinking at the Telecom BCN School (UPC), aimed to help engineering students become better decision-makers. This course uses real-time surveys in class, inspired by the work of Nobel Prize Winner Daniel Kahneman, to get students better involved and motivated to discuss this issue. These surveys have shown that, even when students understand the basics of probability and know they might be tricked, they still tend to fall for cognitive biases. The teaching approach presented in this paper, which has been well-rated by students (Figure 6), increases their awareness of how common these biases are and the need to embrace the so-called debiasing techniques as a fundamental skill to develop in their engineering careers.

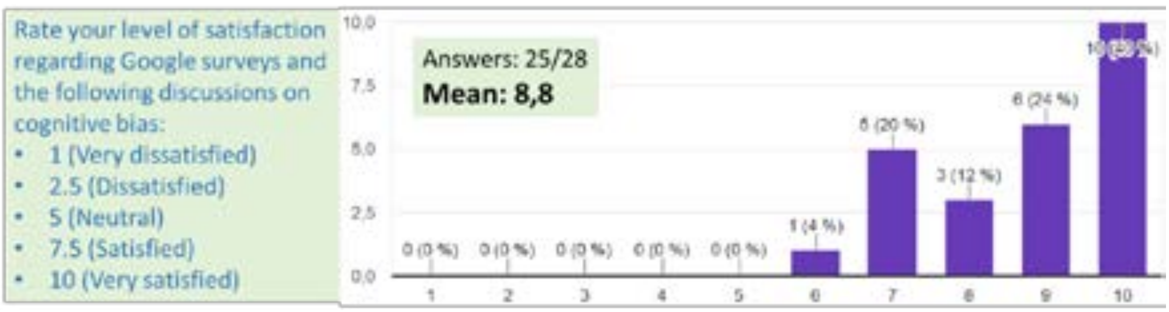

Fig. 6. Satisfaction survey regarding cognitive bias conducted on bachelor engineering students in a Critical Thinking class at UPC
