SEFI

SEFI is the largest network of higher engineering education institutions (HEIs) and engineering stakeholders in Europe. As an international NGO created in 1973. SEFI contributes to the development and improvement of Higher Engineering Education (HEE) in Europe, promotes information about HEE and improves communication between teachers, researchers and students, reinforces the university-business cooperation and encourages the European dimension in higher engineering education. SEFI is an international Forum composed of HEIs, academic staff and teachers, students, related associations and companies in 41 countries.

Our activities:

Annual Conferences, Ad hoc seminars/workshops organised by our working groups, councils and ad hoc committees, organisation of the European Conventions for Engineering Deans, Scientific publications (including the European Journal of Engineering Education), European cooperation projects, position papers, cooperation with other major European associations and international bodies such as the European Commission, the UNESCO, the Council of Europe or the OECD. SEFI also participated in the creation of several organisations such as ENAEE, IFEES, IACEE and IIDEA.

SEFI is based in Brussels.
For further information please visit www.sefi.be or contact office@sefi.be.

Wecolme from SEFI

Dear Participants of the 52nd SEFI Annual Conference,

In the name of the European Society for Engineering Education, I warmly welcome you to Lausanne to the 2024 SEFI annual grand meeting devoted to the education of responsible engineers.

The global landscape is stirred up and this involves all aspects of our life. The new challenges induce major evolutionary changes for both human (slow) and machine (really fast) and require the transformation of teaching, especially within engineering, the technological driving force with an important role in aligning these evolutionary paths.

We, engineering educators, have major tasks and principal responsibility in the transition towards new discoveries and at times unprecedented territories within education.

How can we efficiently and benevolently apply generative artificial intelligence, large language models and machine learning into education and research?

How can we update and upgrade our pedagogical approach towards transversal skills on sustainability, diversity, ethics and core technical skills?

Is the gradual development of teaching the right way forward, or should we venture into fundamental transformations?

Anyhow, we may need to speed up, as technological development will not slow down.

The educational methods and tools that we develop define not only our present and future but also the attitude and motivation of our graduates and university colleagues.

Therefore, it is vital that platforms such as the SEFI annual conference provide an open space to discuss and conclude on the shared understanding of our duties and responsibilities in engineering and its education.
With its workshops, research and practice presentations, symposia, keynotes and panel discussions the 2024 SEFI conference at EPFL will provide us with the opportunity to analyze current challenges, allows us to personally meet our peers and foster impactful dialogues to jointly generate the future of engineering education.

Let us use these days together to foster fruitful discussions and find common solutions!

Balázs Vince Nagy, SEFI President

Welcome from EPFL

To professors, lecturers, students, researchers, and engineering education leaders from across Europe and the world: we are delighted to welcome you to EPFL, Switzerland for the 52nd SEFI Annual Conference.

EPFL is pleased to host this SEFI conference with the theme 'Educating Responsible Engineers'. 'Responsibility' has been a key theme for EPFL in recent years as we have sought to ensure that, in our research, our teaching, and in our operations, we embody a sense of responsibility.

As the person who bore overall responsibility for our education programmes over recent years, that has meant that I have worked with my colleagues to ensure that respect and sustainability are at the heart of our education offer. This has seen the restructuring of our first year programme with the introduction of a new mandatory course in sustainability science for all our students. Later years of our programmes have also been restructured to ensure that at both Bachelor's and Master's level, students will learn the sustainability practices and knowledge that will enable them to research, innovate, design and implement engineering solutions that are ethical and environmentally responsible.

As an education researcher as well as a computer scientist, I recognise that such transformations need to be supported by educational research. EPFL has long been a national and international leader in research on Digital Education with a particular focus on computer human interaction in learning, on learning with robots, and on machine learning in education. Our commitment to world-class research in this area led to the establishment of the Joint EPFL-ETHZ Doctoral Programme in the Learning Sciences (JDPLS), and to us bringing the relevant labs together in our Center for Learning Sciences (LEARN). Through this Center we work to bring together cutting edge technological education research with professors, school teachers, and pedagogical development teams to drive the development of evidence-informed educational practices, and practically useful educational research. We see these same synergies of research-informed engineering education innovation in the SEFI community, and that is why we are delighted to host the SEFI 2024 conference in Lausanne.

We hope you get a lot from your stay at our campus. We are rather proud of our location and we hope you find time to enjoy the lake shore, the mountains and the charming city of Lausanne. We hope too that we will learn a few things from you, and that you will learn something from us, and from each other.

I look forward to the opportunity to discuss with you over the course of the conference.

Welcome to #SEFI2024 at EPFL!

Pierre Dillenbourg,
Vice President Academic Affairs *ad interim*, EPFL

Conference Theme

Building a socially and environmentally sustainable society is intrinsically linked to the work of engineers and scientists. As UNESCO has noted, each and every one of the Sustainable Development Goals (SDGs) requires solutions which are rooted in science, technology and engineering. But there is a concern too that engineering is not only part of the solution but also part of the problem: for many engineers, their work is contributing to carbon emissions, unsustainable resource use, biodiversity and habitat loss, and pollution. There are equally concerns about engineers' responsibilities in warfare and violence across the globe, and in new, technologically-enabled vectors for discrimination, impoverishment and inequalities. A focus on responsibility has also seen a parallel growth in questions about how thinking and feeling interact in engineering: about excitement, anxiety, burnout, compassion, guilt, shame and hope.

Addressing these questions in engineering education is not straightforward: innovative engineering solutions to social and environmental challenges will require the highest levels of technical competence and scientific knowledge. But the centrality of technical knowledge to engineering education can create in students the impression that responsibility is a marginal concern for them. Building a sustainable society means educating scientists and engineers that can apply the best scientific knowledge with ingenuity, with ethical competence and with respect for colleagues, for those in wider society and for the natural environment, and therefore need social and human sciences as part of their education. How can we ensure the highest quality of technical competence while at the same time ensuring that social and environmental responsibility is core to the identity of engineering graduates? This was the focus of the European Society for Engineering Education (SEFI) 2024 conference, which took place at EPFL, Lausanne, Switzerland on 2 – 5 September, 2024.

The conference particularly welcomed contributions aligned with one of the following conference tracks.

- Teaching the knowledge, skills and attitudes of sustainable engineering
- Educating the whole engineer: teaching through and for knowing, thinking, feeling and doing
- Teaching technical knowledge in and across engineering disciplines
- Teaching foundational disciplines of Mathematics and Physics in engineering education
- Teaching social and human sciences to engineering and science students
- Digital tools and AI in engineering education
- Open and online education for engineers
- Diversity, equity and inclusion in our universities and in our teaching
- Continuing education and life-long learning in engineering
- The attractiveness of engineering education
- Engineering skills, professional skills, and transversal skills
- Engineering ethics education
- Curriculum development and emerging curriculum models in engineering
- Outreach and openness: industry and civil-society in engineering education
- Building the capacity and strengthening the educational competences of engineering educators

Keynotes

First keynote:
Johanna Lönngren: Emotions in Engineering Education: The emergence of a new field of research

Biography:
As an associate professor in Science and Engineering Education at Umeå University, starting 2020, Johanna Lönngren brought together, coordinated and led a team of researchers from across the globe to scope out the field of emotions in engineering education research, and to show how emotion could be better understood, theorised and researched in the field.
The result is a new community of engaged scholars who together developed – and continue to develop – a series of publications, seminars and events that are profoundly changing the conversation on engineering education, scoping out new ways of doing and being in engineering education research and practice.

Second keynote:
Margarita Boenig-Liptsin: Computing Education, Cultures of Responsibility

Biography:
Assistant Professor of Ethics, Technology and Society at ETH Zurich, Margarita Boenig-Liptsin completed a Ph.D. in History of Science at Harvard University with a concurrent degree in Philosophy from the Sorbonne.
"Data-driven technologies challenge the fundamental assumptions upon which our societies are built," she explains.
"In this time of rapid social and technological change, concepts like agency,' 'justice,' and 'representation' are reconstituted, with real consequences for how people live".

Third keynote:
Donna Riley: Engaging Moral Imagination in Engineering Ethics Education

Biography:
Donna Riley is Dean of Engineering at the University of New Mexico.
She is vice president of scholarship for the American Society for Engineering Education (ASEE) since 2023 and was program director for engineering education at the NSF (2013-15).
Donna’s work focuses on ethics and social analysis in training engineers.
She is the author of Engineering and Social Justice (2008), she is the recipient of the 2012 Sterling Olmsted Award from ASEE, and the 2010 Educator of the Year award from Out to Innovate.

ABSTRACT

The 8th SEFI Doctoral Symposium in Engineering Education Research, held at the campus of EPFL on Sunday, September 1st, preceded the SEFI 2024 Annual Conference. In all, 31 Ph.D. researchers attended. They came to share and further probe their Ph.D. research topics and study plans and to strengthen and extend their professional networks. During this full and intense day, 22 established scholars provided the Ph.D. researchers with personal feedback and ideas regarding their research. Highlights, according to the Ph.D. student participants, were the welcome and sense of support and belonging they experienced from the engineering education research community, including both the advising senior researchers and the other Ph.D. students. Although SEFI is a European organization, the Ph.D. researchers and senior advisers travelled from Africa, Australia, and North America, as well as from all over Europe, to Switzerland for this event.

1 INTRODUCTION

1.1 The Role of the Doctoral Symposium in Engineering Education Research

Engineering education research (EER) is an emerging and expanding field, and it is now possible to pursue doctoral education in many institutions in Europe and other parts of the world. As in any research field, PhD students can benefit greatly from getting to know the leading scholars. This is, however, particularly true in EER since many Ph.D. supervisors are educational champions with a background in engineering subjects but have not been formally trained in educational research. It is common for a Ph.D. student to be the only one working on EER in their department, faculty, or university. In such cases, it is particularly important to develop a supportive network beyond the immediate environment (Edström et al., 2018). Within this context and in conjunction with its annual conference, SEFI organises an annual Doctoral Symposium (DS). Before this year, the DS has been held in Tampere the day before SEFI 2016, in Copenhagen in 2018, in Budapest in 2019, online in 2020 from Twente, online from Berlin in 2021, in Barcelona in 2022, and in Dublin in 2023. This paper aims to document and share insights from the 8th SEFI Doctoral Symposium in Lausanne in 2024. The paper explains the design of the program and discusses the recruitment of participants – doctoral students as well as experienced researchers, here called juniors and seniors respectively. Then, some of the rich materials created and captured during the event is presented, including introductions, literature, tips and advice from seniors and reflections from all participants. Finally, the authors provide reflections on the 2024 event.

1.2 The SEFI Doctoral Symposium 2024

As with previous SEFI conferences, this year's DS was held as a full-day event on the Sunday preceding the annual conference. The DS is fully interactive and uses a variety of formats to create an enriching experience:

- Short (half-minute) pitches by the seniors so the early career researchers can familiarise themselves with well-established researchers
- Discussions in small groups focusing on each student's Ph.D. project (up to 30 minutes per student)
- Speed-dating activities to grow each participant's network
- Presenting (one-minute) take-home messages to help ensure valuable lessons are crystalised and shared

1.3 Doctoral Student Participants

As in previous years, Ph.D. students were invited to apply via an extended abstract that included:

- *A general introduction* (about their background and interest in EER)
- *An outline of their research* (an elevator pitch, along with identification of their research interest, thesis title, supervisors, and current work)
- *Reflections* (their current questions, challenges, dilemmas, wishes, and ambitions)
- *Preferences for networking* (both at SEFI2024 and after the conference)

The organising team, who has worked together on this and similar events over the years, was delighted by the high number of applicants applying to attend in 2024. The quality of applications was high this year, and 32 proposals were accepted. Ultimately, 31 Ph.D. students attended for the full day, identifying their academic affiliations within 13 countries on four continents: Australia (1), Belgium (2), Denmark

(1), Finland (5), France (1), Germany (3), Ireland (2), Lithuania (1), the Netherlands (6), South Africa (3), Sweden (2), the UK (1), and the USA (3).

1.4 Senior Participants

To provide the doctoral students with feedback, coaching, and guidance, the organising team recruited a diverse group of well-established researchers in the field. To optimally support the Ph.D. students during the day's focused sessions, the organisers aimed for a ratio of three to four juniors to every two senior coaches. This ratio has proven to help ensure diverse, lively, and targeted feedback for juniors. The willingness and eagerness of the seniors to participate in this event in the past few years has been remarkable. Seniors volunteered their time to travel to SEFI a day early and dedicate an entire Sunday to the event, yet their enthusiasm was palpable before and during the event, and nearly every invitation issued was accepted. This year 22 established scholars came to serve as senior advisors, including the organising team (the four authors of this paper). The senior participants and organisers travelled to the DS from Australia, Belgium, Denmark, Germany, the Netherlands, Portugal, South Africa, Sweden, Switzerland, the UK, and the USA.

1.5 Group Formation

The core of the symposium consisted of group activities in which doctoral students and seniors worked together. This year, nine groups were formed, each containing three or four doctoral students and two senior participants. The groups were composed considering a balance between diversity and similarity regarding years of experience, research interests (in terms of topics and methods), university, and country. The group formation was sent out to all participants in advance, with a compilation of all extended abstracts. The instruction was to prepare by reading the abstracts of the doctoral students, particularly ones in their assigned group. The groups were formed a week in advance to allow for last-minute adjustments.

1.6 Event Outline

The program facilitated deep and meaningful discussion among doctoral students and experienced researchers. Group activities were the focus, and these were interspersed with plenary sessions:

09:00-09:30	Arrival, coffee, and tea
09:30-10:00	Introductions and Instructions
10:00-12:00	Group Session
12:00-13:00	Lunch
13:00-14:30	Speed Dating
14:30-14:45	Reflection
14:45-15:15	Refreshments
15:15-16:30	Plenary Report (Take-Home Messages up to minute per person)
16:30-17:00	Final Reflections

2 CAPTURING THE DISCUSSIONS

2.1 Getting to Know the Experienced Researchers

Before the Doctoral Symposium, the senior participants were asked to submit reading tips for the doctoral students. The first question to the seniors was: *If a doctoral student wanted to read something by you, what would you recommend and why?* In response, the seniors mentioned the following selection of their own work (in alphabetical order):

Jonte Bernhard

Issues related to quality in engineering education research (EER):

- Bernhard, J., & Baillie, C. (2016). Standards for quality of research in engineering education. *International Journal of Engineering Education, 32*(6), 2378-2394.

The relationship between "pure" engineering research and EER:

- Bernhard, J. (2015). Engineering education research as engineering research. In S. Hyldgaard Christensen, C. Didier, A. Jamison, M. Meganck, C. Mitcham, & B. Newberry (Eds.), *International perspectives on engineering education: Engineering education and practice in context, volume 1* (pp. 393-414). Springer.

How engineering thinking can improve the methods of EER:

- Carstensen, A.-K., & Bernhard, J. (2019). Design science research – a powerful tool for improving methods in engineering education research. *European Journal of Engineering Education, 44*(1-2), 85-102.

Tom Børsen

If you are interested in curriculum development and interdisciplinary:

- Karadechev, P., Petersen, L. S., & Børsen, T. (2021). *Interdisciplinary competencies in the study program of Techno-Anthropology*. Aalborg University Press.

If you are interested engineering ethics education:

- Børsen, T. Serreau, Y., Reifshneider, K., Baier, A., Pinkelman, R., Smetanina, T., & Zandvoort, H. (2021). Initiatives, experiences and best practices for teaching social and
  ecological responsibility in ethics education for science and engineering students. *European Journal of Engineering Education, 46*(2), 186-209.

Jenni Case

This recent piece tries to frame some important questions on what we are doing / what we think we are doing / what we might be doing:

- Case, J., & Blackie, M. (2022). Engineering Education Research for educational change: the possibilities of critical realism for conceptualising causal mechanisms in education. *Southern Journal of Engineering Education, 1*, 61-74.

Shannon Chance

A collaborative research project that won an award at SEFI:

- Direito, I., Chance, S., Clemmensen, L., Craps, S., Economides, S., Isaac, S., Jolly, A-M., Truscott, F., & Wint, N. (2021). *Diversity, equity, and inclusion in engineering education: an exploration of European higher education institutions' strategic frameworks, resources, and initiatives*. The 49th Annual Conference of the European Society for Engineering Education (SEFI 2021), 13-16 September, Berlin, Germany.

A paper comparing two methodologies and providing examples:

- Chance, S., Duffy, G., & Bowe, B. (2020). Comparing grounded theory and phenomenology as methods to understand lived experience of engineering educators implementing problem-based learning. *European Journal of Engineering Education, 45*(3), 405-442.

Tinne De Laet

This paper is recent work of my student, who was part of the doctoral symposium in 2020 and has now finished her Ph.D. degree. The paper nicely reflects the multi-disciplinary work I enjoy, in this case also together with my colleague Mieke De Cock from physics education research:

- Sijmkens, E., De Cock, M., & De Laet, T. (2023). Scaffolding students' use of metacognitive activities using discipline-and topic-specific reflective prompts. *Metacognition and Learning, 18*(3), 811-843.

Xiangyun Du

- Chen, J., Du, X., Jiang, D., Guerra, A., & Nørgaard, B. (2024). A review study with a systematic approach: pedagogical development for educators in higher engineering education. *European Journal of Engineering Education*, *49*(2), 299-329.

Kristina Edström

Just because this paper was such a joy to write:

- Edström, K. (2018). Academic and professional values in engineering education: Engaging with history to explore a persistent tension. *Engineering Studies*, *10*(1), 38-65.

Aditya Johri

- Johri, A., & Olds, B. M. (2011). Situated engineering learning: Bridging engineering education research and the learning sciences. *Journal of Engineering Education, 100*(1), 151-185.

Here are revised follow-up versions if you so wish:

- Johri, A., Olds, B. M., & O'Connor, K. (2014). Situative frameworks for engineering learning research. *Cambridge handbook of engineering education research*, 47-66.
- Secules, S., Pérez, G., Pea, R., & Johri, A. (2023). Critical and Cultural Analysis of Engineering Learning. In *International Handbook of Engineering Education Research* (pp. 199-217). Routledge.

Christian Kautz

An example of the type of work our research group does. It highlights some of the methods we use, such as open-ended written tests, and briefly mentions other methods, such as student interviews. The paper's objectives can serve as an example of our general research goals within the introductory engineering curriculum. The results are also typical for our work in the sense that student difficulties often arise with the most basic aspects of a certain topic and are often an indication of more general reasoning difficulties.

- Schäfle, C., & Kautz, C. (2021). Student reasoning in hydrodynamics: Bernoulli's principle versus the continuity equation. *Physical Review Physics Education Research*, *17*(1), 010147.

David Knight

A recent editorial in JEE provides some pointers for reviewers and links to resources focused on constructive reviewing. Giving and receiving constructive, critical feedback is a skill that is needed for all career paths. Reviewing for journals should not only be thought about as a professional responsibility, but also as a way to develop this critical professional skill. In the editorial, we describe the kinds of feedback that is most helpful.

- Knight, D. B., & Main, J. B. (2024). Reviewing: A skill we can continuously develop. *Journal of Engineering Education, 113*(2), 222-224.

Anette Kolmos

- Kolmos, A., Holgaard, J. E., Routhe, H. W., Winther, M., & Bertel, L. (2023). Interdisciplinary project types in engineering education. *European Journal of Engineering Education*, 49(2), 257–282.
- Habbal, F., Kolmos, A., Hadgraft, R. G., Holgaard, J. E., & Reda, K. (2024). *Reshaping Engineering Education: Addressing Complex Human Challenges*. Springer Nature.

Greet Langie

This paper reflects the research my research team likes to deliver: clear research methodology and results that have practical implications.

- Pinxten, M., Van Soom, C., Peeters, C., De Laet, T., & Langie, G. (2019). At-risk at the gate: prediction of study success of first-year science and engineering students in an open-admission university in Flanders—any incremental validity of study strategies? *European Journal of Psychology of Education*, *34*, 45-66.

Thomas Taro Lennerfors

Here, the writing style is freer than in many academic papers. We should experiment more with alternative forms of writing (and there is of course a huge literature already doing this, in a much more radical way than my own paper).

- Laaksoharju, M., Lennerfors, T. T., Persson, A., & Oestreicher, L. (2023). What is the problem to which AI chatbots are the solution? AI ethics through Don Ihde's embodiment, hermeneutic, alterity, and background relationships. In *Ethics and Sustainability in Digital Cultures* (pp. 31-48). Routledge.

Johanna Lönngren

I spent a lot of time and effort trying to make the methods understandable for those not used to discourse analysis. However, I used the theory (discourse theory) in a quite superficial and pragmatic way, which could also be useful as a basis for discussing the role and use of theory in EER.

- Lönngren, J. (2021). Exploring the discursive construction of ethics in an introductory engineering course. *Journal of Engineering Education*, *110*(1), 44-69.

Sally Male

This paper draws attention to the need to support students to be aware of future roles and the relevance of their studies to these roles. Engineering education is about development - not just acquiring knowledge and skills.

- Male, S. A., & Bennett, D. (2015). Threshold concepts in undergraduate engineering: Exploring engineering roles and value of learning. *Australasian Journal of Engineering Education*, *20*(1), 59-69.

Diana Adela Martin

I submitted this during my Ph.D., based on the literature review of my thesis. It took two years for the article to see publication after several rounds of peer-review, totalling 7 reviewers. I make this suggestion looking backwards and remembering how challenging it was as a doctoral student to incorporate the – sometimes diverging – feedback and revisit the story that the manuscript initially told. Over the two years, through this invisible collaboration with reviewers alongside the feedback of my supervisors, a new aim and structure came to light. Since publishing, the article has gathered more than 16,000 views, was picked up by several news outlets, and is my most cited publication to date – contributing also to the invitation to join the editorial board of the journal which published it. This is my way of saying: believe in the work you are doing as doctoral researchers, find ways to finetune it and strengthen it, and don't give up! The reviewers and editors can be your supporters.

- Martin, D. A., Conlon, E., & Bowe, B. (2021). A multi-level review of engineering ethics education: Towards a socio-technical orientation of engineering education for ethics. *Science and Engineering Ethics*, *27*(5), 60.

Abel Nyamapfene

My latest paper with Dr Natalie Wint gives insights into the current state of engineering education research in the UK, and it also showcases how researchers can collaborate effectively via current social media tools. When we started the work leading to the paper, Natalie and I had never met. It was during the COVID period. By the time we completed the paper, we were close friends, and – guess what? – we were now working at the same institution.

- Wint, N., & Nyamapfene, A. (2023). The development of engineering education research: a UK based case study. *European Journal of Engineering Education*, *48*(2), 197-220.

Corrinne Shaw

This article comes from an ongoing interdisciplinary collaboration for research and reflexive practice. It provides a useful framing for pedagogical practice in ethics education in first-year engineering.

- Ngoepe, M. N., le Roux, K., Shaw, C. B., & Collier-Reed, B. (2022). Conceptual tools to inform course design and teaching for ethical engineering engagement for diverse student populations. *Science and Engineering Ethics*, *28*(2), 20.

Roland Tormey

Even if the topic of this paper itself doesn't interest you, you will see how we defined a clear research question, designed an approach to answer it, analysed the data, drew conclusions, and specified the limitations. Actually, I hope the topic will interest you – I think what we managed to do was ridiculously cool and unexpected.

- Kotluk, N., & Tormey, R. (2024). The impact of different methods of increasing the intensity of compassion in engineering ethics cases. *European Journal of Engineering Education*, 1-17.

Maartje van den Bogaard

- Van den Bogaard, M., Yeter, I. H., & Strobel, J. (2021, October). A literature overview of differences between engineering education and other disciplinary education. In *2021 IEEE Frontiers in Education Conference (FIE)* (pp. 1-4). IEEE.

Jan van der Veen

This is a multiple-case study design. I learned so much by collecting lots of data and then make a story that highlights some aspects relevant for the audience.

- MacLeod, M., & Van der Veen, J. T. (2020). Scaffolding interdisciplinary project-based learning: a case study. *European Journal of Engineering Education*, *45*(3), 363-377.

Esther Ventura-Medina

This article looks into 'how' students work in teams. 'How' questions are more often approached better through qualitative methods and methodologies. This work exemplifies how naturalistic data can provide insights when studying a situation.

- McQuade, R., Ventura-Medina, E., Wiggins, S., & Anderson, T. (2019). Examining self-managed problem-based learning interactions in engineering education. *European Journal of Engineering Education, 45*(2), 232–248.

Bill Williams

This looks at aspects of engineering practice that are still under-researched by educationalists.

- Trevelyan, J., & Williams, B. (2018). Value creation in the engineering enterprise: an educational perspective. *European Journal of Engineering Education, 44*(4), 461–483.

2.2 Reading Recommendations from the Experienced Researchers

Next, the senior researchers were asked to give input following the prompt to:
Recommend one paper, not your own, for a starting Ph.D. student.
This resulted in a comprehensive collection of publications with some notable overlaps.

Jonte Bernhard

- Case, J. M. (2019). A third approach beyond the false dichotomy between teacher- and student-centred approaches in the engineering classroom. *European Journal of Engineering Education, 44*(5), 644-649.

Tom Børsen

When I did my Ph.D. in university education, this chapter helped me navigate in the different paradigms of qualitative research:

- Lincoln, Y. S., Lynham, S. A., & Guba, E. G. (2011). Paradigmatic controversies, contradictions, and emerging confluences, revisited. *The Sage Handbook of Qualitative Research, 4*(2), 97-128.

Jenni Case

Mike Klassen's Ph.D. on engineering accreditation is one of the most interesting recent dissertations in the field. I recommend an early journal paper that he published in Higher Education:

- Klassen, M., & Sá, C. (2020). Do global norms matter? The new logics of engineering accreditation in Canadian universities. *Higher Education, 79*(1), 159-174.

Shannon Chance

A new open-source handbook (authored and edited by many of the seniors in this room) which will be published in the next few months:

- Chance, S., Børsen, T., Martin, D., Tormey, R., Lennerfors, T. T., & Bombaerts, G. (Eds.). (forthcoming). *The Routledge International Handbook of Engineering Ethics Education.*

Tinne De Laet

This paper links to a recommendation I would make to everyone: when researching a particular topic, also read from a field beyond engineering education research.

- Fleur, D. S., Bredeweg, B., & van den Bos, W. (2021). Metacognition: ideas and insights from neuro-and educational sciences. *npj Science of Learning 6*(1), 13.

Xiangyun Du

- Direito, I., Chance, S., & Malik, M. (2021). The study of grit in engineering education research: a systematic literature review. *European Journal of Engineering Education, 46*(2), 161-185.

Kristina Edström

Identify interesting people and follow their new work. This was published just a month ago:

- Martin, D. A., & Bombaerts, G. (2024). What is the structure of a Challenge Based Learning project? A shortitudinal trajectory analysis of student process behaviours in an interdisciplinary engineering course. *European Journal of Engineering Education*, 1–31.

Aditya Johri

These books are freely available online:

- National Research Council, et al. (2000). *How people learn: Brain, mind, experience, and school: Expanded edition (Vol. 1).*
- National Academies of Sciences, et al. (2018). *How people learn II: Learners, contexts, and cultures.*

Christian Kautz

This paper may serve as a general reminder not to rely on ideas that appear plausible or obvious in education without testing them:

- Pashler, H., McDaniel, M., Rohrer, D., & Bjork, R. (2008). Learning styles: Concepts and evidence. *Psychological science in the public interest*, *9*(3), 105-119.

David Knight

- Cohen, M. D., March, J. G., & Olsen, J. P. (1972). A garbage can model of organizational choice. *Administrative science quarterly*, 1-25.

Anette Kolmos

- Doulougeri, K., Vermunt, J. D., Bombaerts, G., & Bots, M. (2024). Challenge-based learning implementation in engineering education: A systematic literature review. *Journal of Engineering Education*.

Greet Langie

- Direito, I., Chance, S., & Malik, M. (2021). The study of grit in engineering education research: a systematic literature review. *European Journal of Engineering Education, 46*(2), 161-185.

Thomas Taro Lennerfors

- Biesta, G. (2020). Risking ourselves in education: Qualification, socialization, and subjectification revisited. *Educational theory, 70*(1), 89-104.

Johanna Lönngren

- Farnsworth, V., Kleanthous, I., & Wenger-Trayner, E. (2016). Communities of Practice as a Social Theory of Learning: a Conversation with Etienne Wenger. *British Journal of Educational Studies, 64*(2), 139–160.

Sally Male

This paper is an output of a Ph.D. in engineering education:

- Godfrey, E., & Parker, L. (2010). Mapping the cultural landscape in engineering education. *Journal of Engineering education*, *99*(1), 5-22.

Diana Adela Martin

I want to recommend articles by a few (very) recent Ph.D. graduates who are doing admirable work and which, in my assessment, demonstrate their expertise:

- Routhe, H. W., Holgaard, J. E., & Kolmos, A. (2024). Students' learning of management and leadership in engineering education–a literature review. *European Journal of Engineering Education*, *49*(3), 540-576.
- Guanes, G., Leonard, A., & Dringenberg, E. (2023). Undergraduate students' espoused beliefs about different approaches to engineering design decisions. *Journal of Engineering Education*, *112*(4), 938-962.
- Matemba, E., Smith, L., Wolff, K., Inglis, H., Mogashana, D., Jansen, L Hattingh, T., Raji, A., Musa, T. & Nyamapfene, A. (2023). Reflecting on a community of practice for engineering education research capacity in Africa: who are we and where are we going? *Australasian Journal of Engineering Education*, *28*(1), 74-84.

Abel Nyamapfene

Jenny Case has this knack of taking "received wisdom" and turning it on its head to provide another way of seeing and dissecting a problem. Her work epitomises originality, criticality and insightfulness, attributes that are not always present in EER:

- Case, J. M. (2019). A third approach beyond the false dichotomy between teacher- and student-centred approaches in the engineering classroom. *European Journal of Engineering Education, 44*(5), 644–649.

Corrinne Shaw

This is a useful resource for postgraduate students in engineering education. As EER is an emerging field, systematic literature review is a structured way to access appropriate literature for postgraduate study:

- Borrego, M., Foster, M. J., & Froyd, J. E. (2014). Systematic literature reviews in engineering education and other developing interdisciplinary fields. *Journal of Engineering Education*, *103*(1), 45-76.

Roland Tormey

Those from engineering and natural sciences often find it hard to see that qualitative research requires a careful and rigorous design, data collection and analysis. Very few writers convey this care and rigour in engineering education as well as Johanna:

- Lönngren, J. (2021). Exploring the discursive construction of ethics in an introductory engineering course. *Journal of Engineering Education*, *110*(1), 44-69.

Maartje van den Bogaard

Both these discuss what educational research is / could be, and what / who it is for:

- Biesta, G. J. J. (2020). *Educational research: An unorthodox introduction*. London: Bloomsbury.
- Labaree, D. F. (2012). A sermon on educational research. *International Journal for the Historiography of Education, 2*(1), 74.

Jan van der Veen

If you are interested in project based, problem based, and challenge based… This gives a thorough overview of types of interdisciplinary projects. Make sure your audience understands the context of your study:

- Kolmos, A., Holgaard, J. E., Routhe, H. W., Winther, M., & Bertel, L. (2024). Interdisciplinary project types in engineering education. *European Journal of Engineering Education*, *49*(2), 257-282.

Esther Ventura-Medina

Research design is key to doing good educational research. Part 2 of this book offers a good read on this area and links nicely research questions and approaches. This is a good reference book to go to for both starters and experienced researchers:

- Creswell, J. W. & Creswell, J. D. (2022). *Research Design: Qualitative, Quantitative, and Mixed Methods Approaches, 5th Ed.* Los Angeles, CA: SAGE.

Bill Williams

- Case, J. M., & Light, G. (2011). Emerging research methodologies in engineering education research. *Journal of Engineering Education*, *100*(1), 186-210.

2.3 Advice from Experienced Researchers

Seniors were also asked to give one general tip for a starting Ph.D. student.

Jonte Bernhard

Think through YOUR research question(s), i.e. find interesting problems YOU want to investigate. In my opinion the quality of the insights generated is more important than mechanically following a method.

Tom Børsen

Remember, it is your project.

Jenni Case

Read! Read! Read! This is the time of your life to catch up on all that reading you never did as an engineering student. Read widely. Don't just read the stuff that is published in EER journals. Also - be fussy. Follow the things that excite and interest you. There is so much out there, so if something is not grabbing you, put it down (you might return to it but you might not). Research is about exploring things where we don't have the answers. Wrestle with what questions are out there. Find the studies that you think are doing great things (and really grappling with unanswered questions) and start dreaming on what you will do to add to this literature. But don't just dream... Write! Write! Write!

Shannon Chance

Find and cultivate mentors. When you're ready and have enough time to review a manuscript for EJEE, email us (Diana Martin and I have a particular interest in mentoring reviewers), and we will try to match you with a topic of interest.

It's never too early to think about where you want to go after the Ph.D. Consider attending the workshop I'll lead with other seniors in the room, during SEFI, on securing international fellowships for research (Chance et al., 2024), including post-doctoral funding (jobs and fellowships). And during SEFI, you can be on the lookout for people and research centers where you'd like to work a while!

Tinne De Laet

Be open to other disciplines, paradigms, and people! Be welcoming and supportive to others, in short: treat others like you want to be treated.

Xiangyun Du

Feel safe to be creative. A Ph.D. project is a process to construct your own academic identity.

Kristina Edström

Read the old classics and read new works. Notice what you like about the writing: what makes it convincing, what helps the reader, what shows honesty and transparency, what is the contribution, and what stays with you long after. Notice also how you don’t want to write.

Aditya Johri

A good dissertation is a dissertation done.

Christian Kautz

1. Find a topic that genuinely interests you. A dissertation project is a lot of work, and you will very likely experience "ups" and "downs". A topic that you really care about will make it easier to get through harder times.
2. Find a group of people with whom you can talk about your research, ideally even about fairly specific aspects of it. I know of only a few successful and relevant research projects that were carried out by a single person without exchanging important ideas with others.
3. If you have any desire to stay in academia, gather experience in teaching, possibly even larger student groups. There is little need for pure educational researchers who have never put their ideas on teaching into practice.

David Knight

Try to remain centred on a love of and thirst for learning through your doctoral programs and beyond.

Anette Kolmos

Much advice can be given, but I think the most important is to try to boil complex thinking down to simple messages. The articles which will be remembered are those with core and clear messages. It means that when you start articles or other writings, try to formulate the message in laymen’s words and build up the argumentation to support your message.

Greet Langie

Be confident! When your Ph.D. is almost finished, you are the expert in this specific field!

Thomas Taro Lennerfors

Think big. Do not get stuck in a narrow issue / field / discussion. This will prepare you for a long career after the Ph.D.

Johanna Lönngren

Take care of yourself and talk about your struggles with people you trust. Doing a Ph.D. can be very taxing, and if you experience challenges, you're not alone. No one benefits from you pushing yourself too hard and getting burned out!

Sally Male

Remember to test everything well – e.g., questionnaires, interview protocols.

Diana Adela Martin
This group of Ph.D. researchers is here: this is your community. My advice will always be to value collaboration and community-building over competition. You can achieve so much together by developing joint projects, co-writing articles, and submitting grant applications, in a process that, in time. leads to friendships. Academia can be pretty toxic, hostile, lonely and ego-driven, and it is through these accumulated small changes in attitude that we grow together and grow the field of EER.

Abel Nyamapfene
Be yourself, enjoy the ride, and do not be afraid to be different, after all, it's diversity which advances originality in engineering education research.

Corrinne Shaw
Spend time on crafting your research question so that it has appropriate scope and contribution for your degree.

Roland Tormey
Locate yourself in the emotional trajectory of your project (social, epistemic, achievement...), and give yourself time to have the emotions you experience.

Maartje van den Bogaard
Write ugly English: getting clarity on your own logical argumentation is not easy. What really helps, I found, is to force yourself to write short sentences only. Go for logical argumentation, not for eloquence. That will come later, or it will not come at all, and it's of lesser importance than getting your argument straight and communicating it clearly, even if the English is ugly.

Jan van der Veen
Focus: zoom in. You have to write only one thesis.

Esther Ventura-Medina
Whatever your research question(s) is(are), make sure that your approach (i.e., quantitative, qualitative or mixed) is aligned to the question(s) and it is fit for purpose.

Bill Williams
Find your community.

2.4 Group Notes

The groups wrote collaborative notes during their time together and then prepared notes using an online file. These were valuable yet lengthier than could be included here.

2.5 Take-Home Messages

As the final activity of the day, the organisers invited each participant to share one nugget of wisdom gained as a take-home message from the DS. This final plenary allocated each attendee maximum one minute to present their personal message. Some selected messages from doctoral students and seniors appear below:

“We are not alone and our impact is together with those who are working on similar projects. Together we create the space to step into. And together we transform what is there for others to walk on.”

“It was very valuable to hear from Ph.D. students about their topics, problems and solutions I can try to use in my doctoral research.”

“Engineering education research is like a poke bowl where everyone comes in with diverse disciplinary backgrounds and experiences, but it’s this mix that makes the poke bowl so delicious, because everyone brings something unique to the table.”

“This community has an incredibly engaged and supportive culture which is a real asset and so fully on display at the doc symposium.”

“I should think about the impact I want to have and have that drive the research questions and methods. Dive deep into the existing literature. I want to be critical of the existing literature: adopt a post-positivist mindset.”

“There are so many connections (theoretically, methodologically, in terms of process, concerns, etc) between the PhD projects (and other research) in (and beyond) this community. Although sometimes we focus on differentiating ourselves from others through different concepts, methodologies, being unique etc, the core ideas and concerns are often quite similar and can bring us together even more. Unveiling those connections is perhaps best done through oral communication and spending time together, with an attitude of openness and willingness to learn, rather than protecting our own turf.”

“Serendipity remains really important: a lot of work has been done in many places, yet it’s not always easy to find information. We need to (continue to) talk with a wide audience because it is often the way to learn about initiatives/papers/projects/etc. that might be instrumental for our work.”

“I think one of my big takeaways from this symposium is to be a lot more intentional and focused - and kind - with my time and my writing. Approaching what I hope will be the end of my PhD, another takeaway is to take hold of the idea that ‘you can always do more’ and realise, at a certain point, that what you’ve actually done is enough.”

“The importance of definitions. Defining words like ‘effective’ or ‘improve’, and deciding what those words mean inside my project is really important and should be more of a priority!”

“Life is a bit random and non-linear. Look out for the opportunities while following (exploring) a path that you find interesting, but not to forget that interest can be developed over time. Be mindful about your bigger goals and aspirations. Remind yourself of ‘the thing’ that keeps you moving? Don’t worry too much about the performance-related outcomes, do the things you like and do them well, you’ll be fine.”

“Read a lot, find good empirical models, and get inspired by them. If you can copy them, even better. Always keep writing, especially while doing empirical work. And try to fill a gap but don’t fall into a hole – coming up with a good research question will help you achieve this better than almost any other aspect of research.”

“The field of EER is relatively new and is still developing so it’s ok to be confused about approaches, theories, methodologies etc.”

“My main takeaway is that framing and contextualising matters a lot. Think about the audience and think about why your work/the case is informative and relevant for others and what factors you are addressing.”

“Across national contexts there is huge variation in what a PhD is, how it is supported and assessed, in the structure of academic careers and of university programs. It’s great to be in a space where this variation is fully on display, and watching people navigating the career possibilities in their context.”

“Research is not linear, it’s iterative. Don’t get too fixated on one framework. Listen to your data. No need to kill all your darlings, but be open to adopting new ones.”

“I learned that many people here are swimming - or drowning - in an ocean of data. It might be difficult to know where to start. One of the seniors helped me realize we do not have to cram all this data in one paper. Think about different parts, and especially different stories. Cause I also learned that to make your research impactful, there is power in storytelling.”

“Trust the process! Rejections, confusing results and feeling stuck are part of it and can open new doors and lead to new research questions and future work.”

“I continue to be extremely impressed at the depth of thinking among graduate students at this event – connecting with this group has been a favorite activity for me over the past two years. I also appreciate the ways in which projects seem to have an implementation/change element to them and think as a community we need to make sure we are situating our work within organizational/institutional contexts.”

3 REFLECTIONS AND WAY AHEAD

The 8th SEFI Doctoral Symposium, like its predecessors, provided a key event for the engineering education research community. The symposium continues to grow in both size and impact, reflecting the increasing maturity and global reach of the field. This year, 31 Ph.D. students and 23 established scholars contributed to a vibrant and dynamic exchange of ideas. When one of the participants at the 2023 DS called SEFI “her village”, we began to see that the community keeps growing, perhaps becoming a little town, yet still a cosy and welcoming one.

Many insights and experiences shared by participants highlighted the diverse and interdisciplinary nature of engineering education research. From the importance of finding one’s niche and leveraging unique backgrounds to the value of networking and collaboration, the symposium provided rich learning opportunities. The metaphor of engineering education research as a “poke bowl” aptly captured the essence of this diversity, where each participant’s unique contributions enhanced the collective experience.

The vibrant sense of community that characterised this year’s symposium is a testament to the strength of the SEFI network. The symposium demonstrated the supportive and engaged culture of the SEFI community overall. It fostered a mutual exchange of ideas, and the cultivation of new connections was seen as invaluable by all participants. It was also noteworthy that senior mentors and organizers expressed appreciation for the opportunity to both guide and learn from the junior researchers. As we reflect on the symposium, we are inspired by the dedication and passion of this community. The take-home messages from participants emphasised the importance of perseverance, critical thinking, and the continuous pursuit of knowledge. The symposium not only provided a platform for sharing research but also for personal and professional growth. A healthy sense of belonging and the shared commitment to advancing the field were palpable throughout the event.

In reflecting on the 2024 event, the organisers find themselves delighted with the expanded capacity of this community to conduct impactful research and committed to supporting the unique abilities and perspectives each member brings. We look forward to staying connected with this year's participants, and we eagerly anticipate the continued growth and success of the Engineering Education Research community. Together, we are shaping the future of engineering education research and creating a supportive, inclusive, and dynamic community.

4 ACKNOWLEDGMENTS

The authors wish to thank every participant in the DS, from its inception in 2016 to this 2024 event. The activity's success is a direct result of the engagement and enthusiasm of juniors and seniors alike. We also thank all the local and international organising committees over the years. This year, Roland Tormey and his team gave outstanding support. We thank the SEFI staff and board for entrusting us with the facilities and resources to help make this event possible.

ABSTRACT

Despite efforts to attract women into undergraduate mechanical engineering, participation and retention rates remain low. Several studies have identified socio-structural factors that mitigate efforts for inclusion of women and report the challenges for women in navigating the influence of these factors. Considering how the experiences of women within cohorts are nuanced by religious, cultural, and familial circumstances, understanding how women navigate these circumstances to succeed in engineering programs could inform interventions to attract and retain women. This study investigates the influences of family, culture, and social structures with respect to access and participation of women students in engineering

through the use of narratives drawn from interviews of a selection of young women students at two universities, one located in the Global South and the other in the Global North. The use of narratives is explored as a methodological approach for explaining these complex experiences. It was found that narratives combined with thematic analysis provided a holistic approach to understanding how social structures serve to undermine or support student identities in undergraduate engineering.

1 INTRODUCTION

1.1 Background

Globally, the recruitment of women into engineering degrees has seen a steady increase over the past several decades, though large gender disproportions remain (Hill et al. 2010). The gap in participation in engineering disciplines between men and women exists in both developing and developed countries, with this discrepancy typically attributed to factors related to gender stereotypes and discrimination, lack of opportunities in education, and levels of exposure to engineering (Longe et al. 2019). In addition to these factors, there are studies that consider how other elements related to society, culture, and social situations also play a role in the recruitment and retention of women in the study of engineering. For example, Hill et al. (2010) report that some of these supplemental factors include, but are not limited to, societal and religious beliefs, parental influence, and educational circumstances. These factors, thus, could influence not only students' enrolment decisions and their experiences during their studies, but also their engineering and gender identities, their academic confidence, and their levels of engagement in the classroom.

This paper draws on a doctoral research project aiming to investigate how social structures influence the identities of women students in engineering. This investigation uses concepts from identity theory and narrative inquiry to understand how familial, cultural, and social structures contribute to the expression of these identities. It aims to identify how these known structures, as recounted by Stryker and Burke (2000), influence the negotiation of identities as they are expressed through expected behaviour in various social situations. Consequently, it became beneficial to document and analyse how and to what level these structures influence the experiences and expressions of identity of women students in engineering. Data were collected from women students in engineering at two international universities, one in the Global South and the other in the Global North, and narratives were used to meet this objective. What follows is a discussion of the theoretical concepts that were drawn on for understanding human experience in a social context, and thereafter the approach to the empirical study of the use of narratives is explained.

1.2 Theoretical Framework

In this study, several theories and concepts of identity were drawn upon to refer to appearances, behaviours, and characteristics that define an individual's position or positions in society (Fearon 1999). Most notably, Gee's (2000) work presents the enduring framing that there exist four perspectives attributed to identity, which provide a model to describe a person's character, how they are viewed externally, and can be recognised by others according to a state, position, individual trait, and set of experiences (Gee 2000). In contrast, Giddens (1991) argues that identity does not actually exist solely in the behaviour or opinions of others, but rather through one's ability to maintain the representation of a particular, personal narrative. Similar to Gee's work, Giddens (1991) postulates that a person's story or perceived identity is not fixed and can be ever-changing, interpretive, and transformative. From this, it can be deduced that both Giddens' understanding of a person's narrative and Gee's four perspectives can play a role in understanding how a student expresses their identity and attributes this expression to a number of factors relating to the intrinsic self and extrinsic societal factors.

Stryker and Burke (2000) put together these two strands of identity theory, combining the factors that shape identity from origins of both social structures and the self. These strands are given meaning through an individual's social behaviour, continuously negotiated through an individual's commitment to meeting society's identity standards, as well as their internal processes and self-verifications of perceptions of identity (Stryker and Burke 2000). Social structures, which act as margins enclosing a person's relationships and interactions within overlapping social networks, can shape identity and the story of the self, which in turn is expressed through social behaviour. Internally, identities are negotiated through an intrinsic inclination to align one's self with the perceived identity standards fitting the individual's situation (Stryker and Burke 2000). Together, these strands of identity are transformative and interpretive, acting as agents of identity expression in the interplay between social structures and the individual's internal processes. Ultimately, while not deterministic, social structures contribute influences over the behaviours and identity expressions of individuals.

2 RESEARCH APPROACH

The research approach was guided by Maxwell's (2013) qualitative research design, which allowed for context-driven methods to be used to understand how identities can be influenced by social phenomenon. This iterative, non-linear design process was applied to investigate two research sites represented by two international contexts.

2.1 Universities as Research Sites

In order to understand how social structures influence the identities of women students in engineering, two research sites, one located in the Global North (Düsseldorf, Germany) and one in the Global South (Cape Town, South Africa), were chosen. These sites have some similarities: they boast diverse populations, cultures, and societal norms. Notable differences however, related to regional size, national geographical location, and population allowed for influences attributed to national history, makeup of population, and access to education to be particularly considered.

The city of Düsseldorf lies along the Rhein River and is the capital of the North Rhine-Westphalia state of Germany. It is home to a population of approximately 645 000 people, with roughly 153 100 considered to be foreign, particularly of Japanese, Turkish, and Polish descent (Düsseldorf 2021). Düsseldorf rose to prominence in 1288 as a hub for industry and trade as an inland port, and has transformed from a fishing village into a city known for its fashion, art, and boutique shopping (Britannica 2024). Considered to be an old city of Europe, it remains staunch in its beer-brewing methods and predominantly Christian values (Times 2019). Düsseldorf is home to six prominent, state-run universities, providing instruction in various fields which include architecture, engineering, and business. The language of learning and teaching (LoLT), is predominantly German and, in some instances, English.

Cape Town, in contrast, is a coastal city located in the Western Cape province of South Africa and serves as the legislative capital of the country with a population of approximately 5 million people at current estimation (Review 2024). Significant in its role as the point of arrival of the Dutch colonies in the 1650s owing to its strategic trade position at the southern tip of Africa, Cape Town is rich with diverse populations, flora, and fauna (Axelson 2024). Three decades on from the abolishment of the country's ethnic segregation of apartheid, the consequences of the country's dark history are still felt in the city, with ongoing economic fluctuations fuelling movements towards increased racial freedom and national development. Cape Town, as a city, is home to three public universities, with English as the primary language of learning and teaching, and offers various degree programmes including humanities, medicine, sciences and, in two of the three, engineering.

Two universities, in each research site, were chosen as the context for exploring the use of narratives to understand the socio-structural influences on women's identities.

2.2 Interview Strategy

Following appropriate ethical clearance, women studying at undergraduate level in the overarching discipline of mechanical engineering were selected for inclusion in the sample. These students were invited to participate through email invitations and direct contact through faculty members. No limitations were placed on participants' age, nationality, or heritage with the sample intended to benefit from variety in participants who identified as women. Data were collected through the use of semi-structured individual and group interviews. Each included participant was interviewed once, with a follow-up interview conducted on one occasion to seek clarification. The duration of each interview varied from twenty minutes to more than one hour, and they were conducted by the primary researcher in English. All audio was recorded and subsequently transcribed by a confidential transcriber.

The individual interviews were designed to explore three main areas, with the first focused on gathering preliminary biographical information about the participant, such as age, discipline, and hometown. The second involved questions focused on the participant's journey to and through their engineering degree, and the impact of that decision on themselves and their family, friends, and peers. The final area centred on the participant's experiences as a student in engineering, focusing on their time spent in and out of the classroom, their views on the degree, and any instances in which they were made to feel excluded or marginalised.

The sample included six students from the German site and eight students from the South African site, both numbers that fall within a typical sample size for narrative inquiry and allowing for a deeper, more nuanced level of understanding (Kim 2016). Most interviews were conducted face-to-face on the university campus where the students were based. Only one interview was facilitated online to accommodate a student who was unable to meet in-person. In addition to the individual interviews, the group interviews, one conducted per site, offered additional insights and richer stories of the participants' experiences studying engineering. All interviewees were assured of confidentially and anonymity, and were assigned a pseudonym throughout the findings, as indicated in Table 1 below along with gathered biographical information.

Table 1: Participant Pseudonyms and Biographical Information

Pseudonym	Research Site	Age	Nationality	Heritage
Julia	Germany	23	German	German
Claudia	Germany	21	German	German
Kaya	Germany	23	German	Turkish
Veronica	Germany	28	German	Polish
Astrid	Germany	27	German	German
Nehir	Germany	22	Turkish	Kurdish
Crystal	South Africa	23	Zimbabwean	Zimbabwean
Louisa	South Africa	23	South African	South African
Mbali	South Africa	22	Zimbabwean	Zimbabwean
Yusra	South Africa	21	South African	South African
Teresa	South Africa	23	South African	Malawian
Nandi	South Africa	23	South African	South African
Amira	South Africa	22	South African	South African
Zahra	South Africa	21	South African	South African

2.3 Approach to Data Analysis

The data collected were analysed using methods adopted from narrative inquiry, a type of analysis that focuses on exploring the way in which people experience life, particularly by paying close attention to stories of their everyday lives (Moen 2006). It allowed the researcher to go beneath the surface, collecting data in the form of spoken stories and using them to relate human experiences to their actions and behaviours in a social situation (Walker, 2001). Each participant included in the study had an individual story, personal characteristics, and views of themselves in a given context. Each story remained preserved during analysis as key themes embedded in the narrative were identified. Each narrative was, therefore, considered on its merit, as investigative interest remained firmly in the individual participant's story and thus her own experiences (Polkinghorne 1995). All interviews and associated transcripts were summarised to include and highlight pertinent information about each participant's age, family background, nationality, experiences, ambitions, and values.

3 Preliminary Findings

The narratives were considered to be significant contributions and used to document the processes of navigating legitimate identities. Using each narrative as a stand-alone character summary of each participant's story of self, commonalities were identified as part of a first-pass thematic analysis.

3.1 The Role of Family and Peers

In response to questions about their reasons for choosing engineering, all of the participants referred to the views of their parents and other family members regarding their choices of study, highlighting the significance of their influence towards the participants' student identities. From the German sample, all the interviewees made mention of encouragement they received from the women in their lives to pursue engineering, mothers and older sisters alike. One participant, Julia, stated that her mother encouraged her to use her talents in mathematics to secure a strong degree, while Astrid's mother drew her attention to the country's ongoing campaign that 'Germany needs engineers.' Similarly, from the South African sample, Teresa's sister, already a medical student at the same university, encouraged her to consider engineering as a career because of her interest in designing rollercoasters. The interviewees all noted that their nuclear families were largely supportive of their venture into engineering. Coming from a family of architects, Louisa's parents and older sister steered her away from following the same career, with her father suggesting engineering as a way to supplement her talents in mathematics and art.

All but one participant from both samples reported that they had family members who were engineers, ranging from an older sister to a grandfather, thereby having prior knowledge of engineering as a career. Nehir (Germany), at a young age, found engineering to be very interesting and wanted to be just like her sister, who studied to become an industrial engineer. Yusra (South Africa) referred to her uncle's admirable success in the field as a reason for pursuing engineering. Similarly, Amira (South Africa) cited one of her friend's interests in engineering as the catalyst for her own, stating she thought, "If she can do engineering, I can do it." Though, she did add that the engineers in her family, all of whom were men, never spoke about the profession in a way that made it sound inclusive to women, affecting her interest.

While geographical differences were apparent in the samples, it was interesting to note that foreign nationals studying in each country detailed similar pressures from their parents and extended family to achieve academically and secure well-paying jobs. Veronica (Germany) expressed that her family always promoted the idea that she had to study and get a good job. This she saw as a part of the core values instilled in her that aligned with the historical experiences of her Polish grandparents. Similarly, as part of the South African sample, Mbali, originally from Zimbabwe, admitted that she felt the pressure of being the firstborn in her family to pursue in a 'serious' degree such as engineering. Moreover, Crystal, also from Zimbabwe, drew attention to her parents' swaying her towards a 'safer' qualification. She stated, "My parents were very much wanting all their kids to become doctors. So the next best thing, because I didn't want to do medicine was, 'Why don't you try engineering?'"

3.2 Education, Exposure, and Access

From the narratives of students based in Germany, four of the participants spoke of participating in three-week long vocations with various companies of interest during their high school years. Built into the German secondary school curriculum is the requirement for students who are studying towards the leavers' examination, referred to as Arbitur, which is a level of achievement that allows students to enter into a higher education institution. This instruction was especially useful for Astrid, who, after her experiences working in a dentist's practice and subsequently in an aeronautical company, realised that dentistry was not as dynamic a career as she was seeking. While no similar program was reported by participants from the South African sample, Amira alluded to being involved in extracurriculars related to science, though still remarked, "I don't think that engineering is presented as an option for women, generally." About the suggestion to address the exposure to engineering principles more seriously at secondary school level, Zahra (South Africa) mused that it might actually deter women from pursuing an engineering degree if they were more aware of its potential as a career.

None of the participants from Germany claimed Düsseldorf to be their hometown. Originally from as close as one city away to as distant as the country of Turkey, none of them expressed regret over their decisions to move away from home. Initially having a ninety-minute commute, Kaya moved right near the campus in later years, which she found more comfortable and conducive to healthier student practices. Comparatively, half of the South African sample were born and raised in Cape Town itself, opting to remain living at home with their families for the duration of their undergraduate degrees. Zahra referred to the decision as "beneficial and a big advantage," providing her with the safety of home-cooked meals, the familiarity of her own space, and the network of support provided by her family, which all contributed to her ability to focus on securing her degree. As a downside to this, Louisa felt that not living in student residences hindered her adjustment to campus life, affecting her initial drive to socialise with her classmates. Others from the sample reported choosing to move to Cape Town for the prestige of the university, opting to pursue independent living despite the difficulties of being away from familiarity and family.

In contrast to the structure of the engineering degree in South Africa, a requirement to qualify for graduation in Germany is a formal semester-long internship with a professional engineering company. It is normal practice then, among industry partners, to receive and mentor senior students, providing valuable insight into the engineering workplace. From the interviewees, those who had already completed their internship semesters at the time of the interview had mostly positive experiences to report despite their acknowledgement of the glaring gender disparity at all levels within the companies. This requirement for graduation, however, was significant for Nehir, as the companies in Germany require their interns to speak fluent German, which made it difficult for her to find a position. The same standardisation of practice, however, is not prevalent in the South African engineering sector, where a requirement to graduate is to commit to a prescribed number of weeks of vacation work that covers both practical and management aspects of engineering. Owing to minimal university involvement in vacation work placements, the sample reported mixed experiences. In particular, Mbali mentioned working for a company in her home country with the intention of completing this requirement and found that she was the only woman employed. Unfortunately, she was relegated to only reception work and said she felt devalued, belittled, and not trusted as competent personnel. In another instance, Zahra noted receiving advice from a senior woman engineer, instructing her to be upfront and assertive in interactions with male colleagues in order to avoid being spoken to in a condescending or denigrating manner.

3.3 Financial Considerations

It is well documented that South Africa's higher education system continues to carry the burden of the country's history of legalised racial segregation. There have been numerous campaigns, usually initiated by students, to reduce and subsidise the fees to attend university, addressing barriers to access education for many citizens and foreign nationals. For some, the option to study at all relies on securing sufficient funding. The availability of scholarships and bursaries ultimately factored into the choice to study engineering for Zahra and contributed significantly towards her persistence in the degree. She cited the risk of a loss of funding based on poor academic performance as a strong motivation. She alluded to the financial benefits of having a bursary, which included the promise of employment after graduation, but added that she felt trapped by the contractual obligation as it prevented her from exploring new career paths. Likewise, originally intending to study further abroad, Mbali (South Africa) was forced to be realistic about her tertiary prospects by opting to pursue her education closer to home.

While university fees are significantly subsidised by the German government, the cost of living in Düsseldorf remains substantial despite the diminished fee requirements. All of the interviewees mentioned having part-time jobs to supplement their incomes. This had devastating consequences for Veronica in particular, who said, “Instead of quitting the job, I quit the studies,” because she needed the money. Ultimately, it was her fear of being considered to be a failure in her family that made her persist with the degree. Nehir (Germany) admitted to wanting to leave engineering many times, particularly when facing the workload and academic struggles, but repeatedly told herself she needed to finish, as her parents were still supporting her financially. Julia also signified her own ambitions in pursuing engineering by saying, “I wanted to earn a lot of money.”

3.4 Attitudes to Engineering

Persistence within the degree stemmed from various sources, one of which was determined to be the prestige of the degree and profession. Common across both samples was the notion that being an engineering student carries with it a level of kudos that the participants find desirable.

Another perception of engineering that emerged from the interviews is independence, which Nehir (Germany) alluded to in describing how she and her sisters always wanted to appear “strong because [they] don’t have a brother.” Similarly, Kaya (Germany) aspires to follow in the footsteps of other women engineers, expressing her wish that they had more women lecturers. She stated, “If we had them, that would encourage me more to achieve it, because women identify more with women role models, and men more with male role models, so I think that would make things way easier.”

3.5 Engineering Prejudices

Supplementary to challenges associated with gender, there are other ethnic, racial, economic, and religious women groups that experienced additional barriers and discrimination in engineering. Yusra (South Africa) acknowledged the reality of being a woman in engineering, stating, “If I were to have a family, I wouldn’t want to be someone that like has to split their time 50/50. […] If you’re working in corporate, it’s cut-throat and if someone can be there most of the time, they would rather have that over someone that’s there some of the time.” Mbali (South Africa) agreed with this sentiment, saying, “I have realised that, for women, it is a bit impossible to maintain a career, kids, and a husband. One of them is likely suffering somewhere; you can’t have it all.” It was interesting to note that interviewees from the German sample made little to no reference of such concerns.

None of the participants in the German sample reported any substantial and overt instances of gender discrimination in the engineering classroom. Three interviewees, however, mentioned the existence of religiously and sexually discriminatory messages sent to a social media group consisting of engineers that created discomfort among their cohort and ultimately drew the attention of the head of the faculty. Claudia did note an instance where, as part of a group invitation, she attended a small get together of engineers and, upon arrival, was asked, ‘Ah, a girl; to who of them do you belong?’ She found the implication she could not attend on her own merit extremely offensive. In contrast, the narratives helped the researchers to see that the South African sample had differing experiences in this regard. Nearly all interviewees reported situations that they felt undermined by their peers, particularly when involved in group work. Mbali, Zahra, Yusra, and Amira all made mention of an idea or solution they initially presented being taken into consideration only when repeated by another male student. Amira also found that her contribution and point of view held less value than those of a man.

4 DISCUSSION AND CONCLUSION

This paper presents preliminary findings from a first-pass thematic analysis and forms part of a doctoral research project in which they will be expanded upon. It clearly indicates that using narratives from a selection of young women students from two international contexts proved to be a feasible method to document women students’ stories. Understanding the interplay between socio-structural factors and individual identity is important in informing possible leverage points and interventions to support the retention of women and improve inclusivity in the male-dominated field of engineering. Its use provides a means to understand each participant’s story as a whole, as provided in their own words, thereby adding nuance and meaning to their own experiences as students in engineering. Through the interviews, participants were given space to speak of their lived experiences in engineering, offering insight into the external and internal processes of navigating identity. From the literature, participation in what is viewed as a masculine profession can impact students’ identities, with both men and women associating expressions of their gender identity closely with their fields of study (Walker 2001). As such, the collected narratives were vehicles not only for describing long-range accounts, but also for analysing how social structures contribute to the manner in which participants negotiate their expressions of identity. Drawing back to the two strands of identity referred to in the theory, coupled with Maxwell’s (2013) guided design, the narratives were able to provide context behind participants’ behavioural decisions in social situations.

The narratives also provided insights on the human dimension of student experiences. In addition, it offered rich material as a qualitative analysis tool in exploring the influence of social structures on the identities of women students in engineering, as evidenced by the findings. It was clear that their families, religions and core values played a role in their processes for negotiating their identities. Exposure to engineering principles within their education systems and access to engineering as an option, despite its fee constraints particularly in South Africa, also have significant value. In pursuing engineering, women are already choosing a different path, as they are faced with gender, ethnic, racial, economic, and religious prejudices that can challenge the representation of their identities. The value of these findings exists in its potential contribution towards positively influencing women’s experiences and positions at all levels of engineering, as well as providing useful insight towards advancing the levels of diversity, equality and inclusion in engineering education.

ABSTRACT

During the pandemic, many people in secondary school failed to acquire solid and profound knowledge. Teaching maths in remote education with distance learning has been a challenge for both teachers and students. In engineering higher education, several years after the pandemic, we are seeing problems that are having an impact on the overall education not only in the basic subjects but in further engineering subjects. There is a need for an intervention programme that can be applied effectively in large-scale courses where the number of students exceeds 100. Recently, we have created supplementary courses to help students learn the advanced Calculus material more effectively, while ensuring that they can catch up with their secondary school knowledge at their own pace.

This research aims to analyse the changes in student performance of first-year student during the first two semesters of university math courses (Calculus 1 and 2). In our research, we investigated three different groups of students: the “2018 group” studied math traditionally, while the “2020 group” took online education at the end of high school and at the beginning of their university studies. Finally, the “2022 group” spent two years in high school at home in distance learning but started in-person education at the university and had significant problems during the first semester. Therefore, those students participated in an intervention programme. The performance analysis after Calculus 2 shows that we have succeeded in developing an inclusive pedagogical programme that we intend to further develop in the future to reduce drop-out.

1 INTRODUCTION

The effects of the pandemic were immediately felt in higher technical education. Courses with more practical elements during online education had to be significantly transformed. Laboratory exercises could not be held, so students did not gain hands-on experience. During online education, these exercises were almost completely eliminated, which caused serious difficulties for students. After the end of the quarantine, our university offered students the opportunity to make up missed measurements in certain subjects during the summer, but these blocked classes were less effective. This was also confirmed by several recent studies several studies have been published, and it is widely accepted that lock-down cause significant losses in education, (Kuhfeld and Tarasawa 2020), (Kuhfeld et al. 2020), (Kaffenberger 2021).

Another consequence of the sudden closures was that, on more than one occasion, incomplete, quickly put-together teaching materials were produced, which did not really serve independent distance learning. Many had difficulty in preparing themselves from these materials. There were also students and teachers who did not have adequate technical infrastructure, which also hindered effective learning and teaching.

In addition to the short-term effects of the pandemic, we are also facing very serious long-term effects. It is clear from the results of the usual input measures for first-year students that they are experiencing difficulties that cannot be remedied in a short period of time. We need to use intervention procedures that effectively support students' learning processes and thereby improve educational outcomes. The book, edited by Kelum A.A. Gamage, reviews and synthesizes the findings of the international literature on the impact of COVID-19 on global higher education (Gamage, 2022). In the book containing 18 publications edited by Arday, research and data from 16 countries and 5 continents explore the far-reaching impact of Covid-19 on global higher education (Arday, 2022). While, Katsamunska analyses the reaction of the government and higher education stakeholders to the measures implemented in Bulgaria (Katsamunska, 2023).

Programmes providing targeted assistance need to be those that can be delivered to large student populations. Providing online learning resources is such, but they cannot replace face-to-face teacher-student interaction. Intelligent interactive learning interfaces are particularly useful when they personalise learning material and tasks according to the progress of the students. Providing opportunities for group learning and pair learning is also effective. In 2022, we have designed a new intervention programme for our first-year students to help them better adapt to the academic environment, improve their academic performance, and successfully navigate the educational challenges.

1.1 Motivation and goals

This research project is the continuation of our previous research that was presented in the SEFI conferences in 2022 and 2023 (Sipos, 2022), (Berezvai, 2023). In these studies, we analysed the changes in the learning habits and performance of three groups of students: a pre-Covid, a Covid and a post-Covid groups, respectively. It was concluded that in the post-Covid group a significant change was observed in the online learning habits, namely that students spent more time on online learning, but a significant increase in poor results is clearly detectable. Calculus is the most important undergraduate mathematics course in all engineering programmes in Hungary, which aims to ensure the required mathematical foundation for the further engineering subjects. It should be noted that Calculus is typically is taught over 3-4 semesters and includes the topics of algebra, linear algebra and differential equations (see Table 1). Therefore, we found it essential to give a response for the decreasing student performances in Calculus 1 course in order to avoid the drop-out for the Calculus 2 course. The main goal of this contribution is to present the intervention that was applied in the "2022 group" during the Calculus 2 course and to analyse its effect on the performance of students.

Table 1. Curriculum of Calculus 1 and 2 courses

	Calculus 1	**Calculus 2**
Topics	Complex numbers Spatial geometry Numerical series Functions Differentiation Integral calculus	Linear algebra Function series Multivariable functions Multivariable calculus

2 DATA

In this study, three different classes of the mechatronics and energy engineering courses were investigated. The number of groups and the results of the admission and entrance tests are summarised in Table 2 and Fig. 1.

Table 2. Participants of the investigated courses

		2018	**2020**	**2022**
Number of students		120	134	173
Average entrance points		458.62	445.96	454.71
Standard deviation of entrance point		23.22	30.20	26.78
Test 0	Mean and standard deviation	39.38±10.71	46.02±8.84	36.14±12.04
	Percentage of Passed	88%	97%	81.5%
	Percentage of Failed	12%	3%	18.5%

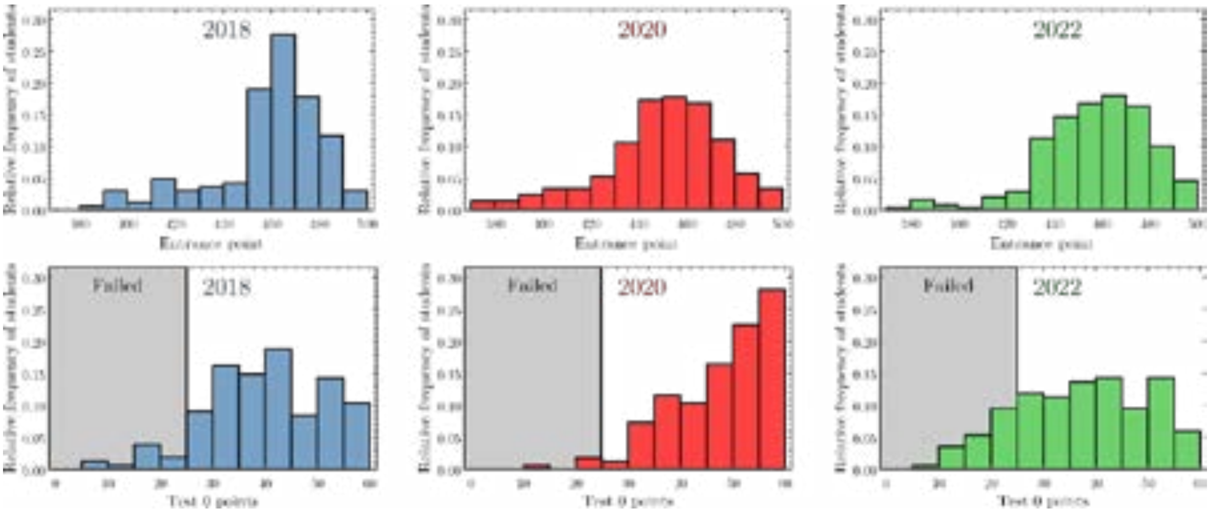

Fig. 1. Relative frequency of a) entrance points (out of 500) and b) entrance test (Test 0) results (out of 60) or all classes 2018, 2020 and 2022 (Berezvai, 2023)

a. The investigated groups

In our research three different classes were analysed: the "2018 group" studied math traditionally, while the "2020 group" took online education at the end of high school and at the beginning of their university studies. Finally, the "2022 group" spent two years in high school at home in distance learning but started in-person education at the university and had significant problems during the first semester.

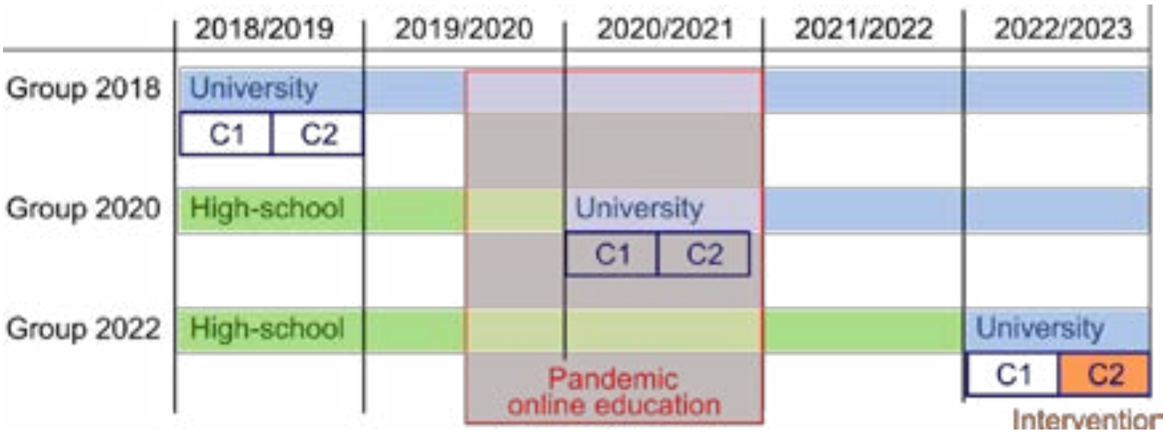

Fig. 2. The temporal distribution of the three groups and the pandemic. (C1 – Calculus 1 course, C2 – Calculus 2 course)

- **The "2018 group" – pre-Covid**

The class of 2018 consists of 120 students with an average admission score of 458.62 points and a standard deviation of 23.22 points. Since nearly all students studied mathematics at an advanced level in high school and furthermore, many of them took advanced A-levels, thus they had no problem in meeting the 40% minimum on the entrance test (Test 0). Only 12 students failed to achieve the required 25 points.

- **The "2020 group" – Covid**

The class of 2020 consists of 134 students with an average admission score of 445.96 points and a standard deviation of 30.20 points. This class received online education from March to May in their final year of high school, and this continued in their first year of university in remote education. Therefore, the pandemic had very minor effect on their high-school backgrounds.

This year, students took the mathematics entrance test (Test 0) online in their homes using the Moodle system of the University. The results were unlikely too good. More than 50% of students got excellent results (above 85%). Only 4 students scored below 40%, one of whom achieved 100% on the make-up test, also online. The results of this assessment cannot be considered relevant to our study.

- **The "2022 group" – post-Covid**

The class of 2022 consists of 173 students with an average admission score of 454.71 points and a standard deviation of 26.78 points. They started university in 2022 in attendance education and received online education in the last two years of high school. These two years are when Hungarian students can choose the two subjects that are relevant for their further studies and study them in higher contact hours in advanced level.

In 2022, the entrance maths test (Test 0) was very poor. Out of 173 students, 32 students failed to score at least 25 points on the in-person test. For this group, the Calculus 1 results (see Fig. 3.) showed significant decline, so for the Calculus 2 course an intervention was applied.

3 METHODOLOGY

The failure of a significant proportion of our students to acquire a solid grounding in mathematics during the pandemic in public education was already apparent from the results of the input measures. This was confirmed by both midterm tests written in the first semester (see Fig. 3) and then by the exam results. The failure rate in Calculus 1 test was significantly higher than in previous years, while expectations of students remained unchanged, with a slight decrease. At the same time, the system of university examinations allows you to retake the midterm-tests more than once. In addition, Calculus 2 can be taken by students who have passed all their midterm tests with at least 40% marks, without the need to pass the exam in the exam period.

Since 2016, the Edubase online learning platform serves the basis of our education (www.edubase.net 2024), (Szilagyi, 2020), (Berezvai, 2019). In EduBase students are assigned weekly homework, interactive exercises and also have the option to engage in additional exercises. With parameterized exercises, there is a technically infinite number of exercises available for practising the different topics throughout the semesters.

Despite the availability of much material to help students catch up individually, including the interactive online practice areas with step-by-step guides, students found it difficult to cope. Catching up and keeping up with current material at the same time proved to be too much of a burden. Where individual difficulties varied, it was practical to use online material supplemented by personal consultations, as there was no way to involve more teachers.

The key solution of the intervention was to reinforce the learning, the understanding and mastering of new (previously unfamiliar) topics. For this, a 90-minute extra course per week was scheduled and offered parallel to the regular Calculus 2 course, which was called as Calculus2+. The Calculus 1 and 2 courses consists of 2x90 minutes of lectures a week and a 90-minute-long practical lesson of problem-solving.

For the Calculus2+ course, we have developed a material that helps to illustrate the theory taught in the lecture through example solutions. In these classes, all students of the class participated together, the lecturer showed examples related to the weekly curriculum and explained the methodology of problem solving. Thus, the students arrived at the problem-solving practical lessons much better prepared, with more opportunity to work independently or in pairs. Group work and pair work help to increase learning efficiency, help students overcome anxiety, motivate them to talk, increase their confidence and develop their social skills. Students can discuss ideas, share knowledge and learn from each other. This can lead to a deeper understanding of the subject matter (McDowel, 2003) (Williams, 2000).

Previously, we had to use face-to-face, frontal teaching on these occasions, because the large amount of material only allowed the instructor to present the basic types of problems that were to be solved each week. The students were then rather passive participants in the lessons. With the new extra Calculus2+ lessons, the additional 90 minutes served as a slower-paced presentation of the similar problems.

4 RESULTS

In the following the statistical summary of the Test results are presented for Calculus 1 and Calculus 2 courses for the three investigated classes (see Table 3. and Fig. 3). The number of students in each course shows that, although there is a high failure rate on the first attempts, only a small number of students dropped out and failed to continue in Calculus 2 due to the many remediation opportunities. Thus, improvement in results is attributed to the outcome of the intervention, not the filtering in Calculus 1.

In Figure 3, the first two rows show the results of the first and second tests in Calculus 1, while the last two rows show the results of the first and second tests in Calculus 2. The results clearly show, that after the well-observable decline of performance in 2022 for Calculus 1 course, a significant improvement of results were detected as result of the intervention. This not only means that the mean value of the tests are improved, but also the standard deviation decreased compared to the Calculus 1 results. This means that the extra Calculus2+ course also had beneficial effects on the heterogeneity of the group.

Table 3. Statistics of the Calculus 1 and Calculus 2 results for all investigated classes

			2018	**2020**	**2022**
Calculus 1	Number of students		120	181	191
	Test 1	Average and SD	64.14 ± 14.17	47.08 ± 17.29	41.89 ± 24.15
		Failed	4.16%	30.93%	40.31%

		Good result	30%	11.04%	10.47%
	Test 2	Average and SD	61.61±17.43	55.02±18.56	25.07±21.03
		Failed	5.83%	13.25%	69.10%
		Good result	21.66%	23.21%	2.09%
Calculus 2	Number of students		112	161	161
	Test 1	Average and SD	59.76±16.72	58.22±15.61	65.27±16.38
		Failed	12.5%	15.61%	9.31%
		Good result	21.42%	23.61%	41.61%
	Test 2	Average and SD	69.68±19.08	45.04±15.33	65.33±20.24
		Failed	4.46%	31.67%	8.69%
		Good result	48.21%	3.1%	47.82%

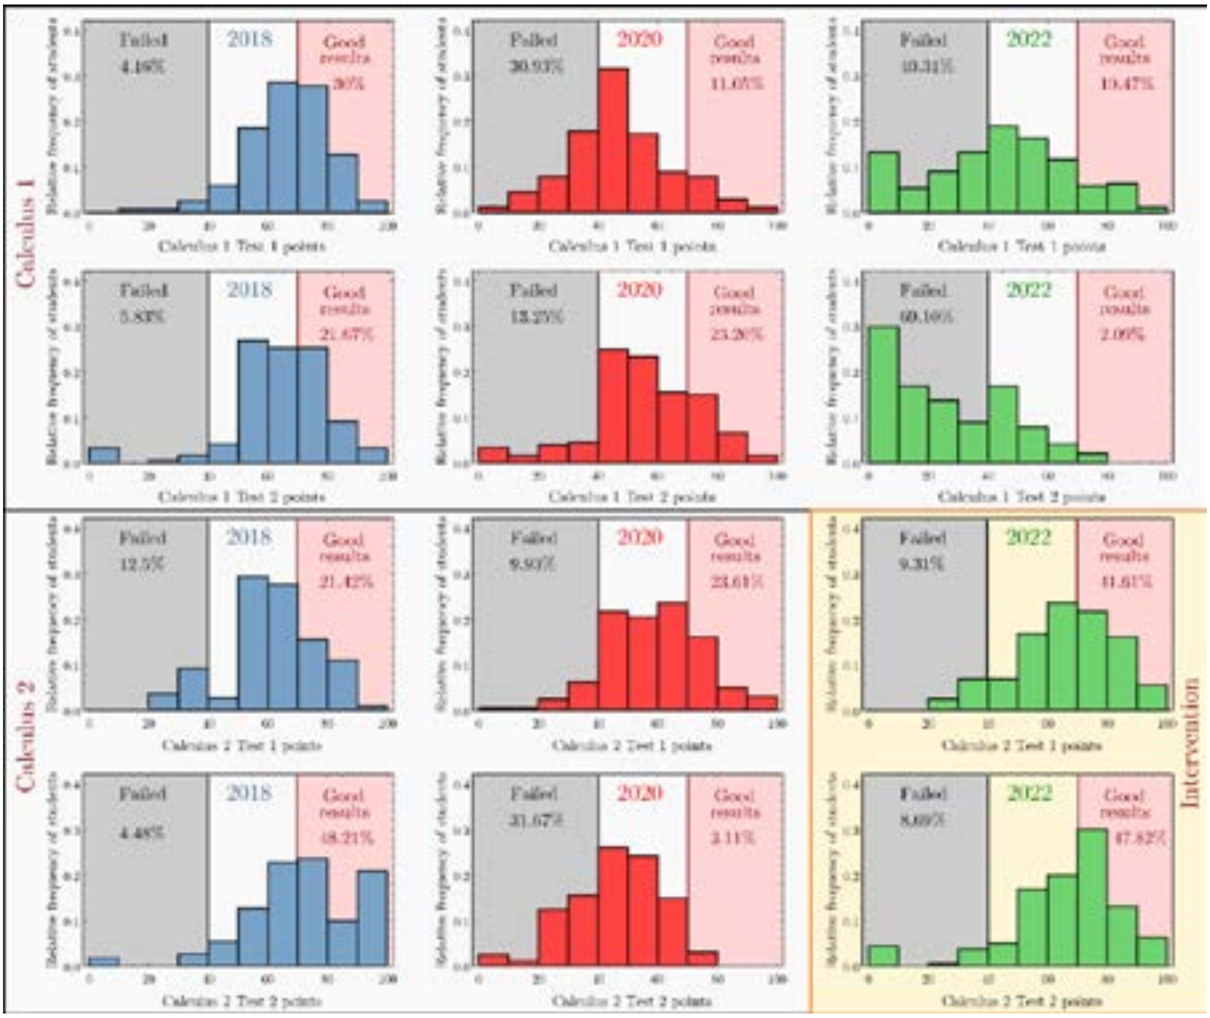

Fig. 3. Relative frequency of Test 1 and 2 in the Calculus 1 and 2 subjects.

5 CONCLUSION

The results illustrate the effectiveness of our intervention programme. It is natural that by increasing the time spent on lectures and learning, our students will achieve better results. However, what makes our results worth mentioning is to show that such a simple intervention can make a difference. Nowadays, frontal teaching is almost a buzzword, even though in many higher education institutions there is no way to provide assistance in small courses, there are not enough instructors and facilities to provide additional small classes. In a university where there are thousands of students per year to be taught effectively, economic issues become an important aspect to be considered. A good combination of large numbers of students and small numbers of students with the opportunity for greater interactivity can provide an economically optimal solution.

Our experience also highlights the importance of the role of the teacher in education. Mathematics is not easy to learn independently, especially for those who have difficulties. The importance of teacher competence may sound trivial, but it was the pandemic that showed that when students were not allowed to go to school, teachers could not help as much, despite the online learning platforms and available digital sources. We can say that students must first be prepared to be able to learn independently. The programme we have developed helps them to do that.

By increasing the number of contact hours, students were able to make more effective use of the interactive, online practice materials, and therefore achieved better results. This form of support was more effective than if we had given our students more material to work on independently.

In the future, we see it as an important task to show students the benefits of increased contact hours at the beginning of their programmes. In the future we aim to extend this method by proposing an extra course immediately after the entrance test based on their measured knowledge, and therefore trying to reduce the trauma of initial failure.*

ACKNOWLEDGEMENTS

The research received funding from the MTA-ELTE Theory of Learning Mathematics Research Group. The project supported by the Doctoral Excellence Fellowship Programme (DCEP) is funded by the National Research Development and Innovation Fund of the Ministry of Culture and Innovation and the Budapest University of Technology and Economics, under a grant agreement with the National Research, Development and Innovation Office.

ABSTRACT

Active learning is commonly defined as an instructional approach that actively engages students in the learning process, aiming to foster improved and deeper comprehension. However, a previous study comparing mechanics labs offered students a choice between probe-ware (MBL) labs [FMCE normalised gain: 48%] and experimental problem-solving labs [18% gain]. Although both options were considered to employ active learning, the substantial difference in gains was noteworthy and contradicted existing literature conclusions. Consequently, a follow-up study was conducted. Analysis of video recordings from the labs revealed that students in the problem-solving labs exhibited interactive learning characteristics according to the ICAP framework, but made limited use of physical concepts in their modeling of phenomena. Nonetheless, they successfully achieved the intended goals of developing skills in experiment planning and mathematical modeling of physical systems in the experimental problem-solving labs. This study suggests the necessity to move beyond surface interpretations of "active learning" and delve into the specific ways in which students are actively engaged in a learning environment. Furthermore, it highlights the importance of a critical and thorough discussion of active learning methodologies.

1 INTRODUCTION

Active learning is commonly defined as an educational approach that involves students actively participating in the learning process, with the aim of achieving enhanced comprehension and retention. However, an earlier investigation (Bernhard 2010, 2011) highlighted an intriguing inconsistency: despite a laboratory course being ostensibly structured around active learning principles, students involved in it performed poorly on assessments measuring their grasp of mechanics concepts. This discrepancy prompted a deeper exploration into students' learning behaviors and activities within the laboratory setting. To gain insight, video-recordings and interaction analyses were conducted. This paper presents some of the key findings derived from this study.

The paper is organised as follows: Section 2 describes the background and theoretical framework of the study, i.e. active learning and variation theory, as well as providing a brief review of the results from the earlier quantitative study, and the research question; Section 3 presents briefly the qualitative methodology used; Section 4 presents the findings of the current study; finally, Section 5 presents an analysis, discussion and conclusion.

2 BACKGROUND

2.1 Active learning

Active learning is commonly believed to foster profound comprehension, deeper engagement with fundamental concepts, and enhanced ability to apply knowledge in novel contexts (e.g., Crawley et al. 2014; Freeman et al. 2014; Prince 2004). Hence, active learning, as a pedagogical approach have garnered significant scholarly focus, is notably recognized as one of the CDIO standards (Crawley et al. 2014) and has been extensively examined in special issues of the European Journal of Engineering Education (De Graaff and Christensen 2004; Lima, Andersson, and Saalman 2017)

However, Despite the widespread interest in active learning, its definition often remains nebulous. Surprisingly, numerous studies fail to provide a clear definition, instead relying on an intuitive, albeit somewhat unsatisfactory, understanding of the concept. The most prevalent definition, drawn from the seminal work of Bonwell and Eison (1991, iii), is: “instructional activities involving students in doing things and thinking about what they are doing”. Similarly, Prince (2004) proposes that “active learning requires students to do meaningful learning activities and think about what they are doing”. It's noteworthy that Freeman et al. (2014), in their meta-analysis, specifically focused only on in-class activities while excluding laboratory exercises. Conversely, Trumper (2003) concentrates on laboratory settings and asserts that successful activities are characterized by “that they are learner-centered. They induce students to become active participants in a scientific process in which they explore the physical world, analyze the data [and] draw conclusions”.

Chi (2009) presents a more precise definition and a more nuanced understanding through the Interactive-Constructive-Active-Passive (ICAP) framework, which categorizes overt learning activities into passive, active, constructive, and interactive domains. Active activities entail physical engagement, while constructive activities involve producing output that extends beyond provided materials. Interactive activities involve collaboration between two or more students, fostering substantive dialogue that incorporates and builds upon each other's contributions. Drawing from literature, Chi suggests that student learning is more effective in interactive activities compared to constructive ones, which are superior to merely active activities, and these, in turn, surpass simple passive learning approaches. In the context of engineering, Menekse et al. (2013) claim to have confirmed Chi's hypothesis for students in a material science course. Moreover, Chi and Boucher (2023, 94) recently argued that evidence demonstrate ICAP-framework "provide [a] heuristics that can help [teachers] differentiate and distinguish between different types of active learning activities in terms of their *effectiveness for improving learning*" (my italics).

2.2 Object of learning

While the object of learning is not foregrounded in the ICAP-framework it is important in Marton's variation theory. Marton (2015, 27, my italics) related learning to what students could *possibly* experience in a particular classroom situation, stating that in a learning situation "the critical aspects that it is *possible* [for a student] to discern … make up the *enacted* object of learning" (cf. Marton, Runesson, and Tsui 2004). Another important distinction in a learning situation is the difference between the *intended* object of learning (the knowledge, values, and skills the teacher or curriculum designer wants the students to learn) and the *lived* object of learning (the critical aspects that *could be discerned* and that the student *actually discerns*, i.e. what the student learns in the end).

2.3 Two supposedly active learning labs

In a previous study conducted by Bernhard (2010, 2011), significant variations in learning outcomes were observed among students enrolled in two distinct laboratory options within the *same* mechanics course. A brief summary of these findings is provided in this section. Engineering students, as part of an introductory physics curriculum, were given the choice between two lab-course options. The conventional labs, known as experimental problem-solving (EPS) labs, were offered as the standard choice. Alternatively, students could opt for labs employing probe-ware technology. Participation in the probe-ware labs was voluntary. Due to legal constraints, students couldn't be randomly assigned to groups, as the EPS labs were designated as the official lab-course according to curriculum documents.

The general organization of the course is outlined in Table 1. All students attended the same 20-hour mechanics lectures and engaged in comparable 12-hour problem-solving sessions with groups of approximately 30 students, facilitated by a doctoral student. The sole difference between the options is the lab-sections that comprised four 4-hour lab sessions, totaling 16 hours of lab work in both groups.

To assess students' comprehension of mechanics in the previous study (Bernhard 2010, 2011), a Swedish version of the Force and Motion Conceptual Evaluation (FMCE) (Thornton and Sokoloff 1998) was administered as both a pre-test and a post-test. The FMCE is a widely utilized and established tool designed to explore students' understanding of one-dimensional kinematics and dynamics through verbal and graphical representations. Table 1 also provides the average scores for both pre- and post-tests, along with the normalized gain and effect size. Normalized gain (Hake 1997) is calculated as g = Actual gain/[Maximum possible gain], where the actual gain represents the disparity between group averages in the pre- and post-tests.

Pre-course conceptual understanding of mechanics, as depicted in Table 1, showed minimal and statistically insignificant differences (t = 0.58, p = 0.36) between the groups and no other overt differences were observed. While the disparities in pre-test scores were negligible, the discrepancies in post-test outcomes are noteworthy. Students engaged in probe-ware labs exhibited a substantial normalized gain of 48%, contrasting sharply with the 18% gain observed in students attending EPS labs – a figure akin to that achieved by traditional labs (Hake 1997). This difference is statistically significant (t = 2.93, p = 0.0003).

Table 1. Organization of the mechanics part of the physics course, and results from the pre- and post-tests using the FMCE (means with standard deviations in parentheses), normalized gains, and calculated effect size from the results in the earlier study (Bernhard 2010).

</table>

2.4 Research question

The good conceptual gains for the probe-ware labs in the previous study were somewhat expected as they were a sub-set of previously implemented “conceptual labs” designed to enhance students’ conceptual understanding of mechanics (Bernhard 2010). However, the EPS-labs were supposedly using a form of “active learning” and despite this did not achieve good results on the Force and Motion Conceptual Evaluation (FMCE) (Thornton and Sokoloff 1998). This, seemingly, contradicts the findings in the literature that “active learning” works and would improve learning.

This led to the following research questions:

- How did the students act and interact in the learning environment of the EPS-labs and how did they approach the object of learning?
- Would a closer investigation of students’ interactions confirm or reject the hypothesis that the EPS-labs could be seen as examples of active learning, and how would the labs be classified according to the ICAP framework (Chi 2009)?
- Could students’ achievements on FMCE-test be understood from students’ observed interactions in the EPS-labs?

It was hoped that answers to these three main questions would provide the basis for additional insights into learning in labs and the general concept of active learning.

3 METHODOLOGY

The analysis of learning within the EPS-labs unfolded through several stages. As detailed in section 2.3, students' conceptual understanding was assessed in a previous study via pre- and post-tests employing the FMCE test (Thornton and Sokoloff 1998). The findings of this assessment are elaborated upon in Bernhard

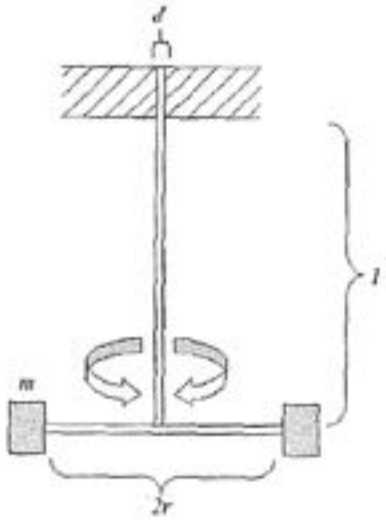
(2010, 2011) and succinctly outlined in Table 1. Moreover, students' activities during certain sessions of the EPS-labs were captured using digital camcorders, yielding 16 hours of video footage. Subsequently, this data was utilized to identify typical interactional patterns and discern evidence supporting or challenging hypotheses concerning the universality of these patterns (Jordan and Henderson 1995) The focus was particularly on observing students' collaborative work dynamics, their actions, relevance, and orientation towards the learning objectives, while also aligning with the ICAP-framework (Chi 2009) for pattern description. After repeated review, select episodes containing noteworthy and comparable activities relevant to the research inquiries emerged. These segments were transcribed to facilitate a meticulous examination of interactional patterns. The transcriptions adhere to the standard conventions of conversation analysis (ten Have 2007), and those included in this paper were ultimately translated from Swedish to English for accessibility.

The study was conducted under the ethical guidelines in place at Linköping University in accordance with Swedish laws. Informed consent forms were signed by each research participant. In this paper, participants have been given pseudonyms to protect their anonymity.

4 RESULTS

Analysis of the video recordings showed that the students’ actions were framed by the task at hand and encounters with the instructions, the technology and experimental setup, the teacher, and other students. Thus, in terms of Chi’s (2009) ICAP framework students’ activities in both sets of labs could be seen as interactive, which further implies that they were also active and constructive. In addition to this, the criteria for active learning proposed by Bonwell and Eison (1991) as well as by Prince (2004) were fulfilled. Yet although the labs fulfilled most of the theoretical criteria to qualify as active learning environments, the way that the students actually worked on their tasks was much more complex and differentiated than might at first be assumed. Some of these complexities will be explored below.

The aim of an EPS-lab is to “highlight what is essential for creating good physics; imagination and initiative to develop hypotheses, use of experimental techniques to test hypotheses, and the ability to find concepts that provide simple descriptions” (course description, author’s translation). The EPS-labs were designed after a proposal by Richards (1971)



a.

$$T = C_1 \frac{1}{d^2}\sqrt{\frac{l(mr^2 + C_2)}{G}}, \text{ where}$$

T = period time,
C_1 = experimental constant,
C_2 = experimental constant (moment of inertia of the rod),
G = shear modulus,
d = diameter of the wire,
l = length of the wire,
m = mass of the additional weights, and
r = distance of the masses from center.

b.

Fig. 1. a) The torsion pendulum setup (drawing from student lab report). b) A mathematical model for the oscillations of this torsion pendulum.

One of the EPS-labs, exemplified by the torsion pendulum lab illustrated in Figure 1a, serves as a prime example. Alongside the torsion pendulum experiment, five additional EPS-labs were conducted, including tasks such as analyzing a sinking boat and observing an oscillating beam. Students collaborated in small groups of 2–3 individuals, tasked with completing two out of the six available labs, each lab session spanning eight hours (4 + 4 hours). Due to space constraints in this paper, the focus will solely be on analyzing and discussing the students' activities within this lab setting. In this specific lab, students were instructed to identify the pertinent physical parameters influencing the oscillation period of the torsion pendulum. They were further tasked with constructing and experimentally validating a mathematical model for predicting the oscillation period, with no additional guidelines provided.

The students had access to two lab sessions, each spanning four hours, with one week between the sessions. In tackling the task of devising a suitable mathematical model, students were encouraged to employ a combination of empirical measurements of the physical system and dimensional analysis.

Fig. 2. Photograph taken during the torsion pendulum lab, depicting students observing the oscillations of the pendulum and measuring its period.

In the initial stages of the EPS-labs, discussions primarily revolved around determining the significance of variables, planning experiments, and devising measurement techniques. Excerpt 1 (Due to space constraints, only one excerpt from the transcripts is provided) exemplifies a conversation between Adam and Bengt, occurring approximately 45 minutes into the first session of the first lab, regarding the measurement of the period time for the torsion pendulum.

Excerpt 1

1.	Bengt	thus we measure (.) we start here
2.	Adam	yes
3.	Bengt	it goes out one time ((swings the rod with masses by holding it in his hand a full period))
4.		(2 s) ((Bengt swings the rod a full period a second time))
5.	Bengt	two
6.		(2 s) ((Bengt swings the rod a full period a third time))
7.	Bengt	three
8.		(2 s) ((Bengt swings the rod a full period a fourth time))
9.	Bengt	four
10.		(2 s) ((Bengt swings the rod a full period a fifth time))
11.	Bengt	five
12.	Bengt	if we should take (.) if we say before it slows down markedly (.) if we take like three swings or something (.) two swings (.) we can do it a few times and take an average

From this excerpt, it may appear as if the conversation lacked interactivity, with Adam seemingly passive, as evidenced by his single-word contribution, "yes." However, approximately half a minute later, Adam takes a more active role by suggesting a method for measuring time, proposing that they record the time whenever the pendulum halts at its maximum excursion. Following some deliberation, they ultimately adopt Adam's suggestion. However, they encounter difficulty implementing this method due to limitations with the available stopwatch. Instead of abandoning their approach, Bengt recalls that his old mobile phone has a feature capable of recording multiple times. Subsequently, they acquire a similar phone from another student in a different lab group, enabling them to proceed with their chosen method.

In their first series of measurements the position r of the masses on the rod was varied with other variables constant. In the second series the length l of the wire was varied with other variables constant. In the third series the diameter of the wire vas varied. In their initial series of measurements, the position r of the masses on the rod was altered while keeping other variables constant. In the subsequent series, the length l of the wire was varied under constant conditions. Finally, in the third series, the diameter of the wire was varied while other variables remained unchanged.

Much of the second session was dedicated to analyzing the data collected during the first session and experimenting with various hypotheses to develop a model for the period time of the torsion pendulum. Adam expressed concerns regarding kinetic energy and sought to incorporate it into the relationship, but struggled to discern how to do so. With a hint from the instructor and the aid of dimension analysis, the students concluded that the shear modulus must be integrated into their model. Towards the conclusion of the second session, the students had formulated the mathematical model depicted in Figure 1b. However, their model overlooked C_2 (representing the moment of inertia of the rod). Even when prompted by the instructor, the students initially failed to recognize that omitting C_2 implied $T = 0$ when no masses were attached to the rod, contradicting observable phenomena. Through Socratic dialogue, the students eventually acknowledged the necessity of including C_2 and finalized the model depicted in Figure 1b. Some groups, where the instructor overlooked this issue during the session, submitted reports with models lacking C_2.

5 ANALYSIS, DISCUSSION AND CONCLUSION

The primary *intended object of learning* in the EPS-labs were aimed at nurturing students' skills in experiment planning and physical system modeling. Conversely, in the probe-ware labs detailed in Table 1, the focus shifted towards fostering students' conceptual understanding. Analysis of the study's data reveals that the EPS-labs effectively achieved their intended goals of experiment planning and mathematical modeling of physical systems. Consequently, students demonstrated *enacted* and *lived object of learning* aligned closely with the *intended object of learning*.

Looking at the students' actions in line with Chi's (2009) ICAP framework, it is apparent that the students in the EPS-labs were steered to construct experiments and mathematical models. The content of students' interactions with each other clearly reflected these differences.

During the laboratory sessions, students exhibited misconceptions regarding fundamental physical concepts. The probe-ware labs were intentionally structured to address and challenge such misconceptions while fostering conceptual under-standing (Bernhard 2010). Conversely, in the EPS-labs, these misconceptions were not explicitly addressed, as indicated by the results in Table 1. Consequently, it appears that students could potentially develop a satisfactory mathematical model of a physical system despite lacking a robust understanding of the underlying concepts. However, upon analyzing the students' performance in the EPS-labs, it becomes evident that deficient conceptual understanding sometimes impeded their modeling process. It suggests that with a more thorough conceptual grasp, students might have formulated a suitable model more efficiently and attained a deeper comprehension.

Variation (Marton 2015) was significant in both the EPS-labs and the probe-ware labs. However, in the probe-ware labs, variation was intentionally integrated into the task structure to facilitate students' comprehension of concepts (Bernhard 2010). Conversely, in the EPS-labs, students themselves introduced variation through their experimental planning, aiding them in identifying pertinent physical parameters. Thus, in both scenarios, variation served to heighten students' awareness of key aspects related to the intended object of learning, aligning with variation theory.

Lastly, it is crucial to underscore the significant role played by the instructors. In both sets of labs it was observed that they assisted students in recognizing and emphasizing important aspects that might have otherwise been overlooked. Moreover, through Socratic dialogues, the instructors scaffolded students' reasoning, facilitating their understanding and learning process.

While the probe-ware labs, as indicated by the data in table 1, exhibited clear superiority in fostering conceptual understanding, it would be erroneous to conclude that these labs were universally superior to the EPS-labs in all aspects. The effectiveness of each type of lab depends greatly on the intended learning objectives. Engineering education should aim to cultivate not only conceptual understanding but also proficiency in experimental planning and mathematical modeling. Thus, when designing lab courses, deliberate decisions must be made regarding the desired outcomes and the activities in which students should engage.

Indeed, Streveler and Menekse (2017) advocate for a more nuanced approach to active learning, urging the engineering education community to precisely articulate the active learning strategies they employ to inform wiser instructional design. Furthermore, Bernstein (2018) contends, in his paper titled "Does active learning work? A good question, but not the right one," that the focus should shift from merely assessing whether active learning works to identifying “which active learning methods, delivered by which teachers, in which contexts, lead to educationally significant, long-term benefits for which students, and are the benefits meaningfully superior to those of traditional teaching methods?” (p. 293).

The conclusions drawn from the case presented in this study align with the perspectives of Streveler and Menekse (2017) and Bernstein (2018), emphasizing the necessity of moving beyond superficial understandings of "active learning." When designing learning environments, it's essential to focus not only on prescribed methods of active learning found in literature but also on how students are genuinely learning and what specific learning objectives they are expected to achieve.

Therefore, as the title of this paper suggests, a critical and nuanced discussion and examination of "active learning" is imperative.

ABSTRACT

This study investigates how students reason about progression in an engineering programme. Here progression refers to the idea of setting up the educational programme so that learning activities build on previous ones and prepare for future ones, allowing students to gradually develop their competence and ultimately achieve the programme goals. It is not trivial to build progression into education programmes, and in particular, there may be differences between how the educators intended the curriculum to work and students' actual experiences. This study is based on 60 reflections on progression, written by engineering students. They were analysed thematically to identify the aspects viewed as important to create a good progression in the programme. The following categories were identified: teaching and assessment, repetition, making clear connections between prior and continuing courses, realistic progression, personal factors and alternative routes to progression.

[1] *C. Björn*
cabjorn@kth.se

These findings give us better insight into the students' perspectives on requirements for appropriately creating progression in education programmes. After all, the students are the ones who experience the curriculum design and teaching in practice.

1 INTRODUCTION

Progression is an important concept in education, defined by Säfström as "*successively increasing requirements, which are possible to achieve with the help of previously expected learning*" (2017, p. 66). In practice, it refers to how courses within a programme can build on each other to support students in gradually developing their competence during their education.

As students are expected to develop in several areas during their degree, a planned built-in progression through their programme is crucial (Canrinus et al. 2017; Hadfield et al. 2011). This requires good connections between courses which necessitates productive communication and collaboration between the educational leadership and the teachers (Canrinus et al. 2017). However, this is not trivial to achieve. There is often a long wish list of what the students should be able to do upon graduation, and many teaching staff involved may have different ideas about the focus and purpose of the education. Course instructors often have much autonomy and freedom in designing and teaching their courses. In addition, the students enter with differences in knowledge, skills, interests, and motivation, which affects how they can tackle their education.

When discussing progression, it is important to make the distinction between the planned progression within the programme, i.e., *the intended curriculum*, and the students' actual experiences, i.e. *the attained curriculum* (van den Akker 2003). In this paper, we will investigate which aspects students see as important for creating progression within their education based on their experience. While students are naturally less familiar with theoretical aspects of course and curriculum design, they are the ones who have a first-person insight into what it means to attend the programme. Students are therefore important informants when it comes to understanding what is required to create a well-built progression in a programme. To increase our understanding, we are guided by the following research questions:

1. *Which factors do engineering students find important to ensure a well-designed built-in progression?*
2. *How do these factors promote and/or prohibit the progression?*

We hope that this study will be helpful for both teachers in course planning and for educational leaders who have an overview of and responsibility for planning clear progression throughout the programme.

2 BACKGROUND

While it is easy to agree upon the importance of progression in educational programmes, Säfström (2017) points out that it often is unclear how the progression is planned out and which aspects of learning the progression refers to. In a previous study, Björn et al. (2023) found several uses of progression in the academic literature and proposed a disambiguation of the term. In this paper, we focus on one of the meanings, namely the built-in progression in the educational programme.

Progression is often seen as a deepening of students' knowledge and skills, but Harden (2007) conceptualises this further. He presents a model consisting of four dimensions: breadth, difficulty, application, and skill. *Breadth* focuses on expanding the students' area of competence by learning about new subjects or areas in which previous competencies can be useful. It is therefore different from *difficulty* (or *depth*) in which the student immerses themself in a narrower area. *Application* concerns students' ability to implement, or apply, their theoretical competencies in practice while *skill* concerns the student's ability to use their competencies effectively. Skill can, for example, regard students' ability to complete tasks faster, with fewer errors, or with less supervision.

To build progression effectively into educational programmes, it is important to understand in which areas and how it needs to take place as well as understand what promotes and hinders it. These are topics on which students could be important informants. Speight et al. (2020) emphasise the value of listening to students, who often are well-informed and able to bring new perspectives to the table. Although taking student perspectives is not uncommon in qualitative research, a small number of studies have taken student involvement further by inviting students to participate in curriculum design (Bovill, Morss, & Bulley 2009; Tuhkala, Ekonoja, & Hämäläinen 2021).

3 METHODOLOGY

3.1 Context

The context of this study is the computer science and engineering programme at KTH Royal Institute of Technology, a five-year programme integrating a BSc and an MSc. Since 2010, the BSc has contained a mandatory so-called *Programme-Integrating Course* (PIC) running through all three years. The PIC aims to create a common thread through the programme by covering important topics without an obvious place in the programme and allowing the students to reflect (Kann 2019).

In the PIC, students are divided into groups (of about 16), mixing the students from different years, and assigned a mentor who is involved in the programme. In addition to a few year-specific activities, the course consists of four seminars per year. Each seminar has a specific theme with an associated reading and reflection assignment (of 500-1000 words) that is submitted and subject to peer feedback before the seminar.

3.2 Data selection and analysis

The data in this study was generated in the programme integrating course. It consists of reflections written by students for a seminar in 2023 on the topic of prior knowledge and progression. As preparation, the students read a text about the planned progression in the program written by a course teacher (the third author). The text addressed, among other topics, why certain courses are required before others and presented statistics on exam results for students who passed the prerequisite course compared to those who did not. In addition to this text, the students also read parts of an article by Valstar et al. (2019) which dealt with the influence of prior knowledge on study results within a computer science course. In their texts, the students then reflected on how courses are or are not connected, the importance of prior knowledge and how deficiencies in these can be handled as well as who or who is responsible for this. They also reflected on how the programme is or is not designed to help them develop their programming skills.

In total 349 students gave consent for us to analyse their anonymised reflections.

To be able to analyse the reflections in-depth, we limited ourselves to 20 randomly selected reflections per grade (years 1–3). We started by analysing 10 reflections from each grade and noticed that we had reached saturation when analysing the remaining reflections.

The students' reflections were then used as a basis for answering the research question through a thematic analysis guided by Braun and Clarke (2006). The first author began the analysis by reading through the reflections and conducting a first coding. The codes were then discussed, after which some of them were merged, some were removed, and some new areas were noted for a more careful exploration during the next read-through. Coding then continued while reviewing potential categories to group the codes into. This continued for several iterations before arriving at and naming the categories presented in the results below.

4 IMPORTANT FACTORS FOR CREATING PROGRESSION WITHIN THE PROGRAMME

In this section, we present the categories most relevant for answering the research questions, also illustrating them with quotes from the reflections.

4.1 Teaching and assessment

Some students comment that the knowledge and skills on which the progression is based must not only be taught but also assessed. Some mention instances when they did not learn or quickly forgot knowledge and skills that later became prerequisites for another course because these were never assessed or were not assessed to the level that the continuation course required. They also find it difficult to use the prior knowledge in other or extended contexts if they do not know it well enough, as this student points out:

> *"Of course, I have not had A's in all courses, and getting a pass in a course is not necessarily a receipt that one possesses the knowledge well enough to apply it in another context."*

4.2 Repetition

Students point out that it is very easy to forget between courses, and it is difficult to build on forgotten prior knowledge. They emphasise that their programme is both broad and intense, which means that there is much to remember from course to course. This is even more difficult when there is a long pause between continuation courses and the courses where the prior knowledge was introduced. The students therefore stress the importance of repeating, reminding, and refreshing. This student recommends as normal practice in the courses to make room for catching up and linking back to previous knowledge:

> *"In a well-planned course, there should be some leeway to deal with this kind of problem [students struggling to remember previous content] without affecting the rest of the course."*

Many students argue that it is especially their responsibility to refresh in cases where they did not study well enough in the prerequisite course but still passed. However, many also believe that it is impossible to remember everything and that universities also have a responsibility to activate the previous knowledge, or at least make clear what the prerequisites for the course are so that they can study on their own. Several students also asked for material to rehearse prior knowledge, although some commented that it might be too much to ask. However, many, including the student below, emphasise that they much prefer to know what knowledge and skills are used in the continuation course, instead of just a list of the formal prerequisite courses:

> *"At the university, you have a big responsibility yourself to make sure that you have made sufficient preparations for a course, especially if you take them outside of a programme. But in order for it to work, it must be very clear what prior knowledge is actually required, so it is an important task for teachers."*

4.3 Making clear connections

It is easier to see relationships between different elements of the educational programme when they are well established, which is true for those who have a more complete picture of the situation (like the teachers). This is not the case, however, for students when they are in the process of learning, and they therefore point out that it is important that the teacher helps them make the connection between the prior knowledge and skills and the new material. Some factors also *hinder* the students from seeing the connections between course content in different courses. For example, a student comments:

> *"KTH should somehow try to standardize the notation used in mathematics at KTH. Maybe it's just me who finds it complicated when different courses write the same thing but in different ways, which makes it a little harder to recognize earlier material."*

In this case, the student struggled connecting knowledge and skills between courses, because the student did not recognize that they dealt with the same areas.

Apart from teachers helping students see the connection between different courses, students also commented that the prerequisite knowledge must be taught. The student below points out that this requires communication between the teachers:

> *"Then I also believe that the teachers between the different courses have the responsibility to communicate with each other about how their courses are structured and what is in focus, which can lead to a reduction in incorrect assumptions regarding what prior knowledge the students have from the previous courses."*

Some students also point out that in some cases there is no strong connection between the official prior knowledge and the continuation course because the latter does not use the prior knowledge in a way that there is a progression or that it is necessary to complete the task. The student below comments that they think this was the case with the course in sustainable development, which is a prerequisite course for their bachelor's thesis.

> *"I doubt that you fail to reason about sustainability [in the thesis] without a pass in that course, quite honestly."*

4.4 Realistic progression

It is important that the progression is well-planned and clear on paper, but it must also be feasible. Students must be given time to learn. The duration of the programme is only five years, which limits the amount of content that the courses can be expected to cover. Some students particularly point out how easy it is to forget between courses, which means that there must be time to both repeat and connect prior knowledge with the new material. This is highlighted, among other things, by the student below.

> *"The mathematics I study right now feels very distant, and even though I feel that I understood a lot of the material during the time I took the course, I am not at all sure that the same applies at the moment. The whole thing is made worse by putting the math skills into a completely new context."*

In addition to having time to learn, several students comment that it also is important to take into account *where they are when they start* a new progression chain. Among other things, several students bring up programming as an example of this because it is an area in which they officially do not need any prerequisites when starting their education. Some students comment that they do not think this is true and that their programming education started at too high a level or at too high a pace. However, other students used the programming courses as an example of when the university has taken their previous knowledge into account, such as the student below:

> *"[The] programme [is] designed in such a way as to take into account the fact that all students who start their studies have different academic backgrounds. Already at the start of semester 1, you had a choice to make regarding which programming group you preferred."*

4.5 Personal factors

Students also bring up different personal factors that can affect how they progress in their studies. These can be anything from interest and motivation to a sense of belonging and mental health. Although it is desirable that the students have an interest in the course content and motivation to learn, this cannot be taken for granted and can be a reflection of the teaching. Struggles in these areas can be detrimental and they can affect the students' opportunity to learn and the quality of their learning. The student below comments that their interest in a subject can determine how well they learn and remember:

> *"While I may like the information presented in the course if I don't have an interest in and feel an intrigue for the subject in question, then I will not try to get into it and understand it on a fundamental level. I will learn well enough that I manage to pass the exam or assignment, but then I will forget about it; you practice short-term memory, but not long-term memory."*

Students point out that their life outside of college also can affect their learning since they might be busy with other things. For example, some students may need to work alongside their studies or spend time on other aspects of life. Students may also suffer from physical and/or mental health issues. The student below shares an example where their studies have been affected by private life.

"During this semester, I have unfortunately had difficulties in dealing with my college work. I have had a very turbulent period in my life that occupied most of my thinking and hence my ability to study."

4.6 Alternative routes

Several students remind us that there are alternative paths for progression in the programme. As mentioned under realistic progression, students can enter the programme with very different prior knowledge. This can be seen as the point of origin of the progression and it is from here the student begins their journey through the programme. However, this is only the first stop when it comes to alternative routes. Some students comment that later courses also could be affected by prior knowledge that they have acquired outside college. This is highlighted by the student below who believes that it would be good if they could take into account all the knowledge and skills the students possess when choosing a course, not just the knowledge and skills taught in previous courses at KTH.

"On the other hand, I think that the requirements can be a bit firm sometimes. Perhaps you should let students decide for themselves whether they want to take a course, for example, if you have learned the prerequisites in other ways."

Several students also mention that the progression through their degree takes different paths both in connection with elective courses and when choosing a master's degree.

4.7 Deepening and broadening

Many students bring up the importance of both deepening and broadening as dimensions of progression discuss programming. Progression is often associated with increased depth and it is also something that many students bring up in their reflections. They write that they gain in-depth knowledge in various areas the more courses they take and that this is important to increase their programming skills. However, they mention that many of their future problems will also require that they have a broad base to stand on. It is not certain that the students will have all the knowledge and skills needed to solve the problem, but a broader base can help them understand the problem better and thus more easily find out from which angle it needs to be approached. Below is a quote from a student who describes how the programme contributes to both depth and breadth.

"In every programming course I've taken, you've always had to learn something new, whether it's [programming paradigm, algorithms, data structures and complexity]. Does this then mean that I am a world champion in Haskell and Java? No. But if in the future I need to use Java streams or other functional elements, I will have a basic understanding of how to think. This will make it faster and easier to read about those parts in the future. Every course I've taken where I've had to write a few lines of code, regardless of language […], I've gained a deeper understanding of programming as a whole."

4.8 Theory vs. practice

Although the programme has many practical elements, it also contains a lot of theory. Some students find it difficult to see how all theory contributes to advancing their programming skills and feel that some of the time would be better spent if they were instead allowed to program more. Others instead see the benefit of the amount of theory in the programme and claim, that it is what makes this an advanced and professional degree as the high-status title suggests. Some of these students, like the student below, also come up with concrete examples of how the theory can help them to develop in programming.

> *"Being exposed to complicated concepts also helps, I think. An example I can offer is when I was reading about <Comparable> in Java and started reading some complicated programming explanations. Instead, when I scrolled down it said to simply treat all functions related as if they were a relation (more specifically a partial order), which made the concept click for me. I read about relationships in the basic and arithmetic course."*

5 DISCUSSION

The results indicate that the students, as a group, are well-informed participants who can share useful insights regarding important factors regarding built-in progression. It is, however, worth noting that the students did read preparatory material with a focus on the importance of prior knowledge to progress from prerequisite courses to continuing courses, and this may have coloured their reflections. The material also pointed out that progression can be both broadening and deepening, which some students referred to, however, most comments addressing this aspect of progression appeared as personal reflections and were not directly related to the preparatory text. The *Deepening and broadening* category addresses two of Harden's (2007) dimensions of progression. However, the other dimensions, application and skill, can also be seen in the students' reflections, especially in relation to programming. For example, both *application* and *skill* are brought up in the theme *Theory vs. practice*.

Although the students had not been introduced to Biggs's (1996) constructive alignment, the category *Teaching and assessment* shows resemblance with the theory. Some students brought up a wish for a close alignment between the teaching and learning activities and the assessment, to ensure they had learned what is necessary for their progression in the programme. These necessary prerequisites could be interpreted as the intended learning outcomes. In the category *Making clear connections*, several students push the idea of alignment further by discussing the alignment between courses. This allows for a clearer progression throughout the programme (McMahon & Thakore 2006). Further, in *Realistic progression*, some students address the potential discrepancy between the planned progression and their actual progression which relates to the danger of viewing constructive alignment from a quality assurance perspective rather than a student-centred constructivist teaching approach (Loughlin, Lygo-Baker, & Lindberg-Sand 2021).

In cases where the students need support to remember important prerequisites, *Repetition* could be seen as a contribution to *Making clear connections* between knowledge and skills in different courses. If the prerequisites weren't appropriately *taught or assessed* the need for repetition will likely be greater. Different *Personal factors* could create further need for repetition.

Some students also commented that *Personal factors* can affect their progression because they can impact students' ability to follow the programme. While some of these factors can be difficult to influence as a teacher, it is still important to try and understand and show empathy. The students may not be able to follow the planned progression. If the students also are taking *Alternative routes* through their education there may be an additional need for repetition since they might have different prerequisites entering the course as seen in one of the quotes that illustrated the theme *Realistic progression*. *Realistic progression* also highlights the gap between intended curriculum and the attained curriculum (van den Akker 2003).

6 CONCLUSION AND ACKNOWLEDGEMENTS

We find that the students show good insight into factors required to ensure well-built-in progression within the programme. They address many significant aspects related to progression such as: *Teaching and assessment*, *Repetition*, *Making clear connections*, *Realistic progression*, *Personal factors*, *Alternative routes*, *Deepening and broadening* and *Theory vs. practice*. Their reflections tend to align with theoretical conceptualisations of progression, and they also provide insight into situations when the programme does not fully live up to the theory. Although it is believed that the students in this study are probably more informed about progression than the average engineering student, we conclude that students can be important informants when it comes to better understanding the programme from the inside.

The authors would also like to thank all the students who gave us permission to read and analyse their reflections in connection with this study.

Keywords: *professional competencies, gender, attractiveness*

ABSTRACT

Despite efforts to increase gender diversity in engineering, significant gaps persist. This study investigates gender differences in professional competencies among engineering students, aiming to address potential barriers to gender inclusivity in the field. Utilizing the PREFER model, three distinct engineering roles were examined: Product Leadership, Operational Excellence, and Customer Intimacy. Through a situational judgment test, participants rated the appropriateness of responses to practical scenarios, allowing for an evaluation of competency levels. Results reveal that female students scored higher in competencies associated with customer-oriented roles, such as empathy or client focus, while male students excelled in innovation and process optimization competencies, such as creativity and vision. However, most competencies showed no significant gender differences, suggesting that gender disparities in engineering competencies may be less pronounced than traditionally assumed. These findings highlight the need for engineering education

[1] *S. Craps,*
sofie.craps@kuleuven.be

programmes to integrate professional competency development, ensuring a comprehensive skill set for all students and preparation for diverse career paths. Addressing these differences through educational curricula could promote gender equality and enhance the attractiveness of engineering for a broader audience. Future research should explore cultural nuances and potential biases in assessment methodologies to further understand gender dynamics in engineering education and foster a more inclusive environment.

1 INTRODUCTION

Despite efforts to increase diversity in engineering, the number of females in engineering is increasing very slowly. For example, in the US, the percentage of engineering bachelor's degrees earned by women has increased from 18% in 1998 to 22% in 2018 (NCSES 2021). In Europe, similar trends are observed with 32,8% of women graduates in tertiary STEM education in 2021. However, there are large differences between countries. The highest shares of female STEM graduates in 2021 were recorded in Romania (42,5%) and Poland (41,5%), the lowest in Belgium (27,4%), Germany and Spain (both 27;7%) (Eurostat 2024).

1.1 Engineering image

A factor hindering the attractiveness of engineering is the harsh technical image, often linked to masculinity. This is also reflected in the gender differences per field. Fields that relate to biology, sustainability or biomedical are generally more attractive for females in contrast to the more traditional fields in engineering such as manufacturing (Tazo et al. 2020; KU Leuven 2024), showing that females identify differently with engineering (Faulkner 2007). The European Commission developed a roadmap with actions to strengthen women's and girl's participation in STEM studies and careers, like the manifesto for gender-inclusive STEM education and careers. One of the actions is to explicitly include arts, social sciences and humanities in STEM education and emphasize the importance of transversal competencies, creativity, and innovation to broaden the image of engineering and increase attractiveness (European Commission 2022).

1.2 Confidence in engineering competence

Increasing the focus on professional competencies is needed. Engineering students acknowledge the importance of professional competencies but can be unsure about which competencies are most relevant or about the required level of performance (Flening et al. 2021; Direito, Pereira, and De Oliveira Duarte 2014; Karataş, Bodner, and Unal 2016).

Engineering competencies and identities are inseparably linked and shape each other simultaneously (Tonso 2014). Naukkarinen and Bairoh (2021) showed that early career female engineers in Finland perceived the importance of social and altruistic aspects, such as communication, ethics, and sustainability, as greater than men do. They perceived the importance and the development of their managerial skills higher than men whereas men perceived competencies related to technical innovations, such as creativity and entrepreneurial capacities to be better. In a US study, Cech et al. (2011) found that female students had less confidence that, after graduation, they would end up in an engineering career they belong in and that they would have the expertise and competencies required for practice in the profession. Building on this work, a Belgian study with engineering students and graduates indicated that a better understanding of the broad field in engineering practice and required competencies enhances students' confidence in their future role and talents and support graduates in making better career choices (Craps 2022). Therefore, it is important to raise awareness about the broad range of engineering jobs and roles, and make more explicit that engineering competencies comprise technical and professional skills (Berdanier 2022).

1.3 Integrating heterogeneity in engineering education

Faulkner (2007) stated that 'promoting heterogeneous images of engineering will create space for a more diverse range of people to become engineers'. Craps et al. (2020) found in their literature review that few research focused on the diversity in engineering roles. The PREFER model is a reference in this regard (Craps et al. 2021). The framework presents a simple, dynamic model representing three roles that early career engineers can take on (engineers in a role focusing on radical innovation, on process optimisation and/or on customised solutions). In each role, essential professional competencies are identified. The model builds upon earlier work of e.g., Passow and Passow (2017) who offered a concise portrait of generic engineering practice and competencies. It makes explicit that professional competencies vary according to the different roles. Hence, the different engineering roles and competency profiles broaden the image of engineering and the option to identify more with one role over another while feeling like a 'real' engineer.

Based upon the PREFER model, tests were developed to support students in discovering their preferred engineering role (PREFER Explore) (Carthy et al. 2019) and in getting insight in different professional competencies (PREFER Match) (Carthy et al. 2022). Earlier research in Belgium and Ireland showed that the PREFER Explore test, a personal preference test, was gender sensitive with female students showing a greater preference for a customer oriented role than males and males showing a greater preference for process optimisation than females (Carthy et al. 2020). To date, the PREFER Match test, a situational judgment test, was not yet investigated for gender differences.

1.4 Purpose of this study

This study contributes to previous literature by investigating gender differences in professional competencies. Whereas previous studies investigated engineering perceptions on competencies (e.g., Naukkarinen and Bairoh 2021) or self-reported levels of competence confidence (e.g., Craps 2022), this study aims to investigate whether there are gender difference in the competency levels obtained via a situational judgment test (the PREFER Match test).

2 METHODOLOGY

2.1 Participants

Table 1 shows the participants per gender that filled in the online PREFER Match tests (there are three tests, see next paragraph) between February 2020 and February 2024. Only participants who identified as engineering students were included in this study. Students indicated to be in different engineering programmes of whom the majority in civil engineering (28%), architecture/ construction/geomatics (20,5%), chemistry (19%), energy (11%), and biochemistry/biotechnical/biomedical (6,5%). About 70% of the students is from Belgium, 8% from Turkey, 3% from the Netherlands. 17% did not identify their country of study while few students study in the UK, Ireland, Spain, Portugal, Germany, etc. Participants who filled in the background information gave consent to use this data for further research with approval of the KU Leuven Privacy and Ethical Commission was obtained (G-2019 10 1792).

Table 1 Descriptives participants per PREFER Match test and gender.

	Test 1 - Product Leadership		**Test 2 - Operational Excellence**		**Test 3 - Customer Intimacy**	
	n	**%**	**n**	**%**	**n**	**%**
Male	725	69,38	575	69,78	549	68,88
Female	304	29,09	233	28,28	234	29,36
Non-binary	2	0,19	4	0,49	2	0,25
Prefer not to disclosure	14	1,34	12	1,46	12	1,51
Total	1045	100,00	824	100,00	797	100,00

Due to the low number, non-binary participants and participants who did not prefer to share information on gender were excluded from further analyses.

2.2 PREFER Match tests

Per engineering role, a separate test was developed. Because there are three roles identified in the PREFER model, participants filled in one, two or three tests via www.fet.kuleuven.be/prefer. Table 2 shows the available tests with role definitions and the professional competencies that were tested. Definitions of the competencies can be found in Craps et al. (2021).

The tests contextualise each of the essential competencies within a practical situation that a young engineer may encounter. The participants rated the level of appropriateness of responses to the given situation: inappropriate, rather inappropriate, neutral, rather appropriate, appropriate. The level of appropriateness was validated by engineers in the field. As such, the judgment of the participants was compared to that of engineers in the field. A detailed explanation of the development, rationale and scoring key of the test can be found in Carthy et al. (2022) and Pinxten et al. (2020).

The maximum scores for the three roles are different due to the number of competencies (situations) included in the test and due to the different scoring of (rather)(in)appropriate and neutral answers. For comparison, items including a neutral level of appropriateness are rescaled leading to a maximum score of 24 per competence. The maximum role scores are rescaled to 100.

Table 2 Overview of PREFER Match tests and professional competencies tested.

PREFER Match test	**Definition of the role** (Craps et al. 2021)	**Professional competencies** (Craps et al. 2021)
Product Leadership	In this role, the emphasis is on innovation and creativity through research and	Innovation, Creativity, Vision, Perseverance,

	development. These engineers explore new paradigms and identify radical alternative solutions. They translate theoretical ideas into marketable applications that provide added value to (yet) unidentified end users.	Persuasiveness, Initiative, Client focus
Operational Excellence	This role focuses on the smooth design and implementation of operational processes. The engineer locates opportunities to create efficiency gains, fixes flaws, and overseas operations, either in psychical production facilities or in the digital domain.	Positive critical attitude, Planning and organisation, Helicopter view, Team player, Work organisation, Stress resistance, Solution-oriented, Initiative
Customer Intimacy	This role entails close collaboration with clients in complex business environments. These engineers develop a (commercial) relationship with clients, help them express their needs, and provide a technical tailored solution to these needs.	Clear communication, Client focus, Capacity for empathy, Negotiation, Networking and relation building, Focus on results, Solution-oriented, Creativity

2.3 Analyses

For the data analysis, R 4.3.2 was used. First, descriptive analyses were conducted to obtain statistics about the sample. Subsequently, the data was explored by examining the means across the competencies for both male and female participants. Following this initial exploration, independent sample t-tests were conducted at the 0.05 significance level to investigate significant differences in competencies scores between male and female participants.

3 RESULTS

3.1 Differences in competency profiles per role

For the three roles, there were significant differences between the competency profiles of female and male participants, with female students showing a higher score on the competency profile of the customer-oriented role and male students showing a higher score on the competency profile operational excellence (process optimisation). However, the differences are small. For the innovative role product leadership, no differences were observed (see Table 3).

*Table 3 Mean scores competency profiles per role and gender (max. score = 100) (Significant scores in bold, * p < .05, ** p < .01, ***p < .001)*

Role	Male		Female		t-stat	p-value
	Mean	SD	Mean	SD		
Product Leadership	61,84	14,08	61,93	12,6	-4,867	1,31
Operational Excellence*	**63,18**	**17,21**	62,4	17,18	-2,197	**0,028**
Customer Intimacy*	60,07	14,42	**61,32**	**13,13**	-2,049	**0,04**

3.2 Differences in professional competencies

Table 4 shows the mean scores for the different competencies per gender. For more than half of the competencies (13 of 23), no differences were noted. For 10 competencies, small but significant differences were observed. Female students showed higher scores for the competencies perseverance, capacity for empathy and client focus. Male students scored higher on creativity, vision, initiative, client focus (market orientation), helicopter view, team player and stress resistance.

*Table 4 Mean scores in professional competencies per gender (max. score = 24) (Significant scores in bold, * p < .05, ** p < .01, ***p < .001)*

Test	Competence	Male		Female		t-stat	p-value
		Mean	SD	Mean	SD		
Product Leadership	Innovation	16,47	3,94	16,42	3,83	-0,555	0,579
	Creativity**	**16,96**	**3,82**	16,75	3,61	-2,622	**0,009**

Operational Excellence	Positive critical attitude	14,63	4,31	14,58	4,21	0,578	0,563
	Solution orientation	17,59	3,46	17,40	3,56	-0,808	0,419
	Team player*	**13,34**	**4,55**	13,13	4,35	-2,511	**0,012**
	Helicopter view***	**15,05**	**4,63**	14,47	4,75	-3,221	**0,001**
	Initiative	17,11	3,85	16,85	3,75	-0,296	0,768
	Work organization	14,74	4,48	14,85	4,56	0,283	0,777
	Stress resistance*	**15,59**	**4,64**	15,02	4,82	-2,043	**0,041**
	Planning	13,49	3,71	13,80	3,83	-0,424	0,672
Customer Intimacy	**Client focus***	13,07	4,6	**13,96**	**4,64**	-2,256	**0,024**
	Capacity for empathy**	16,02	4,24	**17,04**	**3,80**	-2,934	**0,003**
	Clear communication	15,42	4,02	15,41	3,73	0,021	0,983
	Creativity	14,10	3,87	14,13	3,6	-0,079	0,937
	Networking	11,84	3,66	12,07	3,39	-0,673	0,501
	Solution oriented	14,10	4,037	14,21	3,68	-0,334	0,738
	Negotiation	15,22	4,60	15,20	4,32	0,078	0,938
	Focus on results	15,38	4,16	15,59	4,20	-0,639	0,523

It was observed that client focus (on the level of market orientation) in an innovative role has a higher score for males, whereas client focus in a customer-oriented role (attuning action to the feelings, needs and wishes of a client) has a higher score for females. Taking initiative in a product leadership role (undertake actions and make proposals on their own initiative) was significant higher for male students. In the operational excellence role, no gender difference was found for this competence (take initiative where they think they spot opportunities to optimise and to increase efficiency and reliability).

It was noted that all competencies scored above average, except for vision (M_{total} = 10.91, SD = 4.49) and networking (M_{total} = 11.92, SD = 3.58).

4 Discussion

Engaging students in the development of professional competencies during education will provide new ways to excel in engineering, in particular for those students who might not feel like ‘real engineers’. This study delved into the examination of gender differences in the professional competencies among engineering students, shedding light on potential areas for improvement and promoting gender equality within the discipline.

Our findings underscore the nuanced nature of gender disparities in professional competencies within engineering education. Female students demonstrated a higher proficiency in competencies associated with customer-oriented roles, in particular in capacity for empathy and client focus. Male students exhibited greater aptitude in competencies linked to innovation and process optimisation such as creativity, vision, or initiative. These findings align with previous research indicating varied gender perspectives and preferences in the engineering domain (Carthy et al. 2020; Craps 2022; Martin Cabezuelo et al. 2024; Naukkarinen and Bairoh 2021). However, differences were small, and the majority of competencies showed no significant gender differences, suggesting that engineering roles are not inherently gendered. Understanding that there are no (stereo)typical male or female engineering roles can enhance the field’s attractiveness to a more diverse audience.

Integrating professional competency development into engineering curricula is imperative to equip students with a comprehensive skill set essential for diverse career pathways (Royal Academy of Engineering 2019). By making competencies explicit and contextualizing them within real-world scenarios, universities can enhance student engagement, motivation, and overall preparedness for the dynamic engineering landscape. Practical steps include incorporating client-focused projects, creativity-enhancing activities, and interdisciplinary collaboration with industry stakeholders.

Challenges remain in effectively integrating professional competencies. For example when the focus of the project is on the deliverables or, even more, when the competencies are perceived as learning from doing (Picard et al. 2021). Certain competencies like vision or networking are not easily trained and assessed in curricula and were shown to have lower student scores in our study. Addressing these challenges requires innovative approaches and support for both students and teachers in training and evaluating competencies. Additionally, efforts to ensure gender-neutral and culturally sensitive assessment tools are essential to accurately evaluate competency levels and mitigate biases in educational settings. The use of the PREFER Match test seems a valuable instrument in providing a realistic reflection of competencies, irrespective of gender by avoiding self-reported measures.

Professional competencies have a strong process component, therefore, student learning requires opportunities for students to focus on such processes, for example in project work (Shuman, Besterfield-Sacre, and McGourty 2005). A limitation of the study is the lack of registration of students' academic year preventing us from understanding how competencies evolve over time. Future research should consider longitudinal studies to track these changes, providing insights into whether observed differences persist, diminish, or become more pronounced throughout their education and into their careers.

While this study contributes valuable insights into gender differences in professional competencies, cultural nuances warrant further exploration. The PREFER Match test, as a situational judgement test, may have cultural biases in what is considered an appropriate response. Future research should aim to compare results across different cultural contexts and engineering disciplines to better understand these variations. The test was validated with representative samples of engineering students and engineers. Consequently, women and other minorities were underrepresented in the validation process. Given the gender differences observed in this study, a next step is to investigate whether the items and cases are gender and culturally neutral and valid involving a larger and more diverse sample of engineers and engineering students. By advancing our understanding of gender dynamics in engineering education, we can foster a more inclusive and equitable environment for aspiring engineers and contribute to the continued advancement of the field.

ABSTRACT

Pre-university engineering education, providing youngsters with experiences in engineering design, may contribute to attracting more people with appropriate preparation and motivation to engineering. For qualitative engineering education in secondary school, key actors are STEM teachers, who unfortunately do not always have an engineering background. As teachers' classroom implementation is known to be influenced by their attitudes, (pre-service) teacher education has the responsibility to provide teachers with the necessary experiences to prepare them for pre-university engineering teaching and to cultivate a positive attitude towards engineering (design). However, no validated instruments currently exist to measure student teachers attitudes towards engineering education, that can assist pre-service teacher training programmes to assess whether they succeed in achieving this goal. This study aims to evaluate the construct validity of a survey composed of items from previously validated instruments for a new target group of pre-service STEM teachers. Exploratory and confirmatory factor analyses show an underlying factor

[1] *H.Deprez*
Hanne.deprez@kuleuven.be

structure that is partially in line with the factor structure from the original instruments. The findings of this study may be used to further assess construct validity with larger sample sizes, to assess concurrent and predictive validity, and to study the evolution of student teachers' attitudes towards pre-university engineering education and the impact of intervention on these attitudes.

1 INTRODUCTION

Pre-university engineering education has the potential to let pupils experience engineering design as well as the broadness of engineering (Richards and Donohue 2015; de Vries, Gumaelius, and Skogh 2016) and may therefore help attract pupils to engineering programs, which is essential to address the shortage of STEM professionals, especially engineers, on the labour market (Phelps, Camburn, and Min 2018). Furthermore, many pupils who do not opt for engineering studies require a basic understanding of what an engineer does and of the impact of engineering on the world of STEM professionals and on society. Despite pre-university engineering education being part of the curriculum in some regions, engineering is not an established school subject in most countries (de Vries, Gumaelius, and Skogh 2016). Surfing on the success of integrated STEM education (abbreviated iSTEM) (Johnson, Moore, and Peters-Burton 2021) may aid to implement engineering education more broadly in (general and non-technical) secondary education. While various avenues exist for meaningful STEM integration, numerous authors have compellingly advocated for a central place of engineering design tasks in iSTEM projects (Roehrig et al. 2021; Fan, Yu, and Lin 2021), as these tasks inherently facilitate seamless integration among the different STEM disciplines. A central engineering design task guides pupils through problem solving and inquiry processes, which helps them develop 21st century competences (Roehrig et al. 2021).

Teachers' attitudes influence the implementation of new educational approaches (Pintó 2005; Roehrig, Kruse, and Kern 2007), such as iSTEM or pre-university engineering education. In this study and in line with previous research, "attitude" is defined as the overall evaluation of an object on several dimensions (Ajzen 2005; Maio and Haddock 2009; Thibaut et al. 2018a). A conceptual framework for teachers' attitudes towards science was proposed by van Aalderen-Smeets and van der Molen (van Aalderen-Smeets and van der Molen 2015) and further build upon for iSTEM education by Thibaut et al. (Thibaut et al. 2019). This tripartite framework includes a cognitive dimension (perceived relevance), an affective dimension (anxiety) and a perceived control dimension (self-efficacy (SE)). To our knowledge, no similar framework exists for pre-university engineering education.

For iSTEM teaching, positive correlations were found between non-teaching work experience, experience in teaching iSTEM, experience in teaching engineering, participation in professional development and perceived relevance of technology and science on the one hand with teachers' attitudes on the other hand, using the tripartite framework (Thibaut et al. 2018b). Fewer years of teaching experience, experience in teaching technology and participation in professional development were associated with more positive teacher attitudes towards problem-centred and design-based learning (Thibaut et al. 2019). Pre-service teacher training should take these findings into account when designing teaching/learning experiences for student teachers.

Very often, students currently studying to become a teacher in science, technology or mathematics have not experienced these new educational approaches such as iSTEM and pre-university engineering education when they were secondary school pupils. Nevertheless, many of them are expected to teach iSTEM after graduation, in which engineering design tasks are often central (Fan, Yu, and Lin 2021; Roehrig et al. 2021), even if they do not have an engineering background. Pre-service teacher training is therefore tasked with the challenging responsibility to provide these student teachers with first-time, low-threshold, comforting experiences that introduce them to the engineering design process but at the same time prepare them for iSTEM/pre-university engineering teaching. Given the important impact of teachers' attitudes on implementation of novel approaches, valid and reliable research instruments are needed to assess the impact of teaching/learning approaches on student teachers' attitudes. To our knowledge no such instrument assessing students teachers' attitudes towards pre-university engineering design exists up to date.

In this work in progress report, we build upon the tripartite framework (van Aalderen-Smeets and van der Molen 2015). To avoid eliciting generic responses, we required that the survey to be used contains enough detail about specific aspects of engineering (design). Therefore, and because constructing a valid survey is time-consuming, we choose to build upon existing instruments assessing attitudes towards engineering, rather than modifying existing surveys measuring teachers' attitudes towards iSTEM education. However, when an existing research instrument is used with a new target group and/or when items are omitted, its validity should be re-established (Sperber 2004; DeVellis 2017). The research goal of this study is to assess the factor structure and construct validity of a survey aimed at measuring student teachers' attitudes towards engineering, specifically: the importance student teachers attribute to engineering, design and technology (perceived relevance), student teachers engineering design SE and student teachers teaching engineering SE (self-efficacy).

2 METHODOLOGY

2.1 Measures

In line with the tripartite framework assessing perceived relevance, anxiety and self-efficacy, we made maximal use of three previously validated surveys to measure the importance student teachers attribute to engineering (Hong, Purzer, and Cardella 2011), as well as their engineering design SE (Mamaril et al. 2016) and teaching engineering SE (Yoon Yoon, Evans, and Strobel 2014). The affective dimension of the framework of van Aalderen-Smeets and Walma van der Molen (van Aalderen-Smeets and van der Molen 2015) was not included, since no validated instrument was found to measure engineering design anxiety.

First, to assess the student teachers' perceived relevance of engineering, we included items from the Design, Engineering and Technology (DET) survey (Hong, Purzer, and Cardella 2011) relating to the factor 'Importance of DET'. Items referring to learning more about DET through various resources, such as in-service education, workshops, college courses, etc. were omitted. For pre-service teachers taking a mandatory iSTEM didactics course that partially addresses learning more about these topics, these items were judged to be less relevant. Second, engineering design SE was assessed using all four items related to the ‘design’ factor in the Engineering Skills Self-Efficacy (ESS) scale from Mamaril (Mamaril et al. 2016). Third and last, all but one item associated with the ‘Engineering PCK Self-Efficacy’ factor from the Teaching Engineering Self-efficacy Survey (TESS) were included (Yoon Yoon, Evans, and Strobel 2014). The omitted item was considered irrelevant for student teachers as it inquired about taking the necessary time to plan engineering lessons, which is the main assignment of the iSTEM didactics course in which time is allocated for exactly this goal. The list of items included in the survey (back-translated from Dutch to English) is included in Table A1 in the appendix.

In accordance with (Yoon Yoon, Evans, and Strobel 2014) who provided argumentation for the type of scale used (Boone, Townsend, and Staver 2011), 6-point Likert-type scales were used for all items (strongly disagree, moderately disagree, disagree slightly more than agree, agree slightly more than disagree, moderately agree, strongly agree). This is in agreement with the scales used by (Mamaril et al. 2016) as well, while (Hong, Purzer, and Cardella 2011) used 4-point Likert-type scales.

Although these surveys were previously validated with undergraduate engineering students (Mamaril et al. 2016) or in-service elementary (Hong, Purzer, and Cardella 2011) or K-12 (Yoon Yoon, Evans, and Strobel 2014) teachers, re-validation with the target group of pre-service (master level) teachers is necessary due to possible differences between target groups, due to the grouping of items from multiple surveys, and due to the omission of a number of judged-to be irrelevant items.

2.2 Participants

In Flanders (Belgium), teachers are educated both on Bachelor (teaching either in primary or lower secondary school) and Master level (teaching 14-18 year olds in higher secondary education). KU Leuven has ten Masters of Teaching, including the Master of Teaching in Sciences and Technology (MoT S&T) of 60-120 ECTS depending on prior education. Most students enrolled in this program already have a Master’s degree in mathematics, (computer) science or engineering, and take the shortened track of 60 ECTS. Given the high demand for iSTEM teachers, even among students with no engineering background, all student teachers in KU Leuven’s MoT S&T take an obligatory course on integrated STEM education (6 ECTS, n=79 students still enrolled in February ‘24). The course consists of two parts: (1) iSTEM didactics, in which students get acquainted with iSTEM projects and the underlying principles, and design their own iSTEM project, and (2) an internship in which student teachers implement the designed iSTEM project with secondary school pupils of 14 to 18 years old. All student teachers enrolled in the iSTEM course were asked to participate in a survey (see Measures) using Microsoft Office 365 forms in the course of October, before their first iSTEM experiences. Pseudonymized responses were collected, in line with the ethics committee approval (G-2021-3888-R3). 67 student teachers (response rate: 85%, 52.6% male - 47.4% female, 21-58 y/o with avg: 29 y/o, sd: 8.4 y) completed the survey, in which response to all items was mandatory. The number and percentage of student teachers with their prior field of study is shown in Table 1. Although the sample size is small, it makes up approximately one in eight of the total population of MoT S&T students in Flanders in the academic year 2023-2024 (Departement Onderwijs en Vorming 2024). Furthermore, while larger sample sizes are customary for the validation of newly constructed surveys, simulations in (Jackson, Voth, and Frey 2013) indicate that a sample size of 25 *may* already be sufficient in case of high factor loadings, which are expected in our case (Table 1, with p/f=6 or 13,3 factors and α=0.8). The survey validation is still preliminary as we plan to further survey student teachers in the next academic year to further increase the sample size.

Table 1: Amount and percentage of student teachers with prior field of study.

	N	Percentage
Bio-engineering	12	17.91%
Biology, biotechnology, (bio)chemistry, geology, geography	15	22.39%
Engineering	29	43.28%
Mathematics, physics, informatics	9	13.43%
Veterinary	1	1.49%
Pharmacy	1	1.49%

2.3 Analyses

All analyses were executed in R v.4.2.3. (R Core Team 2023). Due to the limited sample size, the 6-point Likert-type scales, and non-normally distributed data (assessed using the Shapiro-Wilk test), the data were treated as ordered categorical variables. Descriptive statistics (mean, standard deviations, interitem polychoric correlations and item-to-(expected) scale correlations) were calculated. As the primary objective of the study is to evaluate the construct validity of a survey composed of items sourced from previously validated surveys, confirmatory factor analysis seems most appropriate. However, to explore the factor structure emerging from the collected data, we first carried out an exploratory factor analysis, using the same dataset.

2.3.1 Exploratory Factor Analysis (EFA)

Due to the limited sample size (n=67), the Kaiser-Meyer-Olkin test indicated it was inappropriate to analyse all 25 items at once. Results of the KMO test (KMO=0.75) and Bartlett's test of sphericity ($p<0.05$) indicated however that EFA was appropriate for two subsets of the data: a first subset containing the first 13 items, relating to perceived importance of engineering education, and a second subset including the last 12 items relating to (teaching) engineering SE. We carried out the EFA using the polychoric correlation values.

2.3.2 Confirmatory Factor Analysis (CFA) and Reliability estimation

Using the *lavaan* package, a weighted least squares (WLSMV) estimator was used for the confirmatory factor analysis, together with the *ordered* parameter set to true. Goodness-of-fit was examined with: RMSEA ≤ 0.06, SRMR ≤ 0.08, CFI ≥ 0.95, TLI ≥ 0.95 and chi-square/df ratio ≤ 3 (Hu and Bentler 1999; Brown 2015; Kline 2016). For each item, the overall reliability (Cronbach's alpha) for the factor structure without that item included, was calculated. After finalization of the factor structure and items, reliability coefficients alpha and omega (McDonald 1999) were calculated for each factor using the *omega* function from the *psych* package. Average variance extracted (AVE) was also calculated for each factor to assess the convergent validity.

3 RESULTS

3.1 Exploratory Factor Analysis (EFA)

Descriptive statistics are included in Table A1 in the appendix. For both subsets of the data (see Subsection 2.3.1), the point of inflection of a scree plot and Kaiser's criterion (the number of eigenvalues greater than one (Kaiser 1960)) indicated that the optimal number of factors was two. The EFA factor loadings (also included in Table A1) were partly in line with the three expected factors based on the existing instruments. However, the scree plot and the EFA factor loadings indicated that the first expected factor ('importance') split into two factors, one relating to the specific learning goals envisioned for the pupils (f1 in Table A1) and the other one relating more to the general motivation for and content in STEM and engineering education (f2 in Table A1). The second ('engineering design SE' – f3 in Table A1) and third ('teaching engineering SE' – f4 in Table A1) expected factor were partially recovered based on the EFA, although some items (TSE1 and TSE2) related to the third expected factor ('teaching engineering SE') loaded better on the second ('engineering design SE'). The phrasing of items TSE1 and TSE2 is also more in line with (general) engineering SE rather than teaching engineering SE. The rather low factor loadings and item-to-scale correlations for items IMP8 (0.43), IMP11 (0.33) and TSE1 (0.44) resulted in specific attention to these items during the remaining analysis.

3.2 Confirmatory Factor Analysis and Reliability estimation

First the default model, consisting of the three factors ('importance', 'engineering design SE', and 'teaching engineering SE') assembled from the pre-existing surveys, was constructed. Second, four CFA models based on the four-factor structure emerging from the EFA ('importance specific learning goals for pupils', 'motivation and content in STEM teaching', 'engineering SE' and 'teaching engineering SE') were made. Model 2 included all items from the survey. In models 3-4-5, respectively item IMP11, IMP8 and TSE1 were excluded due to the observed low factor loadings, low item-to-scale correlations and increased values for alpha-if-item-not-included.

Scaled fit indices are included in Table 2. CFI and TLI indicate a good model fit for all CFA models. The RMSEA value is borderline for appropriate model fit for Models 1-4 (Brown 2015), while the SRMR value is appropriate for good model fit, especially for Model 3. Model 3, with item IMP8 omitted, was selected as the best CFA model. While most items loading onto factor 2 relate to motivations for teaching STEM related to industrial and societal needs in connection to engineering, item IMP8 probes a more general motivation to make learning fun. Factor loadings and standard errors for the final CFA model (Model 3), as well as factor descriptions, factor reliability and AVE for each factor, are included in Table 3.

Table 2: CFA models with the Goodness-of-Fit indices (n=67).

Fit index	Model 0	Model 1	Model 2	Model 3	Model 4
Chi square	389.681	345.183	330.124	313.689	295.100

4 SUMMARY

This study assessed the construct validity of a survey measuring teachers' attitudes based on a tripartite framework (van Aalderen-Smeets and van der Molen 2015). The survey consists of items assembled from previously validated instruments, but was administered to a new type of target group of master level student teachers. Despite the relatively limited sample size, CFA models with satisfactory convergence could be constructed, probably because items from previously validated instruments with high factor loading were used. However, based on the literature describing the existing instruments (Hong, Purzer, and Cardella 2011; Mamaril et al. 2016; Yoon Yoon, Evans, and Strobel 2014), we expected to find a three-factor model, consisting of the factors 'importance', 'engineering design self-efficacy' and 'teaching engineering self-efficacy'. The EFA and CFA results indicate good model fit, however, for a four-factor model, with factors 'importance attributed to learning goals for pupils', 'motivation and content in STEM teaching', 'engineering SE' and 'teaching engineering SE', with the omission of one survey item (IMP8) probing more general dispositions towards STEM teaching.

As – to our knowledge - there are no established test instruments available assessing student teachers attitudes towards pre-university engineering, the current study does not investigate concurrent or predictive validity, which could be investigated in the future. The sample size was also too small for cross-validation based on subsamples or measurement invariance across gender or prior field of study.

We aim to further validate the presented survey with larger sample sizes of student teachers. The validated survey will further be used to study the evolution of student teachers' attitudes towards engineering (design). Qualitative measures, such as interviews with student teachers, should provide more in-depth information, complementing the findings resulting from the quantitative approach using the survey.

Conference Key Areas: *Ethics education*
Keywords: *Engineering Ethics, Accreditation Guidelines, Graduate Attributes*

ABSTRACT

Accreditation documents provide direction for engineering programmes as regards the balance of credits, the knowledge profile and coherent design and of the resourcing and sustainability of the programme. These documents have considerable strategic impact on the identification of learning objectives, the assessment process and, consequently, on the quality of teaching and learning within engineering programmes. This paper uses discourse analysis to examine changes in the formulation of accreditation documents outlining graduate attributes for university-based engineering programmes in South Africa over a twenty-four year period. It examines the potential effect of these changes on the formulation of learning objectives and assessment relating to the teaching and learning of ethics within engineering programmes at South African universities.

1 INTRODUCTION

The paper sets out to examine how changes in policy documents relating to the accreditation of engineering programmes potentially affect the way ethics is taught and assessed within engineering programmes. This builds on the analysis by Gwynne-Evans et al. (2021) as regards the significance of ethics across the graduate attributes in the South African accreditation standards.

This analysis will be done through an examination of the shifts in emphasis in these accreditation documents over time, looking specifically at changes in:

- how knowledge is conceptualised in these documents,
- the formulation of programme level outcomes and graduate attributes,
- the scope of what is addressed in the learning outcomes, including level descriptors, range statements, associated assessment criteria and developmental considerations.

This paper builds on work by Junaid et al. (2021; 2022) that examined how engineering ethics is portrayed in accreditation documents, extending the European analysis to a global perspective. The earlier research examined current accreditation documents from a range of countries to determine trends or differences across countries and aimed to profile similarities and differences in the way ethics is framed in policy documents in a global context. In both the earlier European and the global analyses, the methodology required a comparison of the definitions of key terms in and across accreditation documents; a tabulation of the learning outcomes that refer to ethics, distinguishing between implicit and explicit references, and the examination and analysis of the verbs used to formulate these learning outcomes relating to ethics (Junaid et al. 2021, 2022). Junaid et al. (2021; 2022) drew attention to the way that higher education institutions rely on their respective national accreditation documents as one of their primary resources in programme content and development. This, in turn, draws attention to the way in which programme developers are dependent on the use of language in these documents, including the definitions provided together with the format of learning outcomes, as integral to the process of formulating the engineering curriculum.

This research will examine changes in the South African engineering accreditation policy documents that relate to ethics, over a period of twenty-four years, covering the seven versions of the accreditation standards published during this time. It addresses the research question:

"How do the changes in the definition of graduate attributes over time in a particular context potentially impact the teaching of ethics within engineering programmes?"

This distinguishes the regulator's responsibility for administering and communicating the accreditation criteria for engineering programmes from the responsibility of the higher education institutions to engage with the requirements outlined in the documents so as to articulate learning objectives, to design input and interventions that lead to the assessment of the graduate attributes at exit level. It sets out to identify changes to existing terms and categories in the accreditation standards documents over the years in the different versions of the documents and to examine the potential significance of these changes. The engineering programme involves a structured, integrated teaching and learning arrangement with a defined purpose and pathway that leads to a qualification (ECSA, 2023:10), in terms of specific educational objectives that graduates of a programme must accomplish (ECSA, 2023:7).

2 METHODOLOGY

This analysis uses discourse analysis to build on the research method of the Junaid et al. (2021; 2022) papers, where, instead of examining accreditation documentation in a multi-country analysis, seven different versions of the South African accreditation documentation relating to engineering programme standards are examined.

Discourse Analysis is utilised as an analytical tool to demonstrate how language works to expand and restrict meaning within texts. Discourse is positioned as:

"an ensemble of ideas, concepts and categories through which meaning is given to social and physical phenomenon, and which is produced and reproduced through an identifiable set of practice" (Hajer & Versteeg, 2005:175).

Discourse analysis is proposed as a tool that enables analysis to go beyond the mechanics of the text to include the context and historicity of the text and to enable the examination of contested power relationships (Jorgensen & Phillips, 2002). It builds on and strengthens the internal cohesion between collective forms of reasoning manifested in the societal structures, practices and institutions, including that of policy documents (Rozema & Bond, 2015:67) and codes of conduct.

It recognises the policy making process takes place within a context where meaning is symbolic, inherited and stable, where change itself may be seen to signal significance. This process of discourse analysis recognises that documents communicate both through the stability of the document format over time, as well as in the changes to these documents. It is potentially the changes that signify shifts of meaning and emphasis relating to these terms. As such, the discourse analysis will draw on the structure used by Junaid et al. (2021; 2022) but will execute it differently, focusing in on the changes to the documents over the years and interpreting these changes as significant in terms of the context of engineering practice in South Africa.

The documents examined are the seven versions of the accreditation standards for university programmes within engineering in South Africa, covering a period of twenty-four years, from the passing of the Engineering Professions Act in 2000 to August 2023 (ECSA, 2000; 2004; 2012; 2014; 2019; 2020; 2023).

2.1 Classification of key terms and categories in the documents

Whereas many of the terms are standard across the different versions of the accreditation documents, there are areas where there have been significant changes or where the use of a particular term or concept distinctively contributes to the overarching argument of the document.

The term *exit level outcomes (ELOs)* used in version 2 and 3 to describe the required outcomes of engineering programmes is replaced by *graduate attribute* (GA) in the fourth and following versions (ECSA, 2004; 2012; 2014). Both terms are formulated in terms of a number from one to eleven – relating the required outcomes to the specific exit level outcome or graduate attribute. These learning outcomes are depicted in terms of categories that include:

- Name
- Description
- Range statement
- Associated knowledge & attitude
- Associated assessment criteria
- Developmental considerations.

While the range statement category is consistent across the different versions for all the graduate attributes except ELO/GA1, the associated assessment criteria, knowledge and attitudes and the development considerations appear predominantly in the more recent versions of the documents.

2.2 Identification of explicit and implicit references to ethics

Each of the seven versions of the accreditation standards documents will be examined to see where the following terms that relate explicitly to ethics and professionalism are used:

- Ethics/Ethical/Ethically
- Professional/Professionally/Professionalism.

In addition to these terms, terms that are implicitly related to ethics, that occur in the accreditation document and that are synonyms to those appearing in the table formulated by Junaid et al. (2021), will be traced to see where and how often they occur in the South African Accreditation Standards. The additional terms that implicitly relate to ethics and that can be identified in at least one of the seven versions of the Accreditation Standards examined will be:

- Responsibility/Responsibilities
- Exercise judgement
- Law/Rules/Codes
- Sustainable/Sustainability
- Inclusion/Inclusive/Inclusivity
- Diversity
- Holistic
- Social/Society/Societal
- Safety
- Risk
- Critical thinking
- Values
- Technology/Technologies.

This recognises that several concepts that would potentially be included, such as *social justice* or *ubuntu*, were not found in the documents and so were not included.

2.3 Analysis of the verbs used in ethics-related learning outcomes

Verbs used in the formulation of the ethics-related learning outcomes will be examined to determine the range of actions and reflections required of graduate students. Changes in the formulation of verbs will be examined in terms of how this affects the level and range of what the student is expected to achieve.

3 Results

3.1 The South African Accreditation Standard documents

In terms of South African legislation in the Engineering Professions Act of 2000 (South Africa, 2000), the Engineering Council of South Africa (ECSA) is the professional body mandated to accredit engineering programmes that prepare students for registration as candidate engineers and both to register and regulate the conduct of registered engineers as professionals by assessing their conduct. The ECSA Accreditation Standards form part of a collection of documents that deal with the regulation and administration of engineering education within the public and government sector. As such the language is primarily aligned with the language of public administration and regulation.

The language of the formulation of the original document outlining the Standards for Accredited University Engineering Bachelors' Degrees sets out to be functional and objective. It defines the purpose of the document as ensuring the "outcomes of a university bachelor's degree programme … that is acceptable for accreditation as meeting the educational requirements toward registration with ECSA as a Professional Engineer" (ECSA, 2000:1). This original purpose is updated in the second version to include building "the necessary knowledge, understanding, abilities and skills required for further learning towards becoming a competent practicing engineer" (ECSA, 2004:1). This revised formulation provides a foundation for assessment that goes beyond theoretical knowledge and skills to include values and attitudes. This distinction provides a foundation for expanding the scope of knowledge and assessment beyond theoretical or scientific knowledge and skills to include practical knowledge (Wolmerans, 2022) that responds to context and experience, incorporating and building on values and attitudes. This shift creates the space to moves the focus of the engineering programme from transferring rational and objective knowledge and technical skill to a more responsive, experiential process where developing mindsets and agency are recognised as equally important to the technical or knowledge outputs.

3.2 Identification of key terms and categories used in the South African accreditation documents that impact how ethics is positioned

The ECSA Accreditation Standards are formulated in terms of specific categories and criteria. At a most basic level, *standards* comprise statements of outcomes to be demonstrated and the levels of performance and content baseline requirements in the context of engineering educational programmes (ECSA, 2023: 10).This distinguishes the "*required outcome*" and the "*exit level outcome*" from the "*graduate attribute*" as the "statement of the learning outcomes that a student must demonstrate at the exit-level to qualify for an award of a qualification; these actions indicate the student's capability to fulfil the educational objectives" (ECSA, 2023: 8). This shift from *exit level outcomes* of a **programme** to *graduate attributes* of the **engineering graduate** reinforces the expansion of the accreditation standards to incorporate values and attitudes alongside knowledge and skills. Despite the change of term, the significance of the reference of *exit level outcome* and *graduate attribute* has not been clearly differentiated in the re-formulation of the outcomes as attributes.

Across the seven versions of the accreditation standards, there is noticeable stability in the formulation of these learning outcomes over time, where, for instance, the description of Engineering Professionalism as "Demonstrate *critical awareness* of the need to act professionally and ethically and to exercise judgment and take responsibility within own limits of competence", stays constant over five versions of the accreditation standards (ECSA, 2004; 2010; 2014; 2020; 2021).

These *standards* further distinguish categories including the:

- *range statement* for each particular learning outcome that "provides a context in which assessment may take place against an outcome and is expressed in

terms of situations, activities, tasks, methods and forms of evidence” (ECSA, 2023:10)
- the *assessment criteria* as “set of measurable performance requirements which indicates that a person meets a specified outcome at the required level. (ECSA, 2023: 7)
- the *associated knowledge and attitudes* as a classification of knowledge content into defined types (ECSA, 2023*)* and
- the *developmental considerations* (ECSA, 2023: 7) first operationalized in version 7 across GAs 7-10 and not yet defined.

Table 1 below depicts the occurrence of concepts relating to ethics across the seven versions of the ECSA accreditation standards.

Table 1: Analysis of the occurrence of concepts relating to ethics in the learning outcomes or graduate attributes of the 7 versions of the ECSA Accreditation Standards

Note: Exit level outcomes/Graduate attributes are referred to in terms of their number, 1-11.

Technology/Technologies	5/7	5/5/7	5/5	5/5			9
Sub-total of references to concepts relating to ethics	19	31	27	28	24	24	45

*In the current version ”exercise” has been replaced by “good” judgement.

From the table, the cumulative number of references to concepts relating to ethics can be seen. Whereas the sub-totals stay relatively stable across the documents, with a mid-peak for the second version, there is a significant increase in references in the most recent version of the document. It is evident from table 1 that the latest version of the specified learning outcomes has a far wider range of graduate attributes that incorporate concepts that relate to ethics. The accreditation standards have shifted to seeing ethics as relevant across a wide range of learning outcomes.

3.3 Verbs used in ethics-related learning outcomes in the South African accreditation documents

Level descriptors measure learning demands regarding types of problems, knowledge required, skills and responsibility (ECSA, 2023: 7). The level of achievement shifts from ensuring the graduate “*is competent*” (V1, ECSA, 2000) to “*demonstrates competence*” (V2, ECSA, 2004) for eight of the ten learning outcomes. The shift between the two formulations is subtle, where “*is competent*” suggests a completed achievement, in contrast the revised "*demonstrates competence*" signals both the need for active evidence and, with the present form of the verb, invites continued engagement in the learning process beyond the immediate assessment process. This formulation "demonstrates competence" is used across the majority of the learning outcomes and remains stable across the middle five versions of the standards. Two learning outcomes most obviously connected to ethics, GA7 and GA10, include the word "ethics" or "ethical" in their range statements, and are distinctive in their formulation: rather than requiring *competence*, GA10 requires "*critical awareness of the need to* act professionally and ethically and to exercise judgment and take responsibility within own limits of competence" and GA7 requires "*critical awareness of* sustainability and the impact of engineering on the environment (ECSA, 2004; 2012; 2014; 2019; 2020).

The removal of the verb "to exercise judgement" in the most recent version of GA10, replaces it with the verbs "apply", "commit to" and "adhere to" (ECSA, 2023). "Good judgement" is referenced in the same graduate attribute as a developmental consideration, without clear defining how this is determined. Noteworthily, despite the apparent widening of references to concepts relating to ethics in the documents, the verbs used in the new graduate attribute remove the reference to exercising judgement that is at the heart of ethical decision-making (Gwynne-Evans et al., 2021). This limits the practice of engineering professionalism to application and compliance rather than developing the capacity to make responsible decisions.

This examination of the effect of changes in the use of verbs relating to learning outcomes relating to ethics, demonstrates the importance of a scrutiny of small changes that, potentially, have significant impact on the engineering curriculum and on the learning that is being curated.

3.4 Changes in the conception of knowledge in the accreditation documents

In the documents, engineering is conceptualised as a problem-solving activity, requiring competence to "identify, assess, formulate and solve convergent and divergent engineering problems creatively and innovatively" (ECSA, 2000:1). Subsequent formulations presume a "conscious and logical approach" that relies on the application of engineering knowledge, skills and generic competencies (ECSA, 2023:5). The adjectives used to characterise the problem-solving process include a "fundamentals-based, first principles analytical approach" and "a systematic, theory-based formulation of engineering fundamentals required in the engineering discipline" (ECSA, 2023:17), characterising knowledge as ordered, rational and predictable. These formal characteristics of knowledge are contrasted with the "awareness of the power of critical thinking and creative approaches to evaluate emerging issues" that address complex problem-solving. This involves "wide-ranging and/or conflicting technical, non-technical issues (such as ethical, sustainability, legal, political, economic, societal) and consideration of future requirements", that have "no obvious solution and require abstract thinking, creativity and originality in analysis to formulate suitable models" and may require innovative strategies to address "problems not encompassed by standards and codes of practice for professional engineering" that require "collaboration across engineering disciplines… and diverse groups of stakeholders with widely varying needs" (ECSA, 2023:17). This conceptualisation juxtaposes a view of knowledge as fixed and finite with the recognition of the need for knowledge that is transformative and emerging.

4 Conclusions

In the absence of a definition of ethics in the accreditation standards and in the ECSA Code of Conduct (2017), this analysis will be viewed as contributing to the formulation of a working definition of ethics within engineering in the South African policy context. As such the analysis provides evidence of shifts in the regulator-based requirements for teaching and assessing ethics across the engineering programme. These shifts are impacted by two areas that potentially affect the formulation of the requirements for engineering programme accreditation: how the concept of complexity is positioned and what is considered knowledge.

In the past versions of the accreditation standards, engineering professionalism, as GA10, required that students "demonstrate critical awareness of the need to act professionally and ethically and to exercise judgement and to take responsibility within own limits of competence". This definition encapsulated several concepts that fall outside of the rational and scientific discourse that is associated with engineering and outside the technical management discourse of public administration. The formulation of GA10 was consistent across five of the seven version of the accreditation documents (ECSA, 2004; 2012; 2014; 2019; 2020), where "the need to act professionally and ethically and to exercise judgement and to take responsibility" signalled a conception of knowledge that incorporates norms and values and requires the exercise of judgement rather than mere compliance.

This analysis recognises that policy documents make epistemological and ontological claims that subtly influence how the policy document communicates. As such, it is evident that the vocabulary and concepts encapsulated in engineering accreditation standards necessarily impacts the curriculum and the focus and objectives of learning within the engineering programme.

Engineering ethics is a complex construct that straddles a number of disciplines including philosophy, psychology, law, economics and engineering. As such, engineering ethics needs to be recognised as both integral and peripheral to the practice of engineering, requiring that engineers step beyond the scientific and rational constructs of the sciences to imagine and create a world that incorporates concepts and values such as "diversity", "justice" and "integrity" and "sustainability".

ABSTRACT

There are significant benefits to be gained by incorporating a more flexible combination of synchronous and asynchronous online study activities into academic courses. However, a common concern is that students miss out on relevant campus activities and valuable information. This can pose challenges, particularly for first year students. Therefore, the implementation of an online format for a first year mathematics course warranted close monitoring and evaluation of student behaviour and performance. Following the students during a whole semester we found that students selecting the online course and online activities were slightly older students. The course format did not affect the students exam performance, and students in the online class felt equally well supported, had similar experiences of mastery and expectations for succes.

1 INTRODUCTION

1.1 Background

Many universities have adopted various forms of technology-mediated course delivery to improve student access to courses, course lectures and course materials (Rasheed, Kamsin and Abdullah, 2020). By offering a broad range of synchronous and asynchronous activities both online and in-class, students can study whenever and wherever they prefer. Such a flexible offer to students may combine the benefits of in-class and online courses: students can study at their own pace, experience more autonomy in planning and selecting study activities and they can join both on-campus activities and online fora to connect to other students, teaching assistants and the teachers. Furthermore, online course content can be enriched (e.g., subtitling), allows students to use multiple input devices (e.g., voice-operated) in different languages, and use other tools for narration and/or translation. As such, online course content can create more accessible and inclusive education.

There are different terms for slightly different forms of orgnisation of classes or courses with online components: Blended and Hybrid learning are often used interchageably to indicate courses that combine in class and online learing activities, whereas flipped classrooms is a particular organisation of these components such that instructional digital content, often in the form of videos is provided to students to study at home. And class time is then used for engaging in interactive activities. Reviews of blended and hybrid learning show positive effects of incorporating online components in a course (e.g., Balakrishnan et al., 2021; Bernard et al., 2014; Liu et al., 2016). And this is also true for the flipped classroom approach (Lo and Hew, 2019), although some reviews show no significant difference between flipped and traditional classrooms (Chen, Lui, and Martinelli, 2017).

In conclusion, there are significant benefits to be gained by incorporating a more flexible combination of synchronous and asynchronous online study activities into academic courses. However, a common concern is that the introduction of online studying might lead students to miss out on-campus activities. Hence, on-campus tasks that would otherwise be carried out by the educators or peers, such as goal setting and progress evaluation, fall on the students themselves when the instruction is followed only through online education (Williams, Pollard, Takala, and Houghton, 2019). This shift can pose challenges, particularly for first year students. Another concern revolves around the fact that online study activities are often added on top of the existing in-class activities, leading to increased course workloads for students. Therefore, when implementing a flexible course schedule that includes online activities, it becomes essential to closely monitor and evaluate student behaviour and performance to ensure their successful adaptation to the new learning format.

1.2 The Current Study

The current study focuses on the introduction of online synchronous and asynchronous activities for a first year bachelor mathematics course. Students can enrol in the online course or decide to enrol in an on-campus version of the course. Once enrolled in a specific class, students can still choose to follow online or in-class activities organised by other teachers in other classes, although it is expected that most students will follow the program as prescribed by the class and teacher they selected.

In the study, we monitor what activities students select, how much time they spend on each of these activities, if they feel supported and capable of following the course, and their performance on the exam. We are interested whether the format of the study activities (online, in class, synchronous, asynchronous) is related to student behaviour, or student outcomes (feeling supported and capable, exam results).

1.3 Research questions

The objectives of this study are to address the following research questions:

1. Are certain students – older, repeating students - overrepresented in the group of students selecting online study activities?
2. Does student performance vary based on different study formats? When controlling for time-on-task, is there a performance difference that can be attributed to the study format chosen, whether it be online or in-class?
3. Is there a correlation between the study format and students' perceptions of feeling supported and confident to successfully completing the course?

2 METHODOLOGY

2.1 Participants

During the autumn semester 2023/24 170 first year bachelor students who enrolled in either an online (N= 31, age *M*= 19.9) or on-campus (N=139, age *M*= 18.3) Math course consented to participate in this study. Both the online and the on-campus course were taught by the same teacher, using the same course materials (online book, exercises). Students were be paid for their contribution, and a bonus was be given to students who finished all weekly self-reports.

2.2 Procedure and measurements

To assess the relationship between study format (online, in-class) and student outcomes (feeling supported, feeling capable, exam performance), we collected the following data:

- At the start of the course:
  - students' age
  - whether they'd taken the course the year before (repeating students)
- Weekly self-reports from students:
  - the time they spend on the different study activities
  - how supported they feel by the teacher, TA's and peers
  - whether they had any experiences of mastery
  - if they think they can complete the course successfully.
- At the end of the course:
  - exam score

For the analysis of the weekly self-reports, we only took into account the students that had filled in at least 8 weekly reports.

3 RESULTS

3.1 Descriptives

Table one provides an overview of data on the student's study behaviour and the student outcomes.

Table 1. performance total group of students who consented

	Online group	In class group	
# students	31	139	
	mean	mean	sd
Age	19.9	18.3	
% repeat students	61.3	13.6	
Final grade	4.6	4.3	

Table 2. study behaviour of students with at least 8 weekly surveys

	Online group	In class group
# students	22	107
Age (yrs)	19.7	18.4
% repeat students	63.6	14.9
Final grade (1-6)	4.6	4.3
Time online (mins/wk)	122.9	67.7
Time in class (mins/wk)	49.7	183.7
Time on exercise (mins/wk)	149.3	142.6
Feeling supported (1-5)	4.0	4.0
Experience mastery (1-5)	4.4	4.1
Expectation of success (1-5)	4.3	3.8

3.2 Correlations

*Table 3. Correlations between study behaviours (time for campus activites, for online activities, for individual exercise) and student outcomes (feeling supported, experience of mastery, expecting successful completion, exam grade). * significant at p<= .05, **significant at p<= .001, *** significant at p<= .0001*

	Exam grade	Time in class	Time online	Time on excercise	Feeling supported	Experience of mastery	Expect succesful completion
Age	0.02	**-0.40***	**0.30***	**-0.24**	-0.07	0.03	0.12
Exam grade		-0.10	-0.03	0.12	0.15	**0.31***	**0.37***
Time in class			**-0.57***	0.02	0.04	**-0.23**	**-0.32***

Feeling supported		0.43**	0.18
Experience of mastery			0.63***

3.3 Analysis of Covariance

Table 4. Results of Mancova with Student Outcomes (exam grade, feeling supported, feeling of mastery and expectation of success) as dependent variables, Group(Online or in Class) as Factor and Total Time spent on Study Activities (online, in class and independent exercise) as covariate.

Multivariate tests		**value**	***F***	***df1***	***df2***	***p***
Group	Wilks' Lambda	0.92	2.41	4	117	**0.05**
total_time	Wilks' Lambda	0.95	1.43	4	117	0.23
Univariate tests	**Dependent**	***SS***	***df***	***MS***	***F***	***p***
Group	Grade	2.09	1	2.09	1.94	0.17
	Feeling supported	0.01	1	0.01	0.01	0.92
	Experiences of mastery	1.26	1	1.26	4.96	**0.03**
	Expectation for success	4.09	1	4.09	8.40	**0.00**
Total_time study activities	Grade	1.21	1	1.21	1.13	0.29
	Feeling supported	0.02	1	0.02	0.03	0.86
	Experiences of mastery	0.82	1	0.82	3.23	0.07
	Expectation for success	0.26	1	0.26	0.05	0.82
Residuals	Grade	129.32	120	1.08		
	Feeling supported	89.34	120	0.74		
	Experiences of mastery	30.51	120	0.25		
	Expectation for success	58.54	120	0.49		

3.4 Research Questions

Question 1: Are certain students – older, repeating students - overrepresented in the group of students selecting online study activities?

Looking at Table 1 we can see a higher percentage of repeating students in the online group than in the in-class group, and that the average age of students from the online group is slightly higher than students from the in class group. Table 3 shows us that student age is positively correlated (r =.30, p < .0001) with time spent on online activities.

Question 2. Does student performance vary based on different study formats? When controlling for time-on-task, is there a performance difference that can be attributed to the study format chosen, whether it be online or in-class?

The analysis of covariance (Table 4) with Student Outcomes as dependent variable and Group (online, in class) and Total Time on Study Actitivities as covariate shows a main effect of group (*Wilks' Lambda* = 0.92, F= 2.41, p<0.05). Subsequent univariate tests show signitificant differences between the online and the in class group on experiences of mastery and expectation for succes, with the online group scoring slightly higher on both.

Question 3. Is there a correlation between the study format and students' perceptions of feeling supported and confident to successfully completing the course?

Table 3 shows us that the different Student Outcomes are correlated: students' experiences of mastery and expectatons of success are significantly correlated to exam grade (r= 0.31, p<0.001; r= 0.37, p<0.001 respectively). But correlations between Study Activities and Student Outcomes are less straightforward: there are negative correlations between time in class and experience of mastery (r= -0.23, p<0.01) and expectation for success (r=-0.32, p<0.001), and a weak but posive correlation between time online and experience of mastery (r= 0.19, p<0.05).

4 DISCUSSION

This study is undertaken to monitor and evaluate whether students that select an online class and online activities throughout the semester feel equally supported and perform equally well as students who are enrolled in the on campus course. We were curious to know whether the students who select the online format are different from the students who prefer in class activities. We found that the online group was a little older than the in-class group, and there were more repeating students in the online class.

The students that participated in this study could freely choose to which course they would enrol, and even during the semester it was possible for them to freely choose between several types of online and in-class activities. That is why we collected the time spent on each of the activities each week. Both the student outcomes on group level and the correlations between time spent on learning activities and student outcomes show that student grades and their feelings of being supported are not different for online or in class students; and the online students score only slightly higher on their feelings of mastery and expectation for success than in-class students.

Previous studies have shown that including online learning activities or content in a course generally improves learning outcomes. This study shows only slight differences in some student outcomes, but not in grades. However, we don't feel that our results diverge from earlier research. First of all, previous studies often compared blended/hybrid/flipped formats with the classroom instruction, whereas in the current study students were free to choose both online and in-class activities, and we can see that both groups have included online activities during the semester. Secondly, the students in the online group spent about 60 minutes per week less on total study activity, while achieving similar results, suggesting the online group was more efficient. However, the caveat is that our students could select the format themselves and this autonomy may have been a relevant factor in our findings.

Concluding, offering a broad range of synchronous and asynchronous activities both online and in-class offers students the flexibility that seems particularly appreciated by slightly older and repeating students, while they feel equally supported and perform at equal level.

5 ACKNOWLEDGEMENTS

The authors are particularly grateful for Sacha Friedli's willingness to share his classroom, his online resources and for his continued support and guidance throughout this project. His expertise and commitment to excellence and innovation in education are inspiring.

The authors also like to thank Simone de Paris for funding part of this study, and his guidance during the period of the study.

ABSTRACT

In this paper, we report on two design episodes, to describe engineering students' problem-solving practices, and the underlying reasoning processes, associated with solving complex socio-technical challenges. We show that this form of designing requires reasoning about complex, real world phenomena, using multiple and multi-modal representations, manipulated and integrated throughout the designing process. We describe the interactions observed between the reasoning processes, to derive implications for integrating HSS with engineering curricular practices.

[1] *Kamakshi Khosla*
kamakshi.khosla@iitgn.ac.in

1 Motivation and Background

Designing to solve socio-technical challenges is a highly complex and inherently creative enterprise, requiring the designer to construct several internal and external representations or "models" (e.g., mathematical, geometric, computational, verbal), comprising a combination of abstract and practical concepts, as well as scientific principles and knowledge, spanning across disciplines, to imagine, conceptualize, and reason, to engineer "invisible" phenomena (Boon, 2023). In the literature, the form of reasoning at the core of these modelling activities is classified "socio-technical", and not much seems to have been said about its nature, or the mechanisms that make recognizing the interplay between social and technical factors for, or more importantly, the integration of the resultant interdisciplinary insights into, engineering design (Johnson, Clauson, Leydens, Moskal, Tsai, & Plata, 2022). Studying how this reasoning process is deployed by engineering learners, as reflected in their thinking, problem-solving, and design decision-making, is important therefore, to develop a better understanding of the phenomenon, and to advance it to create effective pedagogical interventions to impart the requisite skills and practices. Our research, albeit preliminary, seeks to address this gap by providing a cognitive characterization of the socio-technical designing practices and cognitive processes of engineering learners, engaged in real-world problem solving. To study these processes, we will adopt the Model-Based Reasoning paradigm (or MBR, see Nersessian, 1999; 2009), which stipulates that conceptual innovation, a requisite for socio-technical designing (Boon, 2023), whether scientific or technological, emerges out of multiple, interconnected, problem-solving episodes, over long spells of time, and maintains that they are shaped by a variety of conceptual, analytical, and material resources and constraints of the environment in which innovators operate. Key cognitive processes prescribed as engaged in MBR include visualization, simulation, and analogical thinking, and are considered to be interconnected, and collectively constitutive of MBR. We consider "tinkering episodes", where learners interact with tools, models, concepts, and other artefacts in the makerspaces, to encompass the creation and incorporation of various internal and external representations, and therefore important sites for witnessing MBR. In our research, we will study: A) the cognitive nature of socio-technical designing, specifically, the sequence of steps entailed in planning and prototyping, and B) the specific episodes of model-based reasoning, with a focus on model construction, and the underlying cognitive and reasoning processes.

2 Study and Methods Overview

We use the case study method to develop our cognitive characterization of socio-technical designing.

2.1 Case Descriptions

The following learner-driven engineering design cases were selected, to study the underlying model-based reasoning processes:

Case A: Comprises data that was collected from a group of 30 engineering students enrolled in a project-based learning (PBL) course within their first semester of study. Unlike the majority of engineering design courses where the emphasis is on (industrial) product development, this PBL course emphasised ideation in relation to problem identification, and allowed students to determine and solve personally meaningful problems, technological or otherwise, through any justifiable technological intervention (e.g., mechanical, electrical etc.) deemed necessary. For their project, the group under observation, identified "indoor toddler safety" as their problem, and developed a toddler safety system to detect and alert guardians, by sounding alarms and sending mobile notifications, for when the toddler was in proximity of a pre-identified dangerous location.

Case B: Here, the design project was conducted in the discipline of Information Technology, and as part of the student's master's thesis (see Muwangi, 2017). Infant abduction from daycare centres located within office workspaces, was the problem being addressed, and the proposed solution entailed a wireless (remote), RFID-based infant-tracking and monitoring system. Significant similarities (e.g., research problem targeted: emphasis on safety, technological functions determined: monitoring, detection, and alerting, and working principle deployed: proximity detection), and differences between the cases (in terms of problem definition, and methodological processes adopted), rendered them appropriate sources for triangulating data to bring out common design and cognitive practices.

2.2 Data Sources and Analysis

We developed the cognitive characterization of socio-technical designing, using the approach outlined in Nersessian (2009, see pp. 133-136). We specifically focussed on designers' problem solving practices, considering it to entail *conceptual representation*, *conceptual change*, and *visualization/imagery*, ubiquitous in engineering design (Dogan & Nersessian, 2005). In our context, we anticipated these to reflect in the way learners identified, defined, and reasoned about the real world, and design problems, constructed arguments to support their design decisions, and constructed numerous representations (e.g., diagrams, models). In case A, audiotaped data of the ideation and prototyping processes (captured during group meetings), videographed data of relevant prototyping episodes, resources consulted (e.g., online/offline articles, reports, product catalogs etc.), and textual and pictorial data (diagrams, project reports, project briefs), were used for analysis. In case B, specific resources consulted (e.g., online/offline articles, reports, product catalogs etc.), and textual and pictorial data (e.g., descriptions of the real world and design problems, specific claims made to support inferences about the problem, deficits with existing technological, required software design etc., nature of the claims made, and diagrams) were used to inform analysis. Note that as data processing and analysis is currently underway for the prototyping phases of the two projects, we will only report on the conceptual designs of technological artefacts developed in cases A and B, using the data as specified.

The problem-solving practices once identified, were subjected to cognitive analysis, using a range of perspectives within the cognitive sciences (e.g., cognitive science of design, cognitive science of science), philosophy of science and engineering, and model-based reasoning in science education, and the learning sciences, to determine the nature of cognitive practices, and the underlying reasoning processes. We used a combination of inductive and deductive methods, to double-fit our data and existing theories of cognition, and thus consider our approach to be “abductive” (Timmermans & Tavory, 2022).

3 FINDINGS

We identified overlaps in the design process and cognition of the 2 design episodes under analysis (Table 1), and report the findings incrementally, beginning with an overview of the design process adopted, followed by an elaboration of the model-building episodes in cases A & B, and finally the cognitive practices and the underlying reasoning processes.

At the level of the design process, socio-technically informed approach begins with the articulation of a *social* problem (e.g., toddler/infant safety) for which a suitable socio-technical artefact is to be designed. A social problem, unlike its counterpart, an ergonomic/logistical issue of social relevance and in need of optimization solutions, which is *framed* by the instructor, often in consultation with other stakeholders (e.g., industry experts, learners), in a “task centric” manner, and specifiable in a “form-function structure” (Pahl & Baitz, 1996), lacks a predetermined set of constraints and requirements, or clear criteria for characterizing existing technological solutions as un/successful (Rittel & Webber, 1973), and must therefore be *translated* into a design problem (see stage 1, Table 1). The socio-technically informed approach thus begins with what we call “task determination” as opposed to “task specification”, where the goal is to understand the real world situation resulting in the undesired outcome to plan intervention mechanisms to be achieved technologically (Boon, 2009), and not specify/formulate the “crux of the task” undergirding a design problem through requirement and constraint identification and/or analysis (Pahl & Baitz, 1996). Another distinguishing feature of the socio-technically informed approach is its focus on situation analysis (Clarke, 2005), where the goal is to (re)construct the mechanism of action resulting in the undesired outcome (e.g., accidental injuries/infant abduction), by identifying relevant situational elements and their relationships (e.g.network of human actors in office and household settings with interdependent actions, commitments for babies' safekeeping), as opposed to task analysis, which entails systematic study of user and product-centric processes/activities underlying task completion (e.g., developing/optimization of company softwares). While task *and* situation analyses yield product-relevant requirements and constraints (see 3A & 3B in Table 1), the latter *also verifies* the technological intervention mechanism identified in the task determination stage of this process, by “empiricalizing” the phenomenon being enacted in the situation under study (stage 2 in Table 1). As for conceptual and prototypal designing (stage 3, Table 1), we found socio-technically informed approach to be similar to its counterpart, entailing the creation, manipulation and use of mental and external representations (e.g., physical, geometric, and schematic models of the artefact, see

Figure 1) to facilitate design decision making (Eckert & Hillerbrand, 2022). However, in addition to the *conceptual* model (i.e., low-fidelity prototype described in 4 A & B in Table 1), we also identified models specific to the socio-technically informed approach, and labelled them *informal* and *empirical* models (see Inference A, and level II inference ii in Table 1).

Informal modelling: begins with problem ideation, and the learners consulting diverse resources and materials: non-academic research reports and articles, newspaper clippings, public opinion polls and surveys, crime reports, product catalogues, and additionally in case A specifically: correspondence with the course instructor, teaching assistants, lab technicians, other engineering faculty, and family members, to meet the twin objectives of a) understanding the situation resulting in the undesired outcome, and consequently, b) identifying suitable technological *solutions* to effect change ("causal models" 1A and 1B, and "technological intervention mechanisms" 2A and 2B in Table 1). It culminates with a (rudimentary) situational representation connecting the undesired outcome to *linearly linked events* occurring within the identified target system (families in households in case A, and working parents, staff in the workspace in B), and a corresponding technological solution (2A and 2B in Table 1), derived through *direct mapping* between the cause (e.g., access to dangerous locations) and the technological solution (e.g., infant tracking, see 1A and 1B in Table 1). Here, the representations of the situational and the corresponding technological intervention are predominantly descriptive (narrative-linguistic), constructed based on public discourses, concepts and ideas of the situation, and through "discursive reconstruction" (see Clarke, 2005).

Empirical modelling: requires deeper, empirical understanding of how the undesired situation unfolds in the social world and within the target system, to *test* and *verify* the fit between the cause and technological action state identified in the preceding step (i.e., 1A and 1B, and 2A and 2B in Table 1, respectively). In case A, this entailed secondary research involving (academic) literature searches to identify: the most prevalent risk/hazard in households, guardians' safety rituals for their toddlers, prevalence of accidental deaths/injuries, and health implications for the users relying on safety-enhancing technological devices (with ultrasonic sensors, for instance). In case B, however, a combination of primary research, conducted using focus-group discussions with employees, field and participant observations, and secondary research methods, such as document analysis (to understand "mechanisms" for enhancing child "protection", existing technological solutions etc.), were deployed. This process culminates with an understanding of the *causal elements and their interaction* within the situation resulting in the undesired outcome, and a list of constraints and requirements for the prototype design, as summarized in Table 1 (see 3A and 3B). Here, descriptions of the causal situation and the corresponding technological solution are also narrative-linguistic, and derived from "process models" of qualitative data (Mohr, 1982), implying that they depict the *structure* of causal action undergirding undesired situations (reconstructed from the sequence of events), and the basic *mechanism* of technological intervention (determined from the constraints and requirements), respectively. The intervention mechanism "alerting" to prevent accidental injuries", conceived as the optimization of an auxiliary cause "Ca" (toddler supervision, see Table 1) to effect primary cause “C1” (access to dangerous locations, also in Table 1), is an example of this form of reasoning.

Conceptual Modelling: Here, the constraints and requirements identified in empirical modelling are transformed into functions, and further into the principle solution (Pahl & Baitz, 1996), to describe the behavior, structure, purpose, and embodiment of the prototype (Hunt, Price, & Lee, 1993), using a variety of representations, including, geometric, schematic, and physical representations of the product, see Fig. 1 for examples from case A, and chapter 5 (Mwangi, 2017), for representations (e.g., system architecture, database design, diagrams) specific to case B. We do not detail the models (space constraints), and point to Eckert & Hillerbrand (2022) instead.

Figure 1

a) Schematic diagram (workflow)   b) Geometric model (dimensioning)   c) Physical prototype

We find that the episodes, albeit described separately, influence each other within the practice of socio-technical design. For instance, in case A the informal, relational understanding of the cause (access to dangerous locations) and the associated technological action state (buzzing/alerting), resulted in influencing the nature and extent of empirical investigation conducted (see D in Table 1), and consequently, the types of constraints identified (e.g., range, efficiency, safety, see 3A in Table 1). In case B, however, it was the empirical investigation that resulted in the broadening of a list of requirements determined during informal modelling (see b in Table 1). Together, these examples suggest an interconnectedness between the two modelling stages (as is also prevalent in hypothetical reasoning within the social sciences, see Basso, Lisciandra, & Marchionni, 2017). With respect to conceptual modelling, we consider the interconnection between the combined outputs to be considerably tighter, as reflected in the following excerpt on the work-flow of the device, derived from the prototype pitch prepared by the students in case A:*“The Bluetooth Low Energy (BLE) tag…to be placed on the toddler is activated near the ESP 32, allowing its address to be captured. The BLE tag…continuously emits signals…[which] the ESP 32 module will monitor, and [subsequently] transmit [the output] to the WiFi module. In the event that the signal strength surpasses the specified threshold, an immediate alarm is sounded, and parents notified through an app installed on their mobiles.” (Participant A).* As part of the mechanism described here, different components of the system (e.g., BLE beacon, BLE tag, WiFi module, server, and mobile device) are configured and integrated to mimic seemingly natural, human *behaviors* and processes enacted during toddler supervision: monitoring the infant and raising alarm to initiate intervention. Here, the model functions as a *functional-analog model* of the surrogate (since ideal) situation (Nersessian, 1999), reflecting its alignment with the outputs of the preceding modelling stages. Further, for drawing inferences about the nature of cognitive processes, addressing the following questions is of relevance: *what is being modelled? How is it being modelled?*, and *to what end?* Concerning the first question, we observe that it is the behaviors and processes that are being modelled incrementally (e.g, sequence of events → structure of causal action → behavior of technological system). As for the second, we find the models' construction to entail a progressive, analogical comparison between source and target domains (here situations: non-ideal, real-world v/s ideal). Finally, our analysis shows that these models are constructed in service of specific epistemic aims (e.g.,hypothesis generation and testing about how to bring about a desired phenomenon). We thus characterize the cognitive processes underlying this form of design as simulative and analogical (Nersessian 2009), and therefore, generative (Rost & Knuutilla, 2022).

4 IMPLICATIONS & CONCLUSION

Overall, our analysis reveals that designing for complex socio-technical challenges requires the generation, interconnection, and transformation of sub-representations of phenomena. On our account, this modelling activity simulates the mechanism of technological intervention, needed to effect a social phenomenon, through a "coupling" of human and technological subsystems (Date & Chandrasekharan, 2016), to account for the multi-agented and spatially distributed nature of a real-world problem situation. In our view, the ability of the constructed models to simulate the *dynamics* of human-technological interaction(s) *to shape* social phenomena, is what renders them as active representations of their target systems (real or surrogate), capable of "loading" and "enacting" aspects of social reality.

Based on these findings, we recommend an epistemically-informed, and fully-integrated approach to teaching HSS through learner-driven, real world, and interdisciplinary projects, in undergraduate and graduate engineering. Consistent with prior literature (e.g., Atman, Adams, Cardella, Turns, Mosborg, & Saleem, 2007) we find limited problem exploration, scoping, and information gathering on the part of learners, as demonstrated in the informal modelling stage in case A, caused by a general lack of awareness of the methods, to affect prototype design. For instance, in the same case, we consider modelling the intervention mechanism after a surrogate target situation (i.e., inferring safety behaviors from unsafe conditions), to have resulted in lack of attention to other crucial factors (e.g., guardians' preference for technological solutions within the Indian context, the toddlers' role in self-preservation etc.), which could have opened avenues for alternative, creative, and contextually appropriate designs (e.g., games to enhance toddlers' self regulatory behaviors). A focus on integration of key epistemic skills: finding patterns within a social phenomenon, understanding "evidence" of a cause within complex socio-technical systems, and visualizing the identified worldly phenomena as an engineer/ing scientist, early on in the project based course, through guided readings, topic-relevant case discussions etc., could help mitigate these challenges.

5. Acknowledgements

This work was supported by the Indian Institute of Gandhinagar, India, through a grant to the "Holistic Reimagining of Engineering Education" project. We are grateful to all our participants for consenting to be a part of this research, and Prof. Sanjay Chandrasekharan, for productive discussions on the topic.

Keywords: *Metacognitive skills, self-awareness, employability, work placements*

ABSTRACT

In today's world engineers need to be equipped with a range of different skills and experiences to succeed. There needs to be a combination of strong levels of meta-cognition and self-awareness. Nineteen final year mechanical engineering students who completed an industry placement and 20 students who did not took a metacognitive Self-Reflection and Insight Scale (SRIS) survey to test their levels of self-reflection and self-awareness. The two groups' results found higher metacognitive skills in the work placement group in all three areas tested: self-reflection, need for self-reflection (self-awareness) and insight. The study suggests that these metacognitive levels could be increased from taking a work placement year Recommendations are offered on how universities can improve the course curriculum to benefit work placement students and non-work placement students.

INTRODUCTION

1.1 Background

In today's competitive job market, companies are increasingly seeking graduates who possess a blend of technical expertise and strong interpersonal skills (WEF 2020). While proficiency in technical knowledge remains essential for engineering roles, employers place a significant emphasis on attributes such as self-awareness, analytical abilities, critical thinking, and work experience. Self-awareness refers to the ability to recognize and understand your own thoughts, feelings, and behaviours. The ability to understand your strengths and weakness as well as knowing your limitations (Eurich, 2018). A key factor to improving self-awareness is through self-reflection, which, with practice, can lead to a deeper understanding of yourself and identifying your strengths and weaknesses (Grant et al. 2002). Many top CEOs exhibit exceptional self-awareness marked by fully comprehending their distinctive work styles and adeptly delegating tasks to employees who excel in areas where they may be less proficient (Resick et al. 2022). Therefore, there is a pattern of success with self-awareness that stems from self-reflection.

Extensive research conducted on the psychology of metacognitive function and self-awareness and their relevance in personal and professional development is well established (Dawson 2008). However, there is a notable absence of research on how self-awareness can enhance employability, despite several studies on graduate employment strategies (Morgan & O'Gordon 2011; Kinash et al. 2016; Su 2014). Similarly, there is a lack of literature focusing on how students' self-awareness evolves with industry experience. Addressing these gaps could provide valuable to the career development of students. This could lead to improvements in students' employability and career prospects as they secure employment more rapidly after graduation.

1.2 Metacognitive Function and Relevance to Employment

Moore and Parker (2013) carried out an analysis using pre-existing data on the importance of teaching critical thinking and problem solving in education. They summarized the importance for practical applications in the real world arguing that these cognitive skills and metacognition are closely related and are vital for students when navigating complex challenges. These challenges could occur in both academic and employment scenarios.

Critical thinking and problem solving are key skills looked for by employers (QS 2021; WEF 2020). These are often assessed through interview questions that demonstrate skills in strategic thinking and planning, for example using the STAR response format (Situation-Task-Action-Result). They demonstrate critical thinking by responding quickly to address questions and showcase time management by adhering to specified response times.

Critical thinking is a transferable skill and can be applied to various situations and fields making it an asset in employment. It allows a person to approach a problem with a structured and analytical solution. Graduates with strong critical thinking and problem-solving abilities are better equipped to handle workplace challenges and can contribute more effectively to their own organisations (Moore & Parker 2013). Therefore, developing metacognitive skills should not be overlooked as a pre-requisite to developing these highly sought skills like critical thinking.

1.3 Research Aim and Objectives

This study will investigate whether there is a difference in metacognitive skills and self-awareness between mechanical engineering students that have undertaken a work placement year and those who have not. A metacognitive survey designed and validated by Grant et al. 2002 will be used to assess three metacognitive areas: self-reflection, need for self-reflection (self-awareness) and insight that can be taken from self-reflection. From this report a summary of recommendations will be put forward to aid in developing the employability of mechanical engineering students in the programme. The objectives were:

1. To carry out a survey on final year mechanical engineering students that have completed an industry work placement year and those that have not.
2. To carry out a comparative analysis of the data between the two groups comparing work placement and non-work placement students.
3. To conclude recommendations for the engineering department for further curriculum development

2 METHODOLOGY

2.1 Survey

This study was carried out by using the Self Reflection and Insight Scale (SRIS) questionnaire that was designed by Grant et al. (2002). The questions were designed to identify three aspects of metacognition: engagement in self- reflection, need for self-reflection and insight. The targeted inclusion criteria for this study focused on final year students enrolled in Mechanical Engineering and Design Engineering undergraduate courses at the author's university.

The survey contained 22 questions in total with the first question differentiating students with and without placement year experience and the second question applicable to the placement students on their job title during their placement. The third question asked for consent. The last 20 questions were the SRIS survey questions, which employed a grading scale ranging from 1-6, where 1 indicated strong disagreement and 6 indicated strong agreement with the statement.

Before proceeding with the survey, the participating students were asked to read the Participant Information Sheet and ask to give consent. Responses were anonymously collected. The Participants were made aware that they had the right to not participate at any point during the survey up until they press submit. The study was approved by Aston University's Engineering and Physical Sciences Ethics Committee.

2.2 Data Collection and Statistical Testing

The survey was distributed electronically via Microsoft Forms and data collected were anonymised. Mann Whitney U test was performed on each question to assess if there was any difference between the scores. The results were also displayed onto bar graphs comparing work placement student's vs non work placement students.

3 RESULTS AND DISCUSSION

3.1 Survey Outcomes

A total of 40 students participated in the Self Reflection and Insight Scale (SRIS) survey, where 20 students had taken a placement year and 20 students had not. One of the results from the placement side was disregarded as they had completed the survey in 11 seconds. The duration of this submission contrasted with the average time taken to complete the survey, which was 4:25 minutes and therefore was unlikely to have been a true reflection of the participant's experience. After this submission was excluded from the data, there were 19 students who had taken a work placement year and 20 students who had not.

4 WORK PLACEMENT STUDENTS VS NON- WORK PLACEMENT STUDENTS

The work placement participants were working in a wide range of roles including manufacturing and packaging, quality testing, mechanical engineering, and financial services.

During the data collection phase of this study, qualitative insights were gathered through conversations held while surveys were distributed, and participants were briefed. It became apparent that several non-work placement students did not take a work placement year by choice, and some didn't go as they didn't get offered a placement when they applied. Several students did not apply for placements a sighted reasons due to not wanting a placement, the desire to graduate earlier or wanting to pursue a Master's degree after graduation. However, all students who applied but were unable to secure placements stated that they stopped applying around December time unlike the successful placement students who continued to apply and often received offers around March. This raises the question of why the non-placement students had prematurely stopped applying. Is there an underlying perseverance trait from the placement students that meant they didn't lose confidence too soon? Perhaps these students didn't have enough knowledge, expectation, and guidance as to the typical time frame required for getting a placement and how many applications were needed. Noting that students start applying during year 2 starting from September, the start of the UK academic calendar, with the expectation that they begin placements the following summer in year 3.

4.1 Metacognition Skill: Engagement in Self Reflection

Questions 1 to 6 of the SRIS survey evaluates "engagement in self-reflection", showing no significant difference in this aspect of metacognition between the placement versus non-placement group except in one question. The statement: "I often think about the way of feel about things," shows significant difference with the work placement group agreeing more strongly (figure 1). It is important to note that the work placement group rated higher levels of engagement in self-reflection for all other statements, even if they were not significant between the groups.

The questions respond to engaging in thinking about thoughts (Q1), spending time self-reflecting (Q2), examining their feelings (Q3), thinking about cause of behaviour (Q4), examining other thoughts (Q5), and examining their feelings (Q6). What would be interesting is to schedule interviews with some students and evaluate how they spent their time evaluating or if they thought emotional reflection was beneficial or not. It is noted that the non-placement students were less engaged with emotional reflection (Q3 and Q6), a sense of how one feels. Perhaps non-placement students are less aware of the benefits of emotional reflection.

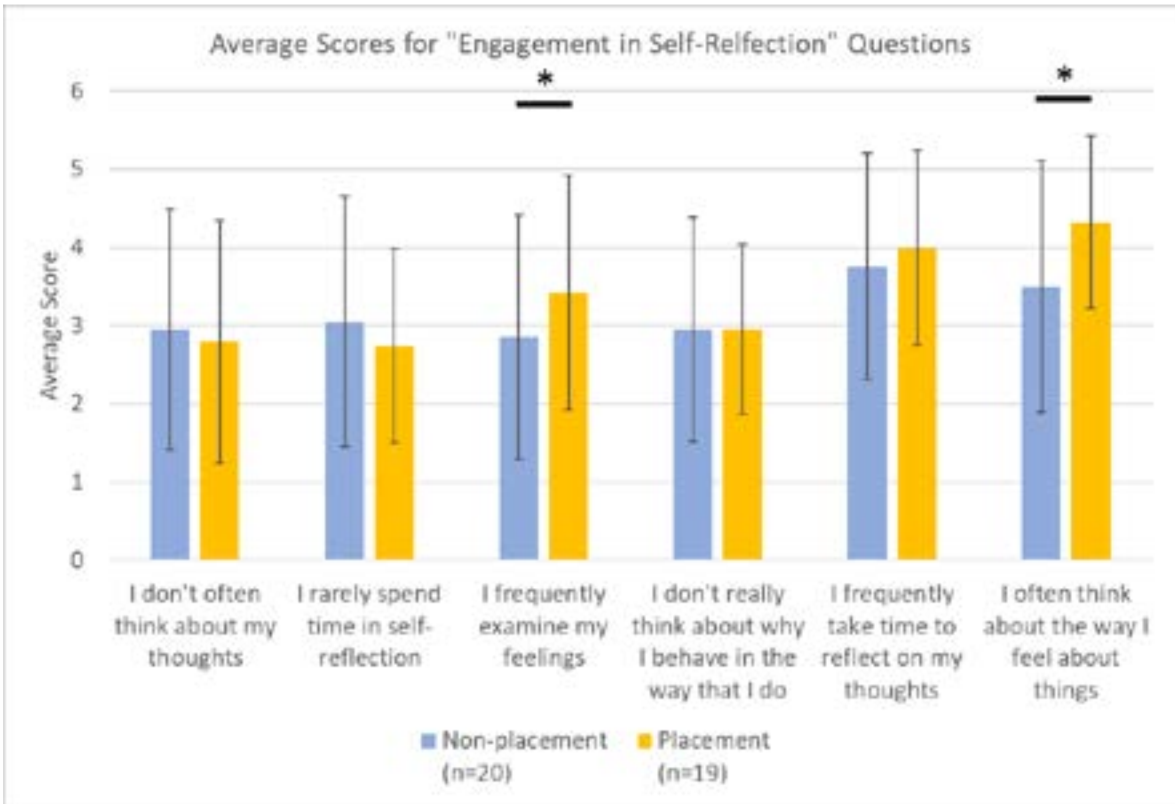

*Figure 1: Average Scores (+/- SD) for the "Engagement in Self-Reflection" questions showing no significant difference between placement versus non-placement students. * Significant difference, p<0.05.*

4.2 Metacognition Skill: Need for Self-Reflection

Questions 7-12 of the SRIS survey evaluates the "need for self-reflection" as shown in figure 2 with a notable increase in average scores among the placement students except for Q7 statement "I am not really interested in analysing my behaviour", where a lower response indicates an interest in analysing behaviour – a metacognitive trait. Therefore, on average, work placement students demonstrated a higher need for self-reflection compared to their non-placement peers. All the questions in this section of the survey showed significant differences in results with placement students performing better in every question, except Q7 where it was not statistically different.

The remaining questions respond to engaging in evaluating the things done by the student (Q8), examining thoughts (Q9), understanding feelings (Q10), the need to understand how their mind works (Q11) and understand how thoughts arise (Q12). Placement students often receive feedback and get challenged with their university knowledge at work, this common practice can push students to analyse themselves more often to improve. It is safe to say that the placement students think it is important to evaluate the things they do as they scored remarkably higher than non-placement students (Q8). It is possible that after partaking in self-evaluation at work and understanding how quickly they developed from this the placement students recognise the benefits of self-reflection.

*Figure 2: Average scores (+/- SD) for the "Need for Self-Reflection" questions showing significantly higher responses in students that completed a placement versus students that had not. * Significant difference, p<0.05.*

A key question for the placement students, is whether the skills of self-reflection and self-awareness is what led them to secure the job in the first place or whether these traits were developed through the work placement. It is very possible that the students that secured a placement were naturally predisposed with higher metacognitive levels to perform better in securing these placements either through experience, a better understanding of the interview process or even personality types. Examining this and whether the university experience does build these skills would be interesting to look at.

4.3 Metacognition Skill: Insight

Questions 13-20 of the SRIS survey evaluates "insight" as shown in figure 3 with varied responses showing no clear distinction between the two groups. The work placement group have a slightly better insight into their thoughts and emotions compared to the non-placement group, however only Q14 and Q20 were significantly different. The score for Q16 "I'm often aware that I'm having a feeling, but I often don't quite know what it is" was almost identical between the groups. This question relates to emotional regulation, with neither group showing any differences.

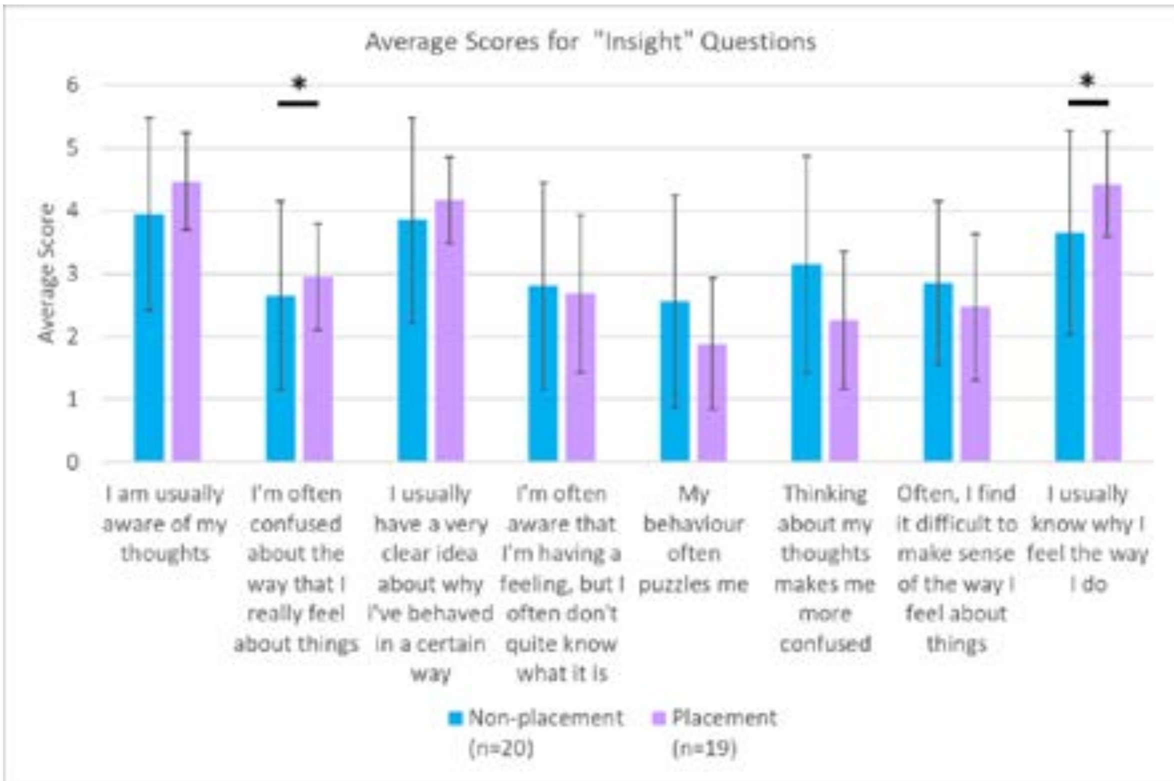

*Figure 3: Average (+/- SD) scores for the "Insight" questions with only the last question showing significant difference in average responses. * Significant difference, p<0.05.*

Emotional regulation is the ability to effectively manage and modulate one's emotions in response to internal and external stimuli (Sanchis et al. 2020). It is interesting that both groups of students scored similarly in this "Insight" section of the survey, showing no clear difference between groups. Exploring the link between work placement experience and developing emotional regulation would be interesting and offer a new understanding into the impact of developing professional skills in the workplace. However, this area is beyond this study and would need to be explored further.

Question 20 "I usually know why I feel the way I do" and question 18 "Thinking about my thoughts makes me more confused" the placement students performed better. Although both groups are usually aware of what feelings they are having (Q19) the placement students are better at understanding why they feel those feelings (Q20, significant). The non-placement students are not as good at making sense of their thoughts and get more confused the more they think about them. These two results argue that a placement year may have some benefits for emotional regulation and the constant behaviour analysis in a workplace supports this finding. It seems logical that an environment where you are being challenged and taught by others on new tasks would be a training ground for emotional regulation and improving communication skills.

The exposure to real-life work experiences gained through a work placement might have contributed to the better metacognitive scores among the work placement group. On the other hand, students who secure placements may have specific personality traits or characteristics that make them pre-disposed to have higher metacognitive skills. However, a longitudinal study is needed to explore this further, particularly exploring metacognitive development at university in comparison to a work placement.

The need for developing lifelong learning and learning strategies has not been missed in engineering curriculums, however, more awareness of how to develop underlying metacognitive skills is needed to provide effective recommendations for programme development. Engineering industries are calling for these non-technical skills, with a recent World Economic Forum reporting “active learning and learning strategies” as a top three skill needed in the advanced manufacturing industry (WEF 2020).

There are several limitations in this study. Firstly, the group sizes for this study were small (n=20 and n=19) and should be expanded in future studies. Secondly, a longitudinal study is needed to also allow a comparison of metacognitive development in the initial years at university while students engage in academic studies and metacognitive development before and after a work placement. Thirdly, a look at other engineering disciplines would also be advantageous, allowing a cross-sectional look across disciplines, which would provide better oversight across the engineering profession. Finally, employer views would be interesting to analyse to see any correlations between students and employer perceptions. However, despite these limitations, the study provides valuable preliminary insights into this field that would benefit engineering educators.

5 SUMMARY

The aim for this project was to determine if mechanical engineering students at a UK university demonstrated different metacognitive skills between students that had completed a work placement compared to students that had not. The study aimed to assess the two groups metacognitive levels through a validated survey assessing three areas of metacognition: their engagement in self-reflection, the need for self-reflection and insight. The results revealed a heavy slant towards work placement students engaging in more in self-reflection and showed a greater awareness of the need for it. Placement students performed better overall with several significant findings, most notably in the awareness of the need for self-reflection. Placement students generally spent more time reflecting on thoughts, feelings, and behaviours in their roles. The results also indicated that placement students drew more insight from their reflection. In a workplace where colleagues challenge and guide interns through new tasks the results suggests that such an environment is highly conducive to developing self-reflection and self-awareness.

While placement students performed better in this study further research needs to be done to understand cause and effect. This will help drive research-informed curriculum development and pedagogical reform towards training highly skilled and employable engineering graduates.

Keywords: *Academic resilience, cross-cultural comparison, engineering education, South Africa, United Kingdom*

ABSTRACT

This qualitative study investigates the academic resilience of engineering students within the distinct cultural, social, and institutional landscapes of the United Kingdom and South Africa. Engaging with 36 participants through semi-structured interviews, the research aimed to discern the elements fostering academic resilience and gauge students' preparedness for professional life. Two overarching themes were identified: similarities and differences in resilience experiences in these two contexts. Under similarities, individual resilience traits such as hard work, determination, and growth mindset emerged prominently, alongside the shared challenges of academic pressures and the transition to university life. The importance of support systems, including the role of peers, faculty, and university resources, was acknowledged across both contexts. Differences highlighted distinct institutional and cultural influences on resilience: South Africa grappled with resource constraints, technological gaps, and historical educational disparities, while the UK experience revealed more detailed insights into the role of institutional support and introspective

curwynm@uj.ac.za

resilience. By contributing to the discourse on engineering education and student success, this research underscores the imperative for engineering programmes to focus on nurturing resilient, future-ready responsible engineers, and emphasises the value of cross-cultural insights and cooperation in fostering inclusive and supportive environments that respond to the unique needs of students in different educational contexts.

1 INTRODUCTION

Engineering education (EE) plays a crucial role in shaping the future of our societies, as engineers are at the forefront of addressing global challenges and driving technological advancements. However, the journey to becoming an engineer is often fraught with obstacles, requiring students to develop and maintain a strong sense of resilience. This work aims to explore how resilience is understood and fostered in two distinct educational contexts: the United Kingdom (UK) and South Africa (SA).

Resilience, defined as the ability to overcome adversity and adapt to challenging circumstances, is a key factor in determining student success and well-being (Mwangi and Watt 2021). Academically resilient students are those "who sustain high levels of achievement motivation and performance despite the presence of stressful events and conditions that place them at risk of doing poorly in school and ultimately dropping out of school" (Alva 1991, 19). In the context of EE, students face a myriad of challenges, including rigorous coursework, high academic expectations, and the need to develop a wide range of technical and interpersonal skills (Cajander, Daniels, and McDermott 2012; Llorens-Molina et al. 2022). Understanding factors that contribute to academic resilience and identifying effective strategies to support its development is essential for promoting student success and well-being.

Recent research has explored resilience in engineering education from various angles. A systematic literature review by Winkens and Leicht-Scholten (2023) found that resilience in EE is connected to both engineering students' personal attributes and to university systems. For students, resilience was linked to persistence, adaptability, learning from failures, coping with stress, and being a desired competence (Winkens and Leicht-Scholten, 2023). Resilience has also been described as the ability to manage or recover from stress (Huerta et al., 2021) and the term 'academic resilience' has been used to examine students' responses to academic challenges (Hunsu, Carnell, and Sochacka, 2021; Martin and Marsh, 2006).

Moreover, studies have associated resilience with self-regulation (Concannon et al., 2019) and self-efficacy (Anthony et al., 2016; Concannon et al., 2019) in engineering students. Resilience has also been investigated in relation to equity, diversity, and inclusion, focusing on specific groups like mature students (McGivney, 2007; Servant-Miklos, Dewar, and Bøgelund, 2021), women (Khilji and Pumroy, 2019), African American and Latino students (Samuelson and Litzlerb, 2016), and black women (Ross, Huff, and Godwin, 2021). Long and Mejia (2016) even present resilience as an asset, arguing that society often overlooks the resilience of minorities while stereotyping them as low-income and poorly educated.

The UK and SA provide unique contexts for examining academic resilience within EE. Whilst both countries have a strong tradition of EE, they also present distinct challenges and opportunities for students. In the UK, as part of the Global North, the

EE system is characterised by well-established infrastructure, a high level of industrial integration, and advanced research facilities (Engineering Council 2014; Polit and Beck 2010). In contrast, SA, situated in the Global South, faces unique challenges such as resource limitations, a need for educational transformation, and the imperative to align EE with rapid economic and social changes (Fisher and Naidoo 2020).

In the UK, the impact of Brexit on the EE sector and the experiences of international students and staff is a pertinent issue (UCL Centre for Engineering Education, n.d.). In SA, the need to increase diversity and representation in the engineering field, particularly among women and underrepresented groups, is a pressing concern (Direito, Chance, and Malik 2019). While the UK also faces challenges in diversifying EE (according to HESA, in 2021/2022 ~80% of engineering students in the UK were male and ~63% were classed as 'home'), it notably differs in its reliance on international students for revenue (PwC, 2024), a trend less pronounced in SA.

By fostering cross-cultural dialogue and collaboration, this paper aims to contribute to the ongoing efforts to create inclusive, supportive, and transformative EE environments that nurture academic resilience and success.

2 METHODOLOGY

2.1 Research approach and design

This study employed a qualitative research design, situated within an interpretivist paradigm, to explore the resilience of engineering students in the UK and SA (Denzin and Lincoln 2003; Kivunja and Kuyini 2017). The interpretivist approach allowed for a deep understanding of participants' subjective experiences and the meanings they attached to their resilience in their respective educational contexts (Oakley 1998).

2.2 Participants and sample

Purposive sampling was used to recruit 36 participants, their characteristics shown in Table 1, with 13 engineering students from Nelson Mandela University in SA and 23 from Swansea University in the UK. The former is a comprehensive university in SA, the latter being a public research university located in Wales, UK.

In both cases, students were studying a broad range of engineering disciplines.

The mean age of participants in both the UK and SA is notably consistent, averaging 23.5 years. This similarity in age distribution underscores a commonality in the student demographics between the two distinct geographical and educational contexts.

Table 1: Participant Information

	SA	UK
	Population	
Student population (Institution)	28, 000	22, 000 (HESA, 2022)
Home students	~95 %	81% (HESA, 2022)

Engineering students		15% (HESA, 2022)
	Sample	
Sample size	13	23
Gender identity (M/F)	10/3	17/6
Age range	21-28	18-39
Level of study	All Bachelors (final year)	2 Foundation Year (pre-Bachelor) 5 First year 5 Second year 2 Third year 9 Masters
Home/International	9/4	9/14

2.3 Data generation

Semi-structured interviews were selected as the primary data generation method, as they provided the opportunity to explore participants' experiences, thoughts, and feelings in depth while maintaining a focus on the research questions (Guba and Lincoln 1994). An interview protocol was developed, which included open-ended questions and prompts to guide the discussions (Jacob and Furgerson 2012). The questions focused on participants' educational experiences, their understanding of resilience, examples of times they demonstrated or developed resilience, and their views on the importance of resilience in education and the workplace. In both contexts, interviews were conducted either face-to-face or via video conferencing, guided by the participants' preferences and availability. Each interview spanned from 20 minutes to one hour. With the participants' consent, all interviews were audio-recorded and transcribed verbatim for data analysis.

2.4 Data analysis

Reflexive thematic analysis, as outlined by Braun and Clarke (2019, 2021) and Byrne (2021), was employed to analyse the transcribed data, underscoring the researchers' active role in identifying and interpreting meaning patterns within the datasets. This analysis adhered to Braun and Clarke's six-phase process: familiarisation with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing the report (Braun and Clarke 2019). Analysis was conducted independently for the datasets from each context, then integrated to compare the resilience experiences of engineering students in both contexts. Reflexive practices were maintained throughout the analysis to recognise the researchers' subjectivity in data interpretation (Braun and Clarke, 2019). To validate the findings, strategies such as member checking—inviting participants to comment on the initial themes—and peer debriefing—discussing the analysis and findings with colleagues for additional insights and to challenge biases—were implemented (Baumbusch 2010; Noble and Smith 2015).

2.5 Ethical considerations

To ensure the integrity and ethical conduct of this research, appropriate measures were taken in both the UK and SA. In the UK, ethical approval was obtained from Swansea University, aligning with institutional guidelines and standards for research involving human participants. In SA, the Research Ethics Committee: Human (REC-H) at Nelson Mandela University granted institutional ethical clearance before the research began. Informed consent was secured from all participants, and ethical standards were consistently upheld throughout data generation in both countries, thus maintaining the integrity of the research processes.

2.6 Limitations of the study

This comparative case study on the academic resilience of engineering students in SA and the UK offers valuable insights but has limitations. Conducted at only two universities, its findings might not extend to other institutions (Polit and Beck 2010). The small sample sizes limit the breadth of student experiences captured (Boddy 2016; Vasileiou et al. 2018). Reliance on self-reported data from interviews may introduce biases (Althubaiti 2016; Rosenman, Tennekoon, and Hill 2011). Finally, its cross-sectional design provides a snapshot rather than a longitudinal view of academic resilience (Caruana et al. 2015; Farrington 1991).

3 FINDINGS AND DISCUSSION

This section describes the results of the thematic analysis results, uncovering the nuanced experiences of engineering students in the UK and SA. It reveals both shared and distinct aspects of their resilience journeys, shaped by their unique educational and socio-cultural environments. Through examining individual resilience traits, coping mechanisms, and support systems, alongside cultural and institutional influences, we unpack the complexities of their experiences.

3.1 Similarities

In the exploration of similarities, we observe common threads in the resilience narratives of engineering students from both the UK and SA. Despite their geographical and cultural differences, these students share key resilience traits and face comparable challenges. This section highlights these shared experiences, emphasising universal aspects of academic resilience in EE. Excerpts are numbered to allow the reader to identify quotes from the same participant.

Individual resilience traits: Students in both contexts emphasised the importance of personal characteristics such as hard work, determination, and a growth mindset in fostering resilience. For example, a UK participant remarked, "*I approached this more as an opportunity to learn… because I'm not treating this as someone else's mistake. I rather try to take it as my own and see if actually there's something wron*g" (UK#23), underscoring the significance of self-reflection and personal growth. Another UK student shared, "*the idea that instead of focusing on the fact that last time when I did a lot of work, it didn't go so well, like its instead trying to build on what I did for the last assignment*" (UK#6), highlighting the importance of building on past experiences to improve future outcomes. Similarly, a SA student stated, "*I am a person who does* *not give up so easily, and when I tell myself that I need to fight, besides passion because at some point it's not all about passion, but it's about achieving what you want*" (SA#4), illustrating the significance of perseverance and goal attainment.

Coping with challenges: Engineering students in the UK and SA faced similar challenges, including the transition from high school to university, balancing academic demands with personal responsibilities, and navigating the coronavirus (COVID-19) pandemic. One UK student highlighted the distractions and temptations encountered when starting university: "*now you can do whatever you want to… so like that's also kind of one that pushes my resilience because now I have to keep my morals... there's no reason for you to get up early or anything*" (UK#1). This reflects the personal responsibility and self-discipline required at this educational stage. Similarly, an SA student shared, "*Interacting with people was a bit challenging to me, and even speaking or asking lecturers was a big challenge to me*" (SA#4), indicating the social and communicative hurdles faced in the university environment.

Support networks: In both the UK and SA, the significance of supportive networks including lecturers, tutors, and peers was universally recognised for providing essential guidance and encouragement. The influence of these networks extended to shaping students' sense of belonging and, consequently, their resilience. Engaging educators were seen as having the potential to "*inspire you to be a bit more resilient*" (UK#19) and to "*initiate the curiosity in someone, like the desire to learn*" (UK#12), making clear "*why you have to learn this*" (UK#12) to motivate students in a manner that supported resilience. Lecturers were appreciated for "*trying their best to give me as much as they can, and they even make themselves available*" (UK#9), enhancing student motivation and accountability. The motivational advantage of group settings was highlighted by a UK participant: "*when you're in a group you've got the motivation of working with people around you, whereas alone you don't have that so it makes it harder*" (UK#13). Within SA, the value of peer relationships, as well as the support from tutors and lecturers, was strongly emphasised, with students articulating the vital assistance they received from these relationships during their academic journey. SA#10 described a more informal peer support by saying that "*having a friend from South Africa that helped you with the English enough to transition with the language … built confidence*." This sentiment was echoed by another SA student who mentioned, "*Lecturers give you, like, personal contacts, email. Talk to me whenever we have a problem with this, just communication*" (SA#1), illustrating the critical role of accessible and interactive support systems in fostering resilience among engineering students.

Gender dynamics: The conversation around gender dynamics in EE revealed additional layers of complexity. Female students face unique challenges, including gender discrimination and heightened pressures to prove themselves in a predominantly male sector. For example, the UK data touched upon these gender-specific resilience demands, as a student recounted, "*horror stories from like woman being groped and stuff… I think that requires a lot of resilience. Also, I wouldn't want to work in like a super macho cultural workplace. I couldn't come to work like I know I couldn't handle it. It's too much. That would require a lot of resilience*" (UK#8). In SA, the sentiment resonates, with a student expressing, "*When you go into the engineering field as a lady, already people think that it's a male-dominated field. So, you go in with like a two mind of working as much as harder as them so you would end up maybe working like two times extra*" (SA#4). This underlines the critical intersection of gender and resilience, highlighting the necessity to address and comprehend these dynamics within the EE sphere, across both SA and the UK.

3.2 Differences

This section describes how varying cultural, social, and institutional factors uniquely shape participants' resilience journeys and abilities to navigate and overcome the specific challenges they face. For example, the UK findings offered more detailed insights into the role of institutional support in fostering resilience. A UK participant noted a "*myriad of things*" (UK#2) that were offered in terms of support with another saying, "*I have the full support I need*" (UK#11). Others listed the types of facilities they had access to with one saying the "*support team is really, really helpful to the students. They are on call to take measures to ensure students are at their best and also the psychological support from the students' support at university and also mentors, especially my project guide is really good to help me be more resilient towards situations*" (UK#14), with another explaining that "*suppose if you are facing struggling you can go to the Students Union and discuss with them. If you are some struggling in economies. You can get economic support, if you are struggling in your wellbeing or something there is some group where you can just pop in and just discuss with them. So, like there are more resources*" (UK#7). This indicates that responsive and supportive institutional practices are essential in enhancing resilience among UK engineering students. In contrast, in the SA context, institutional support was not as prominently or favourably discussed. A South African student expressed, "*I haven't necessarily used any support from the varsity system*" (SA#6), indicating a potential gap or underutilisation of institutional support mechanisms in enhancing student resilience.

Differences in support may be a result of the general marketisation of higher education within the UK (Brown, 2015) which has meant that the ability of the higher education institutions to charge increased fees became dependent upon their ability to demonstrate 'excellence' as part of the Teaching Excellence Framework (Department for Education, 2015) and thus an increased focus on metrics such as student satisfaction which is measured via the national student satisfaction survey (NSS). With this in mind, it is interesting to note that the majority of participants who spoke favourably of support within the UK context were international students and often compared the situation to their experience within their home country, with one saying "*general support is a lot more positive…I found, like professors here are lot more friendly than they are back in, my hometown or my country*" (UK#2). Much of these discussions were based around hierarchy and status and the fact that lecturers were more accessible in the UK "*because back there in my country… what I see in my university is that you can't sit next to the lecturer and talk about different subjects, because the lecturer is something up high, and you can't even get in touch…But here there are too many staff everyone. I think everyone tries to help you*" (5). In comparison, home students in the UK tended to be more critical of the support provided by university, thus highlighting the way in which experience and expectations shape resilience, this being articulated by one student who said "*to be honest its [resilience] very rare in the Western world… Very, very rare. Because, for example, the only way you can really get resilience, like I was saying is going through tough times or going through hardships of some sort, and the thing here is life I've seen is generally too easy*" (UK#1).

4 SUMMARY AND ACKNOWLEDGEMENTS

This study examined the academic resilience of engineering students in the UK and SA, uncovering nuanced experiences shaped by individual traits, cultural backgrounds, and institutional environments. While students in both regions face common academic pressures and life balance challenges, those in SA additionally navigate resource constraints, technological disparities, and the enduring effects of historical inequalities (Mapaling, Webb, and du Plooy 2022). Despite these hurdles, students from both countries exhibit significant resilience, harnessing personal strengths, supportive networks, and university resources to manage their challenges.

The findings emphasise the necessity for engineering programmes in both countries to bolster academic resilience through tailored support, inclusive curricula, and the creation of nurturing educational environments (Mapaling 2024). Such strategies are vital for developing a cadre of engineers who are not only academically adept but also socially responsible and prepared to tackle global challenges (Engineers Without Borders UK n.d.).

In conclusion, this study not only highlights the resilient nature of engineering students in diverse settings but also underscores the pivotal role of individual, communal, and institutional support in fostering academic success (Mapaling, Webb, and du Plooy 2021). It advocates for global collaboration in EE to equip students as future innovators and leaders. Future research should explore the efficacy of specific resilience-enhancing interventions, sampling multiple universities, recruiting larger and more diverse participant groups, incorporating additional data sources beyond. self-report, and adopting longitudinal designs to examine the long-term effects of resilience on the academic and professional journeys of engineering students.

ABSTRACT

Problem-solving and collaborative skills are crucial transferable skills for professional practice in engineering, as acknowledged by universities, employers, and accreditation bodies. However, there are engineering teachers who maintain a dichotomous perspective on the balance between transferable skills and academic knowledge, prioritizing the latter. Consequently, they are reluctant to integrate these

[1] *L.Y.Y. Luk*
lyyluk@hku.hk

skills into the curriculum at the expense of technical knowledge. Project-based learning (PjBL) has demonstrated potential in fostering both academic knowledge and transferable skills (Nguyen et al. 2020). However, existing research primarily focuses on students' perceptions on their learning outcomes (Guo et al. 2020). This study addresses this gap within the context of a first-year PjBL activity for biochemical and biomedical engineering students in a UK university by evaluating students' learning outcomes using both direct and indirect assessment methods. Findings from the study suggest that the PjBL activity can cultivate both technical knowledge and transferable skills. These results may help dispel misconceptions among engineering teachers that transferable skills can only be developed at the expense of technical knowledge. Interestingly, this study also found that engineering students perceived the development of critical problem-solving skills, but not collaborative skills from the PjBL activity. This observation warrants further investigation to determine the factors that influence students' perceptions of skill development in PjBL activities.

1 INTRODUCTION

Problem-solving and collaborative skills have been widely recognized by universities, employers and accreditation bodies as important transferable skills (Chan and Luk 2021) for professional practice in engineering (Passow and Passow 2017). Despite increasing efforts made by universities to introduce or integrate these competencies into the engineering curriculum, employers continue to express their dissatisfaction with engineering graduates, complaining about the gap between their expectations and the competencies an engineer graduate should possess. At the same time, engineering teachers were found to hold dichotomous perspective regarding the balance between transferable skills and academic knowledge in engineering, with some teachers seeing transferable skills to be secondary and continue to emphasize the importance of academic knowledge for engineers (Chan and Luk 2022). To put it simply, they do not want to help students to develop these competencies at the expense of technical knowledge and skills. They also find integrating the teaching of these competencies into their already dense course curriculum time-consuming and resource-intensive (Krause 2014; Chan et al. 2017).

Project-based learning (PjBL) has shown promise in developing both academic knowledge and transferable skills (Nguyen et al. 2020), increasing students' motivation (Wijnia et al 2024) and career aspirations in STEM disciplines (Beier et al 2019). However, studies on its impacts have largely focused on the perceptions of students (Guo et al. 2020). This study does not only provide an example of a one-week intensive project-based learning activity that is integrated into the engineering curriculum in an UK university, but also reports on findings from an evaluation of engineering students' learning outcomes through the use of both direct and indirect assessment. During the week, students were exposed to engineering design principles and theoretical knowledge related to assigned projects, as well as product development process, project management and teamwork skills. As previous studies mainly looked at undergraduates' perceived learning outcomes from their project-based learning experiences, there is a lack of empirical evidence on academic outcome indicators (i.e. technical knowledge gain) which provide more direct evidence of student learning. This study addresses this gap in the literature in the context of a first year PjBL activity for biochemical and biomedical engineering students by measuring their perceived transferable skills development with a validated instrument, which also include a direct measure of their technical knowledge. It aims to examine the research question: What are the learning gains in technical knowledge, problem-solving skills, and collaborative skills experienced by biochemical and biomedical engineering students as a result of a one-week intensive project-based learning activity?

2 LITERATURE REVIEW

2.1 Project-based Learning in Engineering

Project-based Learning (PjBL) offers engineering students the chance to apply their knowledge in practical situations (Mitchell and Rogers, 2020). According to Palmer and Hall (2011), this approach engages students in solving problems that lead to the creation of an artifact, which can be a model, an application, etc. Typically, students work in teams, and the projects can be multidisciplinary, requiring collaboration over an extended period of time.

2.2 Impact of Project-based Learning on Student Learning in Engineering

There is a general agreement in the literature about the benefits of project-based learning to students' development of technical knowledge and transferable skills. For example. Rodríguez et al. (2015) found that space engineering students who participated in PjBL activities felt more confident about their technical subject knowledge compared to students who did not. In a study conducted by Alves and colleagues (2017) in Portugal, it was found that industrial engineering students who participated in PjBL self-reported enhanced teamwork skills, leadership skills, communication skills, adaptability and sense of responsibility and self-reflective skills.

However, studies (e.g. Palmer and Hall 2011; Hall, Palmer and Bennett 2012; Alves et al. 2017) have largely focused on student perception. Majority of these studies have adopted self-reported questionnaires, with few using direct measures, such written tests or multiple-choice questions (Guo et al. 2020).

3 RESEARCH CONTEXT

This study took place in an Engineering Faculty in a UK university that has been implementing project-based learning (PjBL) activities across the first two years of undergraduate engineering programmes (Mitchell et al. 2021). Survey data was collected during the one-week scenarios that are central to the undergraduate engineering programmes.

In the biochemical scenario, students had to work in teams of four to five as part of a consultancy company that aims to tackle problems relating to the quality of ice cream production. By understanding the science behind ice cream (e.g. its multiphasic nature and the impact of certain ingredients such as emulsifiers) along with the manufacturing process, students were able to redesign the manufacturing process and provide advice on raw materials and additives to better enhance the quality of the end product. Students also had to provide a cost analysis and present their research and new process design to the client (staff). To further assist them, students visited an ice cream manufacturing site and were able to tour the facility, observe and participate in ice cream production and ask questions to the facility director to aid them in their own research. In the Biomedical scenario, students had to work in a team of three to develop a useful healthcare application which can identify objects.

4 METHODOLOGY

4.1 Participants

A total of 106 engineering undergraduates in a UK university participated in the Pre-Scenario Survey and 111 students participated in the Post-Scenario survey. After removing incomplete responses, the final student sample of the Pre-Scenario Survey consists of 104 biochemical and biomedical engineering undergraduate students, while the final student sample of the Post-Scenario survey consists of 80 biochemical and biomedical engineering undergraduate students. All the participants are first year undergraduate students, between 18 and 26 years old.

4.2 Instrument

The survey instrument consists of 2 sections. The first section consists of a technical knowledge test developed by the module leader. Here is an example of one test question taken from the test for Biomedical engineering students:

In a Matlab app, which function is executed first after the app has started? Answer Options: (a) startupFcn, (b) main, (c) function, (d) ButtonPushed.

The second section contained two scale (10 items), presented in Table 1, measuring students' perceived competency in problem-solving and collaborative skills, adapted from a validated Student Holistic Competency developed by Chan and Luk (2021). Each of the 10 items was rated on a 5-point Likert scale ranging from 1 (not competent) to 5 (very competent). Students were also required to provide demographic information including their gender, age, year of study, programme of study at the end of the questionnaire.

The 10 items soft skills questionnaire was piloted on 88 students from electrical and electronic engineering. Exploratory factor analysis was conducted on the 10 items to assess construct validity of the instrument. Presented in Table 1, factor analysis yielded two factors based on the eigenvalue greater than 1 criterion (Kaiser 1974). The two factors accounted for 55.98% of the total variance. Factor 1 consisted of seven items related to critical thinking and problem-solving skills. This factor was labelled as 'Critical problem-solving skills'. Factor 2 contained three items referring to the ability with work collaboratively with others as a team. This factor was named as 'Collaborative skills'.

Table 1. Exploratory Factor Analyses of the Transferable Skills Items

	1	2
Critical Problem-solving Skills		
Questioning values, practices and opinions	**0.43**	

Reflecting on and challenging one’s values, perceptions and actions	**0.53**	
Taking your own position or viewpoint	**0.47**	
Taking a holistic overview of complex problems	**0.61**	
Applying different problem-solving frameworks to complex problems	**0.71**	
Collectively developing viable solutions to solving complex problems	**0.84**	
Analysing complex problems	**0.94**	
Collaborative Skills		
Learning from others		**0.77**
Understanding and respecting the needs, perspectives and actions of others		**0.91**
Handling conflicts in a group		**0.58**

4.3 Procedures

A purposive sampling approach (Johnson and Christensen 2014) was undertaken, such that students were approached by the researcher on the first and last day of the scenario project, which is held in the second term of Year 1. The students were given approximately 15 minutes to complete the questionnaire.

4.4 Data Analysis

Data analysis was undertaken using SPSS 24.0 and R. Before conducting independent samples t-test to investigate differences between students’ technical knowledge and perceived soft skills development before and after the scenario, confirmatory factor analysis was conducted on the Pre-Scenario survey data to confirm the internal structure of the transferable skills questionnaire. This step is undertaken to ensure that survey is valid for biochemical and biomedical engineering students as well. Based on the criteria suggested by Hu and Bentler (1999), the results show an acceptable fit of the ten items to the two-factor structure for the questionnaire, which is indicated by a Comparative Fit Index (CFI) above 0.90, a Root Mean Squared Error of Approximation (RMSEA) below 0.08, and a Standardized Root Mean Squared Residual (SRMR) below 0.08. The item-factor loadings were all significantly different from zero ($p<.05$), with values ranging from 0.52 to 0.77, as reported in Table 2. The Cronbach alpha coefficient (see Table 3) for the two scales ranged from 0.77 to 0.89, suggesting that the questionnaire is reliable.

Table 2. Confirmatory Factor Analyses of the Transferable Skills Items

	1	2
Critical Problem-solving Skills		
Questioning values, practices and opinions	**0.71**	
Reflecting on and challenging one’s values, perceptions and actions	**0.74**	

Taking your own position or viewpoint	**0.57**	
Taking a holistic overview of complex problems	**0.56**

Table 3. Reliability and Validity Evidence at Scale Level

	No. of items	*n*	*M*	*SD*	Cronbach's Alpha	Eigenvalue	% of Variance
Critical Problem-solving Skills	7	100	3.54	0.67	0.89	4.23	60.38
Collaborative Skills	3	100	3.82	0.76	0.77	2.08	69.33

5 RESULTS

Table 4 and 5 presents the means, standard deviations, and t-values for the two scales, as well as Cohen d as a measure of the effect size.

Comparison of biomedical and biochemical engineering students' perceived competency in transferable skills through the use of independent samples t-test revealed no substantive differences between students' perceived competency in collaborative skills before and after the scenario project. This finding suggests that the students perceive themselves as competent in collaborative skills, and do not see the scenario project as an opportunity to further develop their collaborative skills.

However, there is a significant difference between their perceived competency in critical problem-solving skills before ($M_{Biomed}=3.48$, $SD_{Biomed}=0.74$; $M_{Biochem}=3.63$, $SD_{Biochem}=0.54$) and after ($M_{Biomed}=3.93$, $SD_{Biomed}=0.63$; $M_{Biochem}=4.04$, $SD_{Biochem}=0.56$) the scenario project. The calculated effect size is medium ($d_{Biomed}=-.66$; $d_{Biochem}=-0.75$). The independent samples t-test also indicated that there is a significant difference between their technical knowledge before ($M_{Biomed}=2.60$, $SD_{Biomed}=1.15$; $M_{Biochem}=4.82$, $SD_{Biochem}=1.32$) and after ($M_{Biomed}=3.95$, $SD_{Biomed}=1.30$; $M_{Biochem}=5.55$, $SD_{Biochem}=0.69$) the scenario project. The calculated effect size is large ($d_{Biomed}=1.09$) for biomedical students and medium ($d_{Biochem}=-0.64$) for biochemical students. The findings suggest that students perceive an improvement in both critical problem-solving skills and technical knowledge after completing the scenario project.

Table 4. Comparison between Biomedical students before and after the PjBL activity

6 DISCUSSION

The findings of this study suggests that PjBL can foster the development of both technical knowledge and transferable skills, especially when the activities are designed with both aspects in mind. These results can help dispel the misconception among engineering teachers that transferable skills can only be developed at the expense of technical knowledge. Building on the finding in Rodríguez et al.’s (2015) study, findings from this study suggest that PjBL does not only help to increase engineering students’ self-confidence in their technical knowledge, but also improve their technical knowledge.

An interesting finding from this study is that engineering students perceived the development of critical problem-solving skills, but not collaborative skills.

One possible explanation is that collaborative skills were heavily emphasized during the Engineering Challenges module, which occurs in the first term of their undergraduate studies. Consequently, students might view the second-term Scenario module as an opportunity to apply, rather than develop, these skills. The findings from this study contrast with those of Alves and colleagues (2017), who found that engineering students perceived an increase in teamwork skills from their PjBL experiences. However, comparison is difficult because the students in Alves et al.'s study were Masters-level students who worked in teams to propose solutions for an ill-defined problem, which was not described in detail in their paper.

Another potential explanation is that transferable skills, such as collaborative skills, require time and multiple opportunities for practice or application to develop fully. In other words, students need to apply these skills in various contexts before perceiving their development. For critical problem-solving skills, students may have had numerous opportunities to apply them in other modules and prior to their university studies, leading them to feel they are progressing in this area. In contrast, teamwork might be a relatively new concept for them compared to problem-solving. They may have only begun practicing these skills during the first term of their university studies, and thus, require more time to feel comfortable demonstrating their collaborative abilities and perceiving their development.

To gain further insights, follow-up interviews need to be conducted with the students. This will help explore the reasons behind their perceptions of skill development, and allow for a more in-depth understanding of the factors influencing these perceptions. Future research can also involve collecting feedback from alumni on whether their learning and skill development through PjBL is helpful in preparing them for the workplace.

ABSTRACT

The study conducted by Lee *et al.* (2019) delves into the impact of exposure to STEM learning on the participation and retention of women in engineering studies. Building upon this research, this study explores the intricate relationship between individuals' formative educational experiences and their career pathways, investigating the factors that shape these decisions. Utilising online focus groups, the research engages two distinct participant groups: practicing engineers and individuals who diverted from pursuing a career in engineering. Thematic analysis

[1] *M. McNea*
meryn.mcnea@ul.ie

was employed to decipher the data, revealing multifaceted challenges such as confidence barriers, gender dynamics, and mismatches between academic theory and industry demands. The study underscores the significance of holistic support systems, practical learning experiences, and critical thinking skill development to empower students and better prepare them for the complexities of the engineering profession. It advocates for inclusivity, diversity, and hands-on learning initiatives within engineering education, emphasising the importance of bridging the gap between academia and industry. By prioritising the development of critical thinking skills and fostering a culture of support and collaboration, we can ensure graduates are adequately equipped to tackle engineering challenges effectively, thus enhancing both educational experiences and the advancement of the engineering field.

1 INTRODUCTION

Engineering education serves as the cornerstone of technological advancement and innovation across diverse industries. The cultivation of skilled engineers is pivotal for addressing complex societal challenges and driving economic growth. However, despite concerted efforts to recruit and retain talented individuals in the field, challenges persist in comprehensively understanding the multifaceted experiences and decision-making factors within engineering education and careers. Scholarly research such as that by Cheryan *et al.* (2017), Buckley *et al.* (2019), Ishikawa and Newcombe (2021) and Lane and Sorby (2022) underscores the importance of elucidating these dynamics to optimise educational practices, inform policy initiatives, and foster a supportive environment conducive to the success of aspiring engineers. Recent studies have highlighted various factors influencing the decision to pursue engineering as a field of study. For instance, research conducted by Tyler-Wood *et al.* (2018) explores human constructivist learning and how it influences students' attitudes, interest and performance in STEM (Science, Technology, Engineering and Mathematics) education and their later career choices, emphasising the importance of active engagement and learning in modern education. Furthermore, findings from a longitudinal study by (Cheryan et al. 2017) underscore the impact of stereotypes and societal perceptions on the underrepresentation of certain demographic groups, emphasising the need for targeted interventions to promote diversity and inclusivity within the engineering profession.

While existing literature provides insights into specific aspects of engineering education, there remains a gap in comprehensively exploring the educational experiences of practicing engineers and those diverging from engineering careers. Understanding these experiences is crucial for addressing barriers, enhancing support mechanisms, and fostering inclusivity. This study addresses this gap through a thematic exploration of formative educational experiences in engineering, using qualitative methods such as online focus groups with two distinct participant groups: practicing engineers and individuals pursuing non-engineering careers. By examining their narratives, this research aims to uncover the challenges, successes, decision-making processes, and socio-cultural influences in their educational and professional journeys. Exploring spatial thinking in engineering education and careers is significant due to its profound impact on practice. Spatial thinking, involving understanding and manipulating spatial relationships, is fundamental in visualizing systems, designing structures, and solving spatial problems (McNea et al., 2023). This study investigates how individuals perceive and apply spatial thinking throughout their educational and professional paths in engineering, aiming to underscore its importance and identify areas for improvement.

To summarise, this research seeks to shed light on three critical questions. Firstly, we aim to explore the challenges and opportunities encountered by engineering aspirants during their academic journey, and how these experiences influence their career decision-making processes within the field of engineering (RQ1). Secondly, by examining the insights garnered from this study, we seek to inform the development of strategies and initiatives aimed at enhancing diversity, inclusivity, and support mechanisms within engineering education and professional practice (RQ2). Lastly, we aim to investigate how individuals perceive the evolution and application of spatial thinking throughout their journey in engineering education and career, unveiling the efficacy and importance of spatial thinking education and training initiatives in the engineering domain (RQ3). Through addressing these research questions, this study aims to contribute to a deeper understanding of the challenges and opportunities within the engineering pipeline and to provide evidence-based recommendations for fostering a more inclusive and equitable environment within the engineering profession.

2 METHODOLOGY

Recognising the complexity and diverse nature of individuals' journeys in the engineering profession, qualitative methods are chosen to capture the richness of participants' narratives, perspectives, and insights. The research methodology encompasses the following key components:

- **Formulation of Research Questions**: The research questions were carefully formulated to address specific topics relevant to the study's objectives. They were designed to be focused, feasible, and aligned with the study's scope and purpose, as detailed in Section 1.
- **Participant Recruitment**: As a preliminary study, participants were selectively chosen to ensure diverse representation relevant to the research goals. Eligibility included practicing engineers or those who had considered engineering careers, convenience sampling was used with small participant numbers due to this being the pilot phase of the study. Upon meeting criteria, participants were assigned time slots for online focus groups. Transparent communication channels were established throughout recruitment to address inquiries promptly, ensuring informed consent.
- **Ethical Considerations** were crucial in every stage. Participants provided informed consent before data collection, understanding the study's purpose, procedures, risks, benefits, and their rights. Confidentiality and anonymity were strictly preserved to protect participants' privacy and sensitive information. Identifiable data were pseudonymised during analysis to maintain confidentiality.
- **Data Collection**: Arrangements were made with all participants for synchronous online discussions (focus groups) using Microsoft Teams. Prior to the sessions, they were briefed on the objectives of the focus groups and provided with necessary instructions for participating in the online environment. Throughout the sessions, the principal investigator facilitated discussions, steering the

conversation toward predetermined topics or questions aligned with the research objectives;

1. Can you share what influenced your decision (not) to pursue a career in engineering? How did these expectations align with your actual experiences or career trajectories?
2. Reflecting on your educational journey in engineering education, can you share specific moments or aspects that surprised you, made your experience enjoyable, or influenced your overall recommendation for others considering a path in engineering?
3. How do you believe the engineering education system could be enhanced to better prepare individuals for the challenges they may face in their careers? What advice would you offer to someone currently navigating their path in engineering or considering a different career direction?
4. Can you talk to me about your experiences with spatial thinking / learning throughout your education and career?

All sessions were recorded with consent, allowing for a comprehensive capture of verbal exchanges, non-verbal cues, and group dynamics. Following the completion of each focus group, recordings were transcribed verbatim, ensuring an accurate representation of participant dialogue. The transcriptions were then subjected to thorough quality checks to maintain fidelity to the original recordings.

- The **Data Analysis** process employed in this study was a theoretical thematic analysis as described by Braun and Clarke (2006 and 2012) aimed at uncovering the diverse and multifaceted narratives embedded within participants' experiences in engineering education and careers. It consists of six steps:
  1. Data Familiarisation
  2. Initial Coding
  3. Code Development and Organisation
  4. Iterative Refinement
  5. Theme Elaboration and Definition
  6. Interpretation and Synthesis

3 RESULTS

Table 1 presents the themes that emerged from the focus groups listed by the theme’s appearance in transcriptions. These findings encapsulate insights from both active engineers *(n=7)* and individuals who previously considered pursuing engineering *(n=3)*. Formulated meanings from each focus group were arranged into clusters which resulted in six themes: “challenges”, “confidence”, “social dynamics & influence”, “personal factors”, “opportunities & surprises” and “skills & competencies”.

Table 1: Frequency Distribution of Themes across all 3 Online Focus Groups

THEME	FREQUENCY & VALID PERCENTAGES*					
	All Participants (n=10)		Practicing Engineers (n=7)		Engineering Contemplators (n=3)	
Challenges	50	(12%)	43	(13%)	7	(5%)
Confidence	70	(16%)	27	(8%)	43	(32%)
Social Dynamics & Influence	71	(16%)	44	(14%)	27	(20%)
Personal Factors	97	(22%)	72	(23%)	25	(19%)
Opportunities & Surprises	54	(12%)	47	(15%)	7	(5%)
Skills & Competencies	93	(21%)	87	(27%)	26	(19%)
Total:	435	(100%)	320	(100%)	135	(100%)

3.1 Emerging Themes

While a relatively small sample size, in the combined results (n=10), 'Personal Factors' emerge as a significant influence, with both positive and negative aspects. This theme encompasses various codes like "personal background," "interests," "lifestyle choices," and "expectations versus reality." Among practicing engineers (n=7), 'Skills and Competencies' such as "work experience," "cross-experience collaboration," "critical thinking," and "spatial thinking" are highlighted as primary influencers on their educational journeys. These factors often steer individuals toward unexpected career paths. For former aspiring engineers (n=3), 'Confidence' emerges as the key influencer, with factors like "imposter syndrome," "self-belief," "fear of failure," and "undermining" playing significant roles in their decisions. These insights underline the complex relationship between personal confidence and career aspirations.

3.2 Challenges

The results of the analysis provide a comprehensive understanding of the challenges individuals encounter throughout their career trajectories. Despite proactive efforts, participants faced limitations in job opportunities, suggesting potential mismatches between skills and market demands. Communication hurdles, including difficulties in professional presentations and articulating needs without conflict, emerged as significant obstacles. Additionally, participants expressed dissatisfaction with the theoretical nature of their education, particularly in engineering, longing for more practical, hands-on experiences. Feelings of self-doubt and a lack of confidence were prevalent, influenced by academic performance, gender dynamics, and peer comparison. External influences, such as societal expectations, also played significant roles in shaping career decisions. Furthermore, participants identified challenges within the educational system, notably in navigating administrative processes like the Irish Central Applications Office (CAO), adding complexity to career planning. These findings highlight the multifaceted nature of career challenges and underscore the importance of holistic support systems to address them effectively, empowering individuals in their professional journeys.

3.3 Confidence

Participants expressed a variety of experiences and perspectives, illustrating both positive and negative effects on their educational journeys. On one hand, confidence was identified as a catalyst for enhanced engagement and enjoyment in engineering coursework. Participants described how gaining a deeper understanding of concepts or receiving support positively impacted their confidence levels, leading to greater satisfaction with their studies and aspirations for future careers. Overcoming initial apprehensions, particularly regarding the rigorous mathematical aspects of engineering, contributed to a sense of personal growth and empowerment among participants. Moreover, embracing mistakes as integral to the learning process and fostering belief in oneself were identified as crucial factors in cultivating confidence and resilience within the academic setting. Conversely, the discussions also revealed the presence of social dynamics, particularly concerning gender, that could negatively influence confidence levels among certain participants. Female students, in particular, recounted experiences of feeling outnumbered, overlooked, or underestimated in predominantly male environments, highlighting the challenges of navigating gendered spaces within engineering education. Instances of "mansplaining" and unsolicited advice further underscored the need for greater awareness and inclusivity to mitigate gender biases and promote a supportive learning environment for all students. Furthermore, participants shared personal struggles with self-doubt and fears, particularly related to mathematics, a cornerstone of engineering curricula.

"It was the fear of failing … that fear put me down the route I am as well (non-engineer)" (female)

Intimidation by perceived difficulty and pressure to excel in mathematical coursework were identified as significant barriers to confidence and academic persistence. These narratives underscored the importance of addressing psychological barriers and fostering a culture that embraces failure as a natural part of the learning process, thereby promoting confidence and academic success. While confidence can fuel engagement and personal development, it's imperative to tackle systemic barriers and cultivate inclusive environments to foster confidence and empower every student to excel in engineering fields.

3.4 Social Dynamics and Influence

Role models, particularly those within families, profoundly influenced participants' educational paths. Often family members with engineering backgrounds, these figures not only inspired but also shaped career aspirations. Their guidance from a young age instilled a passion for engineering, impacting decisions to pursue this field. This influence extended beyond individuals, inspiring peers and colleagues to follow similar paths. Teamwork emerged as fundamental in engineering education. Collaborative efforts cultivated interpersonal skills, problem-solving abilities, and collective responsibility. Group projects mimicked real-world workplaces, emphasising effective communication and interdisciplinary cooperation. Diverse team backgrounds enriched problem-solving, though challenges like communication barriers were acknowledged, highlighting the need for ongoing interpersonal skill development alongside technical competencies. Support systems were crucial in nurturing individuals' growth. Peer interactions provided motivation and camaraderie, spurring excellence in studies and projects. Mentorship programs and practical experiences, like internships, offered guidance from seasoned professionals, enhancing learning and skill development. Moreover, individuals influenced each other, shaping experiences and decisions through peer interactions and collaborative efforts, fostering a sense of community and propelling collective growth towards shared goals and success.

3.5 Personal Factors

The exploration of participants' experiences in engineering education uncovered a notable contrast between initial expectations and actual realities. Many were surprised to find themselves drawn to aspects of engineering they hadn't initially anticipated, such as software development or research, while others noted a disconnect between academic theory and real-world engineering demands. Additionally, participants emphasised the significance of teamwork, problem-solving, and practical skills throughout their educational journey. These findings underscore the necessity for a curriculum that harmonises theoretical knowledge with hands-on experience to better equip students for the multifaceted challenges of the engineering profession. Lifestyle decisions emerged as pivotal factors shaping educational pathways in engineering. Participants cited personal considerations like family responsibilities, career aspirations, and shifting values as influential in their decision-making processes. Some pursued engineering education to advance their careers or foster personal growth, while others altered their paths to align with evolving priorities.

"It was primarily driven through a lifestyle decision. You know, young baby on the way". (male)

This highlights the intricate interplay between individual circumstances and educational choices within the engineering realm. The analysis of participants' personal backgrounds revealed diverse routes into engineering education, shaped by prior qualifications or experiences in related fields such as teaching or software development. Participants also discussed the influence of upbringing, ranging from farming backgrounds to legal professions, underscoring the diverse influences shaping individuals' interests and motivations in pursuing engineering. Overall, these findings emphasise the multifaceted nature of personal backgrounds in shaping educational experiences and career trajectories within the field of engineering.

3.6 Opportunities and Surprises

Participants highlighted how positive experiences, particularly from secondary school projects like Formula One in Schools, sparked their interest in engineering disciplines. Internships were pivotal in shaping career paths and providing practical application of knowledge. Collaborative teamwork enhanced problem-solving skills. The flexibility of educational programs, exemplified by internship opportunities, influenced students' decisions to pursue engineering studies. Opportunities were crucial in instilling confidence and fostering growth, advocating for early exposure to practical learning experiences. Surprising elements, such as unexpected career paths and challenges in transitioning between undergraduate and postgraduate studies, underscored the importance of adaptability. Participants expressed astonishment at the emphasis on teamwork and the level of detail in specialised programs. Moreover, the absence of continuity between school-based initiatives and higher education highlighted the need for greater integration of hands-on initiatives throughout the educational pipeline to sustain interest in engineering disciplines from school to college.

3.7 Skills and Competencies

Participants offered varied perspectives, with some praising the invaluable role of internships in shaping their academic journey and career trajectory, while others stressed the importance of practical learning in real-world engineering contexts. Despite positive attitudes toward work experience, concerns were raised about the disparity between academic studies and practical learning in engineering education. Participants suggested integrating hands-on experiences into curricula to align better with industry standards.

"The problem-solving skills, critical thinking that you will use on a day-to-day basis are probably the lesser focused topics" (male)

Cross-experience collaboration was highlighted as vital, emphasising the value of diverse perspectives and problem-solving approaches. Recommendations included enhancing collaboration between educational institutions and industry partners to cultivate critical thinking skills. Participants underscored the need to prioritise critical thinking in engineering education and recommended incorporating more diverse courses to prepare graduates for real-world challenges. Overall, there was a consensus on the importance of balancing practical experience with critical thinking skills in engineering education to adequately prepare students for professional complexities. In light of the diverse perspectives on spatial thinking in engineering education, there is a pressing need to prioritise critical thinking and problem-solving skills to adequately prepare graduates for the complexities of the profession. While spatial thinking plays a crucial role in engineering tasks, it is just one aspect of the multifaceted challenges engineers encounter. By emphasising critical thinking and problem-solving, engineering education can equip students with the ability to approach problems holistically, analyse situations from multiple angles, and devise innovative solutions. This broader skill set not only enhances their capacity to navigate spatial challenges but also equips them to tackle the intricate socio-technical problems prevalent in today's engineering landscape. Moreover, fostering critical thinking cultivates a mindset of continuous learning and adaptability, essential for engineers to thrive in an ever-evolving technological environment. Thus, by integrating spatial thinking within a framework of robust critical thinking and problem-solving skills, engineering education can better prepare graduates to tackle the diverse and dynamic demands of the profession effectively.

4 DISCUSSION

This study aimed to explore the educational experiences within engineering education and careers, with a focus on uncovering challenges, triumphs, decision-making processes, and the role of spatial thinking in participants' journeys. Through online focus groups engaging practicing engineers and individuals who diverted from pursuing engineering careers, valuable insights were gained into the multifaceted nature of experiences within the field. In this discussion, we will analyse and interpret the findings considering existing literature, addressing key themes such as "Personal Factors", "Confidence" and "Skills & Competencies". Firstly, the narratives of practicing engineers shed light on the practical aspects, dynamics, and factors contributing to success within the engineering field. Their experiences underscore the importance of practical learning, interdisciplinary collaboration, and ongoing skill development in navigating the complexities of engineering careers. Additionally, insights into the experiences of individuals who diverted from engineering careers offer valuable perspectives on the diverse reasons and decision-making processes guiding them away from their initial aspirations. By examining both groups' narratives, we can gain a comprehensive understanding of the challenges and opportunities present within engineering education and career trajectories.

The notion of students experiencing a disconnect between their initial expectations and the realities of engineering education resonates with existing literature on the mismatch between academic preparation and industry demands (Brunhaver et al. 2018; Trevelyan 2019). Research suggests that students often have idealised perceptions of engineering careers, and the actual experiences may differ significantly, leading to challenges in academic and professional adaptation (Eliot and Turns 2011; Morelock 2017). The emphasis on teamwork, problem-solving, and practical skills aligns with the literature advocating for hands-on, experiential learning approaches in engineering education (Sorby *et al.* 2018; Van den Beemt *et al*. 2020; Bower *et al*. 2022; Maker *et al*. 2023). Studies have shown that integrating practical experiences into the curriculum enhances students' abilities to apply theoretical knowledge to real-world challenges and fosters a deeper understanding of engineering concepts (Ring et al. 2017; Lobovikov-Katz 2019; Dare *et al.* 2021; Le *et al.* 2023; Nipyrakis *et al.* 2023).

The findings regarding the positive impact of confidence on academic engagement and enjoyment in engineering coursework align with existing literature on self-efficacy theory (Bandura 1997). Research suggests that students with higher levels of confidence are more likely to persevere through challenges, actively engage in learning activities, and experience greater satisfaction with their academic experiences (Cheryan *et al*. 2017; Gagnier *et. al* 2022; Miola *et al.* 2023). The identification of overcoming apprehensions about the mathematical aspects of engineering as contributing to personal growth resonates with literature on mathematical anxiety and its impact on STEM education (Close and Shiel 2009; Shiel and Kelleher 2017; Delage et al. 2022). Studies have shown that students who experience mathematical anxiety may exhibit avoidance behaviours and reduced performance in engineering disciplines, highlighting the importance of addressing these barriers to promote academic success (Sorby *et. al* 2018; Daker *et al*. 2021). The discussion on gender dynamics and their influence on confidence levels among female students reflects broader research on gender disparities in STEM fields (Stoet and Geary 2018). Literature suggests that women in male-dominated environments may experience stereotype threat, imposter syndrome, and microaggressions, which can negatively impact their confidence and sense of belonging in STEM disciplines (Cheryan et al. 2017). The discussion underscores the need for inclusive environments to mitigate gender biases and promote confidence among all students, which aligns with literature on diversity and inclusion in engineering education (Scott 2020; García-Holgado *et al.* 2021; Verdugo-Castro *et al.* 2022) Research emphasises the importance of creating supportive learning environments that value diversity, equity, and inclusion to enhance engagement, retention, and success in STEM disciplines (O'Leary et al. 2020).

It is noteworthy that participants in the study struggled to provide a clear definition of spatial thinking. This observation aligns with existing literature that acknowledges the complexity and multidimensionality of spatial thinking, which encompasses various cognitive processes such as mental rotation, visualisation, and spatial reasoning (Newcombe and Shipley 2015; McNea et al. 2023). While participants may not have articulated a precise definition of spatial thinking, their experiences and insights shed light on its importance in engineering education. This aligns with literature emphasising the significance of spatial thinking abilities in engineering tasks, including the visualisation and manipulation of complex structures, analysis of spatial relationships, and design of innovative solutions (Sorby 2009; Gagnier *et al*. 2017). Moreover, the data highlights the necessity for a holistic approach to problem-solving in engineering education. This aligns with literature advocating for integrative and interdisciplinary approaches, recognising that addressing engineering challenges requires students to consider multiple factors, perspectives, and constraints (Hegarty 2018). Critical thinking skills are essential for students to analyse problems from various angles and develop effective solutions.

This emphasises the role of critical thinking in fostering a mindset of continuous learning and adaptability, essential for engineers to thrive in an ever-evolving technological environment. This aligns with literature highlighting the importance of lifelong learning and professional development in engineering practice (Power and Maclean 2013). Engineering graduates must be equipped with the skills to adapt to rapid technological advancements and evolving industry trends. The integration of spatial thinking within a framework of robust critical thinking and problem-solving skills is paramount for adequately preparing graduates to tackle the multifaceted demands of the profession (Gagnier *et al.* 2022). By prioritising these skills and adopting interdisciplinary approaches, educational institutions can ensure that engineering graduates possess the analytical acumen and problem-solving capabilities necessary to succeed in today's rapidly evolving technological landscape.

5 CONCLUSION

In conclusion, the study provides valuable insights into the challenges, experiences, and opportunities encountered by individuals in engineering education and career paths. It emphasises the importance of holistic support systems, inclusivity, and practical learning experiences in empowering students to succeed in the engineering profession. By addressing systemic barriers, fostering confidence, and promoting critical thinking skills, educational institutions and stakeholders can better prepare graduates to navigate the diverse and dynamic demands of the engineering landscape.

It is essential to continue advocating for inclusivity, diversity, and hands-on learning initiatives within engineering education. By prioritising the development of critical thinking skills, fostering a culture of support and collaboration, and bridging the gap between academia and industry, we can ensure that graduates are equipped to tackle the challenges and complexities of the engineering profession effectively. This comprehensive approach will not only enhance the educational experiences of students but also contribute to the advancement of the engineering field as a whole.

Communication Competence (CCC) Model, this study explores engineering students' experiences in a multicultural engineering education research project, aiming to identify specific challenges that hinder competent communication and propose actionable strategies for improvement. Through qualitative interviews and content analysis, the research highlights challenges in comprehensibility, team bonding, and navigating diverse disciplinary languages and cultural norms. The findings advocate for proactive measures such as early training in common language establishment, trust-building activities, and engaged reflexivity to enhance communication dynamics within multicultural research teams.

1 INTRODUCTION

Today's world faces significant environmental and societal challenges, including climate change, population growth, disasters, and equity disparities. To tackle these challenges effectively, groundbreaking scientific and technological research among individuals with varied expertise and cultural backgrounds is essential (Aldert 2019; Leevers, H 2020). Diversity of knowledge, skills, and cultural backgrounds is crucial, as it brings fresh insights and perspectives and enhances problem-solving capabilities needed to address complex challenges (Aldert 2019; Chubin, May, and Babco 2005; Euro-CASE 2020). Cultural diversity, sometimes referred to as multiculturalism, is "a system of beliefs and behaviors that recognizes and respects the presence of all diverse groups in an organization or society, acknowledges and values their socio-cultural differences, and encourages and enables their continued contribution within an inclusive cultural context which empowers all within the organization or society" (Rosado 2006). Thus, effective communication is vital in culturally diverse engineering research environments to ensure successful collaboration and knowledge exchange (Varhelahti and Turnquist 2021). This paper aims to identify factors hindering competent communication among engineering students in multicultural research project settings and proposes strategies to promote improved communication. By promoting competent communication and recognizing individual differences, engineering environments can thrive and effectively tackle complex societal and environmental challenges.

1.1 Background and Theoretical Framing

Engineering education must develop technically and professionally competent graduates to meet the ever-changing demands of engineering practice. This necessitates curriculum reform incorporating early exposure through hands-on, practical activities that reflect real engineering practices (Crawley et al. 2014). Engineering research projects provide an excellent avenue for such exposure, equipping students with essential competencies and leading to notable outcomes such as career readiness, disciplinary knowledge, and an understanding of how engineering practice functions (Seymour et al. 2004).

Supported by funding bodies like NSF and Horizon 2020 Europe (Castelpietra et al. 2020; NSF 2008), these engineering research projects involve culturally diverse teams with varied skills and expertise crucial for enhancing creativity and advancing science (Leung et al. 2008). However, this multiculturalism introduces complex communication challenges crucial to a team's success and cohesion (Varhelahti and Turnquist 2021). Cultural differences, language barriers, varying communication styles and tools, and differences in professional roles or power dynamics can lead to miscommunication and misunderstandings (Liu et al. 2021; Varhelahti and Turnquist 2021). Such challenges threaten the efficiency and effectiveness of research collaborations and risk undermining trust among team members, potentially affecting the quality of work (Walther and Sochacka 2014) and resulting in decreased performance and project failure (Marlow, Lacerenza, and Salas 2017).

Addressing these communication challenges requires a nuanced understanding of the factors influencing information exchange and comprehension within multicultural research teams. Given cultural diversity's essential role in shaping how individuals communicate and understand shared information, developing competent communication skills is crucial (Ravesteijn, Graaff, and Kroesen 2006). These skills are essential for research members to learn and carry forward into their future careers in both academic and industrial settings (Lappalainen 2009). By fostering an environment that promotes effective communication practices, multicultural engineering research teams can leverage their diversity to overcome communication challenges and enhance collaboration (Mohanty 2018).

Competent communication within a multicultural engineering research group can be defined as interactions that effectively achieve objectives in a manner suitable to the context in which they occur (Spitzberg 1988). Employing frameworks such as Thompson's Collective Communication Competence (CCC) Model to guide competent communication practices can be beneficial. Thompson’s CCC model, built originally on an ethnographic study of an interdisciplinary academic research team, stems from the understanding that interactions among group members are intertwined, necessitating appropriateness and effectiveness (Thompson 2009). This model identifies processes fundamental to and that hinder CCC, such as task talk, reflexive communication, backstage communication, spending time together, building trust, demonstrating practice, discussing language differences, and shared laughter (Thompson 2009).

This study, utilizing Thompson's model within a multicultural engineering research setting, focuses on illuminating students' experiences with competent communication, especially during the formative stages of a project, as it can provide valuable insights for improving their engagement in multicultural engineering settings. Specifically, this research focuses on the formative stage of a multicultural engineering education research project called ‘Critical Conversation.’ This team is engaged in NSF-funded research aimed at empowering Black PhD students in engineering programs to act agentic in the face of systemic and racial biases. The team consists of three engineering education faculty mentors and five engineering students, all culturally diverse and possessing at least one underrepresented identity in engineering (e.g., Black and Latine’). This study aims to identify communication challenges that may hinder or limit interactions among team members by examining the communication dynamics within this engineering education research project. The goal is to help guide engineering education research teams seeking to effectively kickstart their projects from the outset.

Research Question: What specific communication challenges do engineering students encounter when collaborating in multicultural engineering education research teams, and how do these challenges impact the team's ability to communicate competently?

2 METHODOLOGY

2.1 Context and Participants

This study is part of a broader research project investigating the agency of Black graduate students in engineering at a highly research-intensive public institution in the United States. The research project team comprises three culturally diverse subgroups collaborating to achieve the project's objectives. Each subgroup is led by the principal investigator (PI) or one of two co-investigators – each from a different department. The PIs are two self-identified Black women and one Latine' woman. Additionally, five research students are working alongside the investigators to contribute to the successful completion of the project. This study focuses on the research students involved in the project, and the authors of this paper are members of the research project. Table 1 details the demographic information of the research students involved in the study.

Table 1: Demographic Information of Research Students

Research Student's Pseudonym	Self-identified Gender	Race/Ethnicity	Discipline	Academic Level
Hassan	Man	Asian/Pakistan	Engineering Education	Ph.D.
Kim	Woman	White/Columbian	Engineering Education	Ph.D.
Kiki	Woman	Asian/not identified	Computer Science	Master's
David	Man	Hispanic/not Identified	Electrical Engineering	Undergraduate
Bima*	Woman	Black/ Nigerian	Civil Engineering	Ph.D.

*Bima is the pseudonym of the first author conducting the research. Her demographic info is listed; however, this study does not include her interview data.

2.2 Data Collection

The data for this study was collected through qualitative interviews using a protocol designed based on the Team Effectiveness Questionnaire by the London Leadership Academy and the CIMER Mentorship Model (Law 2020; Pfund et al. 2021). Initially, semi-structured interviews were conducted to understand how an interdisciplinary, multicultural, and multidisciplinary team can effectively initiate collaboration from the project's start and identify what elements influenced this process. The preliminary findings highlighted communicating competently as a significant challenge for the research students. Consequently, follow-up semi-structured interviews were conducted to dive deeper into the engineering research students' challenge with communicating competently. The follow-up protocol was structured using the critical incident technique (Flanagan 1954; D. Simmons and Martin 2010) to identify and analyze specific communication challenges the students face, clarify meanings, and facilitate exploration of impactful incidents to improve practices and contribute to theoretical knowledge. The interviews were recorded, transcribed, and coded.

2.3 Data Analysis

The qualitative nature of the data led to using content analysis to examine the recorded and transcribed interview data (Weber 1990). This analysis involved two distinct coding processes: a deductive code employing Thompson's Collective Communication Competency Model as a conceptual framework and an inductive coding approach allowing for emergent codes from the interview data (Saldaña 2016). To generate the study findings, the first author familiarized herself with the dataset and then coded using the CCC framework. Following this, the first author ensured the validity of the findings by engaging in peer debriefing with the second author and members of her subgroup research lab. This debriefing involved scrutinizing the coding procedure and triangulating the data with other sources (i.e., memos, the first author's diary entry, and the first interview) (Creswell and Miller 2000). Once an interrater agreement was reached, the first and second authors collectively categorized the codes to answer the research questions (McHugh 2012). This approach ensured a thorough analysis of the qualitative data, allowing for interpretation within the social and cultural context and providing a deeper understanding of communication relevant to the research objectives.

3 RESULTS

3.1 Tables

Analyzing the data through the CCC model made it apparent that the research students encountered challenges in comprehensibility, team bonding, and skills gap insight while collaborating within the multicultural academic research team. These challenges resulted in deficits in the team's integrative task discourse, integrative team harmony, and engaged reflexivity. Table 2 is a structured presentation of the analytical process and findings.

Table 2: Content Analysis: Defined Categories, Codes, and Sample Quotes

Category (Impact on Team)	**Description**	**Communication Process Codes**	**Exemplar Quote**
Integrative Task Discourse	integrates task-focused conversations with the mindful negotiation of language differences, thereby facilitating a more cohesive and productive team dynamic	Task Talk Discussions of language differences	One project investigator sent us an e-mail requesting that research participants be contacted. However, it was not clearly mentioned which students should send the e-mail. (Kiki) I worked with [my advisor] on [research topic], and then there were two other areas [other research topics], which were very new to me. So, those are challenging for me to understand. (Hassan)

Integrative Team Harmony	holistically integrates spending meaningful time together, fostering trust (both swift and deep), and encouraging open, informal communication	Spending time together Practicing trust Backstage communication	The best way to collaborate is first by being friends. You can't have random strangers work together because they don't know how even to start the conversation and work together because they don't know each other well [...]then it's weird just communicating. (David) If I'm very near to someone, if I'm going to ask something from that person, there might be some points at which the other person or even myself will not answer those specific questions. So, you must remove those boundaries. You have to give the other person more clarity about your intentions. (Hassan) I feel like it's just a lot of behind-the-scenes things which sometimes can be hard for me to catch up with […] I sometimes feel like the communication can be a little spotty. (Kim)
Engaged Reflexivity	underscores the importance of both being wholly present in collaborative efforts and maintaining an ongoing, reflective dialogue that	Reflective talk	I'm an undergrad, and compared to (other teammates), they have a little more experience and knowledge of the project […] But for me, I just try to build the best effort I can and show them the best work I can provide. (David)

	encourages mutual trust, shared understanding, and collective growth within teams	Demonstrating presence	Qualitative analysis is something new for me right now, and at some point, I know that in the future, when we do the analysis portion, it will be a challenging part for me as well. (Hassan)

Integrative Task Discourse (ITD) relates to the dual focus required in interdisciplinary teams: concentrating on the project's tasks and objectives while acknowledging and addressing the linguistic and conceptual differences inherent in diverse academic fields. By promoting an approach that values clarity in task-related communication and sensitivity to disciplinary languages, teams can achieve a more effective and inclusive CCC, enabling them to navigate the complexities of interdisciplinary research more smoothly. Task talk is crucial to achieving ITD. However, students encountered challenges in understanding the roles delegated to them through written documents guiding the project, leading to disrupted project timelines, misaligned expectations with project investigators, feelings of being out of the loop, and unfamiliarity with the project's status. These challenges may have stemmed from the fact that the research team was in their first year or early stages of their careers, and the students were likely unfamiliar not only with the research process but also with the nuances of the products generated by the three different disciplinary strands of the project.

Moreover, addressing language differences and establishing a common language among teams in multicultural academic research settings can be highly beneficial. Students in the study struggled to comprehend the disciplinary jargon and acronyms common to the other sub-groups and the linguistic and pronunciation variances across the team, thus affecting their ability to comprehend the information they received.

Integrative Team Harmony (ITH) highlights the multifaceted approach to building a cohesive team, where each member feels valued and understood, trust is woven into the fabric of the team's interactions, and informal communication channels are recognized as vital for the team's emotional and social cohesion. This integrated approach ensures that teams are effective in accomplishing their tasks and enriched by the shared human experience, fostering a sense of unity and collective purpose. Communication processes such as spending time together are invaluable for fostering better ITH. However, students in the study faced challenges in effectively communicating with one another, stemming from infrequent team interactions and limited time to bond. Thus, their ability to interact, build trust, cultivate shared understanding, and foster clear communication, which promotes team harmony rather than a sense of estrangement, was stymied. Students also identified trust-building, which supports team harmony, as a barrier to team interactions. Practicing trust-building helps team members overcome perceived boundaries in relationships and fosters interpersonal bonding. Additionally, backstage communication, a form of informal verbal communication, also facilitates harmony. Students recognized the benefits of backstage communication, such as one-on-one meetings with advisors and informal discussions with team members, for understanding projects and overcoming challenges. However, the students also acknowledge that such communication, especially involving discussions about project changes with specific individuals outside general team conversations, led to miscommunication and confusion regarding tasks and project developments. Additionally, the fact that all teams were not only in different disciplines but also located in different buildings posed an additional challenge.

Engaged Reflexivity (ER) emphasizes the outward actions of being present and participative and the inward reflection that enables individuals to contribute more meaningfully and cohesively to their teams. It is about creating a culture where team members are encouraged to be fully there, both physically and mentally, while also being mindful of how their contributions, behaviors, and interactions influence the collective output and team spirit. ER suggests a dynamic interplay between being present and being thoughtful, ensuring that team collaboration is vibrant and considerate, and students can successfully engage reflexivity by integrating communication processes such as reflexive talk and demonstrating presence. According to Thompson's CCC model, reflexive talk is vital in students' ability to observe, reflect upon, and ultimately effect changes within a multicultural academic research setting. The self-awareness from students' reflective talk can significantly impact their ability to demonstrate their presence and effectively communicate within the group. Students showed they were team players by supporting each other and sharing presentation responsibilities. However, their awareness of personal differences, lack of experience, and doubts about their skills posed a challenge and created perceived barriers in their interactions, leading to uncertainty about how their contributions would be received during team meetings. Therefore, understanding diversity can foster confidence and trust in group settings.

4 SUMMARY AND ACKNOWLEDGEMENTS

4.1 Summary

Using Thompson's CCC model, this study aimed to identify specific communication challenges engineering students encountered when collaborating in multicultural engineering education research teams and how these challenges impact the team's ability to communicate competently. Consistent with Thompson's CCC study, this research highlights the necessity for trust-building time, explicit conversations around disciplinary research concepts and languages, and the inclusion of social activities to strengthen research team communicative interaction (Thompson 2009). A nuanced addition to Thompson's CCC study is the need for skill training and critical conversations around the research team ethos, as many of the students' challenges stemmed from their skill gaps and unfamiliarity with the team's research process, expectations, and culture.

Engineering employers prioritize technically and professionally skilled graduates, which calls for engineering education to incorporate training instrumental for students' skill development (Simmons, McCall, and Clegorne 2020). Communication skills are essential to engineering practices because nearly all engineering activities rely on communication. Therefore, there is a need to shift from viewing communication merely as information sharing to recognizing it as a means to establish and nurture relationships (Trevelyan 2009). Engineering education research teams are encouraged to utilize models such as CIMER and CDIO (Conceive, Design, Implement, Operate), focusing on knowledge-building and facilitating professional skill development through active and experiential learning (Crawley et al. 2014; Janet, Amanda, and Amber 2020). Direct student engagement in learning contributes to lifelong learning skills and a stronger sense of responsibility (Seymour et al. 2004).

The findings of this study also call for engineering educators engaged in multicultural and interdisciplinary research to collectively uncover the hidden curriculum behind the cultural norms and expectations around communication, project, and task-related activities within their research settings. This will ensure students' alignment and enhanced comprehension for task execution (Villanueva Alarcón 2022). Competent communication is a holistic process involving both educators and students (Rosado 2006). Therefore, engineering students are encouraged to proactively seek clarification to build familiarity with the research setting and team's ethos (Ravesteijn, Graaff, and Kroesen 2006). Engineering research teams should prioritize active listening, constructive critique, and continuous learning within the team for successful engagements and collaboration, free of internal resistance and fear (Ravesteijn, Graaff, and Kroesen 2006). Based on the findings of this study, the Principal Investigators of this research project have collectively established a more defined research ethos, detailing the research process, team communication methods, frequent in-team interactions, and skill development training to help all team members communicate competently and collaborate effectively to achieve the research goals.

4.2 Limitations and Future Directions

The research findings primarily reflect students' perspectives in a multicultural engineering education research project. Future research could broaden its scope by investigating the viewpoints of the principal investigators to gain insights into the factors that may promote competent communication and cultural and disciplinary differences within research environments. The findings of this study may not be broadly transferable. This research was conducted within a research-intensive public institution in the United States; hence, future research may replicate this study in a different region and/or institution type to uncover other challenges preventing students from communicating competently within a multicultural setting.

ABSTRACT

Recently there has been a diversification of student profiles across the UK at all taught levels. The student fee freeze for home students, increasing fees for overseas students and other financial considerations have led to many universities announcing that they are considering increasing their student intake, which will undoubtedly impact modes of delivery and our student body representation, which implicates the need for a new approach to instilling a sense of belonging and a review of university provisions and support mechanisms (all of which have been shown to impact student performance). UCL Engineering has seen a sharp increase in student numbers (>40% in 3 years), with a large portion comprising of international students. The sector is often cited as one that actively promotes social mobility, however the Engineering UK briefing *Social Mobility in Engineering* (2018) argues that there is further work required due to performance outcomes of different student cohorts. This study investigates the contributing factors towards creating a good holistic student experience for both home and international students with the aim of developing and adapting current university provisions. A combination of surveys, focus groups and interviews were used to capture the student voice. The main outcomes of the survey will be presented in this paper. Overall, the results indicate that the extent of university integration is impacted by factors related to living arrangements, student societies and perceptions of the university's efforts to address EDI-related issues.

1 INTRODUCTION

The landscape of higher education in the UK has increasingly diversified in recent years. According to the latest government report *International students in UK higher education* (Bolton et al., 2023), a record high of 24% (679,970) of the total student population in British universities has an overseas background in 2021/2022 with about 18% from the EU and the remaining from elsewhere. China, India, and Nigeria are the top three countries in terms of the number of students studying in British universities. China accounts for the largest proportion, with 151,690 students, followed by India with 126,535 students. The number of Nigerian students has more than doubled, increasing from 14,270 in the 2020-2021 academic year to 32,945 in 2021-2022. The new report also highlights that the proportion of EU students has decreased by 21.4%, while the number of non-EU students has grown by 23.8% (Bolton et al., 2023; Universities UK, 2024).

With a mix of home and international students navigating their academic journeys in the UK, understanding the unique challenges faced by each cohort is vital for institutions aiming to provide inclusive and supportive environments. This section aims to explore challenges experienced by students from home and international backgrounds. It will cover perspectives on student experience, well-being, and cultural challenges, including visa application difficulties, as well as language differences that are particularly related to international students.

A large and growing body of literature has investigated the obstacles encountered by international students and what factors might affect their sense of belongings. Hoffman et al.'s (2002) mixed methods study concluded that five factors affect students' sense of belonging: peer support, faculty support, classroom comfort, isolation, and empathetic faculty. More recently, Cena et al. (2021) examined the experiences of 16 international students at Queen's University Belfast (QUB) in

Northern Ireland, focusing on their sense of belonging and the challenges they face both academically and socially. Through semi-structured interviews, researchers identified four domains impacting their feelings of belonging: educational differences, on-campus social interactions, influences from the home society, and the wider off-campus environment.

Ramachandran (2011) has identified eight common challenges, which are financial issues, academic issues, English proficiency, social and cultural issues, university administrative procedures, issues of transnational student, bilateral state relationship and its effect and information and support systems. Along the same lines, Khodabandelou et al. (2015) interviewed 21 Iranian postgraduate students in Malaysian universities, identifying four challenges: financial matters, visa, culture and insurance. It should be noted that some of the challenges might also apply for home students, such as financial issues, academic issues (Office for Student, 2022). However, these challenges can affect international student sense of belonging even more profoundly. For instance, social and cultural issues and the anxiety of being far from their home country can be significant (Taylor and Ali, 2017). Additionally, lack of participation and engagement due to English proficiency have also been identified (Cammish, 2002; Carroll, 2007; Trenkic and Warmington, 2019). Even when students are able to adapt to the new environment quickly and have met language requirements, they might have difficulties in understanding different variants of English (Pho, 2019).

There is a large volume of published studies describing the significant role of support mechanism with regards to increase student wellbeing and experiences in universities. Stress is not uncommon among university students, particularly since the outbreak of COVID, there has been an increase concern for student wellbeing considering factors related financial pressure, worry for academic performance, university experience, social isolation, and career prospects (Son *et al.*, 2020; Appleby *et al.*, 2022). Engineering students, in particular, face additional challenges due to their demanding curriculum, heavy workload and low retention rates (Chadha *et al.*, 2021; Jensen and Cross, 2021). Yet the literature specific to the experience and support mechanism of engineering programme students is relatively limited.

Chadha *et* al., (2021) has conducted a mixed methods research study exploring student experiences of support mechanisms to enhance wellbeing on an engineering programme in the UK. A variety of supporting scheme has emerged and put into practice in British universities setting to enhance engineering student wellbeing, such as peer mentoring, wellbeing officers, tutorial support system (personal tutor). However, with many types of assistance available, it is difficult to assess their impact. Concerns from students include a lack of clear links and coherent organization in these initiatives. Additionally, although peer to peer support has gained popularity among British universities in recent years and it has been suggested to have positive impact on student integration (Collings, Swanson and Watkins, 2014), a clear scope of responsibilities of the role is essential to make sure the system runs smoothly. Moreover, tutorial support system has received positive feedback, but the lack of training and specificity of the personal tutoring role, staff hiring freezes and increases in student numbers is leading to less regular contact with students and eventual student detachment. As several students state: “I would not go to my personal tutor for anything”, and “I feel detached from it and that I can’t really make any change” (Chadha *et* al., 2021, p. 642).

Many British universities and organizations have taken actions to help students. According to the Department for Education (2023), Office for Student (OfS) has distribution 276 million of government funding to help students. The University of York which announced that £150 would be given to student households who are finding it difficult to pay their bills as part of a £6 million package to support students most in need (Department for Education, 2023; University of York, 2022). The University of Southampton which has made a total of £1.1 million in the current academic year available to students to cover emergency costs (Department for Education, 2023). Turning the focus back to the capital city, Queen Mary University of London which has a bursary scheme automatically provided to any domestic undergraduate from a family whose annual taxable income is below £20,000 (Department for Education, 2023; Russel Group, 2022). Similarly, UCL has announced the following financial support to students since September 2022. There is a permanent £500 increase to the UCL Undergraduate Bursary, supporting students with an annual household income of £42,875 or less (UCL, 2022). Additional funding for students in financial need can be accessed from the Financial Assistance Fund and the Sarah Douglas Hardship Fund, enabling us to support more students dealing with unexpected financial pressure. However, it should be noted that a number of these funding opportunities are only open to home students.

2 METHODOLOGY

The results discussed in this paper focus on the data gathered from the survey, although data was also collected from focus groups and interviews which will be analysed in the future. The survey was disseminated to the entire faculty (undergraduate and postgraduate taught >1500) and was completed by 87 students (~5% of the cohort). The survey mainly uses a combination of Likert scale and free text questions, with a mix of obligatory and non-obligatory responses. The survey comprised of 36 total questions split into 6 sections: Section 1: Demographics, Section 2: Sense of Belonging, Section 3: Course Experience, Section 4: Student Values, Section 5: EDI at University, Section 6: Open-Ended Questions. This research has been approved by the UCL Research Ethics Committee.

3 RESULTS

For the purposes of this paper, we have provided a brief overview of all of the sections of the survey but honed in specifically on the overall sense of belonging, the evolution of their mental health during their time in the engineering department, their perspectives on EDI issues and involvement in extracurricular activities as these categories provided a diverse set of responses across different personal characteristics.

3.1. Sense of belonging

A summary of section 1 shows that there were an equal number of home and international (overseas) student participation (44% each) and 12% International EU with a near enough equal split of male: female respondents. 30% of respondents were noted as having a disability. Approx. 60% of respondents were of Asian background, 30% Caucasian, 10% Black, mixed, Arab or other.

Section 2 of the online survey focused on the feelings of belonging, comfort and connectedness that students developed during their time at university. Figure 1 shows the distribution of all answers received, on a scale of 1 to 5 (where 1 is strongly disagree and 5 is strongly agree) for various Likert scale questions.

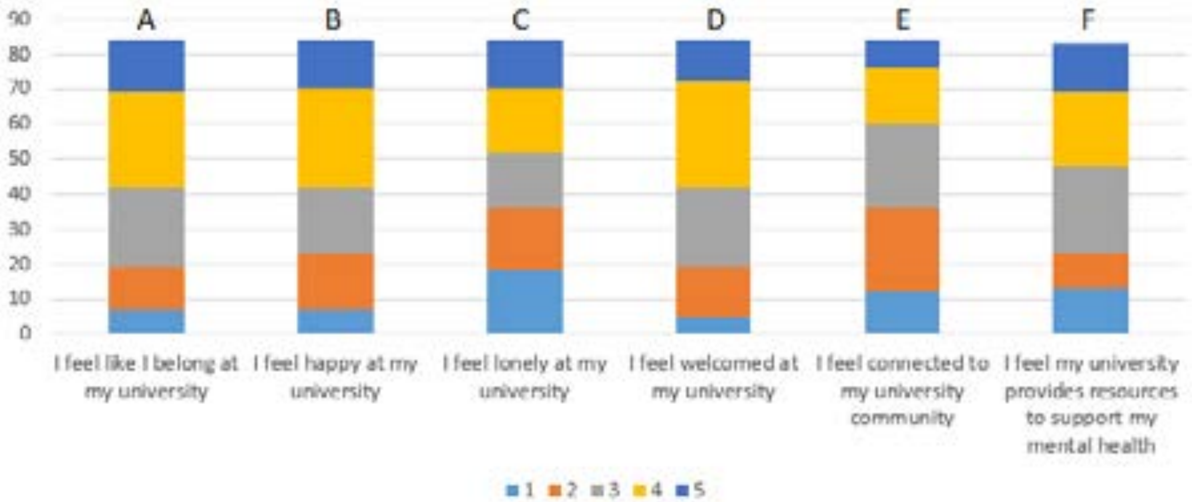

Figure 1: Students perception of their sense of belonging, happiness, loneliness, welcome, connectedness and resource availability at university

The overall averages of the answers for the 6 categories (A-F) of questions shown in Figure 1 were 3.37, 3.31, 2.9, 3.36, 2.81 and 3.16 respectively. It is interesting to note that whilst students appear to have developed a feeling of belonging and feel welcome at the university, they also feel lonely and sometimes disconnected from it (categories that scored the lowest averages). We further disaggregated these results to observe whether there were any deviations from the averages occur when looking at various categories of students. We only report on those where the sample was larger than 5 students and where a deviation was noticed.

Table 1 shows the average answers given by students, based on their fee status, where Home refers to home fee payers, Intl-EU represents international students from the European Union and Intl-OS represents overseas students or international students from outside of the European Union. The number of students in each category is shown in the first column. The bottom line shows the overall average for comparison.

Table 1: Averages of answers to questions in Figure 1, based on fee status.

Fee status	A	B	C	D	E	F
Home (35)	3.26	3.2	2.77	3.14	2.74	2.94
Intl-EU (12)	3.83	3.67	3.17	3.83	3.08	3.58
Intl-OS (37)	3.32	3.3	2.95	3.41	2.78	3.14
Overall (84)	3.37	3.31	2.9	3.36	2.81	3.16

Table 2 shows the average answers given by students, based on their accommodation type. The number of students in each category is shown in the first column. The bottom line shows the overall average for comparison. As can be seen, students living with their families are generally less connected to the university and feel the loneliest, whilst students in private shared flats have the scored the strongest.

Table 2: Averages of answers to questions in Figure 1, based on living arrangements.

Accommodation setup	A	B	C	D	E	F
With family (17)	2.88	2.88	3.12	2.88	2.41	2.82
Student accommodation (25)	3.44	3.32	2.76	3.64	2.88	3.12
Private shared flat (28)	3.79	3.68	2.89	3.36	3.04	3.14
Private single flat (14)	3	3.07	2.93	3.43	2.71	3.43
Overall (84)	3.37	3.31	2.9	3.36	2.81	3.16

When focusing on ethnicity, lower scores were given by Arab students, indicating that they feel less integrated at university. No significant deviations from the overall averages were observed for other ethnicities or based on gender identity, sexual orientation, age, or level of study.

3.2. Mental health evolution

Another important factor in assessing the student experience, is the evolution of their mental health while at university. Overall, 34% respondents state that their mental health has improved during their studies, 44% that it has worsened and 32% that there has been no change (last column in the chart of Figure 2) and for various categories of students, where a deviation from the overall numbers is present. As can be seen in Figure 2, students with disabilities and those living with their families show a decline in mental health while at university.

The survey also directly addressed students' perspectives of whether their experience at UCL had improved, worsened or made no impact on their mental health. The figure below reflects the responses to this question, showing that the most popular answer was that student's felt that their mental health had worsened since coming to UCL. A significant proportion also reported that there had been no change in their mental health – which suggests that the relationship between mental health and a students' experience at the university was more complex than could be captured in a survey.

3.3. Extra-curricular activities

This section of the survey explored students' experiences with extra-curricular activities such as joining clubs, groups or organisations. The survey highlighted that over two thirds of the respondents engaged in extracurricular activities. The most popular reason that respondents did not join societies was due to lack of personal time or extracurricular activities occurring at unfeasible times for students. Other significant reasons for not joining clubs or societies included commuting students finding it difficult to justify the journey and transport costs, social anxiety & insecurities and no personal interest.

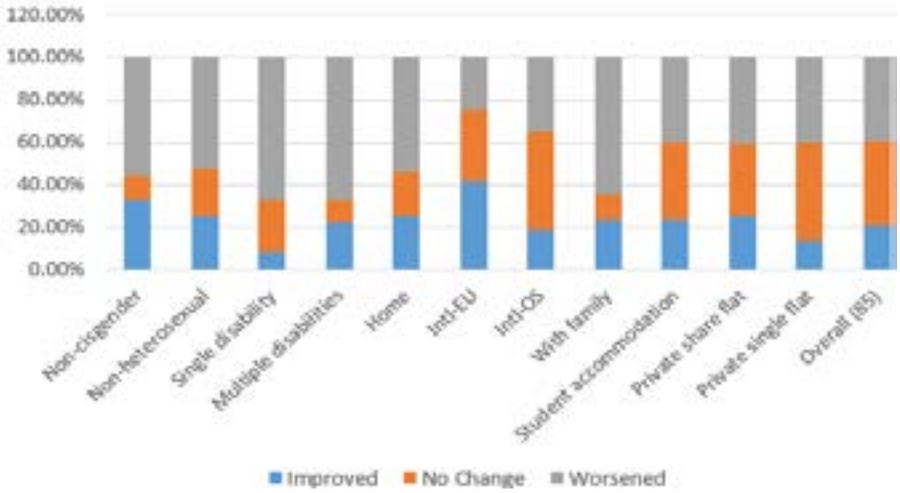

Figure 2: Evolution of mental health of different groups whilst at university

In section 6 one student stated:

*"I do not live on campus so **I do not feel it is worth commuting for an hour for club activities**. Most social activities are centred around alcohol, and **I work while studying so I do not have enough free time**"*

Others reflected that:

*"**work load is difficult to manage** alongside personal life"*

and

*"As a girl who lives far from school, **I felt very insecure**, so it was impossible for me to participate"*

3.4. Students' perceptions on how EDI is addressed

Section 5, Question 28, of the online survey focused on students' perceptions of the extent to which their institutions were prepared to listen to, and to address, issues pertaining to diversity, equity and inclusion. Table 3 shows the distribution of all answers (84 respondents) received, on a scale of 1 to 5 (where 1 is strongly disagree and 5 is strongly agree).

Approximately 70% of the respondents (Likert scales 1,2, and 3) were either uncertain that they would know how to raise with their university an issue to do with diversity, equity and inclusion (68.96%), did not feel confident that an issue to do with diversity, equity and inclusion would be listened to by their university (68.66%) or did not feel confident that an issue to do with diversity, equity and inclusion would be addressed appropriately by their university (69.33%).

Table 3: Average scores for student perception on how EDI concerns are addressed

Likert Scale Question:	1	2	3	4	5
I would know how to raise an issue to do with diversity, equity and inclusion if I see any. (n=87)	11.49%	26.44%	31.03%	16.09%	14.94%

I feel confident that an issue to do with diversity, equity and inclusion would be listened to. (n=67)	14.93%	16.42%	37.31%	2.99%	28.36%
I feel confident that an issue to do with diversity, equity and inclusion would be addressed appropriately by my university. (n=75)	13.33%	18.67%	37.33%	8.00%	22.67%

4 SUMMARY AND ACKNOWLEDGEMENTS

Overall, the results show that there are a number of differences in challenges faced by international vs home students, and these can be further exacerbated by delving deeper into other characteristics related to gender, disability and ethnicity. The main outcomes show that the sense of belonging is felt the least by certain populations in the international student body, but also by home students (particularly those who live at home), reasons for which are explored in the next phase of the study.

The results also show that student experience may differ based on living arrangements. Home students are likely to live with family which may impact on their integration with university life given the central location of UCL. This is contrary to international students who will most likely live with fellow students closer to campus. The results also explored the impact on mental health, engagement with student societies and student perceptions on how inclusion concerns are handled by UCL, all further explored in the next phase. The next phase of this study delves further into the main outcomes of the survey through focus groups and interviews with cohorts of home students and international students to compare and contrast experiences and their perspectives on what support looks like for them. Questions we intend to ask during focus groups and interviews include how comfortable students feel within their department and on their course. Specifically, we want to know if they feel like they belong, and if so, why. Furthermore, we will explore what impacts their sense of belonging. Additionally, we will evaluate the current measures to improve students' sense of belonging and discuss how we can further enhance it.

These authors acknowledge and thank the Centre for Engineering Education, UCL for funding this research.

ABSTRACT

In the discourse of technology assessment, future engineers are expected to contribute to inter- and transdisciplinary processes of responsible technology development. However, the role they are expected to play contradicts prevailing principles of engineering culture that engineering students internalize during their studies. To support them in developing competences for ethics integration in technology development, they need to be encouraged to question disciplinary attitudes and assumptions as well as to develop an appreciation for the diversity of perspectives. One approach to triggering such personality-effective processes is by irritating people's routines of reasoning and thinking. For this study, a new project course was developed with disciplinary and academic irritation as central didactic

[1] *I. Peters*
ina.roeder@tu-berlin.de

elements. Using a multi-method design, the first cohort's changes in appreciation for the diversity of perspectives. was investigated over one semester to test the approach's usefulness, making the start of a longer study with growing sample size. The first results discussed here are very promising and indeed invite further research.

1 USING DISCIPLINARY IRRITATION FOR ENGINEERING ETHICS EDUCATION

Technological innovation has the potential to steer human development in a more sustainable direction. At the same time, anthropogenic perturbations of the Earth's systems are themselves a direct consequence of technological innovation. Thus, engineering students need training in responsible technology development as part of their engineering ethics education. Since responsible technology development is necessarily inter- and transdisciplinary (Grunwald 2017), engineers need competences in knowledge integration (Repko and Szostak 2017; Klein 2012, Godemann 2008) which relies heavily on an appreciative attitude for a broad diversity of perspectives, as a prerequisite for developing competences for *interpersonal relations and collaboration* as well as for *interdisciplinary work* as described by Lozano et al. (2017). However, this request is at odds with present-day engineering culture (Faulkner 2015) and requires a shift in attitudes and assumptions. At the Berlin Ethics Lab of the TU Berlin, we wanted to know how engineering students can be encouraged to rethink their fundamental epistemic attitudes and assumptions in favor of appreciation for diversity of perspectives as an inter- and transdisciplinary-oriented mindset.

To initiate such personal learning processes (Combe and Gebhard 2009, 550f.), the didactic approach of *irritation* seems promising since irritation results from challenged attitudes and assumptions, which is seen as a necessary trigger for changing mindsets (Koller 2016). Such irritations occur through encounters with people who have different perspectives (ibid., Swierstra 2017) or through disruptions of routines where standard procedures fail and new solutions must be sought (Combe and Gebhard 2009, 552). To test the effects of irritation on engineering students' appreciation for diversity of perspectives, we developed a new project course based on the irritation paradigm. We collected data following a multi-method approach by carrying out 1. a qualitative data analysis of students' reflection papers, 2. an online survey on students' change in self-perception, and 3. a group discussion. In this paper, we provide the theoretical foundation upon which the research question was built in chapter 2. In chapter 3, we describe our methodological design before presenting our research findings in chapter 4 and concluding them in chapter 5.

2 HOW TO INITIATE COMPETENCE BUILDING FOR RESPONSIBLE TECHNOLOGY DEVELOPMENT IN ENGINEERING EDUCATION

The history of engineering shows that new technologies always have consequences for the way we live, both intended and unintended. This requires engineers to be particularly aware of the responsibility they bear for society. Since technologies' unintended negative effects are not primarily related to the engineering context but affect all areas within and outside of society, it is impossible for engineers alone to comprehensively assess such potential consequences. Therefore, widespread "microethical" (Martin, Conlon and Bowe 2021) approaches to ethical engineering education, which aim to make engineers aware of their individual responsibility in decision making, are too short-sighted. Instead, responsible technology development requires integrated technology assessment that includes a variety of disciplinary (interdisciplinarity) and even non-academic (transdisciplinarity) perspectives (Grunwald 2017).

Although from a production perspective, engineering has always been interdisciplinary, inter- and transdisciplinary collaboration for ethics integration in responsible technology development represents a fundamental shift in the role of engineers. Traditional engineering interdisciplinarity is aligned to the needs of engineering solutions. As a result, engineers are accustomed to processes, values, and a language of collaboration based on engineering reasoning and thinking. However, responsible technology development through technology assessment considers ethical values and societal impacts by integrating broader disciplinary and non-academic perspectives (*Fig. 1*). As a result, not only is the set of stakeholders much more diverse, but engineering reasoning and thinking is no longer the exclusive guiding framework. Instead, the engineering perspective is one position among many in a framework of responsible technology development.

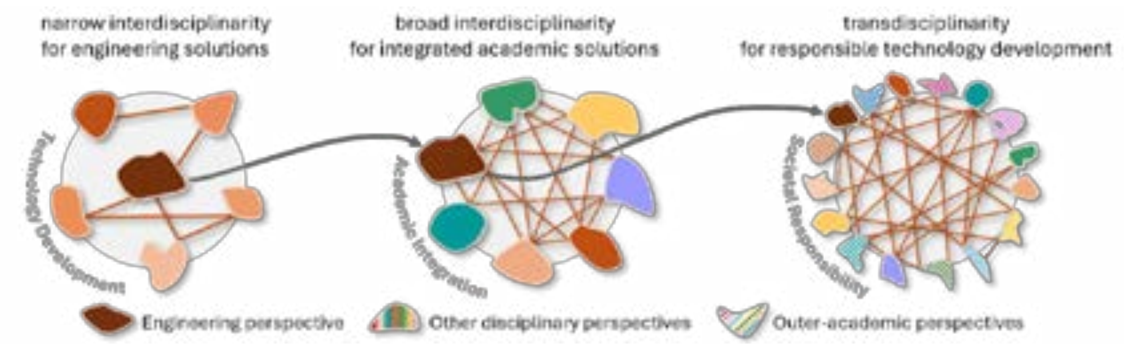

Fig. 1. Change of engineers' role for responsible technology development

This is nothing less than a break with the dominant engineering culture, which in its continuous reproduction refers almost exclusively to the technical dimensions of engineering, while neglecting its social and therefore also its ethical dimension (Faulkner 2015). This engineering culture is largely constructed through the socialization processes of education, defining a conceptual framework through which students will see and judge all experiences, actions and ideas. The effect of this socialization process can be seen e.g. in engineering students' significant decline in welfare orientation over the course of their studies as identified by Cech (2014).

Therefore, engineering ethics education faces the challenge of working against an established paradigm of reasoning and thinking. Thus, successful engineering ethics education might be less about ethics knowledge than about a cultural change of the conceptual framework that shapes the professional attitudes and assumptions of future engineers in favor of an appreciation for diversity of perspectives. This cannot be achieved alone by adding more formative learning of ethical content but calls for transformative learning which focuses on experiences that challenge students on a cognitive, conative, and emotional level (Mezirow 1998).

From a didactic perspective this enters the challenging realm of competence-oriented teaching. In contrast to mere knowledge, competences refer to an individual's network of knowledge and skills, as well as to socio-psychological elements such as attitudes and assumptions. Therefore, competences cannot be explicitly taught; the learner individually combines all these individual resources in such a way that he or she can consistently shape and manage situations in a specific context (Vitello, Greatorex and Shaw 2021). However, teachers can try to initiate personal learning processes in their students (Combe and Gebhard 2009, 550f.) which may affect their conceptual framework and thus allow for competence development. For this, it takes a learning environment in which students can experiment with combining their personal resources . In our case this would be an environment stimulating (re)combinations in favor of the competence for *change of perspective*.

Disciplinary and academic irritations, as we want to argue in the following, can be an important stimulus to initiate these processes in engineering students. According to the transformative understanding of education (Mezirow 2002), people only fundamentally adapt their views when they experience an irritation of their existing perspective, so that taken-for-granted ways of thinking are challenged (Koller 2016). Since irritation occurs through confrontation with other perspectives or disruptions of routines, it should be possible to deliberately stage moments of irritation in the classroom to expose learners to a "pressure to change" (ibid., 30). We have taken advantage of this possibility to initiate this kind of re-sorting with respect to diversity of perspectives by deliberately irritating the disciplinary and academic attitudes and assumptions of engineering students.

3 RESEARCH DESIGN FOR TESTING IRRITATION FOR CHANGING CONCEPTUAL FRAMEWORKS IN ENGINEERING STUDENTS

Inter- and transdisciplinary collaboration, as needed for responsible technology development, requires competence of *change of perspectives* (Barth et al. 2007, Brandstädter and Sonntag 2016) which is defined as the ability to place oneself into the perspective of another person without neglecting one's own (Repko and Szostak 2017). However, the willingness to consider other perspectives is based on the acceptance that knowledge is always fragmented (Parker 2010) and situated (Haraway 1988), meaning that all knowledge has been developed under particular historical, political, and disciplinary conditions that have given it its specific epistemic perspective. This results in the necessity of recognizing other bodies of knowledge and appreciating them as a supplement to one's own knowledge. Additionally, students need to understand that epistemological perspectives often are value-loaden and come with a normative stance engrained in the disciplinary culture. Thus, what engineering students need as a prerequisite for building competence for *change of perspective* is an *appreciation for diversity of perspectives* by recognizing their own epistemic and ethical values as well as those of others (Ammon et al. 2022) This requires that attitudes and assumptions of traditional engineering culture towards diversity of perspectives are challenged.

Thus, following the transformationalists in educational research, we decided to expose engineering students to diversity of perspectives in two successive settings of increasing complexity: a) broad interdisciplinarity and b) transdisciplinarity. This was meant to cause epistemic and normative irritation of their a) disciplinary and b) academic conceptual framework. The inter- and transdisciplinary set-up thus functioned as vehicle to confront the students with increasing diversity of perspectives which was meant to rupture the students' perspective to observe how they reacted to that stimulus. Our research hypotheses were:

H1: Broad interdisciplinary collaboration irritates the disciplinary framework of reasoning and thinking and thus leads to an increase of engineering students' appreciation for other disciplinary perspectives.

H2: Transdisciplinary collaboration irritates the academic conception of knowledge and thus leads to an increase of engineering students' appreciation for non-academic perspectives.

In the case of verification of those hypotheses we expected to see first an increase in irritation in the students after each new stimulus, as expressed through emotional reactions to the new perspectives or perspective pluralism they encountered such as discomfort, insecurity, puzzlement or surprise. This would be followed by increased tolerance for those perspectives as expressed through comments of acceptance, respect or appreciation for the other perspectives or descriptions of changes of their own perspective due to the encounters.

3.1 Research environment

To test our hypotheses, we developed a new project course at TU Berlin as research environment, for which students from the city's three major universities could enroll as free election course in addition to their compulsory courses. In this course, engineering students were to identify societal challenges and plan a transdisciplinary project together with broadly interdisciplinary groups of other students, e.g. from philosophy, humanities, or natural sciences, to irritate their disciplinary perspective on problems and adequate scientific problem-solving approaches (testing H1). Subsequently, the groups should initiate and carry out the transdisciplinary projects together with non-academic stakeholders so that their attitudes and assumptions regarding academic knowledge and its role in society vis-à-vis other perspectives would get irritated (testing H2). To make the experienced irritation explicit and thus accessible for ethical reflection, the students were to write individual reflection papers after each project phase.

We chose the course topic "Transdisciplinary Technology Development for Sustainable and Fair Urban Mobility" as an overarching reference to responsible technology development as contribution to sustainable development. However, in the module description, the grading and in the interaction with the students, we set the focus on the reflection of the collaboration experiences rather than on project success. Failed collaborations or reflections that concluded that transdisciplinary research is useless, for example, did not automatically lead to poor grades. In this way, we wanted to ensure that the reflection papers were not written according to social desirability standards. The students were asked permission to use their data for scientific evaluation of the didactic approach and participation in the research project was voluntary.

3.2 Research method

The results of this study are based on three different sets of data from three different survey instruments. We chose this multi-method approach to include both the students' subjective perceptions of shifts in their appreciation for diversity of perspectives and more objectively observable indicators of such shifts over time.

For the latter, we collected students' reflection papers at the end of three different project phases: interdisciplinary identification of project topics (t1), interdisciplinary (partly transdisciplinary) development of a methodological design (t2) and working transdisciplinarily with stakeholders (t3). Thus, irritations of disciplinary values were to be expected for t1, even more so for t2 with initial irritations of academic values and strong irritation of academic values at t3.

The reflection papers were subjected to qualitative data analysis using double coding following a strict code book with descriptions and examples of how to code statements to determine intrapersonal changes in students' appreciation for diversity of perspectives. Six characteristic values were differentiated according to the students' conceptualization of knowledge. These were later translated into a nominal scale to help track and compare observed changes. Regarding the qualitative nature of the researched characteristics, the scale only marks qualitative differences and makes no claim to be an interval or ratio scale. The defined levels ranged from claiming a single truth, which denies the fragmented and situated nature of knowledge, to the assumed absolute necessity of inter- and transdisciplinary knowledge generation for certain research fields, which shows the highest possible recognition of knowledge fragmentation and situatedness. The characteristic values were defined as 0 – holistic knowledge claim, 1 – abstract recognition of fragmented knowledge, 2 – acceptance of concrete other disciplinary epistemic values, 3 – appreciation of interdisciplinary epistemic values, 4 – appreciation of transdisciplinary values, 5 – assumption of the necessity of knowledge integration through interdisciplinary collaboration, and 6 – assumption of the necessity of knowledge integration through inter- and transdisciplinary collaboration.

The students' reflections were analyzed and categorized according to this scheme, allowing for both intra- and interpersonal comparisons over time, although statements about averages must be treated as tendency, not as absolute values due to the qualitative origins of the data. It is important to note, however, that no reflection papers were written before the start of the course, so that even those from t1 were already written under the impressions of the course input and the first interdisciplinary exchange. Thus, no statement can be made about the level of appreciation the students showed when they decided to enroll in the course.

To assess the students' subjective perception of shifts in their appreciation for diversity of perspectives they were surveyed during the last course session using an online questionnaire that asked the items listed in

Table 1. All items were asked on a 5-point scale except item 2.3, which was an open-ended question.

Table 1. Items of the online questionnaire

No.	**Item**
1	***Comparison of perceived competence before and after taking the course***
1.1	Theoretical knowledge of td research
1.2	Skills for interdisciplinary (id) collaboration
1.3	Skills for transdisciplinary (td) research
1.4	Multi-perspectivity on societal challenges
1.5	Multi-perspectivity on technological solutions
1.6	Ethical reflection of challenges/ technology

No.	**Item**
3	***Comparison of meaning attribution before and after taking the module***
3.1	Meaning of id collaboration for societal challenges
3.1	Meaning of td collaboration for big challenges
4	***Influence of an id and td approach on ...***
4.1	Understanding other values
4.2	Reconsideration of one's own values
4.3	Probability of finding a fair solution

2	***Perception of the id of the project groups***
2.1	Perceived degree of group interdisciplinarity
2.2	Satisfaction with group interdisciplinarity
2.3	Reasons for satisfaction level
4.4	Probability of finding a feasible solution
4.5	Probability of finding a good solution

In addition, we organized a group reflection and discussion at the end of the course to find out what collective experiences and opinions the students would formulate regarding irritations and coping strategies in inter- and transdisciplinary collaboration.

4 FINDINGS FROM TEACHING FOR DISCIPLINARY AND ACADEMIC IRRITATION

Our sample so far consisted of the 16 students who were accepted into the course. Slightly more than half of the students were enrolled in bachelor's programs, and the other half were enrolled in master's programs. The sample had a diverse disciplinary background, with half of the students coming from engineering and the other half from philosophy, humanities, natural sciences, and computer science. The analysis showed that the characteristics of the engineering students' data did not differ on average from those of the other disciplines at t1, because the math and computer science students lowered the average appreciation level of the non-engineering students. Therefore, we decided to include all students in our analysis to have more data on the attitudinal change processes of students based on the element of irritation than if we had focused on the engineering sample alone.

4.1 Qualitative analysis of the reflection papers

Mapping the students' reflective statements onto the appreciation scale, the first observation is a great diversity of initial appreciation levels among the students in the early phases of the course as can be seen in Fig. 3. However, none of them showed a holistic claim to knowledge, i.e. all of them already had some perception of fragmented knowledge. Only one student started at level 1, recognizing other epistemic values but not necessarily accepting them as useful. Another student started at level 2, accepting other epistemic values as probably useful, but not necessarily valuing them. The remaining 14 students started at level 3+ and already expressed appreciation for perspectives other than their own. One student showed the highest level of appreciation from the beginning, leaving no room for improvement on our scale.

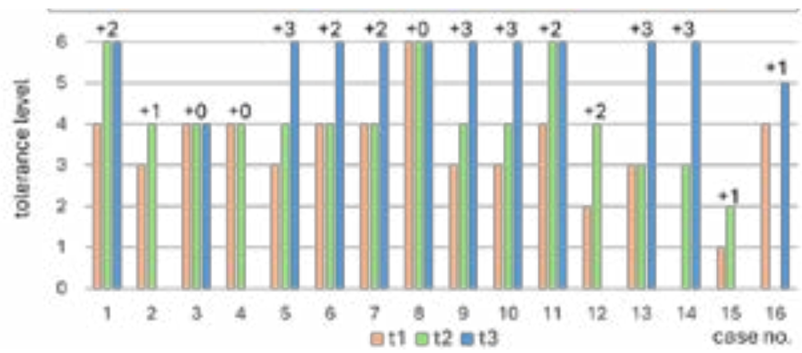

Fig. 3. Shift in students' appreciation for diversity of perspectives over time

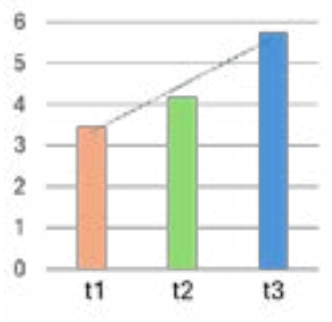

Fig. 4. Average increase in appreciation

Of the remaining 15 students who could show an increase in tolerance, 13 did. Three of them showed an increase of +1 level, five of +2 levels, and five of +3 levels. At the end of the course, 10 out of 12 students had reached the highest level of tolerance, assuming that knowledge integration through inter- and transdisciplinary collaboration is a compelling necessity for projects striving for societal impact. Four students did not submit their final reflection paper in time for this publication. On average, the increase in appreciation during the main phase of *disciplinary irritation* (t1 to t2) was from level 3.5 to 4.2, showing a shift from an already clear appreciation of interdisciplinary epistemic values to an appreciation of transdisciplinary epistemic values (Fig. 4). For the main phase of *academic irritation* (t2 to t3), the average increase in appreciation was from level 4.2 to 5.8, showing a shift from appreciation of transdisciplinary epistemic values to acceptance of the compelling necessity of knowledge integration through inter- and transdisciplinary collaboration. The average overall increase in tolerance was +2.3.

In-depth interpersonal analysis revealed not only a positive shift in expressed attitudes and assumptions on diversity of perspectives, but also a clear qualitative shift in the emphasis with which students argued their positions. At t1 many students showed a theoretical awareness of the importance of other perspectives in research and technology development and much appreciation for the interdisciplinary group constellation, but also exertion and insecurity about developing a common understanding of the project and their own role therein. Few weeks later, at t2, they gave many concrete examples of how extraordinarily fruitful interdisciplinary collaboration was, rating their group work as smooth and easy. However, they now expressed concern and, to some extent, overwhelm when reflecting on collaboration with extra-academic stakeholders, particularly in view of the low relevance that they and their scientific interests and approaches had in the practical context of the stakeholders. At t3, most students expressed high levels of confidence in transdisciplinary collaboration, often expressing strong emotions of surprise, pride, gratitude, and excitement. Thus, even the two students for whom our scale showed no increase in appreciation showed a very different level of personal commitment to their position in later stages of the course.

4.2 Quantitative analysis of data from the online questionnaire

The survey revealed that students felt that their participation in the course had led to a significant increase in their personal resources in all areas surveyed (Table 1), as shown in Fig. 5. While the arithmetic mean of all items was reported as low to medium at the beginning of the course, it was reported as rather high on average at the end of the course. The increase in knowledge (+2 scale points) and in one's own ability to act (+1.8 scale points) in relation to transdisciplinary research were perceived as the strongest effects. The smallest perceived increase was reported for the ability to act in interdisciplinary collaborative settings (+0.8 scale points). This is also the item that had the highest score at the beginning of the course, suggesting that students already had some previous experience with interdisciplinary collaboration. Regarding ethical reflection on societal challenges and technologies, there was an increase of 1.3 scale points.

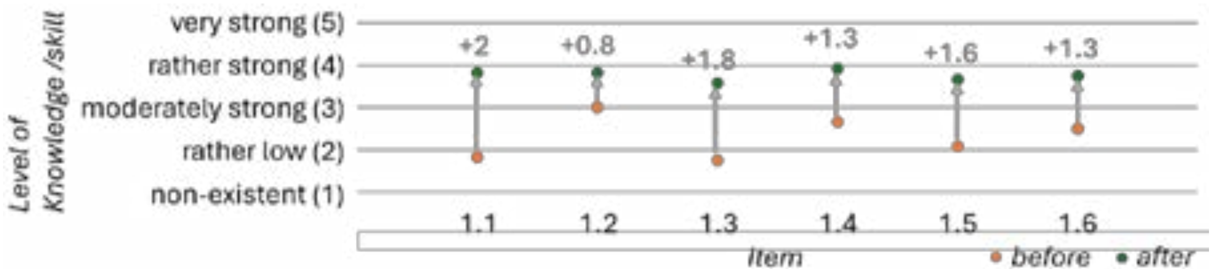

Fig. 5. Students' perception of their knowledge and skills development (n=11)

The greater prior familiarity with interdisciplinary than transdisciplinary approaches is also reflected in the responses to item 3. While students indicated that they considered interdisciplinary approaches to be important for solving major societal challenges already before taking the course (scale value 3.8) and very important at the end of the course (scale value 4.6), they gave transdisciplinary approaches only moderate importance at the beginning of the course (scale value 3.2). At the end of the course, however, they also considered these approaches to be very important (scale value 4.7). Thus, although the students rated interdisciplinary and transdisciplinary approaches almost equally at the end of the course, their attitudes toward transdisciplinary approaches had evolved significantly more.

4.3 Summarizing data from the group discussion

The group discussion showed that all students agreed that research questions whose outcome affect broader sections of society profit greatly from inter- and transdisciplinary diversity of perspectives. Especially students from technical subjects expressed that they would have never considered this in the realm of their usual disciplinary studies and that even during our course it was not before practically interacting with other perspectives that they could fully comprehend the advantage. Several students stated that the inter- and especially the transdisciplinary experience changed their entire perspective on science and academia, effecting the way they planned to continue their studies, their private engagement, and their job orientation. The participants of one group that turned out to be less broadly interdisciplinary than expected, expressed their regret about lacking the same interdisciplinary input that they had observed with the other teams. The students started by themselves to discuss moments of strong irritation and feelings of severe disorientation when collaborating with people from other fields, especially outside academia, which was replaced by confidence and powerful enrichment after a while.

5 DISCUSSION OF OUR FINDINGS

The sample size of this execution was too small to make valid statistic statements. At this early stage, the study must therefore be regarded as a case study intended to highlight tendencies rather than facts. The statements will become more valid as the sample size increases over the coming semesters in which we will repeat the study and accumulate the data. However, the found tendencies are encouraging. The results of the qualitative data analysis show an increase in appreciation for disciplinary diversity of perspectives among the students, following a phase of insecurity after confrontation with other disciplinary perspectives . However, the increase in appreciation for diversity of perspectives is even more pronounced after confrontation with non-academic perspectives in the transdisciplinary work phase. In fact, according to the reflection papers, the students showed a high level of appreciation towards other disciplinary perspectives at an early stage, which, under the task of increasingly integrating different epistemic perspectives into their projects, turned into a clear and continuously increasing appreciation for non-academic perspectives as well.

The student questionnaire revealed a similar picture. The students stated that they already felt they had a relatively positive attitude and competence regarding interdisciplinary collaboration from the start, which nevertheless increased further while taking the course. However, they perceived their increase in competence in transdisciplinary research as significantly stronger, as well as the change in their attitude towards transdisciplinary approaches in general.

Finally, the group discussion highlighted the irritational effect as a direct precursor to the students' changed perception and sense of competence regarding diversity of perspectives. The combined results of the multi-method approach thus tend to confirm H1 and H2. Disciplinary and, to an even greater extent, academic irritation can thus be expected to be an effective means of strengthening *appreciation for diversity of perspectives* as a basic prerequisite for the competence of *change of perspectives*, a central competence for responsible technology development in inter- and transdisciplinary teams. We therefore believe that the didactic element of irritation can make an important contribution to the education of engineers and shows that engineering ethics education is indeed inter-and transdisciplinary ethics education with benefits for all disciplines involved.

We thank the Stiftung für Innovation in der Hochschullehre [Foundation for Innovation in University Teaching] for funding this project.

ABSTRACT

This study explores differences between perceptions of Traditional and Non-Traditional engineering students of their sense of belonging with a view to how this informs student intention to persist. This paper presents findings from an exploratory survey of (N=365) 1st year Bachelor of Engineering students at a Nordic Technical University. The survey was developed to explore background factors influencing student motivation and persistence. The results were analysed via R statistical software and reveal that nontraditional students, particularly those from diverse ethnic backgrounds, perceive a lower level of sense of belonging and academic support compared to traditional students. The results point to the need for universities to develop early-stage initiatives sensitive to the different challenges integrating academically and socially as is often experienced by non-traditional

[1] *E Rees Chin*
elchin@dtu.dk

students. Thereby enhancing inclusivity and improving student persistence within engineering education.

1. INTRODUCTION

1.1 Background

In academic contexts, a sense of belonging is foundational for student success and well-being (Tinto, 2022; Strayhorn, 2018; Ulriksen, Madsen, & Holmegaard, 2015). A sense of belonging can enhance students' engagement in their studies, leading to increased effort, positively impacting achievement and increasing self-efficacy (Tinto, 2022). For students to perceive they belong is to perceive they are connected to and supported through their university experience by friends and colleagues, teaching staff and family (Strayhorn 2018; Tinto 2017a). Student connections to these groups and often to the university itself, contribute to their sense of identity (Ulriksen, Madsen, and Holmegaard 2010) and in turn their motivation (Tinto 2017a). Sense of belonging is often disrupted during transition to university, and so when necessary connections cannot be made, students may withdraw from activities, both social and academic, decreasing the likelihood of persistence (Tice et al., 2021; Rainey et al., 2018; Strayhorn, 2018; Tinto, 2017).

A sense of belonging for minority students can be especially important for persistence at university. This is emphasised further in STEM fields where altogether dropout is higher than other disciplines (Fan, Luchok, & Dozier, 2021) and minority students tend to dropout more than majority students, which is often influenced by non-inclusive learning environments (González-Pérez et al., 2022; Whitcomb & Singh, 2021; Hansen, Palakal, and White 2023).

Understanding and enhancing students' sense of belonging can therefore play a central role in promoting student persistence in higher education, as students who do not feel they belong are unlikely to persist (Tinto, 2017; Strayhorn,2018; Hansen, Palakal, and White 2023).

1.2 Literature Review

In many academic institutions the norms and values of university cultures are reflective of student groups that have traditionally been the majority, in terms of the characteristics they display. In many STEM academic settings, the majority of students have traditionally been white male students(Eastman, Miles, and Yerrick 2019; Park et al. 2020). This study uses the terms of "Traditional" and "Non-Traditional" students, introduced by Holmegaard, Madsen, and Ulriksen (2017), to explore the experiences and perceptions of those historically underrepresented in these fields, such as women and ethnically diverse students.

A student's journey into higher education, particularly within STEM degrees, is influenced by how well they can integrate socially and academically (Hansen, Palakal, and White 2023; Tinto 2022). As Ulriksen (2009) highlights, students who do not align with the traditional student archetype may find it challenging to be recognized and accepted as legitimate members of their academic community. This misalignment and resultant lack of recognition can set students apart. Those from non-traditional backgrounds may be especially affected, leading to a disengagement from their studies (Ulriksen, Holmegaard, and Madsen 2017; Strayhorn 2022;

González-Pérez et al. 2022). Therefore, the processes of integration and socialization will vary across different students in various STEM educations (Hansen, Palakal, and White 2023). These students engage in a continuous process of interpreting, balancing, and negotiating their educational experiences (Tinto, 2022). How students navigate this process is linked to their personal backgrounds and their cultural, ethnic, and socioeconomic origins (Tinto 2017; Ulriksen, Madsen, and Holmegaard 2017). Tinto (2022) and Strayhorn,(2018) emphasise the role of the university community in developing students' social integration and engagement. Teachers, support staff, and fellow students are key to fostering students' sense of belonging. This is particularly important in the first year of higher education, where the highest proportion of students leave (Tinto, 2017). However, it is not engagement per se, but the quality of the engagement which is important (Tinto, 2017). How the students interact and how they perceive their interactions, determines their sense of belonging (Gasiewski et al. 2012; Tinto, 2022). Conversely, the absence of belonging can erode students' commitment to the university and decrease their likelihood of persisting in their studies. This dynamic is particularly pronounced for non-traditional students in STEM fields, where the barriers to success are often greater (Holmegaard, Madsen, and Ulriksen 2017; Tinto 2022). A robust sense of belonging, therefore, becomes key for their academic advancement and persistence (Rainey et al., 2018; Strayhorn, 2018, 2022). While social belonging, fostered by shared interests and communal experiences within the university is key for the engagement of 'nontraditional' students', Tinto (2022) argues that it is academic belonging that exerts a more substantial influence on success. This form of belonging significantly boosts students' self-efficacy and enhances learning outcomes (Ibid). Supportive classroom environments and empathetic teachers underpin academic belonging through encouraging student motivation (Tormey, 2021; Hartikainen, Pylväs, and Nokelainen 2022). Consequently, this generates increased effort, leading to a more conducive environment for learning (Tormey 2021; Hartikainen, Pylväs, and Nokelainen 2022; Kirby and Thomas 2022; Holmegaard, Madsen, and Ulriksen 2017).

The objective of this study is to explore potential differences in the sense of belonging between traditional and non-traditional engineering students at a Nordic Technical University.

The research aims to identify specific areas where engineering institutions can enhance support and inclusivity measures which has resulted in the following research question:

Research Question: Are there differences in perceptions of belonging between traditional and non-traditional Bachelor of Engineering students?

2 METHODOLOGY

2.1 Study Design

In this exploratory study, we developed a survey targeting first-year engineering students at the end of their first semester in the Bachelor of Engineering degree. Data were collected from 365 first-year engineering students, representing 34% of the study population for that year. Among the participants, 67% identified as male, 32% as female, and 1% as non-binary or prefer not to say. Regarding ethnicity, 65%

identified as Nordic Traditional Ethnicity (NTE), 27% as Non-Traditional Ethnicity (NTE), and 8% as International (INT).

The survey included 11 items designed to measure various dimensions of sense of belonging, including academic support, social integration, and institutional support. These items were developed based on existing literature on student sense of belonging, motivation, and educational engagement. Responses were collected using a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Additionally, the survey included demographic questions on ethnicity and gender.

Data were collected from 13 study lines across 12 Danish language engineering courses. Data collection commenced in January 2023 using an online survey tool (Surveyxact.dk) and was subsequently imported into R for analysis. The data collection period spanned the first and second weeks of a 3-week course period to avoid biases from study fatigue or exam stress.

In order to evaluate the internal consistency of the survey instrument, which has not been previously validated given its exploratory nature, a Cronbach's alpha analysis was performed. This analysis yielded a reliability coefficient of 0.83 (see Table 1), surpassing the acceptable threshold of 0.70 and thus affirming the interrelatedness of the survey items. However, it is important to note, following Grau (2007), that this score does not necessarily imply unidimentionality of the construct being measured.

To investigate differences in perceptions of belonging among students of different ethnicities and genders, we conducted a series of statistical tests on our survey data. The primary aim was to determine if there were significant differences in how various student groups perceive their academic and social belonging within the university.

Prior to analysis, data were cleaned to remove cases with missing values and to ensure the integrity of the dataset. Despite likert scales being ordinal and non-normally distributed, we refer to (Norman 2010; Mircioiu and Atkinson 2017) who state that parametric tests are appropriate for likert scale analysis.

We employed two main types of statistical tests to analyze the data: Welch's t-tests and Analysis of Variance as well as a Tukey's Honest Significant Difference (HSD) post-hoc tests to identify which specific groups differed from each other.

We used the Welch's t-test to compare the mean levels of agreement between male and female students for each variable related to the sense of belonging. We used this test instead of the standard t-test because it is preferred when dealing with unequal variances between groups robust against violations (Ruxton 2006; Delacre, Lakens, and Leys 2017).

2.2 Statistical Tests

To compare the mean levels of agreement across the three different ethnic groups simultaneously, we used ANOVA as advised by (Maxwell and Delaney 2004). When ANOVA indicated significant differences, we used Tukey's Honest Significant Difference (HSD) post-hoc tests to identify which specific groups differed from each other.

3 RESULTS AND DISCUSSION

3.1 Tables

Table 1. T-test Results by Gender (Percent Agreement and P-values)

Variables related to sense of belonging	**% Agreement Males (N=244)**	**% Agreement Females (N=124)**	**P-value (significance p ≤ 0.05) of observed differences between groups**
My teacher explains things well	54	40	**0.004****
My teacher encourages me to do well	45	37	0.326
The social relations with other students	63	66	0.421
I am well supported by my network	69	66	**0.750**
The university helps to provide a good social network	62	42	**0.0003*****
Good student-teacher interaction is important	84	82	0.458
I have a sense of belonging at university	55	51	0.261
My teachers respect me and act with empathy	49	41	0.246
The university values my opinions	46	33	0.027*
The university has an open-door policy and I am comfortable using it	50	42	**0.037***
The university creates an environment where I am included	63	54	**0.065**

* p < 0.05, ** p < 0.01, *** p < 0.001

Table 2: ANOVA and Tukey HSD Results by Ethnicity, the significant responses are highlighted in bold type.

Variables related to sense of belonging	**Proportions of agreement for each statement according to ethnicity group**			**P Value (significance p ≤ 0.05) of observed differences between groups**
In relation to my motivation to study I believe:	Nordic Traditional Ethnicity (NTE) (65%, n=238)	Non-Traditional Ethnicity (NE) (27% n=98)	International (INT.) (8% N=29)	
My teacher explains things well	0.57	0.31	0.62	**0.00*****
My teacher encourages me to do well	0.48	0.30	0.42	**0.03***

The social relations with other students are important	0.68	0.60	0.42	**0.04***
I am well supported by my network	0.76	0.56	0.42	**0.00*****
The university helps to provide a good social network (via activities and clubs)	0.62	0.42	0.50	**0.01***

3.2 Perceptions of Belonging in Traditional and Non-Traditional Students

This study highlights the significant variation in students' perceptions of belonging and academic support across different ethnic backgrounds and, to a lesser extent, gender. Traditional students predominantly reported higher levels of agreement regarding positive interactions with faculty and a sense of being valued and supported within the academic environment. This comparison demonstrates a consistently higher level of agreement among traditional students for all statements relative to their non-traditional counterparts. The analysis, as detailed in Tables 1 and 2, utilizes Welch’s T-Tests and ANOVA tests to examine the differences in perceptions related to sense of belonging and motivation to study across both gender and ethnicity. Statistical significance conveyed those results that can be considered representative of student perceptions.

Academic Belonging

Regarding the statement ‘*My teacher explains things well’*, both Traditional (NTE) and International student groups displayed similar levels of agreement, contrasting with the Non-Traditional Ethnicity (NE) students, who exhibited a significantly lower rate of agreement at 31%. A gender disparity was also noted, with a higher percentage of males (54%) in agreement compared to females (40%), a difference that was statistically significant.

For the assertion '*My teacher encourages me to do well*', NE students again showed the lowest percentage of agreement compared to the other groups, with none surpassing 50% agreement. This was also statistically significant, and the finding suggests a universal perception of limited encouragement from teachers across ethnic groups. This aligns with the literature indicating that non-traditional students often struggle with recognition and acceptance in academic communities, which can lead to disengagement (Ulriksen, Holmegaard, and Madsen, 2017; Strayhorn, 2022; González-Pérez et al., 2022). Although this was not significant for the gender group, there were observed low levels of agreement, particularly among females, which may either underscore the challenges faced by women in feeling supported and encouraged within the academic setting or the lack of significance indicates that this is not an influential factor for motivation and belonging.

Although over 70% of respondents acknowledged the importance of student-teacher interaction for motivation, the actual agreement levels on good student-teacher interactions were not statistically significant. This highlights either a potential gap between the recognized importance of these interactions and the actual experiences of the students. Tinto (2022) and Strayhorn (2018), Tormey (2021) and Hartikainen et al. (2022) all agree teacher-student interaction can have yield a considerable influence on student sense of belonging. Alternatively, it could be interpreted as students are in agreement and uniformly experiencing these interactions, but the quality or depth of these interactions may not be meeting their expectations or needs.

Supportive classroom environments and empathetic teachers are an important part of developing academic belonging (Tinto, 2022; Tormey, 2021; Hartikainen, Pylväs, and Nokelainen, 2022). However, the notable decrease in agreement regarding the statement that teachers respect students and act with empathy, especially among non-traditional ethnic groups, signals that these supportive conditions are not universally experienced. Although this was not found to be statistically significant, this could be a case of students only 'knowing what they know' and may possibly reflect general norms in teaching as 51% or less agreed. Although students may not directly perceive this as an influence of motivation either at this stage or generally, it is nevertheless a factor that may impact student motivation over time, leading to lower self-efficacy and diminished learning outcomes for students in general but especially non-traditional students (Tinto, 2022; Holmegaard, Madsen, and Ulriksen, 2017).

Social Belonging

The assertion that '*The university has an open-door policy and I am comfortable using it*' received lower agreement rates from females compared to males, a difference that was statistically significant. This reveals gender disparities in perceived accessibility to support, aligning with findings from González-Pérez et al.(2022), that women in STEM often feel less included and supported.

Similarly, both International and NE students reported lower agreement levels than NTE students, albeit not significantly. This could suggest that non-traditional students may perceive institutional support structures as less accessible or welcoming, yet not to the extent that it influences motivation.

The statements regarding inclusivity of the university environment *'The university creates an environment where I am included'* highlighted lower agreement rates for NE students relative to NTE and International students, and lower for females than males – both differences reaching statistical significance. This supports the literature that non-traditional students often feel marginalized in academic settings that reflect the norms and values of the majority group (Ulriksen, 2009; Eastman, Miles, and Yerrick, 2019). Therefore, including students that are outside of the cultural norm, becomes a fundamental element when developing sense of belonging (Strayhorn, 2018; Tinto, 2022).

The perception that '*The university does well in providing a good social network*' showed reduced agreement among both female and NE students, compared to their male and NTE counterparts, respectively. This aligns with research indicating that social integration is a significant challenge for non-traditional students (Hansen, Palakal, and White, 2023; Tinto, 2022).

The significant finding that international students viewed social relations with other students as less important for their motivation further complicates the picture. It suggests that international students may prioritize other aspects of their university experience over social integration, potentially due to cultural differences or varying expectations of academic life – such as being temporary students (Tinto, 2022; Ulriksen, Madsen, and Holmegaard, 2017).

Conversely, the statement '*The university values my opinions*' received less than 50% agreement from all surveyed students but was not statistically significant. This suggests a broader issue where students across all demographics feel undervalued. This finding highlights the importance of creating a participatory and inclusive culture where all students feel their voices are heard and valued (Gasiewski et al., 2012; Tinto, 2022).

4 SUMMARY

The study's results show that indeed there are differences in the perceptions of sense of belonging variables between traditional and non-traditional students. Although there were differences between male and female perceptions, the differences were more pronounced between traditional students and non-traditional students based on ethnicity. This indicates that there are some underpinning cultural factors, perhaps related to communication styles, cultural norms, and the level of encouragement offered by teachers, that could be further studied in order to bridge the gap. There is a completely different make-up of the student population than has been traditionally. The new student population has a less positive perception of their experience at university in these initial months than traditional students, suggesting that the culture is still orientated to a previous type of student. As the first year is so important in order to mitigate dropout, paying attention to academic sense of belonging and in particular teacher encouragement and teacher explanations could be prudent. Studies show that more explicit communication is beneficial for non-traditional students, as they are less likely to be as fluent in the norms and values of university culture as traditional students. Furthermore, by creating a more 'humanised' approach enables students to develop more connections between each other, the teacher and the university.

Further studies should investigate effective initiatives to increase students' sense of belonging, considering how various student characteristics factor into this dynamic. For instance, it would be valuable to examine whether students who perform well academically tend to have a higher sense of belonging.

ABSTRACT

The aim of this research is to understand students' perceptions of the flipped classroom model used to teach sustainability in an operations management module, and moreover, to understand the extent to which students are self-regulating their learning outside of the classroom. This is a follow-on study, and a further aim is to examine whether changes to the online learning environment have made any difference. This research used a validated and ethically approved survey to collect data, which was analysed using descriptive statistical analysis that involved the calculation of frequency, means and standard deviation from the responses using SPSS and Excel software. Results indicate a surprising consistency with the findings of the previous research, with only one aspect, the VLE (Virtual Learning Environment) facilitating interactions within the cohort, recording a notable positive difference. Whilst this supports and reflects the changes made, the intention to facilitate self-regulated learning and students' engagement with online learning was not improved. Therefore, further research (and action) is required to address the lack

of student engagement with self-regulated learning. This study provides useful insights into student learning behaviour in a flipped classroom environment that requires self-regulated online learning. Furthermore, other research could use the same tool to evaluate their own students' perceptions and compare results.

1 Introduction

1.1 Literature

The Flipped Classroom (FC) paradigm has emerged as a compelling pedagogical approach, substantiated by ample empirical support (Mason, Shuman, and Cook 2013; Shih, Liang, and Tsai 2019). FC revolutionizes traditional learning dynamics by reversing the conventional sequence, shifting lecture content delivery to online platforms and allocating in-class time for active engagement in problem-solving or collaborative tasks (Lage, Platt, and Treglia 2000; Shih, Liang, and Tsai 2019). Contemporary FC frameworks integrate two primary components: Online Learning Activities (OLA) and Face-to-Face instruction, blending theoretical concepts with hands-on applications (Youhasan et al. 2022; Jowsey et al. 2020). However, the delineation between FC and blended learning, wherein both online and in-person approaches converge, remains blurred in scholarly discourse (Youhasan et al. 2022).

FC and blended learning models optimize face-to-face class time for higher-order cognitive tasks such as problem-solving and collaborative projects (Flumerfelt and Green, 2013; Shih, Liang and Tsai, 2019). Self-Regulated Learning (SRL) denotes learners' deliberate orchestration of the learning process (Cho, Kim, and Choi, 2017; Shih, Liang, and Tsai, 2019). Empirical evidence highlights a positive correlation between SRL and learning satisfaction, emphasizing its role in achieving educational objectives (Artino and Jones, 2012; Sun et al. 2008; Wang, Shannon, and Ross, 2013; Broadbent and Poon, 2015; Wu et al. 2023).

Scholars have noted enhanced student engagement and self-awareness through FC implementation, emphasizing its efficacy (Gilboy, Heinerichs, and Pazzaglia 2015; Joy et al. 2023) and positive effect on reducing dropout rates (López-Pérez, Pérez-López, and Rodríguez-Ariza 2011). Contrary to expectations, subsequent research confirms that, akin to traditional study outcomes, blended curriculum cohorts display substantially diminished satisfaction with their overall study experience, highlighting that the present iteration of online teaching technologies falls short of being a "panacea for higher education challenges" (Chingos et al. 2017).

Further challenges persist, particularly concerning educators' apprehension regarding increased workload and students' struggles with SRL (Hill, Riha, and Wysocki 2014; A Rahman et al. 2015) contrasting with the fact that when adequately used it can optimize educators' time and quality of the teaching process (Buran and Evseeva 2015). Successful FC deployment necessitates proactive academic support to scaffold students' engagement with learning materials (Jovanovic et al. 2019; Sletten 2017). Furthermore, academics need to actively and in a coordinated manner engage students to facilitate social interactions (Finlay, Tinnion, and Simpson 2022). Insufficient SRL skills hinder students' ability to effectively manage pre-class activities, impeding participation and learning outcomes (Mason, Shuman, and Cook 2013; McLaughlin et al. 2013)

Thorough course design, enriched with interactive online activities and instructor scaffolding, fosters SRL development (Lock et al. 2017; Cho, Kim, and Choi 2017). In the FC context, where autonomous learning is encouraged, students' adeptness in time management and strategic learning approaches are pivotal for academic success (Connor, Newman, and Deyoe 2014). Nonetheless, students may find it challenging adhering to prescribed online study schedules, affecting engagement and performance (You 2016; Jovanovic et al. 2019; Panzarasa et al. 2016) while the lack of live and reliable information about their diversity in personal motivations makes a gap in addressing those needs in the course design (Vanslambrouck et al. 2018).

Collaborative Learning (CL) complements FC by nurturing essential skills like problem-solving, teamwork, and communication, vital in engineering education fostering inclusivity and peer learning (Wieman 2019; Madland and Richards 2016).

Intentional Behaviour towards FC denotes students' willingness to engage with the FC model (Sletten 2017). Positive attitudes towards FC correlate with effective SRL strategies, underscoring the importance of aligning students' perceptions with learning objectives (Winne and Jamieson-Noel 2003). Blended learning practice reveals importance of the face-to-face (even brief) in managing and driving other learning activities (Baragash and Al-Samarraie 2018).

1.2 Context

Technical Operations Management is a mandatory module in the School of Engineering (SoE). The SoE uses a Learn-Apply-Reflect (LAR) model to structure learning in each module and the module was designed to meet these requirements:

a. Learn: intended to provide knowledge. A fortnightly face-to-face lecture provides content and scaffolding for the additional asynchronous online material on Moodle (the VLE) which provides additional depth through short videos, research papers and e-book chapters. The asynchronous learning requires students to demonstrate self-regulated learning (SRL) skills.
b. Apply: designed to encourage application of learning. Moodle contains activities/tasks/quizzes/questions aligned to the Learn SRL tasks and designed to deepen subject understanding and test knowledge. Again, SRL skills are required.
   'Apply' also occurs in the fortnightly face-to-face flipped classroom style seminars in which students collaborate to apply their knowledge and solve more challenging problems. Furthermore, these seminar activities are constructively aligned to the summative assessments.
c. Reflect: created to enable students to evaluate and self-assess their knowledge. Timetabled drop-in sessions, academic office hours and discussion forum (on Moodle) provide students with the opportunity to request further support and inform their self-directed study.

Therefore, the module (and VLE) is structured around 4 fortnightly learning cycles (weeks 1 and 10 introduce and conclude the module). Moodle is structured to mirror the LAR phases and has a consistent layout across the weeks. It should be noted the other modules concurrently studied whilst using LAR, maintain 3 one hour-long lectures each week and are all numerically based.

2 METHODOLOGY

2.1 The Study Aim

This longitudinal study examines the experience of 328 second year engineering students on a module in the UK. The study started in the autumn 2022 (year 1, 22-23), firstly to assess whether the implemented LAR Flipped classroom model that combines the teaching approaches of Flipped Classroom and Collaborative approach was perceived positively by students and secondly to explore how the students self-regulated their online experience (Cooke, et. al, 2024).

In response to the earlier research findings and student feedback, actions were implemented, and the study was repeated in academic year 23-24 (research study year 2). The specific changes focused on improving students' engagement with the VLE as follows: (i) simplification and consistency in Moodle asynchronimous material, (ii) forums to allow students ask questions on weekly material, (iii) videos shortened to 15-20 mins to maintain student interest and (iv) added Moodle activity progress indicators. Therefore, results will be critically compared between cohorts (22-23 versus 23-24).

2.2 Research question and Objectives

This study's primary research question is:

What are the students' perceptions of the LAR flipped classroom/Collaborative learning model?

The objectives are consistent with the previous study:

- Examine the students' perception of the interaction in the physical class (seminars) when the Flipped Classroom-LAR model is use.
- Explore how the students self-regulated their online learning experience. Identify the student's perception of the overall experience of the LAR-Flipped classroom model.

2.3 Methodological Approach

The research premise is based in objectivism; specifically, a pragmatism philosophical approach is adopted indicative of the research teams' ontology and epistemology in addition to the need to the focus on problem solving and informing future practice (Saunders, Lewis, and Thornhill 2019). Furthermore, positivism underpins a deductive approach. A mono-method quantitative study, using the pre-validated survey (Shih, Liang, and Tsai 2019) will be used to understand student perceptions of flipped classroom learning and their behaviours in online self-regulated learning. Permission to use the survey was sought and obtained.

2.4 Data Analysis

Likert-scale surveys (Shih, Liang, and Tsai 2019), with prior ethical approval, were administered online via Qualtrics during the week 9 seminars; and to ensure further consistency with the preceding year, students were advised about the study's purpose, confidentiality, and voluntary completion. The sample size was 80 students who attended week 9 seminar sessions, from which 75 students submitted their answers achieving a response rate of 94%. The answers were revised, and 24 answers were removed from the analysis during the cleaning process due to lack of

50% or more of the answers required from both questionnaires. This represents almost 16% of the cohort.

Responses from both questionnaires OSLQ- Online Self-Regulated Learning Questionnaire and PFCQ- Perception of Flipped Classroom Questionnaire, were analysed using SPSS and Excel.

OSLQ, consisted of 26 questions organised in six dimensions and PFCQ consisted of 17 questions organised in four dimensions (Shih, Liang and Tsai, 2019, Cooke, et al., 2024). Frequency, mean and standard deviation values were calculated for each question and dimension using the SPSS software and interpreted using the Table 1 shown below.

Table 1. Mean interpretation of the 5-point Likert type of questions (Mendoza et al. (2021)

5-point Likert scale	Mean range (μ)	Interpretation
1	1 – 1.80	Strongly disagree
2	1.81 – 2.60	Disagree
3	2.61 – 3.40	Neutral
4	3.41 – 4.20	Agree
5	4.21 – 5.00	Strongly Agree

3 RESULTS AND DISCUSSION

3.1 Online Self-Regulated Learning Questionnaire (OSLQ) results

The results from this first questionnaire (**Error! Reference source not found.**-full results available on request) suggest that students: manage well the aspects of online self-regulated learning that refers to setting goals(Goal setting dimension); study in an environment that is effective and suitable for online learning (Environment Structuring dimension); and are proactive seeking help from lecturers and colleagues to solve doubts encountered when using online learning (Help seeking dimension).

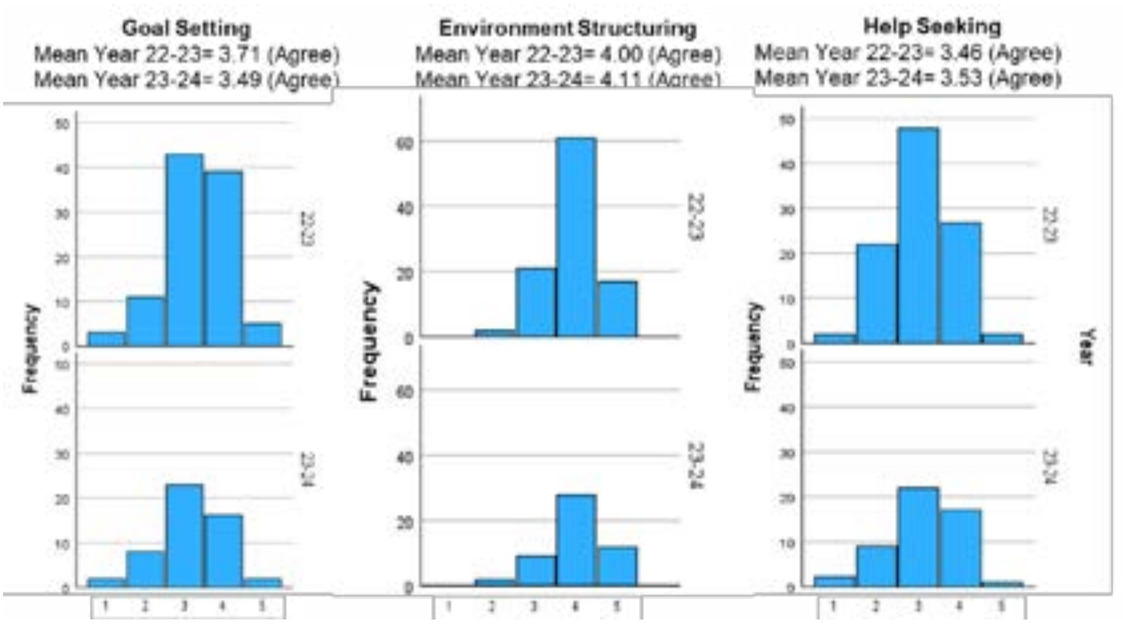

Figure 1. OSLQ results for Goal Setting, Environment Structuring and Help Seeking dimensions

Results in both academic years in the dimensions Task Strategy, Task Management and Self-Evaluation that show the lack of engagement with asynchronous material (see Figure 2). This behaviour can be observed specifically in the response to questions such as "*TS1-I prepare my questions before attending to seminars"* and *"TS2- I work through the problems in my online course on top of the set ones to master the course content*".

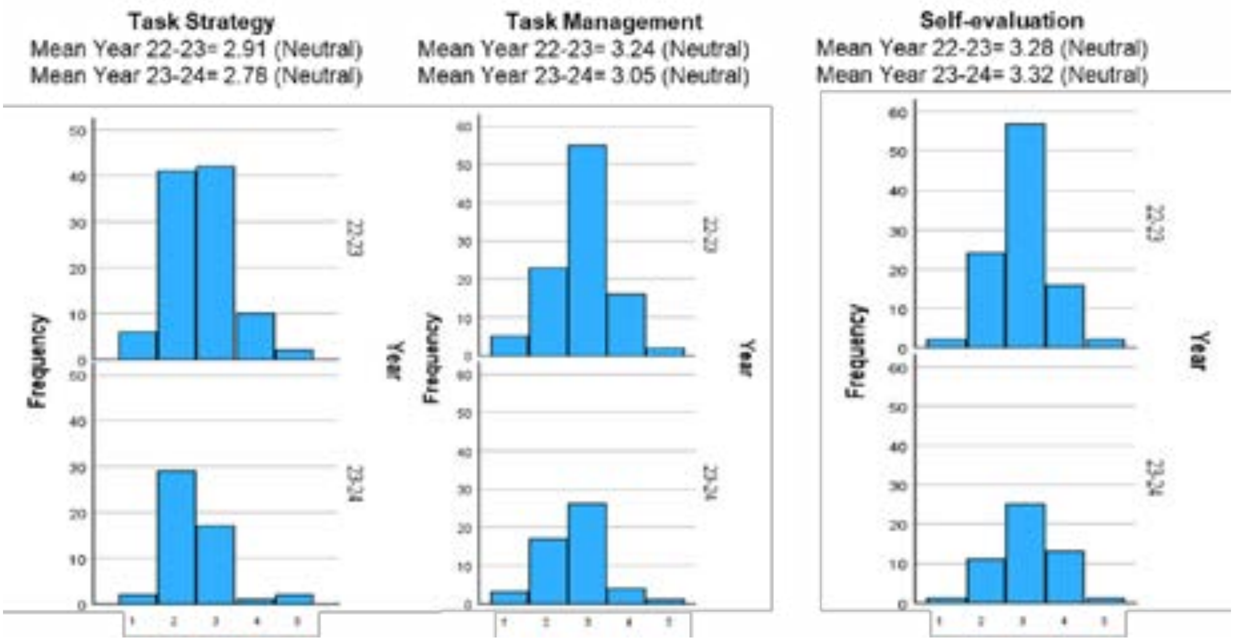

Figure 2.OSLQ results for Task Strategy, Task Management and Self-evaluation dimensions

Furthermore, the mean value for TS1 and TS2 decreases from year 22-23 to year 23-24 (TS1-year 22-23, $\mu=2.56$ to year 23-24 $\mu=2.13$ and TS2-year 22-23, $\mu=2.52$ to year 23-24, $\mu=2.43$). These results are in accordance with the lecturers' perception that the students from year 23-24 were less participative in class and demonstrated less evidence of using the material available online prior to the seminars.

Commensurate with the 22-23 study, the authors analysed the logs of access to online learning activities prior to seminars on Moodle. The percentage of students who accessed the asynchronous material provided prior to attending the fortnightly seminars was unsatisfactorily low (between 40% and only 6% of the whole cohort) and was dropping throughout the semester (Table 1).=

Table 2. Number of students actively engaging with the online material before the seminars and throughout the academic semester

Semester Week (out of 10)	**3**	**5**	**7**	**9**
Active use of the online resource before the f2f seminar				
AVG Active Engagements	130	25	24	19
% of the enrolled students	40	8	7	6
Active use of the online resource in the academic semester				
AVG Active Engagements	230	49	99	83
% of the enrolled students	70	15	30	25

Similar trends were observed in the literature (Jovanovic et al. 2019; Turhangil Erenler 2020; Wu et al. 2023). These findings agree with the behaviour observed by the authors and are in line with the questionnaire 1 results (**Error! Reference source not found.**). This validates the observation that, despite academic endeavours to enhance online resources, offer improved guidance to students in navigating the LAR model, and place increased emphasis on FC, there persists a deficiency in students' early engagement with the VLE and the LAR model. This can significantly affect the effectiveness of students' learning experience and their perception of usefulness of the FC combined approach as it is demonstrated further in the results from questionnaire 2.

3.2 Perception of Flipped Classroom Questionnaire (PFCQ) results

3.2.1. Interaction in face-to-face learning in class

Consistently, in both academic years, the results of the first dimension in PFCQ indicates that students value and perceive as positive the activities in the physical class. In addition, students indicated there is a positive impact from their participation and physical interaction with colleagues and lecturers on their learning (*Table 3*).

Table 3. Experience of the face-to-face seminar dimension results of the PFCQ

Code	***Description:*** ***Students perceive that in the physical class when using the Flipped Classroom model they...***	Mean (μ) Year 22-23	Mean (μ) Year 23-24
IPC1	Effectively exchange information and knowledge	*3.56*	*3.51*
IPC2	Get support from cooperative learning and group work with other participants.	*3.57*	*3.82*
IPC3	Easily get counselling and support of learning by the tutor.	*3.65*	*3.65*
IPC4	Learn more from my team members.	*3.45*	*3.41*

IPC5	Participate more in peer discussion that the lecturers tend to facilitate during the seminars.	*3.79*	*3.80*
IPC6	Can interact online and that the Online learning platform (Moodle) makes it easier the interaction with instructors and other students in the module.	*3.12*	*3.61*

Interestingly, year 23-24 results compared to those obtained in year 22-23, show a positive response to the changes implemented. In contrast to last year, in 23-24 most students agree that the use of Moodle makes it easier to interact with instructors and other students (Figure 3).

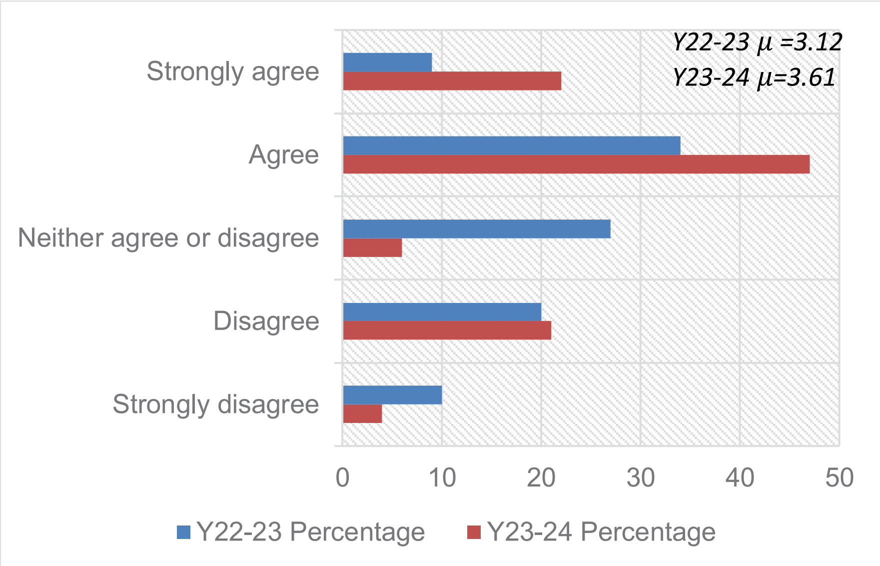

Figure 3. IPC6 Histogram of frequency results

3.2.3. Positive experience and Intentional Behaviours

Whilst the results of the Intentional behaviours in year 23-24 (IB1, IB2, IB3 and IB4 in Table 4) demonstrated, that students who engaged earlier with the online learning activities are largely satisfied with the overall learning experience using the LAR model and there is a consensus in feeling that the blended learning model used requires more self-regulated learning skills (PEFC4 in Table 5).

Table 4. Intentional Behaviours results for year 22-23 and 23-24

Code	**Intentional Behaviours – IB**	Mean (μ) Year 22-23	Mean (μ) Year 23-24
IB1	I feel I feel satisfied with flipped pedagogy.	*3.76*	*3.70*
IB2	I am satisfied feel I learn better in blended learning model.	*3.82*	*3.92*
IB3	I would like to continue using the FCM in my learning.	*3.76*	*3.84*
IB4	I would like to learn using the Moodle LAR activities as much as possible.	*3.65*	*3.92*

Table 5.PEFC results

Code	**Positive experience of Flipped Classroom - PEFC**	Mean (μ) Year 22-23	Mean (μ) Year 23-24
PEFC1	I feel in favour of participating in blend learning activities	*4.12*	*3.38*
PEFC2	I feel I learn better in blended learning model.	*3.76*	*3.23*
PEFC3	I feel that my learning time is more flexible with the use of the blended learning model.	*3.82*	*3.76*
PEFC4	I feel blended learning model requires more self-regulated learning skills.	*4.24*	*4.23*

These results demonstrated once again that the students are finding it difficult to adapt to the different mindset and to satisfy the demanding self-regulated learning skills of a combined FC and Collaborative learning delivery model.

It is worth noting that the consensus feeling that more self regulated skillls are required to learn using the combined approach (Table 5) could explain why even though the students are overall satisfied with the approach (Table 4), and would like to continue earning using the LAR model, the majority reported not to be in favour of participating in the online learning activities.

4 DISCUSSION

The positive findings associated with managing self-regulated learning, setting goals, a suitable study environment and seeking help to support online learning are consistent with research (He et al. 2022; Sletten 2017) and demonstrates the students are willing to engage. The challenges which result in failing to dedicate time in a consistent or structured manner to complete the online activities before the seminar also align to research (You 2016; Jovanovic et al. 2019). Whilst trends around low and reducing engagement with online learning material aligns to literature (Jovanovic et al. 2019; Turhangil Erenler 2020; Wu et al. 2023), this lack of engagement with asynchronous material before seminars impacted engagement in seminars and in turn learner satisfaction with the module; again, consistent with research (Sarker et al. 2023). This presents a challenge for the learning design which must be addressed; how can engagement with asynchronous online material prior to the seminars be enhanced? Additionally, how can students be equipped with self-regulated learning skills.

Furthermore, these results align to current literature that states FC encourages student collaboration and offers additional chances for teacher-student engagement through the teaching and learning process (Güler, Kokoç, and Önder Bütüner 2023; Cheng, Wu, and Su 2021; Okolie et al. 2022). Notably the updates to the VLE facilitated improvements in interactions.

5 CONCLUSIONS

The research aligns to the findings from research year 1 and indicates that students who engaged with the VLE prior face-to-face sessions found the LAR model useful and express overall satisfaction and intentions to continue using the LAR model.

Whilst there is evidence that the changes in VLE had a positive impact in students' engagement with asynchronous material prior to the face-to-face sessions, action is required to carry on supporting the transition from a traditional teaching approach to one that requires more self-regulated learning skills and externally motivated students to engage with the VLE. For future work the authors are also working on changes that involves linking and recognising engagement with VLE in summative assessment.

Despite lack of student engagement with the VLE, students find the seminars collaborative and activity led learning approach useful and agree the approach has a positive influence.

ABSTRACT

Engineers have a particular role in fostering an inclusive society since engineering solutions can either advance or hinder inclusion. Educating engineers about inclusivity involves not only teaching inclusive principles but also fostering an inclusive mindset. However, the concept of an 'inclusive mindset' lacks a universally agreed-upon definition and conceptual framework. To address this gap, we conducted a scoping review of existing literature that discussed an inclusive mindset as their main theme to explore and clarify the concept of an 'inclusive mindset'. Our review encompassed 47 papers from diverse global regions and research domains, including education and organisation research. Data extraction and coding were conducted systematically, focusing on research areas, types of inclusivity addressed, definitions, related attributes, and factors influencing an inclusive mindset. Through numeric and thematic analysis, we provided insights into the prevalent themes and concepts surrounding an inclusive mindset. We then developed an inclusive mindset model to conceptualise our scoping review findings. This model offers a conceptual framework to identify factors influencing inclusivity and guide interventions aimed at educating inclusive mindsets among engineering students.

1 INTRODUCTION

Engineers have a particular role in fostering an inclusive society since engineering solutions can either advance or hinder inclusion. Notably, inclusive design innovations not only provide products, services, and built environments that are accessible to all but also offer business opportunities to expand into new markets and cultivate long-term customer loyalty (Dong et al. 2004). Conversely, biased technology as shown in predictive software (Angwin et al. 2016), medical implants (Hutchison 2019), and facial recognition systems (Taati et al. 2019) perpetuates inequalities and exacerbates exclusion. These examples underscore the importance of educating an inclusive mindset and inclusive principles in engineering education.

Currently, the primary approach to teaching inclusivity in engineering education is through inclusive and universal design (Blaser et al. 2015; Clarkson et al. 2003; Valgeirsdottir 2021). These approaches not only teach students how to design inclusively but also aim to motivate them to do so. Some scholars (e.g., Nezafati et al. 2022; Valgeirsdottir 2021; Zallio and Clarkson 2021) refer to this latter process as fostering an 'inclusive mindset'. However, despite being widely discussed, the term ‘inclusive mindset’ lacks a universally agreed-upon definition. Existing definitions, such as Forsberg's (2022) workplace-oriented conceptualisation, may not fully encapsulate the nuances of inclusivity within engineering education. To better nurture an inclusive mindset in engineering students, we need first to clarify the constructs of an inclusive mindset.

Therefore, this study aims to develop an inclusive mindset model to represent various constructs underlying an inclusive mindset. We first explored the concept of an 'inclusive mindset’ through a scoping review of existing literature. Since the overall societal context can influence engineering solutions (Kille-Speckter and Nickpour 2022), the reviewed literature extends beyond engineering education research. The findings from the review then inform the development of the inclusive mindset model, encapsulating the diverse dimensions and implications of an inclusive mindset. Ultimately, this study seeks to provide a framework that guides the enhancement of the interventions, tools, and methods for promoting inclusivity within engineering design research, education, and practice.

2 METHODOLOGY

This study is part of a larger research project aimed at enhancing inclusive mindset educational strategies (e.g., workshops, courses, and learning materials) in engineering education. Following an iterative approach of Educational Design Research (McKenney and Reeves 2019), this study is situated in the analysis/orientation phase. To clarify an ‘inclusive mindset’ concept, we employed Arksey and O'Malley's (2005) five-stage framework for scoping reviews.

2.1 Identifying the Initial Research Questions

The focus of this review was to identify the key constructs of an 'inclusive mindset' and its related attributes. The research questions guiding this inquiry were:

RQ: How might we conceptualise the constructs of an inclusive mindset?

1.1 In which research areas or disciplines has the concept of an inclusive mindset been discussed, and to what extent?

1.2 What kind of inclusivity (e.g., disability, gender, age) are addressed?

1.3 What are the definitions and conceptualisations of an inclusive mindset?

1.4 What are the related attributes of ‘inclusive mindset?

1.5 What influences an inclusive mindset?

2.2 Identifying Relevant Studies

A systematic search was conducted across three major databases: Scopus, Web of Science, and Google Scholar. The search strategy focused exclusively on identifying studies that explicitly discussed the search terms "inclusive mindset" or "inclusive mind-set" as their primary theme, whether in the title, abstracts, or keywords. As societal context can influence engineering solutions (Kille-Speckter and Nickpour 2022), we did not limit our search to engineering education papers alone. This broader scope allowed us to capture diverse perspectives on the inclusive mindset concept, thereby enhancing the current understanding and practices of inclusivity in engineering education. Both published and unpublished literature were considered for inclusion. This search yielded 65 results in total (38 from Scopus, 12 from Web of Science, and 15 from Google Scholar). After duplicate records were removed, 47 relevant papers were identified.

2.3 Study Selection

Studies were included if they addressed the concept of an inclusive mindset in any context or domain in the title, abstracts, or keywords.

2.4 Charting the Data

We conducted data extraction from the reviewed studies to gather bibliographic details, such as authors, title, year of publication, and document types, along with responses to the five guiding research questions. The extracted data was manually coded and organised using Microsoft Excel.

The coding process followed an inductive approach, where key information from the studies was systematically categorised to facilitate further analysis. The categories included research areas and related terms, types of inclusivity addressed, definitions of an inclusive mindset, related attributes of an inclusive mindset, and factors influencing an inclusive mindset. As part of this iterative approach, the coding categories were continuously developed, revised, and refined over time to accommodate new insights emerging from the data. This iterative process allowed for a comprehensive exploration of coding categories, ensuring a thorough understanding of the reviewed literature (Thomas 2003).

To ensure the reliability and validity of the coding process, a subset of the papers was independently coded by the second author. The second author conducted the coding process without access to the initial codes generated by the first author to minimise potential bias. Following the completion of coding, a comparison was made between the codes. Discrepancies were identified and resolved through collaborative discussion and consensus-building. This process aims to enhance the consistency and accuracy of the coding process and validate the reliability of the findings.

2.5 Collating, Summarising, and Reporting the Results

We conducted a numerical and thematic analysis of the coded data (Levac et al. 2010). The numerical analysis involves frequency counts to quantify the occurrence of different categories and concepts within the data. Meanwhile, thematic analysis qualitatively searches for themes or patterns within the dataset concerning research questions (Braun and Clarke 2006). Detailed findings from these analyses are reported in the next section.

3 FINDINGS

The scoping review comprised 47 papers from diverse geographical regions, reflecting a global engagement with an inclusive mindset concept. The literature encompassed various publication types, including journal articles, conference proceedings, book chapters, and theses.

Temporal analysis revealed an increasing trend in scholarly engagement with an inclusive mindset concept. While the earliest paper was from 2002, the major contributions were published post-2020 (see *Figure 1*).

The key findings according to each guiding research question are presented below.

3.1 Research Areas or Disciplines

The concept of an inclusive mindset has been mentioned across various research areas and disciplines, with a predominant focus on education and organisation contexts (see *Figure 2*).

Over two-thirds of the papers (n=32) discussed an inclusive mindset in educational settings, covering topics such as inclusive pedagogy, educational policy, and curriculum development. Within this category, higher education emerged as the most prominent sub-discipline, comprising 20 papers. These studies addressed an inclusive mindset in multiple disciplines including engineering education (n=7), teacher education (n=4), and management education (n=2). Additionally, other education levels (e.g., primary and secondary education), and areas (e.g., special and music education), were also represented.

Organisational contexts accounted for approximately one-third of the literature (n=11). Among these papers, four addressed the role of inclusive mindsets in fostering diverse and inclusive workplace environments. An additional four papers focused on inclusive leadership, highlighting the significance of leaders' attitudes and behaviours in shaping inclusive organisational cultures. The remaining studies discussed inclusive mindsets within the context of recruitment processes, emphasising the necessity for unbiased and inclusive hiring approaches.

A small subset of the literature (n=3) discussed the concept of an inclusive mindset within the realm of accessibility, addressing issues related to web accessibility, museum design, and architectural accessibility.

Lastly, a few papers explored inclusive mindset within other domains such as AI, tourism, and social quality. Notably, several studies addressed more than one research area, demonstrating the multifaceted nature of the inclusive mindset concept across diverse contexts.

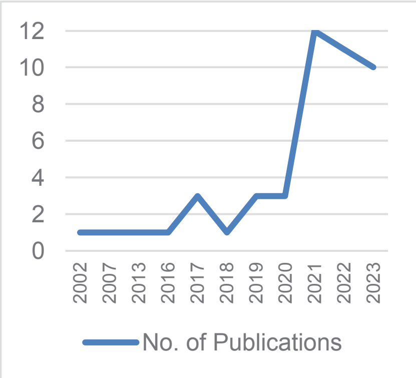

Fig. 1. Publications per year

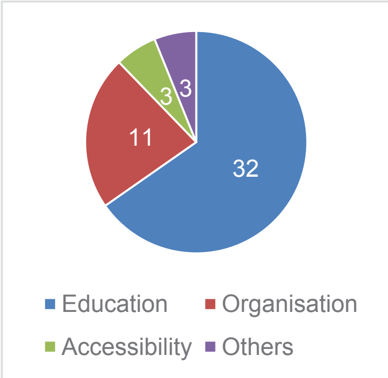

Fig. 2. Research area

3.2 Types of Inclusivity

An analysis of the reviewed literature uncovered various types of inclusivity and beneficiary groups when discussing an inclusive mindset.

Slightly more than half of the papers (n=25) focused on a specific dimension of inclusivity or targeted groups. Disabilities emerged as a prevalent theme in these papers, with 14 studies centring their discussions on individuals with disabilities (e.g., physical impairments, learning disparities, and neurodiversity). Additionally, the remaining 11 papers in this category addressed various types of inclusivity including genders, sexual orientations, races, cultural and sociological backgrounds, opinions, and individuals with criminal records. While these studies emphasised specific forms of inclusivity, many also acknowledged other kinds of inclusivity in their papers.

Conversely, another half of the papers (n=22) adopted a broader perspective. They discussed multiple types of inclusivity or the general concept of inclusion. These types of inclusivity included, but were not limited to, disabilities, gender, sexuality, age, generation, ethnicity, culture, region, socioeconomic status, physiological differences (e.g., left-handed, obese), organisational tenure, political view, and academic background. Some studies explored general inclusion principles, referring to terms such as 'under-represented groups', 'different social identities', 'team inclusivity', and 'diverse learners'. Besides, two papers did not explicitly state the types of inclusivity they addressed but referred to an 'inclusive mindset' as part of an Essential Skill (Chan et al. 2023) and a trait of Generation Z (Seibert 2021).

3.3 Inclusive Mindset Definition

Among the 47 papers reviewed, only one study by Forsberg (2022) provided an explicit definition of an inclusive mindset. Derived from the concept of workplace inclusion, her definition emphasised actions that conveyed perceptions of value and respect for different perspectives. Additional 10 papers implied that an inclusive mindset involved learning and embracing differences (Eadens and Eadens 2016), providing flexibility (Wiebusch 2013; Young Jones 2022), embracing social justice (Cherrez et al. 2023), respecting diversity (Cohen Carrus 2017; Purwanto et al. 2019), designing with accessibility in mind (Altinier et al. 2022), serving all stakeholders (Prasad et al. 2019), pursuing diversity and equity (Bosio 2023), and thinking inclusively (Valgeirsdottir 2021).

Nevertheless, most papers did not offer explicit definitions of an inclusive mindset. This absence may have stemmed from an assumption that the term is widely understood; however, our review demonstrated a diverse range of interpretations among scholars. This dissimilarity underscores the complexity of the concept and the necessity for further clarification and exploration of its related attributes.

3.4 Related Attributes of an Inclusive Mindset

A content analysis of the 47 reviewed papers exposed a wide range of attributes associated with an inclusive mindset. These attributes can be classified into two intertwined categories: invisible and visible.

3.4.1 Invisible Attributes

Invisible attributes encompassed cognitive facets such as motivations, awareness, emotions, attitudes, and viewpoints that exist within an individual's mind. They are essential components of an inclusive mindset as they constitute the internal mechanisms that propel inclusive behaviour. These invisible attributes included open-mindedness, awareness of biases and social issues, self-reflection, empathy for diverse individuals, inclusive competencies and knowledge, inclusion and diversity value, positive attitudes and feelings towards inclusion and diversity, respect, sensitivity, compassion, and acceptance.

3.4.2 Visible Attributes

Visible attributes are observable actions or behaviours that demonstrate inclusivity. They serve as tangible indicators of an individual's inclusive mindset. These visible attributes included designing with accessibility in mind, providing flexibility, involving others, challenging current approaches, creating supportive relationships, using inclusive language, going beyond legal requirements, and treating others with respect.

3.5 Factors Influencing an Inclusive Mindset

An analysis of the literature revealed that an inclusive mindset is influenced by both internal and external factors.

3.5.1 Internal Factors

Internal factors encompass individuals' attributes and characteristics, such as self-reflection and awareness, attitude and beliefs, understanding, intention and motivation, competency, personality traits, bias and assumptions, feeling, relationship, learning, experience, and sense-making.

3.5.2 External Factors

On the other hand, external factors include broader societal influences, such as learning intervention, social and work environment, standard and dominant practice, social norms, regulatory framework, resources and barriers, interaction with diverse individuals, global trends, and communication.

A table summarising the references to those related attributes and factors can be found in the appendix.

4 AN INCLUSIVE MINDSET MODEL

We developed an inclusive mindset model to conceptualise the findings of the scoping review. The model intends to identify the factors influencing the development of an inclusive mindset and its translation into inclusive behaviours. While the model is still a work in progress, the initial draft is presented below.

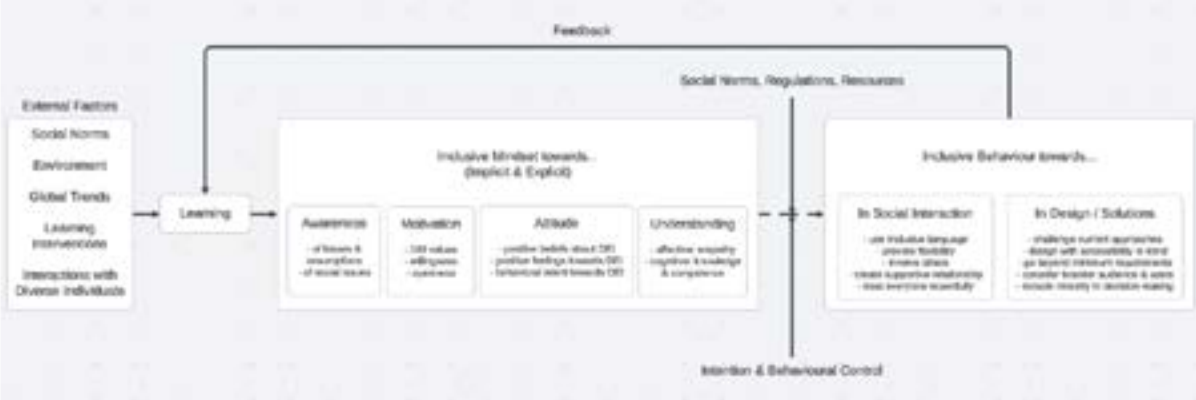

Fig. 3. An inclusive mindset model (version 1)

The model is structured into three main sections: the factors influencing an inclusive mindset, the constructs of an inclusive mindset, and the manifestation of inclusive behaviour.

4.1 The Factors Influencing an Inclusive Mindset

According to the findings in *section 3.5*, an inclusive mindset is shaped by various external factors, including social norms, cultural influences, global trends, learning interventions (e.g., training or education programmes), as well as interactions with individuals with diverse backgrounds and abilities. Learning from these experiences and surroundings, people form a mindset that either supports or opposes inclusion. We define the mindset that supports inclusivity as an inclusive mindset.

4.2 The Constructs of an Inclusive Mindset

An inclusive mindset consists of awareness, motivation, attitude and understanding. These constructs are informed by the findings presented in *section 3.4.1.*

Awareness refers to individuals being aware of their biases and social issues. Motivation involves valuing diversity and demonstrating a willingness to learn about differences (i.e., openness). Attitude has three main components: cognitive, affective and behavioural (Eagly and Chaiken 1998). Thus, attitudes within an inclusive mindset comprise positive beliefs about DEI and people with different backgrounds, positive feelings towards them, and intention to behave accordingly. Understanding encompasses both affective empathy and cognitive knowledge and competence in inclusion principles and practices.

An inclusive mindset can exist implicitly or explicitly. One may believe that they value inclusiveness but have an implicit bias towards some minority groups. Additionally, an inclusive mindset varies depending on the population under consideration. Individuals may exhibit inclusivity towards certain groups but not others.

4.3 The Manifestation of Inclusive Behaviour

While an inclusive mindset lays the foundation for inclusive behaviour, its translation into action is influenced by external and internal factors. External factors include social norms, cultural expectations, regulatory frameworks, and resources. Meanwhile, internal factors encompass intentions and behavioural control.

Based on the findings in *section 3.4.2*, inclusive behaviour can manifest in both social interactions and design solutions. Examples of inclusive behaviour in social interaction include using inclusive language, accommodating diverse needs, treating others respectfully, and actively involving individuals from different backgrounds. Inclusive behaviour can also be observed in design solutions, such as products, innovations, learning interventions, and policies. This inclusive behaviour often impacts broader audiences and involves challenging conventional approaches, prioritising accessibility, going beyond minimum requirements, and including under-represented groups in a decision-making process.

Lastly, feedback received from engaging in inclusive behaviours further reinforces or prohibits the development of an inclusive mindset.

5 DISCUSSION AND CONCLUSION

This study explored the concept of an 'inclusive mindset' through a scoping review of existing literature. Our primary objective was to conceptualise an inclusive mindset and provide a structured framework for enhancing interventions, tools, and methods promoting inclusivity within engineering education.

To our knowledge, this is the first study that provides a conceptual framework of an inclusive mindset based on a systematic literature search. As our literature search did not focus exclusively on engineering education, it aids in understanding the concept of an inclusive mindset from a broader perspective. We found discrepancies in the meaning of an inclusive mindset even within engineering education literature. Therefore, we took a broader approach to define an inclusive mindset as a mindset that supports inclusivity. This definition differs from Forsberg's (2022) definition of an inclusive mindset as it covers contexts beyond workplace interpersonal relationships. In engineering education, an inclusive mindset is needed in both interpersonal interactions and design practices (Nezafati et al. 2022).

While our inclusive mindset definition is broad, our inclusive mindset model offers a structured framework for identifying the constructs of an inclusive mindset, its influencing factors, and its translation into inclusive behaviours. Educators can use this model to analyse and enhance their pedagogical approaches, measurement frameworks, and related policies. For example, they can examine whether their learning programmes address all four constructs (awareness, motivation, attitude, and understanding) of an inclusive mindset or identify specific areas for improvement. It can also serve as a guideline for setting learning objectives and developing measurement tools.

The model also calls for attention to other factors influencing an inclusive mindset. Six of the seven papers that discussed an inclusive mindset in engineering education in our review attempted to foster an inclusive mindset through interventions including learning programmes (Nezafati et al. 2020; Nezafati et al. 2021; Nezafati et al. 2022, Wu 2021), learning materials (Valgeirsdottir 2021), and virtual reality (Vignola et al. 2019). However, factors beyond these learning interventions, such as social norms, regulatory frameworks, and institutional resources, also play a crucial role in shaping an inclusive mindset. Furthermore, even with the successful adoption of an inclusive mindset, its translation into inclusive behaviour depends largely on external factors. For instance, Moriarty (2007) found that lack of time and resources are significant barriers for STEM faculty members in adopting inclusive pedagogy. Thus, to successfully promote inclusivity in engineering education, it is important to consider environmental factors such as social norms, regulatory frameworks, and resources that facilitate or hinder an inclusive mindset. More research is needed in this area.

In conclusion, our research offers valuable insights for both theory and practice. Through a comprehensive scoping review, we have clarified the multifaceted nature of an inclusive mindset, highlighting its various dimensions and the factors that shape its development. By synthesising this knowledge into an inclusive mindset model, we provide a practical framework for stakeholders to understand and promote inclusivity within engineering education. This research lays the foundation for future studies aimed at validating the model and exploring diverse dimensions of inclusivity within engineering education. By implementing this model, engineering educators can enhance the inclusivity of their teaching practices and learning environment to better prepare students to develop accessible and equitable technologies.

Keywords: *Industrial engineering and management, University attractiveness, Engineering students' university choice, Covid-19 impact*

ABSTRACT

The Industrial Engineering and Management (IEM) degree merges engineering and managerial concepts, and has reaffirmed itself as an attractive degree for students in the Portuguese university landscape. This paper aims to investigate the attractiveness factors of 5 Universities in Portugal, according to their IEM students at those mentioned universities and how these compare between pre- and post-pandemic times. This analysis was done through two quantitative surveys shared among students of the ESTIEM network (European Students of Industrial Engineering and Management), in 2021 and 2024. The universities under analysis were Porto, Minho, Aveiro, Coimbra and Lisbon (IST). Responses showed that the most relevant factor for choosing universities is its prestige, followed by the city the university is located in, with over half the students inquired pointing to these two factors. Corporate-related factors such as the university's recognition by companies and the employment rate of the degree were highlighted as very relevant too. Differences were also found between the universities studied from Lisbon and Porto giving a bigger importance to prestige, while Aveiro's, Coimbra's and Minho's students prioritise the city of the campus. The results from 2021 and 2024 have coincident findings, pointing to the conclusion that the Covid-19 pandemic did not play a significant role when it comes to shifting Portuguese IEM students' attractiveness perspective. These findings not only allow universities to have an overview of their main potential selling points and what students deem as critical factors, but they also indicate that pre-Covid-19 studies' conclusions are likely still

relevant, as there are no critical differences seen between responses from 2021 and 2024.

1 INTRODUCTION

Industrial Engineering and Management (IEM) is a university degree that encompasses both a strong engineering basis and relevant management concepts. The degree has established itself as one of the preferred options of Portuguese high school students, gaining an increased visibility in the country since its introduction around 30 years ago. This was particularly evident in the last 7 years, where engineering degrees have become the top choice for students, having the highest entrance grades. In fact, Industrial Engineering and Management is a clear example of this, with the degree from the University of Porto in the top 4 since 2016, which in the academic year 2023/2024 held the fourth place, with an entrance grade of 18.55 out of 20[1].

These consistent results can be tied to the high employability of IEM graduates in Portugal, associated also with the diversity of careers and fields that an industrial engineer can partake in. Once graduated, the students can work in fields ranging from supply chain management, quality control, operations optimization, management, marketing, strategy, among others.

The *numerus clausus*, number of the students who applied, and number of students who enrolled in each university and degree as their first option are summarised in Table 1, for five of the top Portuguese universities, with data from 2023.[1]

Table 1. Numerus clausus, number of applicants and number of students that selected first option for each University

University	Aveiro	Coimbra	Lisboa	Minho	Porto
Numerus Clausus	74	57	81	68	111
Nº applicants	500	363	362	425	514
Nº students in their first option	45	30	75	35	111

Several factors contribute to a student's choice of university, and IEM being a degree with a consistent high demand, before, during and after Covid-19, it is interesting to explore further factors that make it attractive to students, and if these factors could have shifted due to the pandemic. This knowledge is highly valuable for the universities, who can work towards improving these factors and communicating them more efficiently to prospective students. It is also critical for them to understand if these factors changed during the pandemic, so that they can update their knowledge. Such an impactful event, tied to the digitalisation that it brought, could potentially have a strong influence on students' choices. Therefore, this paper aims

[1] Data from the Direção-Geral de Estatísticas da Educação e Ciência (DGEEC) - General Center for Statistics of Education and Science.

to address not only the attractiveness factors for students, but also how they compare to the most relevant factors pointed by students before Covid-19.

For this, a quantitative study was conducted by ESTIEM (European Students of Industrial Engineering and Management), a student organisation that operates at a European level, connecting Industrial Engineering students with each other, as well as with academics and professionals in the field. This study is tied to previous research conducted in 2021, to allow for a comparison between a pre- and post-pandemic scenario.

2 LITERATURE REVIEW

With the transformation of higher education to a highly competitive and globalised environment, and especially now in post Covid times, there is a high interest in researching the choices that potential engineering and IEM students make regarding their university, and if these have changed over the Covid-19 pandemic.

Students undergo a difficult decision process when facing the choice of degree and university. Han (2014) reported that it ultimately results from a combination of interconnected factors, such as demography or institutional characteristics. Perna (2006) addressed this multitude of factors through a four-attribute conceptual model that grouped several influences of students' choices. These attributes were habitus, school and community context, higher education context and social-economic context. Habitus encompasses demographic characteristics and social and cultural capital, while school and community context englobe the availability of resources, type of resources, structural supports, as well as barriers. As for higher education context, the focus was on institutional characteristics, location, marketing and recruitment. Several studies highlight the prestige and recognition of the university as one of the main influences of high school graduates' choice regarding their university (Cyrenne and Grant 2008; Do and Le 2020; Briggs 2006). Other research also points to the city the university is located in, and the distance from the student's hometown as being relevant factors (Baharun et al. 2011; Briggs 2006). On the other side, information availability by the university and research reputation were considered factors with low relevance (Briggs 2006).

Narrowing it to Engineering, Alpay (2013) provided research on the attractiveness of general engineering degrees in the UK with high school graduates. Special emphasis was put on the attractiveness traits of flexibility in engineering specialisation, combined degree options and exposure to non-technical courses. These were deemed as very attractive factors for students that were already considering an engineering degree before, as well as those who were not pondering it so far.

Regarding potential changes in the attractiveness factors for university students since previous years, Nanath et al. (2022) shows that the perspectives of students' decision-making criteria have indeed changed and there is a new perspective for university selection. The critical factors affecting a university choice in the digital era are the cost of education (such as tuition fees), the quality of student life at a university, the presence of e-learning and the opportunities in terms of employment and earnings. Indeed, Ramalhete et al. (2020) highlights that the transition to an e-learning model in Portuguese universities was made possible by the use of new information and communication technologies that come with advantages. One of the main benefits for this new teaching methodology is the absence of commuting times, followed by the development of students' autonomy and therefore has potential to transform teaching and learning contexts in the future, and making factors such as distance to the university less relevant.

Looking specifically at changes coming from the pre-pandemic students to the ones that made the choice to enroll in the university during and after that time, this research will be based on the factors previously presented by Serodio et al. (2021). In that quantitative study, an analysis of factors that influence Industrial Engineering and Management students' choice of university in Portugal was presented, dating from the beginning of the Covid-19 pandemic, with students that enrolled before this period. The most important factors concluded were the prestige of the university and the city of the institutions, followed by job market opportunities that students expect to access after their graduation.

3 METHODOLOGY

To identify the most important attributes for Industrial Engineering and Management students in Portugal and how these preferences were affected by the pandemic, a comparative analysis was made between two quantitative studies, based on online surveys to students.

The survey was filled two times, the first time in March of 2021, when it was created, in full pandemic times, and one time during March 2024 in a post pandemic scenario. In order to ensure the answers from both years were comparable, new items were not added in 2024 as options for the relevant factors.

The data was collected through the student associations that are members of ESTIEM (European Students of Industrial Engineering and Management), with the student's permission and taking into consideration the general data protection regulation, with all data being handled anonymously. Five relevant Portuguese Universities with IEM degrees were selected for this study: Universities of Aveiro, Coimbra, Lisbon, Minho and Porto. It was ensured all answers collected within the survey are from engineering students in the Industrial Engineering and Management degree.

While in the first survey in 2021, the target group were both bachelors and masters' students, the second survey in 2024 was only sent to bachelor IEM students, all from the above-mentioned five universities. This study will compare only the results from Bachelor students, as the aim is to be able to distinguish between pre- and post-Covid-19 university applicants.

In the current study, 209 answers were collected. From 2021's study, we used 214 of the 255 answers completely filled, corresponding to a selection of only Bachelor students. The distribution between female and male respondents was approximately 60% and 40%, respectively, in both years. The percentage of answers from each of the five Universities analysed is displayed in Table 2.

Table 2. Distribution of responses per surveyed university

% respondents (Bachelor students) per survey run	Aveiro	Coimbra	Lisbon	Minho	Porto
2021	17%	25%	20%	19%	19%
2024	35%	16%	14%	14%	21%

The survey questions investigate IEM students' first choice of university. Participants of the survey were asked about the university they selected as first choice, and were able to give multiple answers and indicate other possibilities besides the already presented, to make sure all options were considered. This was then compared to their current university to understand the degree of mismatch between preferred and current universities. The survey also focused on the factors that influenced their decision, asking students what were the features that lead them to put that university as their first choice for bachelors, in a closed multiple selection question, with a total of 16 answer possibilities. The definition of the options had as basis the revised literature. Finally, students were also questioned on whether they would change their university if they could, to which one they would have preferred to go, and if they would consider now taking their degree abroad.

The data collected was analysed and compared to the data collected in the previous survey. The influencing factors for first choice were through percentages, having each percentage calculated through the number of times that factor was pinpointed as relevant in the total number of survey responses for the five main universities. The answers were also subsequently separated by location, in order to obtain the top 5 factors indicated for each university.

4 RESULTS

The first choice of university was analysed on the perspective of influencing factors associated with universities' characteristics, related to its location, teaching, interaction with the corporate landscape of the country, among others. Figure 1 shows the general results obtained in both questionnaires. For 2021, 207 out of the 214 answers were used for this analysis, as four students stated they would have liked to study in University Nova Lisbon (FCT/UNL) and three in Instituto Superior de Engenharia do Porto (ISEP), universities not considered in the study, similarly to one student in 2024 who also chose this last university as first choice.

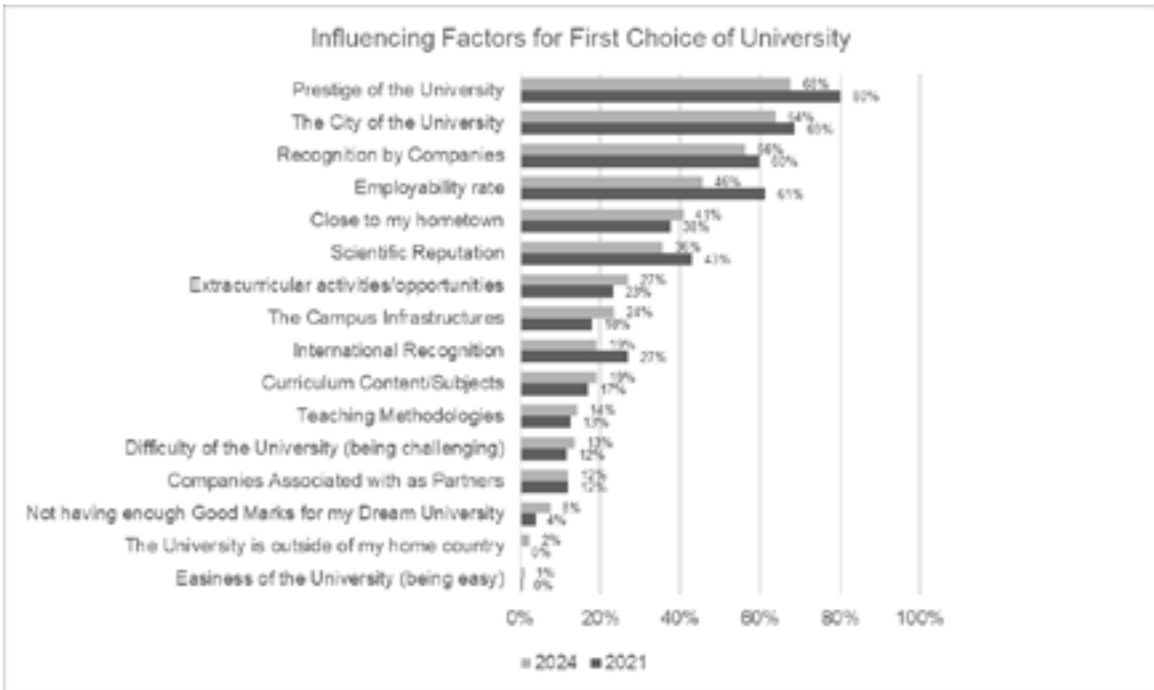

Fig. 1. Distribution of influences of student's first choice factors for 2021 and 2024

From the overall results it is possible to see that the first four influencing factors are the same between the two analyses, even though the percentage of people that selected them was lower in 2024. The prestige of the university is once more the most influential factor, followed by the city the university is located in. These results are in line with the literature, being mentioned by several previous studies performed in different countries. Furthermore, recognition by companies and employability rate are also to be highlighted, as it was also described by Nanath et al. (2022), who underlined the importance of good employment in the area and potential earnings. These factors are in line with the Portuguese landscape where engineers, and particularly industrial engineers, have an extremely high employability rate and a wide range of career options available. Comparing 2021 to 2024, the percentage of people that selected recognition by companies and employability rate decreased and the employability rate ranked lower in 2024 than recognition by companies, being the inverse in 2021.

Overall, the least relevant factors of students' choice are the easiness/difficulty of the university, not having a sufficient application grade to enter their most preferred option and the partner companies of the University.

When making a division per city, the conclusions are slightly different. The top 5 factors for each university can be seen in Figure 2.

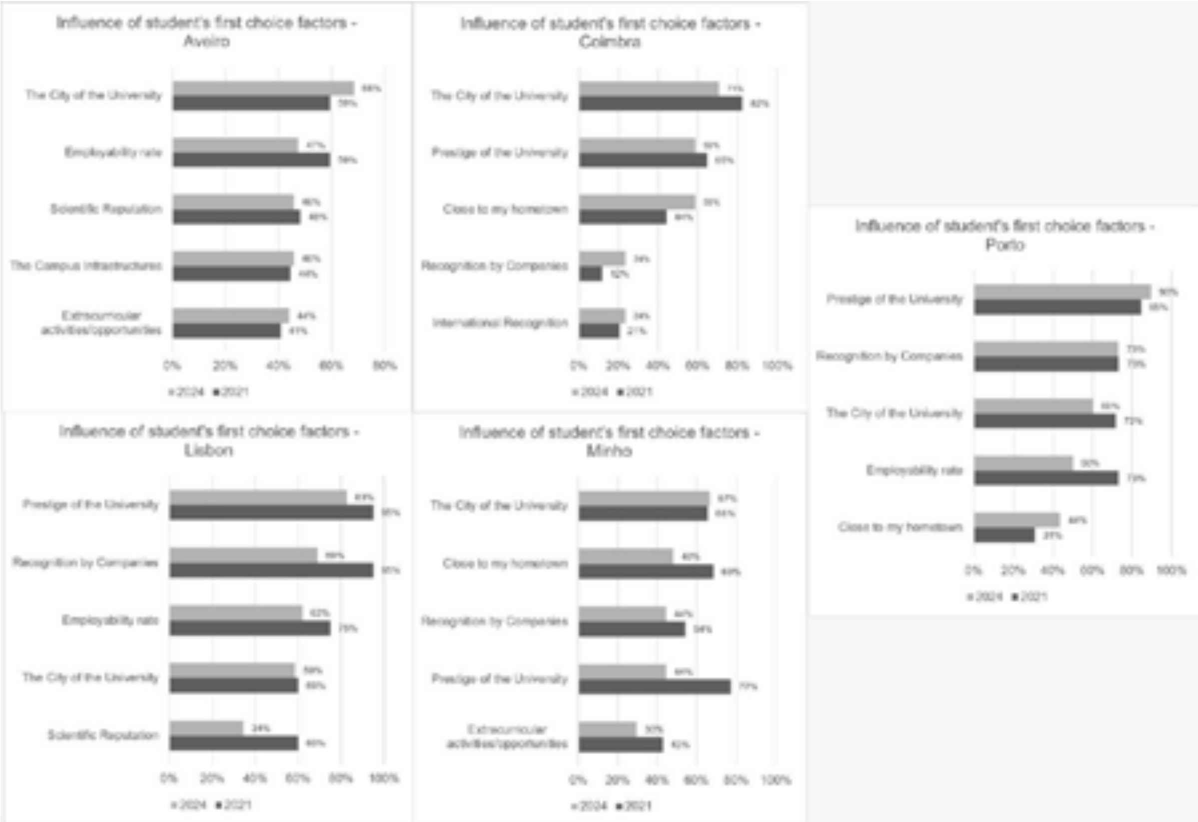

Fig. 2. Top 5 Influencing factors for first choice per university

Unlike the overall results, the city of the university is the main factor for Aveiro, Coimbra and Minho, being still in the main five factors for all universities. Students from Coimbra, Minho and Porto underline not only the city itself, but also the importance of it being close to their hometown.

For Lisbon and Porto, the most influential factors are the prestige of the university and the recognition by companies, in this order. Prestige is stated in the top factors for all universities except Aveiro. Students from Coimbra are the only ones selecting international recognition as a top factor.

Some factors that are not in the main five of the overall results are however part of the main five factors of some cities. For example, Scientific reputation is a chosen factor for only Aveiro and Lisbon, while Minho and Aveiro have their extra-curricular activities highlighted. Finally, only Aveiro students pinpoint the campus' infrastructures as one of the main five factors.

Overall, the results from 2021 and 2024 point in the same direction, except for university of Minho, where there was a shift in the main factors in 2024, with prestige exchanging positions with city and proximity to hometown. As for Coimbra, in 2024 students give the same importance to company and international recognition, while in 2021 the second had more weight. Porto maintains the general trend, but having in 2024 the factors of company recognition, city and employability more balanced.

It is important to note that while some factors such as the city, closeness to hometown and the grades of the students, several others are directly or indirectly changeable by the Universities. Universities can directly impact their infrastructures, factors related to teaching (teaching methodologies, course curriculum and how easy or hard it is to complete the degree) and opportunities for students (extracurricular activities and partner companies). The remaining factors - scientific reputation, recognition by companies, prestige, international recognition and employability rate – are not directly changeable, but are the result of the decisions and investments of the Universities.

Besides the factors for first choice, the match between the first choice of the inquired students and the university they were currently attending was also analysed. The 2021 study concluded that 16% of students were not enrolled in their first choice, and that the University of Porto was the main first choice among them. Results from 2024 are coincident, with a 17% mismatch, and 36% of these students having preferred to study at the University of Porto.

Finally, students were also questioned on whether they would now change the University they chose, if they could. The conclusion for both years is that students are comfortable with their choices and would not change them after joining their university, as indicated by 71% of the 2024 study participants. However, 14% of students still indicated that they would like to change to University of Porto, and the remaining percentage would have preferred other universities, in the country or abroad, or were unsure if they would want to change.

This study poses some limitations, such as the fact that both times only IEM students from the above-mentioned universities were respondents, and therefore due to practical reasons, if a first-choice university was not one of those (which was permitted in the survey), the data was excluded from our analysis. Regarding the distribution of the data collected, the distribution between locations, with Aveiro having a bigger percentage of the students surveyed, could influence the overall results. Also, the timing of the two surveys generated that the student samples are not clean when it comes to the two groups being compared. The study done in 2021 had a minority of the students surveyed making the university choice in the summer of 2020. However, despite the date, the general expectation in the country was that there would not be a significant impact of the disease on the school year, since overall in the country restrictions were low (*Jornal de Negócios* 9 Nov. 2020), so the answers were still considered. As for 2024, although the research objective was communicated to the IEM students completing the survey, there is no assurance that everyone considered this aspect when deciding whether or not to fill the survey. Lastly, the generalisation of this data conducted from IEM students in Portugal to other fields of study or other countries. Arguably, being the results in line with previous literature, it could be inferred that they can provide relevant insights.

5 CONCLUSIONS

This paper portrays an analysis of the attractiveness factors perceived by students when choosing their universities, and makes a comparison between the most relevant factors chosen by Bachelor students in 2021, with students that chose their university before the pandemic years, and students from 2024, which started their Bachelor in pandemic times.

The overall results for the first-choice attractiveness were aligned between the two studies, with the prestige of the University being the most influential one. The campus's city was the second most voted factor, also for both years, followed by company recognition and employability rate. The scenario is different when looking into the universities individually, both in terms of the selected top factors and the shifts between the two years. This shows that the different students associate each place with distinct valuable assets, which is highly valuable information for these Universities. Moreover, it was concluded that most students (70%) were happy in their current university and would not change, but when questioned on studying abroad a relevant percentage (40%) would consider it.

The conclusions drawn from these studies provide an overview of the Portuguese landscape when it comes to attractiveness factors affecting IEM students, as well as allowing universities to understand the reasoning behind the students that selected them as first choice. This allows universities to have a better understanding of their potential selling points when attracting new recruits, and adapt recruitment and marketing strategies to this.

Plus, this study also indicates that there are no significant differences between the main factors impacting student's choices before and after the pandemic, which indicates that other pre-pandemic studies conducted still provide valuable input and could be used by the corresponding universities with a certain degree of confidence.

Further research could, on the one hand, compare different research questions with 2021 data, such as the most relevant factors of student's current universities, rather than on their first choice, or how influential different people and channels (parents, media, high school professors, etc.) are to a students' decisions. Also, new options could be added as factors for the first choice, to update the study according to new factors mentioned in the literature, namely related to e-learning. On the other hand, a larger study could also be conducted, collecting and comparing data between different countries to validate if the results can be generalised for European students and if there is a European alignment on what makes Universities attractive for IEM students.

ABSTRACT

This research paper presents an overview and evaluation of existing instruments utilized to assess epistemological beliefs, beliefs people hold regarding the nature of knowledge and knowing, including how knowledge is constructed and its certainty or tentativeness, within the context of engineering education.

Assessment of epistemological beliefs in engineering education is crucial for understanding students' perspectives on knowledge and learning. To successfully carry out such an assessment, we need validated reliable psychometric tools. A literature review on the subject revealed a lack of evidence on the state of knowledge on epistemology in engineering education.

[1] *A. Abdalla*
a.e.s.a.abdalla@tue.nl

To address that gap, we conducted a systematic literature review spanning from 1997 to 2023 across representative databases and journals in the field and guided by the question, "What existing instruments are designed to measure or characterize epistemological beliefs in engineering?"

The search revealed two instruments, and upon further examination, we concluded that none of the quantitative instruments already available are based on a conceptually coherent and empirically robust model of epistemic development in engineering, and hence can't be used to produce reliable measures.

The engineering education research community need to dedicate efforts towards designing and validating an engineering-specific epistemological tool. The creation and validation of such an instrument is a step towards understanding epistemological beliefs among engineering students, which in turn is crucial for effective instructional design and curriculum development. We posit that such development offers a nuanced supplement to conventional grading-centric assessments.

1 INTRODUCTION

1.1 Background

There are four popular types of beliefs typically studied in engineering education: epistemic, self-efficacy, mindset, and goal-orientation beliefs (Kramer et al., 2024). This study will focus on epistemic beliefs, which are the beliefs that people have about the nature of knowledge and knowing, such as what counts as knowledge, how knowledge is constructed, and how certain or tentative knowledge is (Hetherington, 2012).

Assessing epistemological beliefs in engineering education is crucial for understanding students' perspectives on knowledge and learning. They also have implications for various aspects of cognition, motivation, and achievement (Chai et al., 2006; Muis et al., 2006). Carberry (2010) and Frye et al. (2012) both found that engineering students often hold simplistic and certain views of knowledge, which can impact their learning and comprehension of engineering concepts. Ghazali et al. (2021) further emphasizes the importance of understanding and shaping students' epistemological beliefs, suggesting that educators play a key role in this process. An educator's own epistemological beliefs influence teaching and learning (Bendixen & Rule, 2004; Green & Hood, 2013; Montfort et al., 2014) which underline all instructional design aspects including teaching strategies, learning objectives, and assessment techniques. Educators need to know what the students know to in turn design better educational experiences (Turns et al., 2005), further proving the practical implications of measuring and characterizing epistemic beliefs (Yildirim et al., 2010). These studies collectively highlight the significance of assessing and addressing epistemological beliefs in engineering education, which in turn responds to recent calls in the field for explicitly defining and measuring beliefs as a construct (Kramer et al., 2024), and addressing the lack of philosophical engagement with epistemology in the context of engineering disciplines (Boon & Baalen, 2018).

1.2 Literature Review

Looking at all existing instruments to measure epistemic beliefs, we grouped existing instruments into three groups: 1- Domain-general: typically have been created by psychologists to be widely applied to various contexts or majors of study e.g. Epistemic Beliefs Inventory. 2-domain-specific-non-engineering: Instruments that are designed for a specific field or context outside of engineering, and at times borrowed and applied to engineering. e.g. MED NORD a tool designed for medical students' conceptions of knowledge (Lonka et al., 2008) 3- Domain-specific engineering: Instruments that are designed for engineering and have been validated to be used with engineering students. This paper and the following analysis focused only on instruments falling in the third category mentioned above, engineering-specific instruments.

Research in the field of epistemological beliefs among university students has revealed notable disparities in how individuals perceive knowledge across different academic disciplines. Hofer (2000) discovered such disparities between first-year college students studying science and psychology. Similarly (Palmer & Marra, 2004) found similar differences in epistemological perspectives of science and engineering university students varying across the disciplinary areas of the sciences and the humanities. Faber & Benson (2017) further emphasized that epistemic cognition in engineering may diverge from other fields due to the distinctive nature of engineering knowledge and problem-solving demands. A component of studying knowledge – epistemology- is looking at individuals' justification of knowledge claims. DeBacker et al. (2008) argue that epistemic beliefs are domain-specific, as individuals may employ varying standards and justifications across different fields.

Hence, the study of epistemic beliefs can't be separated from the standards and practices in a given context, because those beliefs are contextualized within a context and hence ruled by disciplinary boundaries (Pintrich, 2002; Yu & Strobel, 2011) which raised criticism against domain-general instruments for their inability to capture the nuances of disciplinary differences (Hofer, 2000). These arguments collectively point towards the discipline-dependent nature of epistemic beliefs and consequently should be the instruments measuring them, therefore the focus of our paper here is on domain-specific engineering instruments.

2 METHODOLOGY

2.1 Method

Systematic Literature Review (SLR) is a research methodology aimed at critically appraising patterns or gaps in a given topic through synthesizing prior work on a given subject within a defined time frame to better identify new directions of research (Petticrew & Roberts, 2006). SLR can be done for different primary goals including tracing historical development, describing the state of knowledge or practice, or evaluating or developing theory (Borrego et al., 2014). This review will focus on the second purpose which is to identify existing research instruments designed to characterize epistemological beliefs. The particular focus of the search was on seminal research that documents the creation of such instruments, as well as research done on the validation and use of those instruments across contexts. The search is guided by the question: What are the existing instruments designed to measure/characterize epistemological beliefs in engineering?

The selection of the search terms was informed by the team's expertise as well as referencing the engineering education research taxonomy (Finelli & Borrego, 2015).

The resulting search combination is Epistem* AND Engineer* AND (Beliefs OR persp* OR cogniti* OR thinking) AND (instrument OR test OR questionnaire OR survey).

To define the inclusion and exclusion criteria of the papers found, we considered the language of publication, type of content (excluded editorials), population targeted by studies (exclude studies of children, K-12), discipline (as explained by the typology) and bounded the search with a year range.

Following the official language of our institution, our intended study will be conducted in English. Therefore the instrument has to be originally written in English, or a version translated to English is validated [when an instrument is translated or adapted from a different language, new evidence of validity should be conducted (American Educational Research Association et al., 2014)].

Data collected included studies from 1997 to 2023. The start of the date range was decided based on the publication of Hofer and Pintrich's (1997) meta-analysis of students' epistemological belief research that critically examined different research projects' use of definitions and theoretical framework related to the subject and presented theoretical and methodological issues in those studies.

The number and categories of databases to use for the SLR is a vital step in ensuring accurate search results and reducing selection bias as much as possible. While there is an agreement on the importance of defining and restricting the number and type of databases to include in a search (Mengist et al., 2020) the exactness of the criteria is less agreed upon. To decide on that step, we referenced multiple sources (Borrego et al., 2014; Bramer et al., 2017) and decided to focus on the databases Web of Science and Scopus to guarantee efficient coverage.

2.2 Analysis

Studies were screened following the pre-defined criteria, as reported in Table 1. Initial screening was performed by studying the title of the publication and categorizing it into one of three buckets: To include (Yes, No, or Maybe). Publications that didn't develop an instrument, or use a domain-general instrument to address engineering university-level education were labelled "No" and excluded. The publications where it wasn't clear from the title whether they developed or applied an instrument were labelled "maybe". The second round of the search tackled the group labelled as "maybe" by reading the abstract and deciding whether or not to include them. The last round of the search retrieved the full papers that got labelled as "Yes". If any of those papers didn't discuss an instrument, they were further excluded. This resulted in two instruments discussed across six papers as shown in Table 2.

Table 1: SLR search results and filtration

Database searched	Example journals and conference proceedings included in the database search	No. of results yielded in the initial search	Results based on initial categorization	Results based on intermediate categorization	Final results
Web of Science	International Journal of Engineering	112	Yes: 4 No: 86	Yes: 17 No: 95	Yes: 6 No: 106

	Education; Journal of Engineering Education; Frontiers in Education		Maybe: 22		
Scopus	European Journal of Engineering Education; American Society of Engineering Education	134 (55 overlapped with WoS results, 79 new papers)	Yes: 0 No: 63 Maybe: 16	Yes: 0 No: 16	No new papers added beyond the 5 above

Table 2: Finalized list of papers included following the search criteria

Instrument	Paper	Paper purpose
The Epistemological Beliefs Assessment for Engineering (EBAE)	1- A Pilot Validation Study of the Epistemological Beliefs Assessment for Engineering (EBAE): First-Year Engineering Student Beliefs (Carberry et al., 2010)	Instrument developing
	2- Assessing Engineering Service Students' Characteristics (Carberry, 2010)	Instrument application
The Engineering Related Beliefs Questionnaire (ERBQ)	3- A first step in the instrument development of engineering-related beliefs questionnaire (Yu & Strobel, 2012)	Instrument developing; Analysis of EBAE
	4- Exploring engineering students' epistemic beliefs and motivation: a case of a South African university (Makhathini et al., 2020)	Instrument application
	5- Measuring engineering epistemic beliefs in undergraduate engineering students (Faber et al., 2016)	Instrument application
	6- Engineering Students' Epistemic Cognition in the Context of Problem Solving (Faber & Benson, 2017)	Instrument application

3 RESULTS

3.1 Summary of Papers

3.1.1 A Pilot Validation Study of the Epistemological Beliefs Assessment for Engineering (EBAE): First-Year Engineering Student Beliefs

EBAE (Carberry et al., 2010) is a quantitative instrument to assess engineering students' epistemological beliefs. It is based on Hofer and Pintrich's (1997) dimensions of epistemological beliefs and includes items concerning the nature of engineering knowledge (certainty of knowledge, simplicity of knowledge) and the nature of engineering knowing (source of knowing, and justification of knowledge). It was piloted with 43 first-year engineering students in the US context resulting in thirteen validated items in four constructs.

3.1.2 Assessing Engineering Service Students' Characteristics

This paper studies students' epistemological development in the context of service learning. To understand how to integrate service opportunities into engineering education, the author set out to understand why students are drawn to these experiences and the reasons behind their inclination towards service. The paper has a significant focus on assessing students' engineering epistemological beliefs, and hence its inclusion in our selected papers. Using EBAE as a data collection tool, preliminary results suggested students exhibiting sophisticated engineering epistemological beliefs.

3.1.3 A first step in the instrument development of engineering-related beliefs questionnaire

The paper presents a framework for understanding engineering-related beliefs, which are crucial for students' learning and problem-solving in engineering. They aim to develop a reliable and valid Engineering-related Beliefs Questionnaire, focusing on engineering knowledge, skills, attitudes, identity, and values. The paper contributes to the field by attempting to measure and support the change in students' beliefs, hence its inclusion in our final list of papers.

3.1.4 Exploring engineering students' epistemic beliefs and motivation: a case of a South African university

The paper investigates the epistemic beliefs and motivations of chemical engineering students from low-income communities in South Africa. The study explores how students perceive knowledge construction, using the Engineering Related Beliefs Questionnaire (ERBQ). It reveals that many students view engineering knowledge as unchallengeable and learning as a passive process.

3.1.5 Measuring engineering epistemic beliefs in undergraduate engineering students

The paper investigates undergraduate bioengineering students' epistemic beliefs. It utilizes ERBQ and open-ended items to validate the instrument, hence we included the paper in the final list. The researchers' analysis revealed inconsistencies in students' interpretations of survey items, suggesting a need for clearer language to accurately capture their epistemic beliefs.

3.1.6 Engineering Students' Epistemic Cognition in the Context of Problem Solving

The study explores the connection between engineering students' epistemic cognition and their motivation when solving open-ended problems. Utilizing a mixed methods approach, partially based on ERBQ, the research identifies clusters of students based on their beliefs about the source and certainty of engineering knowledge, as well as their openness to new ideas. Findings suggest that students' approaches to problem-solving are influenced by their epistemic beliefs and motivations.

3.2 Analysis of Papers

3.2.1 The Epistemological Beliefs Assessment for Engineering (EBAE)

As reported by the authors of the instrument, the sample size they used (N = 43) is smaller than the minimum recommended for performing a factor analysis, which affects the validity of the results they reported. Also, no internal consistency measures (Cronbach alpha) were reported. The authors also ran into the problem of low participation rate (27%) which raises concerns about the generalizability of the findings to all first-year engineering students.

In terms of other works that tried using this instrument, (Carberry, 2010) didn't validate the instrument items using factor analysis or test for reliability as the study reported in the publication was a work-in-progress. (Yu & Strobel, 2011) analysis of the instrument found that only two items were directly related to engineering epistemology, while the rest addressed learning or general epistemological beliefs without adopting domain-specific constructs. (Faber et al., 2016) reported a similar critique that although the instrument is intended for engineering-specific epistemology, it is not specific enough to engineering.

Overall, the limitations reported for the EBAE suggest that further refining of the items to accurately measure engineering-specific epistemological beliefs is needed, as well as validating the instrument with a larger and more diverse sample of responders.

3.3 The Engineering Related Beliefs Questionnaire (ERBQ)

To establish this instrument, the researchers (Yu & Strobel, 2011) first developed a conceptual framework that acknowledges the connection between epistemological beliefs, epistemic beliefs, and ontological beliefs. Following that framework, as well as Hofer and Pintrich's (1997) framework (similar to EBAE) the researchers collected several engineering-related beliefs items from existing studies that address each of the three aforementioned constructs, and after refinement, they presented a total of 22 items.

Although content validity testing was performed by the research team where they discussed the instrument in focus groups, they acknowledged that further testing of the instrument with engineering students is needed to produce the final version of the instrument. Their paper introduces a version of what the instrument could look like, but does not pilot test it. According to our search, this pilot was never performed by the research team or by other researchers.

Similar to the lack of addressing engineering-specific domain constructs reported for EBAE, Faber & Benson (2017) reported that ERBQ only includes two items directly related to engineering epistemology. Also, in their attempt to use the instrument they faced low internal consistency for the sub-scale of simplicity and knowledge. Faber et al.(2016) used ERBQ along with open-ended items to study how the students interpreted the items. Their analysis revealed inconsistencies between how the items are worded and the student's understanding of the items, which goes to show the importance of including some qualitative measures along with the numerical instrument.

Some researchers tried to implement that suggestion (Makhathini et al., 2020) by augmenting the items on the ERBQ with open-ended responses to invite the students to engage more deeply with the items on the instrument, and those responses were used for further validation. Their results discarded four of the original twelve items under the source of engineering knowledge construct due to claimed low-reliability factors. Similarly, they also discarded two of the original seven items under the certainty of knowledge construct, leaving 16 out of the original 22 items.

Overall, ERBQ needs iterative refinement of its items, as well as further testing, especially with engineering student populations to ensure the development of a robust and reliable instrument.

4 SUMMARY AND FUTURE WORK

In summary, the EBAE, as it stands, is compromised by several methodological limitations, including a small sample size (N = 43) for factor analysis, a lack of internal consistency measures, and a low participation rate (27%). These factors undermine the validity and generalizability of its findings. Additionally, critiques from subsequent studies (Carberry, 2010; Yu & Strobel, 2011; Faber et al., 2016) suggest that the EBAE fails to adequately capture engineering-specific epistemological beliefs, instead addressing more general epistemological constructs. To address these concerns, there is a clear need for refining the EBAE items to better reflect the unique aspects of engineering epistemology and for conducting rigorous validation studies with larger and more representative samples.

Similarly, the ERBQ also faces significant challenges. The absence of pilot testing and the reported low internal consistency of some sub-scales (Faber & Benson, 2017) cast doubt on its reliability. Furthermore, the findings from Faber et al. (2016) highlight the necessity of incorporating qualitative measures to complement quantitative data. Efforts by Makhathini et al. (2020) to augment the ERBQ with open-ended responses represent a promising step towards enhancing the instrument's validity. However, their results also led to the elimination of several items due to low reliability, underscoring the need for iterative refinement.

Overall, we were surprised by the small number of engineering epistemology-specific instruments found. In contrast to the science field where various quantitative instruments have been developed and utilized to measure epistemological beliefs about the nature of science e.g. the Nature of Scientific Knowledge Scale (NSKS), engineering lacks a contrasting domain-specific instrument dedicated to engineering knowledge.

Given the importance of domain-specific instruments (Faber & Benson, 2017; Hofer, 2000; Palmer & Marra, 2004), the engineering education research community needs to dedicate efforts towards designing and validating an engineering-specific epistemological tool. Such a tool would serve to guide, enable, and constrain the analysis and articulation of how knowledge is produced within the engineering field (Boon & Baalen, 2018). Which in turn enhances students' learning, motivation, and achievement (Chai et al., 2006; Muis et al., 2006), and teacher education (Bendixen & Rule, 2004; Green & Hood, 2013; Montfort et al., 2014) ultimately enabling educators to design better learning experiences for students (Tan et al., 2019; Turns et al., 2005).

Future work will expand the analysis by comparing the engineering-specific instruments presented here with some of the domain-general instruments like the

Epistemic Belief Inventory. In accordance with (Muis et al., 2006) epistemic beliefs are both domain-general and domain-specific, and such comparison will enable us to test this argument and consequently design an instrument that potentially provides a balance between domain-general and domain-specific beliefs. We believe this will be particularly useful in characterizing epistemic beliefs at interdisciplinary boundaries when more fluid dimensions are needed to account for the moving lines of context and domain in interdisciplinary work.

ABSTRACT

We present an analysis of the professional competencies encountered by engineering students during their capstone projects. We collected weekly reflective journals from 32 students completing their capstone projects at ETH Zurich. Through a deductive quantitative content analysis, we identified the professional competencies posing the greatest challenges for students and examined the frequency of their resolution. Additionally, we explored the distribution of challenges across different project phases and assessed their difficulty levels. Our findings reveal that while capstone projects aim to cultivate professional skills, they primarily challenge students' technical abilities. Moreover, most encountered challenges are those directly assessed through project deliverables, such as applying technical foundations that are assessed through technical artifacts and communicating effectively which is assessed through the final presentation. The majority of challenges arise during the implementation, testing, and prototyping phases, with fewer reported during problem definition and solution design phases, suggesting potential disparities in attention and time allocation across project stages. Notably,

[1] *Victoria Abou-Khalil*
victoria.aboukhalil@epfl.ch

although the problem definition phase encounters fewer challenges, students perceive the challenges within this stage as more difficult. Consequently, we conclude that allocating additional time and importance to solution design and problem definition phases may effectively foster a broader range of professional skills among students, including creative thinking and decision-making abilities.

1 INTRODUCTION

Today, engineering students will graduate into a workspace characterized by constant changes in technologies and an increase in automation, and will also be asked to solve complex issues. To confront these challenges successfully, students must possess professional skills to find creative solutions to new problems, promote sustainable development, and adapt to the constantly changing workplace.

To prepare engineers for such challenges, there has been a rise in the past 50 years of engineering programs adopting inquiry-based learning due to its anticipated benefits in fostering professional skills (Bielefeldt, Paterson, and Swan 2009; C.-H. Chen and Yang 2019; Jamison et al. 2022). For example, project-based learning (PBL), an instructional approach in which students learn new skills by solving real-world challenges, has been integrated into curricula. Most engineering students encounter projects for the first time during their capstone projects (C.-H. Chen and Yang 2019; Dutson et al. 1997) and are expected to develop various professional skills by completing them. A capstone project is designed to bring all aspects of an undergraduate student's experience together by allowing students to apply the breadth of knowledge and skills they have learned. Traditionally, engineering curricula have typically included major group and/or individual design projects aimed at cultivating graduates with essential professional engineering skills. These skills encompass data interpretation, application of theory, problem-solving, design, multidisciplinary teamwork, communication skills, and ethical considerations (Ward 2013)

PBL is a learning method that extends over a longer time and follows a process. Stoller defines PBL as "having a process and a product" and "extending over a period of time" (Stoller 2006). Projects have different phases such as problem definition, solution design, implementation, evaluation and testing, and presentation (Honglin and Yifan 2022). The project process is not linear, and each phase may require different professional competencies. Understanding which competencies students use during different project phases would allow instructors to provide better support for the activities. Few studies have discussed PBL theory or practice from this perspective. In their paper, (English and Kitsantas 2013) described teaching practices to foster students' self-regulating activities in each phase of PBL. They highlighted the fact that accounting for PBL phases when studying PBL may lead to a better understanding of learning processes during PBL and help educators better facilitate the development of self-regulated learning (English and Kitsantas 2013).

Typically, the evaluation of projects explicitly targets some professional competencies, such as problem-solving through the delivery of the end product and communication skills through the final presentation of the work. However, many important competencies are neither evaluated nor explicitly taught. In this study, we are interested in the professional competencies encountered by students in capstone projects. We analyze weekly reflective journals collected during students' capstone projects to: 1) extract the professional competencies encountered by students as a challenge during capstone projects, 2) identify how frequently students encounter the different specific challenges, and 3) identify how the challenges are distributed across project phases.

We assumed that when students encounter difficulties practicing a certain competency, they experience that competency in a meaningful way, which could eventually lead to learning.

1.1 Professional competencies

Passow and Passow's review highlighted that such research has been extensive, involving interviews with over 500 individuals, analyzing over 36,000 job postings, and surveying more than 1,500 employers and employees (Passow and Passow 2017). Interestingly, the identified competencies do not always align with the outcomes specified by accreditation bodies. As an example, Passow (2012) found in a survey involving graduates from 11 programs across different graduation years that eight competency sets did not match the ABET categories.

In this work, we adapt the professional competencies identified by Passow and Passow as the foundation for our analysis. Our selection is influenced by the fact that these competencies are derived from the most extensive meta-analysis we encountered. The analysis draws upon a significant number of quantitative studies (27 studies with 14,429 participants) and qualitative thematic analyses (25 studies with 2,174 participants plus 36,100 job postings). Furthermore, they prioritized high-quality studies that take into account the presence of a comparison group, the use of validated measures, and a detailed description of participants' experiences. Their research identified 16 key engineering competencies, which are categorized into:

- Applying technical foundation (e.g., interpreting data, applying knowledge),
- Collaborating (e.g., effective communication, coordinating efforts),
- Engineering effectively (e.g., taking initiative, thinking creatively),
- Managing personal performance (e.g., devising processes, taking responsibility).

2 METHODOLOGY

We collected reflective journals from 32 engineering students enrolled in the Department of Information Technology and Electrical Engineering, conducting their theses at ETH Zurich. The students were working on their bachelor's thesis, semester thesis (which they undertake at the end of their second semester during their master's degree), or their master’s thesis. The complexity of the projects varied depending on whether the students were working on their bachelor's thesis, semester thesis, or master's thesis. Some students were conducting group projects, while others were working alone as it is common practice in the world's top-ranked engineering universities to simulate authentic engineering projects and working environments (Ward 2013).

The thesis advisors met with the students once a week. During these meetings, the students shared their progress, discussed any issues blocking their work, and briefed the advisors about their plans. Although the students did not have access to the evaluation criteria, they could inquire about them if interested, and very few did so. All students were required to submit a report describing their work, along with any resulting prototypes or code. Additionally, they had to present their thesis in a 30-minute presentation open to members of their groups and to the department.

2.1 Data collection

At the beginning of the semester, the students were introduced to the purpose of the study and asked to fill out their reflective journals at the end of each class. The reflective journal included open-ended questions about the tasks they worked on that week, the challenges they faced, and the difficulty of the challenges they faced on a Likert scale ranging from 1 to 5. We also asked them whether they were able to resolve the challenge. We sent out weekly reminders every week, asking the students to fill out the reflective journal that contained the guiding questions. To protect the anonymity of students and make sure that their fear of being identified does not constrain their reporting, we asked them to use the nickname of their choice instead of their name in the weekly journal entry. There were no inquiries about background, gender, or any other information that might be used to identify students. Furthermore, the surveys were disseminated via a QR code and were not associated with the students' email addresses. It was also emphasized that completing the journal was optional and would not influence their grades. The student responses were accessed only by the researchers and were not made available to the instructors. There were 192 entries submitted by the students. Each of these entries contains one or more encountered challenges.

2.2 Data Analysis

We analyzed the data using a deductive quantitative content analysis following Mayring’s recommendations (Mayring 2015). Our choice was motivated by three main reasons: 1) Professional competencies have been extensively defined, making a deductive approach suitable for further study comparisons. 2) Mayring's method accommodates inductive reasoning, enabling us to refine categories based on emerging patterns. 3) Given our large dataset, quantitative content analysis facilitates potentially generalizable statistical comparisons. We chose the Passow and Passow 16 competencies as a sampling unit to code the students’ answers. We used the definitions and examples of the competencies provided by Passow and Passow as coding guidelines. We coded students' answers based on Passow and Passow's competencies, adding new categories as they emerged. Through an initial categorization of the data, we found categories that are missing from Passow and Passow's list of competencies. Students’ answers to the question “What are the challenges you faced this week?”

Two coders initially coded approximately 20% of the data and then compared their codings, revising the categories accordingly. The discussion led to merging two codes, "Applying knowledge" and "Applying skills," into a single category. Additionally, the code "Regulating emotions" was added while the code "Defining constraints" was removed. The two coders agreed to reorganize the categories by adding the code "Solving problems" and expanding the code "Skills" into the category "Applying technical foundation." After these revisions, the two coders continued coding the remaining answers. They subsequently met again to review the codes together, discussing any differences that emerged. The final codes as well as corresponding examples are shown in Appendix 1.

Furthermore, students' activities were coded to correspond with the various stages of a project. Since the project process is inherently iterative, we used their accounts of the activities they engaged in as a proxy for determining the main stage they were focused on each day. We analyzed the competencies experienced by students by computing the percentage of students encountering each competency.

3 RESULTS

We first analyzed the challenges experienced by students when they conduct projects. Table 2 shows the percentage of students who encountered difficulties with each of the different competencies. The results show that "expanding skills" is the competency that is encountered by most students (n= 17, 53.12%), followed by solving problems (n= 16, 50%), and applying knowledge skills (n= 12, 37.5%). These three competencies belong to the category of *Applying technical foundation*. Other competencies that are highly experienced by students are *communicating effectively* (n= 11 34.38%), gathering information (n= 10, 31.25%), and devising process (n= 9, 28.12%).

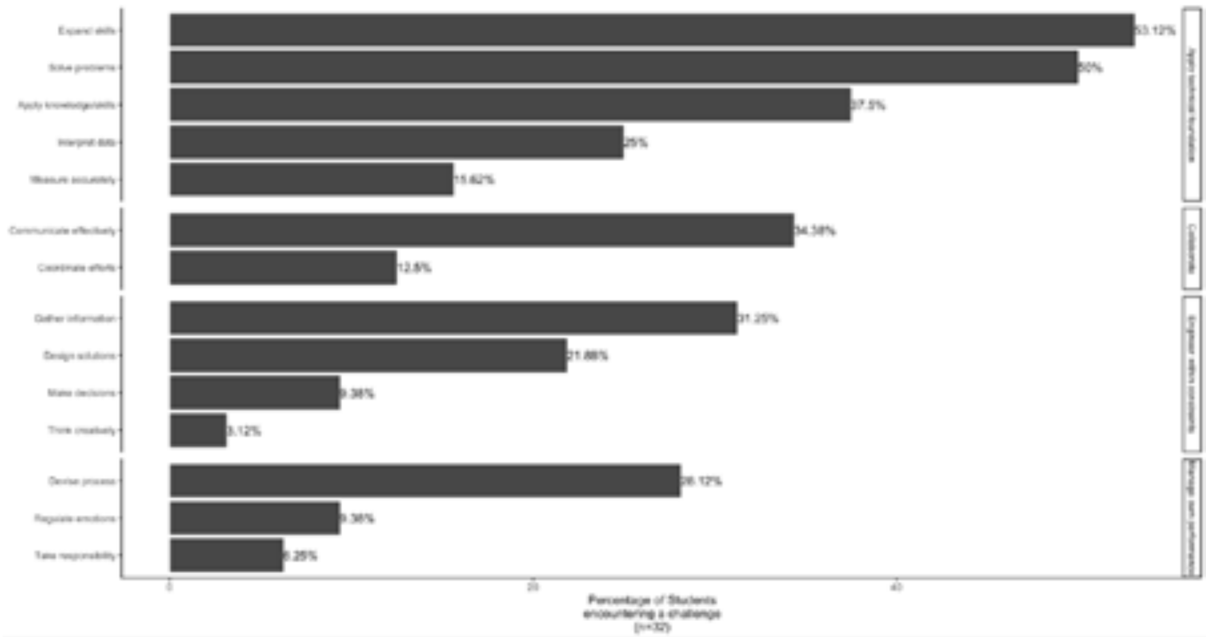

Fig.1 Percentage of students experiencing a professional skill as a challenge.

In analyzing the challenges, we focused on the frequency with which each challenge was successfully resolved, rather than the number of students who resolved each challenge. This means we counted every instance a challenge was resolved, even if the same student encountered it multiple times. We specifically examined challenges that occurred at least 5 times. As shown in Figure 2, Among the challenges, the challenge that remained least resolved related to the competency "designing solutions" (n= 8, resolved 12.5% of the times) followed by "applying knowledge/skills"(n= 17, resolved 35.29% of the times), and "expanding skills" (n=29, resolved 41.38%

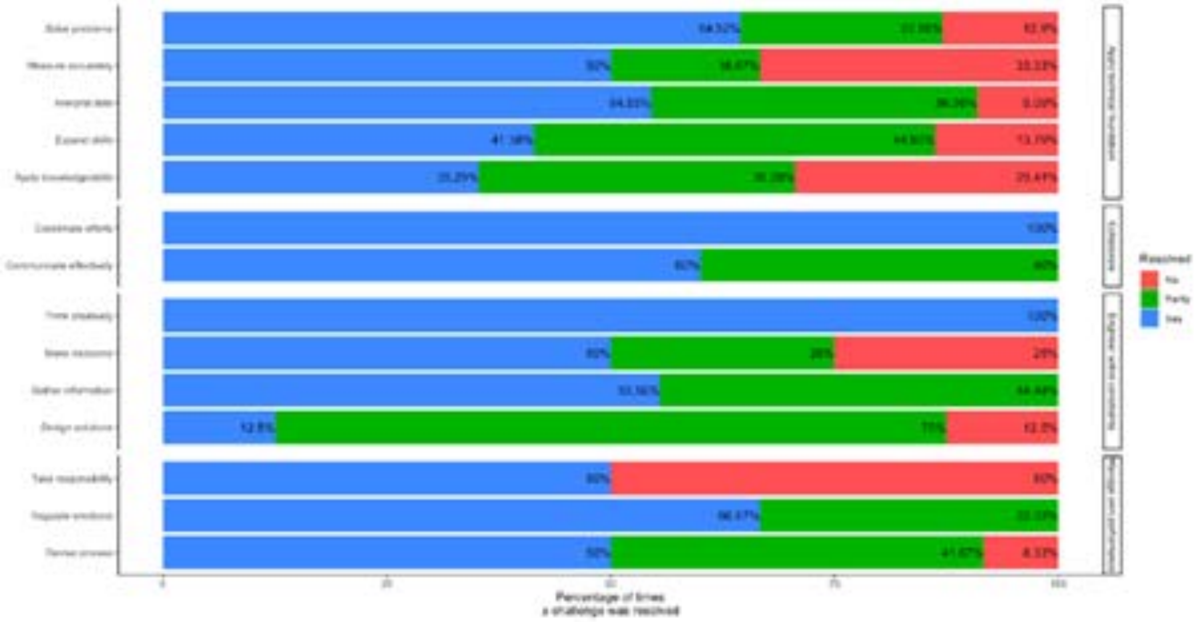

Fig. 2 Percentage of times a challenge was resolved.

Further on, we looked at the distribution of challenges by project phase. Most of the challenges are encountered during the implementation phase (n=45, 52.3%), followed by the prototyping and testing phase (n=21, 24.4%). The least represented phases during the challenges were problem definition (n=10, 5.8%), and solution design (n=10, 5.8%).

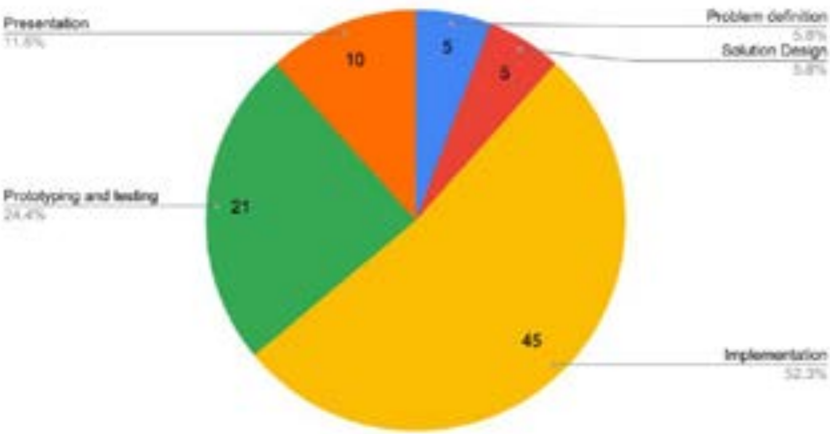

Fig. 3 Distribution of challenges by project phase

Finally, we looked into the perceived difficulty of challenges by project phase. We see that students perceived the challenges encountered during the Problem definition phase and presentation phase as more difficult compared to the other project phases.

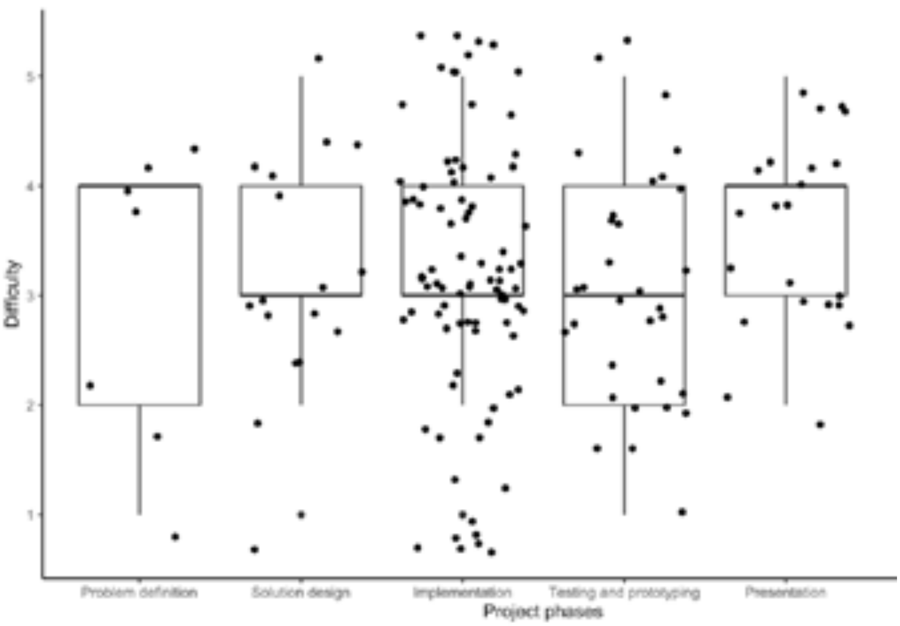

Fig. 4 Perceived difficulty of the challenges by project phase

4 DISCUSSION AND CONCLUSIONS

We identified the professional skills that students experience during project work by analyzing the weekly journal responses of 32 engineering students during their capstone projects. We also analyzed the frequency of the challenges that students were able to resolve. Finally, we identified the change in competencies experienced by students at the different phases of the project. In the following section, we discuss our results in relation to the previous literature.

Limitations

Some limitations affect the study's generalizability. We relied on self-reports to identify the competencies that students are exposed to. Students might have experienced competencies in a form that was not a challenge. They could have also missed reporting some challenges. They also could have reported additional challenges to appear socially desirable or more in distress than they were and gain certain benefits like appealing to the indulgence of the faculty (Nederhof 1985). To mitigate this risk, we designed an anonymous reflective journal and clarified that the results were not shared with the instructors.

In this study, bachelor's theses, semester theses, and master's theses are collectively analyzed under the term "capstone engineering projects," with both group and individual projects considered together. Future studies could benefit from investigating the professional competencies in different types of project and group work.

Capstone projects challenge students' technical competencies

Capstone projects' goal is to provide engineering graduate students with professional skills that are desired in the workplace such as problem-solving, design, communication skills, and ethics (Ward 2013). Our results show that the capstone projects mostly challenge students in technical competencies such as expanding their technical skills, solving problems, and applying the theoretical knowledge and practical skills they had learned during their course.

The competencies that are the most encountered are the ones that are explicitly evaluated

Additionally, we show that other highly experienced competencies include effective communication and information gathering. These competencies, along with technical skills, are directly evaluated through project deliverables. Applying technical foundations is assessed through technical artifacts, while effective communication is assessed through the final report and presentation. This emphasis on evaluated competencies may stem from students investing more effort in areas that directly impact their grades. Although capstone projects' evaluations usually include diverse professional skills, these criteria are often not explicitly communicated to students, potentially affecting their focus during the project. Introducing alternative evaluation methods could positively impact the development of professional skills. For instance, Friess and colleagues proposed a peer-evaluation method that encourages students to practice professional communication, including giving and receiving critical feedback (Friess and Goupee 2020).

We also show that some critical competencies are not, or little experienced by students during projects. These competencies include thinking creatively, making decisions, taking responsibility, and coordinating efforts. This sheds light on the need to design projects that specifically target these competencies since stronger learning takes place when there is explicit teaching and regular feedback on professional skills (Picard et al. 2022). Arguably, students could be learning these competencies without experiencing them as a challenge. For instance, existing papers showed that PBL has a positive effect on students' ability to work in a team (Berbegal Mirabent, Gil Doménech, and Alegre 2017; Reis, Barbalho, and Zanette 2017; Vogler et al. 2018) which is not reflected in our results. However, these effects should be considered with care as they most often result from self-reported measures. Students tend to report positively about an experience when the activity is fun and engaging, which is often the case with PBL (Thomas 2000).

Under focus on problem definition and solution design phases

We also show that students face fewer challenges in the project phases that involve defining the problem and designing the solution. This could indicate a lack of time and dedication to this important phase of the project.

These project phases foster skills that are essential when dealing with open-ended problems and will be particularly needed when working as engineers (Korte, Sheppard, and Jordan 2008; "The Future of Jobs Report 2020 | World Economic Forum," n.d.). Additionally, we see that students find the problem definition phase particularly challenging. It is not surprising that students encounter difficulties dealing with open-ended problems since many of them never had to practice the required skills before taking the PBL class. This is actually common practice in the current curricula where students face projects for the first time during the capstone project, which limits the improvement of their professional competencies (J. Chen, Kolmos, and Du 2021; Dutson et al. 1997). Beginning to practice professional competencies so late in the curriculum might leave the students totally unprepared for their future jobs. It is therefore important to provide projects to students early on in their studies which allows them to repeatedly face challenges and better prepare them to join the workforce.

Appendix 1

Table 1. The final codes as well as corresponding examples

Category	Code	Definition	Example
Apply technical foundation	Apply skills and knowledge	Challenge applying theoretical knowledge as well as technical skills.	*I'm still struggling with the Verilog syntax. I think I'm not yet used to the syntax or how to approach problems.*
	Interpret data	Challenges with organizing, analyzing, and interpreting data. Usually encountered during debugging activities, or when making sense of results.	*Interpolating the data and assessing it’s uncertainty.*
	Measure accurately	Challenge with measuring accurately and quantifying errors.	*I didn't know how to start building our own game. It was a bit overwhelming.*

	Solve problems	Challenge identifying, formulating, and solving, engineering problems within defined constraints.	*Get communication to work between Chip and mcu.*
	Expand skills	Challenge expanding skills, and learning new skills.	*learning to parse JSON format with Telegraph.*
Collaborate	Communicate effectively	Challenge with communicating effectively with people that have diverse backgrounds through listening, oral, written, and graphical means.	*Breaking down the content of your thesis such that it can be transmitted within 15mins without having to leave out large parts of what you've done*
	Coordinate efforts	Challenge with collaboration to achieve goals shared with co-workers.	*Me and Sebastian both did the same work on dockerizing the Zephyr OBC project which was disappointing.*
Engineer within constraints	Gather information	Challenge gathering information as needed by searching literature/ the internet.	*look at resources on the subject and understand them; Understand the state-of-the-art time series forecasting models.*
	Think creatively	Challenge thinking creatively when problem-solving and designing solutions.	*Thinking about alternative ways to test some characteristics.*
	Design solutions	Challenge designing a system, component, or process.	*Create layout & routing from schematics.*
	Make decisions	Challenge while making decisions about problem-solving and designing solutions.	*I had to decide which serial protocols are suitable for on board communication.*
Manage own performance	Devise process	Challenge devising and managing one's own process to accomplish a goal. e.g., Estimate time and cost; plan; set and adjust priorities.	*One problem is that I'm involved in another part of the project with higher priority and it's hard to find enough time to work on both.*
	Take responsibility	Challenge taking professional and ethical responsibility for decisions and behavior.	*Getting everything done before the deadline.*
	Regulate emotions	Challenge recognizing and regulating negative emotions	*Was in small motivation slump*

DEVELOPING A BETTER UNDERSTANDING OF IMPACT EVALUATION OF STEM OUTREACH PROGRAMMES – A COMPARATIVE STUDY EXPLORING TEACHERS' AND OUTREACH EVALUATORS' PERSPECTIVE

ABSTRACT

STEM outreach is a potential route to showcase the engineering discipline in secondary education, in the hope that more young people veer towards the subject in tertiary education and as a career. Impact evaluation of outreach helps determine the success of the programme with respect to its objectives, as well as informing future initiatives. However, impact evaluation of STEM outreach programmes has proven cumbersome and differs across the literature due to the informal space that

[1] *Y. Affejee,*
youn.affejee@warwick.ac.uk

outreach occurs and stakeholders with differing goals. This paper seeks to explore the operational intricacies involved in the STEM outreach landscape that affects impact evaluation. To this end, interviews were conducted with stakeholders involved in STEM outreach, namely teachers and evaluators, to enquire about their experiences regarding outreach evaluation. Interview transcripts were analysed using thematic analysis. Participants' perception of evaluation was generally positive but mentioned several barriers that impeded conducting rigorous evaluation in outreach programmes. It is hoped that this paper can elicit further discussion regarding improving impact evaluation in outreach programmes from a pragmatic perspective.

1 INTRODUCTION

1.1 Background and literature review

Science, Technology, Engineering and Mathematics (STEM) education plays a pivotal role in the modern world. The fact that the United Kingdom (UK) has been facing a STEM skill shortage over the last few decades is of concern to policymakers (Morgan, Kirby, and Stamenkovic 2016). This phenomenon has been fuelled by the fluctuating job market following the coronavirus pandemic (Powell, Francis-Devine, and Foley 2022). Yet engineering, one of the STEM pillars, is almost non-existent in secondary education in the UK – it is not a specifically designated subject in the National Curriculum albeit some of the skills and practices associated with the subject is arguably taught in other subjects such as design & technology (Bonsall, Bianchi, and Hanson 2020).

Outreach, both as ad-hoc activities and long-term programmes, is seen as a potential solution to motivate young people in secondary education towards STEM subjects such as engineering in tertiary education and ultimately as a career (Tillinghast et al. 2020). Outreach exists in the informal education space and as such is an umbrella term that represents a wide range of activities, from industry-led activities such as out of school visits to STEM after school clubs (RAEng 2022). Furthermore, there is a variety of stakeholders involved in outreach with different needs and goals, including facilitators whose main task is to ensure successful delivery of outreach activities, funders whose main concern may be the financial efficiency of an outreach programme on participants and teachers who are keen for their students to develop or enhance their passion for STEM subjects (Appel et al. 2020).

As such, evaluation of outreach programmes has struggled to provide causal evidence of its impact on individuals over an extended timeframe (Banerjee 2017; Robinson and Salvestrini 2020). Whilst recently there have been guidance towards 'best practices' suggested in the literature, this has been limited to theoretical concepts such as methodologies (e.g., suggestions to use validated questionnaires or more broadly encouraging Randomised Controlled Trials (RCTs)) (EngineeringUK 2023; TASO 2020). These best practices tend to be based on the wider evaluation literature, rather than empirical research exploring the STEM outreach landscape. Furthermore, the perpetuation of RCTs may strengthen the narrative of evaluation being a top-down approach which seeks accountability mainly from operational stakeholders (e.g., teachers) against the promise of continuation or reactive change (Kelly 2021). Given teachers are already tasked to fit outreach initiatives within the formal education schedule, often with little help from their school, evaluation of outreach needs to overcome social and practical barriers (Aslam, Adefila, and Bagiya 2018). In other words, evaluators need to cater not only for theoretical best practices but also for operational realities when evaluating outreach. Theoretical best practices (e.g., conducting data collection in multiple instances to increase reliability of results) can be at odds with operational realities (e.g., time constraints) and raises the question of how evaluation of STEM outreach should be conducted.

In this paper, we seek to explore the STEM outreach landscape regarding evaluation, to develop a better understanding of the operational realities where evaluation takes place in. The following research questions are thus proposed:

RQ1: What are the perceptions of teachers and outreach evaluators regarding STEM outreach evaluation?

RQ2: What is the impact of operational challenges on impact evaluation of STEM outreach programmes?

2 METHODOLOGY

2.1 Study Design

This paper is part of a doctoral research project that explores the formulation of a software system to facilitate impact evaluation of STEM outreach. A sequential explanatory study design is used in this instance, whereby quantitative data collection is followed by qualitative data collection. The quantitative element is conducted using a Delphi study, a research method that has previously been used in engineering education and aims to achieve consensus among a panel of experts through a series of rounds of questionnaires (Linstone and Turoff 1975; Rossouw, Hacker, and De Vries 2011). In this study, the Delphi study focussed on impact indicators that are used in STEM outreach evaluation, including aspiration towards STEM educational opportunities, knowledge of STEM opportunities beyond secondary school and attainment in STEM subjects, and was deemed beyond the research questions. On the other hand, qualitative data collection is achieved through phenomenological interviews. This sequential explanatory design allows for further exploration of concepts identified in the Delphi study (Creswell 1999; Johnson and Onwuegbuzie 2004). It has been preferred to a concurrent study design whereby quantitative and qualitative data are collected simultaneously, because:

1. it allows for dissemination of the quantitative data with participants,

2. of practical time constraints - quantitative data will need to be analysed in a short space of time following data collection, as the study involves two rounds of questionnaires (Leech and Onwuegbuzie 2009).

It is worth noting that this paper is solely based on the interview data collected as part of the wider project.

This research was granted ethical approval by the Biomedical and Scientific Research Ethics Committee at the University of Warwick (**BSREC 127/22-23).**

2.2 Sampling Framework

Two groups of STEM outreach stakeholders were identified as participants for this study, namely STEM teachers and STEM outreach evaluators. STEM teachers were previously identified as playing a key role in enabling STEM outreach to occur in schools (Aslam, Adefila and Bagiya 2018). The role of STEM outreach evaluators merit further investigation as despite their involvement in STEM outreach evaluation, they are often unrecognised (Appel et al., 2020). An expansion on the role of evaluators outside the realms of STEM outreach have been beneficial (Rogers, McCoy and Kelly 2019). Purposive sampling was used for the overall research project, whereby the lead author identified participants through the literature and their own professional connections (Etikan, Musa, and Alkassim 2016). Participants were contacted via email or LinkedIn. Inclusion criteria were set for each group of participants, to ensure that participants were familiar with the topic of STEM outreach evaluation:

- STEM teachers: STEM teachers, working in UK secondary education, who identify as being involved in STEM outreach in one or more of the following defined roles: coordinator, evaluator, facilitator, manager or participant, and who is deemed to have substantial involvement in STEM outreach by the lead author. Additional personal information (such as number of STEM outreach programmes an individual is involved in, or length of longest outreach programme they were involved in) was collected to determine substantial involvement in this instance.
- STEM outreach evaluators: Employees of outreach providers OR employees of independent outreach evaluation institution who have conducted evaluation of STEM outreach programmes in the UK.

At the time of writing, interviews have been conducted with five STEM Teachers and four STEM outreach evaluators by the lead author, with an aim of interviewing at least 10 participants from each group of participants in the next three months. A sample size of 10 is regarded as a suitable number for each group of participants for phenomenological interviews (Moser and Korstjens 2018; M. Saunders, Lewis, and Thornhill 2019).

2.3 Research Protocol

The protocol used in this instance is semi-structured interviews, focussing on participants' lived experience regarding STEM outreach. Most of the interviews were conducted using Microsoft Teams with audio recording except for one face to face interview which was conducted in a school. The start of interviews included an introduction of the research from the researcher followed by a brief discussion of participants' occupation, which provided a platform for further questions. The interview spanned participant's involvement and perception regarding:

1. STEM outreach in general, including their aim for facilitating outreach activities and perceived effectiveness of certain activities across different age groups,

2. impact evaluation of STEM outreach programmes, including if evaluation was perceived as part of a programme or a standalone concept and how they envisaged carrying out different stages of evaluation from 'design and implementation' to 'reporting and future changes' (the focus of this paper),

3. impact indicators used in impact evaluation, including discussing results of Round 1 of the Delphi study whereby participants had previously rated various impact indicators in terms of their importance and feasibility of measurement.

The interview guide was informed by various sources including Aslam, Adefila and Bagiya's (2018) exploration of STEM teachers' role in STEM outreach including evaluation, Robinson and Salvestrini's (2020) review of the standard of evidence of outreach evaluation and Tillinghast et al.'s (2020) review of STEM outreach. The interviews' audio recordings were then transcribed by the lead author, with pseudonyms assigned to participants to ensure their anonymity is preserved. Participants were offered the chance to choose their own pseudonym prior to interviews.

2.4 Analysis Method

Thematic analysis was employed in this study to analyse interview transcripts. This involved familiarising oneself with the data, generating initial codes to specific groups of data, searching and subsequent reviewing of themes from similar codes in multiple transcripts that tended to answer the research questions (Braun and Clarke 2006). Those themes were labelled 'emergent' and were then used to inform this section of the paper.

3 PRELIMINARY RESULTS

In this section, we discuss the results from five initial interviewees regarding STEM outreach evaluation. Their profiles are shown below in Table 1 and Table 2 respectively. It is worth noting that this paper does not aim to draw systematic findings across this sample, and the current sample size is unlikely to reach any type of saturation for a qualitative study (B. Saunders et al. 2018). However, the lack of research in this area, as well as the emergence of themes from the current transcripts validates dissemination of preliminary results with the engineering education community.

Table 1. STEM Teachers' profiles

Interview Pseudonym	Involvement in STEM outreach	Occupation	Year in occupation	Number of STEM outreach programmes involved in	Longest involvement in STEM outreach
Ash	Facilitator, Participant	Chemistry teacher and examiner	23	Many	Not sure
Ber	Coordinator, Facilitator, Participant	Engineering lecturer	3	2	5 months
Guy	Coordinator, Facilitator, Participant	Engineering and Construction teacher	20	4	5 years

Laurie	Participant	Design & Technology teacher	10	4	Not sure
Melody*	Coordinator, Facilitator, Participant	Subject lead for science/ Biology, Chemistry and Physics teacher	14	100	3 years

*It is worth noting that Melody's high number of STEM outreach programmes involvement also accounts for her role as a volunteer STEM outreach facilitator at multiple schools, beyond her role as a teacher.

Table 2. STEM outreach evaluators' profiles

Interview Pseudonym	**Involvement in STEM outreach**	**Employer(s)**	**Occupation(s)**	**Year in occupation(s)**
Anne	Coordinator, Evaluator, Manager, Facilitator, Participant	Higher education provider	Manager	6 years in total
Casey	Coordinator, Evaluator, Manager, Facilitator, Participant	STEM outreach provider and higher education provider	Director and senior lecturer	29 years in total
Dana	Coordinator, Evaluator, Manager, Facilitator and related PhD	Various STEM outreach providers including higher education institutions	Various occupations related to outreach including Outreach Manager in Engineering	20+ years in total
Olukọni	Evaluator, Researcher	Higher education provider	Researcher	14 years in total

3.1 Overall perception of evaluation

All participants deemed evaluation an important aspect of STEM outreach programmes, but for various reasons. Amongst teachers, Melody perceived it as a means to an end, primarily for outreach providers to gain more credibility and further funding whereas Guy alluded to evaluation being a chance to sit down and reflect 'in a more formal way' on whether an activity is boosting engagement in engineering and more students are choosing the subject at the end of Key Stage 3 (Year 10). Similarly, Laurie added that evaluation allows you to spot mistake and make appropriate changes.

Certain evaluators also had managerial responsibilities in overseeing outreach programmes but still had an obligation to do evaluation either for external funders or superiors within their respective institutions. Casey as the director of an outreach provider, felt that evaluation was a personal mission above all, in her quest to know if her and her enterprise were having an impact on participants. Similarly, Anne argued that firstly evaluation ensures that an intervention is not having a negative effect on participants. Dana felt that evaluation allowed her to gauge if the knowledge and understanding of STEM subjects amongst participants had changed after being involved in an outreach programme but had mixed feelings regarding evaluation as it was often conducted without any strategic planning of how it will inform a programme post reporting. Dana recalls an occasion in one of her previous roles, where data collected was not used to make any changes,

"*We had one evaluation, it was two A4 sides of questions... we never used the data. We collected it, inputted it [into the system]… we had this data every year and at no point the wider team said, 'What learning can we take from it?', and it just seems pointless."*

This lack of evaluation use is common in non-profit organisations and there is a need to raise evaluation literacy, an individual's understanding and knowledge of evaluation, amongst stakeholders in outreach to enhance evaluation use (Rogers, McCoy and Kelly 2019)

The overall perception of evaluation amongst participants was that it was either beneficial to themselves, students, or outreach providers, with Dana also questioning if evaluation is always appropriate.

3.2 Limited time: evaluation v/s 'more activities'

Time constraints placed on outreach activities is the most common barriers to evaluation (Ruhf 2022). This was a common theme discussed by participants, with several participants highlighting the inevitable consideration of either dedicating more time to an activity or conducting evaluation. Melody admitted that she would prioritise more activities over conducting evaluation, as she felt that benefited the students more. Ash also erred on having more activities, bemoaned lengthy evaluations, and felt other quicker and more enticing media such as taking pictures or 'using props' should be used to capture data. Casey conceded this is a topic her enterprise has to tackle when they visit schools for activities that are time limited (e.g., they might be given 50 minutes in between lessons) and mentioned,

"*So we have to make the decision, is it ethically fair to give them 10 minutes less of content and spend that 10 minutes on getting data?*"

Furthermore, Dana questioned whether finishing an activity with evaluation would taint the memory of an outreach activity amongst participants as they didn't enjoy filling questionnaires. This echoes with a previous study whereby teachers alluded to dialogue as an alternative to questionnaires (Bagiya 2016). However, Ber felt that there was 'no harm' to add on evaluation throughout or at the end of an activity.

3.3 Other challenges to evaluation

There were other challenges explored by participants regarding conducting evaluation in STEM outreach. Casey highlighted that she would like to conduct more academically rigorous evaluation but not only is it time consuming, it is also costly and often funders won't pay her enterprise for the additional costs. Dana agreed that it is unfeasible to do 'adequate' evaluation unless ethical approval has been obtained for a longitudinal research study with a group of participants. Olukọni presented a more theoretical argument, stating that there is a need for a change in mindset amongst stakeholders from short term, which are often superficial (e.g., how many people engaged), to longer term effects.

In terms of the data collection instrument, Casey alluded to digitising paper questionnaires was a tedious and time-consuming process. She hoped that this process would be automated in the future through a dashboard that could display live evaluation data as they are collected. Melody for her part deemed online questionnaires harder for her as a teacher, as she needed to 'book the laptops' prior to the activity for students to fill in 'Google surveys'. It is worth noting in that instance, the activity involved 90 participants. Ber mentioned that there were no such challenges when students who went to a selective activity were then asked to fill in a post-activity survey. Guy went on to add that it was a pleasant experience,

"*We got the students to do Google Forms and they quite liked that because they could go on the computers*."

Melody also revealed that ultimately teachers remain the gatekeeper, not only to evaluation but to the outreach activity reoccurrence itself, by stating that it'll be her decision solely whether 'I'll get them back in'. It is worth noting that what Dana mentioned in section 3.1, in terms of evaluation reports not always being used, can also influence teacher's perception of outreach providers. In this regard, Melody and Guy highlighted that they would like to hear back post-evaluation from outreach providers. Additionally, Anne claimed that communication with teachers was a two-way exchange, and she would often use email exchanges as a form of informal evaluation. Ultimately, good relationship with teachers lead to better outreach provision (Aslam, Adefila and Bagiya 2018).

4 SUMMARY

At this stage, it not fair to draw definitive conclusions. However, we felt a few emerging trends were worth discussing in this section. Whilst both groups of participants acknowledged the importance of evaluation in STEM outreach programmes, participants were divided into whether there are mutual benefits in always conducting evaluation as it is time consuming and a resource intensive task. Melody as the teacher most involved in outreach, felt evaluation had little value to her as a teacher and was more of a favour to the outreach evaluator. In contrast, Guy sought external input to reflect on not only the outreach delivered, but also the wider performance of his team. It will be interesting to see if future participating teachers view evaluation as mutually beneficial or not. Sections 3.2 and 3.3 highlighted there are various challenges, in terms of resources, relationship between stakeholders and time constraints, involved in conducting evaluation in outreach programme, each with their own implications. However, further communication between each group of participants would mitigate some of these challenges and would also be beneficial for the delivery of outreach programmes. For example, teachers would appreciate if outreach providers highlighted that evaluation were not only conducted as a requirement by external funders but rather to improve delivery of the next cycle of outreach activities, and shared some of the findings back to teachers.

4.1 Limitations

The sample size that forms the basis of this paper does not reach any type of saturation for a qualitative study. However, the final sample size of this research project should reach a number deemed appropriate for qualitative research (M. Saunders, Lewis, and Thornhill 2019). Furthermore, non-random sampling was used in this research, which introduces an element of researcher's bias. The researcher used multiple strategies to recruit participants as a mitigation. The results of this study are not generalisable but should depict the complex nature of the STEM and engineering outreach landscape.

4.2 Acknowledgements

This work was supported by Royal Academy of Engineering, Lord Bhattacharya Family Trust Fund and Lord Bhattacharya Engineering Education Programme.

ABSTRACT

In response to the current demands for increased interdisciplinary collaboration, innovation, and sustainability considerations in engineering, this paper discusses a case study conducted at the Department of Industrial Information Technology, Technical University of Berlin. The study employed project-based learning to address these challenges, focusing on the development of sustainable, complex product systems and corresponding business models. The research methodology, including comparisons between start and end of the project, and surveys, is presented along side with the applied teaching concepts, including project structure, deliverables, and methodological support. The analysis includes an overview of the utilized IT tools, an assessment of collaboration efforts, and presentation of survey results. The results highlight the value of methodical collaboration support, emphasizing the targeted collaboration promotion for more structured approaches, enabling faster technical collaboration while acknowledging the persistent challenges of human factors.

1 INTRODUCTION

Project-based learning (PBL) is a fundamental pedagogical approach in university engineering education. Its aim is to provide students with essential skills that bridge the gap between technical knowledge and practical engineering practice.(Frank, et al. 2003) At the Department of Industrial Information Technology at TU Berlin, PBL courses take on a special form in which interdisciplinary student project teams are entrusted with the challenging task of designing and developing mechatronic products. Collaborative PBL in product development not only emphasises the practical application of theoretical concepts in authentic engineering contexts, but also highlights the collaborative dynamics inherent in engineering projects. Collaboration should always be part of teamwork. However, collaboration must be methodically encouraged. It requires students to communicate effectively, share resources and solve problems not only with and within the teams, but also with the lecturers. Within the project teams, the focus is on developing self-management skills as students need to manage the complexity of product development and improve their ability to plan, organise and execute tasks independently. Collaborative PBL therefore not only teaches technical expertise, but also important soft skills and prepares students for the diverse challenges in the engineering industry.

2 THEORETICAL BACKGROUND

2.1 Learning Method – Project-Based Learning

PBL is a transformative pedagogical approach rooted in progressive educational philosophies that emphasise experiential learning. (Shin 2018)

Students, organised in interdisciplinary teams, engage in practical, collaborative endeavours that mirror real-world problem-solving scenarios. In addition, the lecturer in PBL takes on the role of a facilitator and mentor, guiding students on their learning journey. PBL goes beyond the mere transfer of knowledge and actively promotes problem-solving skills, critical and creative thinking, effective communication and teamwork. (Anazifa and Djukri 2017). By integrating theoretical knowledge and practical application in authentic, project-based settings, PBL cultivates competences that are seen as essential in both academic and professional settings.(Brundiers and Wiek 2013) In engineering, PBL has emerged as a central element of education that fosters essential skills and enhances students' professional maturity. (Kolmos 2017)

2.2 Collaborative Engineering in Product Development

Collaborative engineering in product development is intrinsic and represents the pinnacle of collective human endeavors, fostering collective innovation and shared expertise, surpassing mere cooperation and coordination (Lu et al. 2007). The collaboration life cycle provides a structured approach to address challenges and delineate project-specific aspects. It unfolds in four distinct phases (see Figure 1). Implementing basic collaboration practices within the collaboration lifecycle and technical activities requires a structured approach. The integration of digital tools has changed technical collaboration and enables the exchange of information and collaboration without spatial and temporal restrictions. (Köhler-Schute 2022) It changes processes and supports remote and hybrid work, providing increased flexibility and virtualized collaboration. (Bauer et al. 2021) However, challenges in maintaining social interaction in virtual and hybrid teams needs to be addressed (Balder et al.2024). Yet, effective digital collaboration is crucial for success of product development with IT Tools and systems covering communication, project management, and content creation and sharing.(Deuse et al. 2023) Therefore, providing technical infrastructure and selecting appropriate tools are crucial.

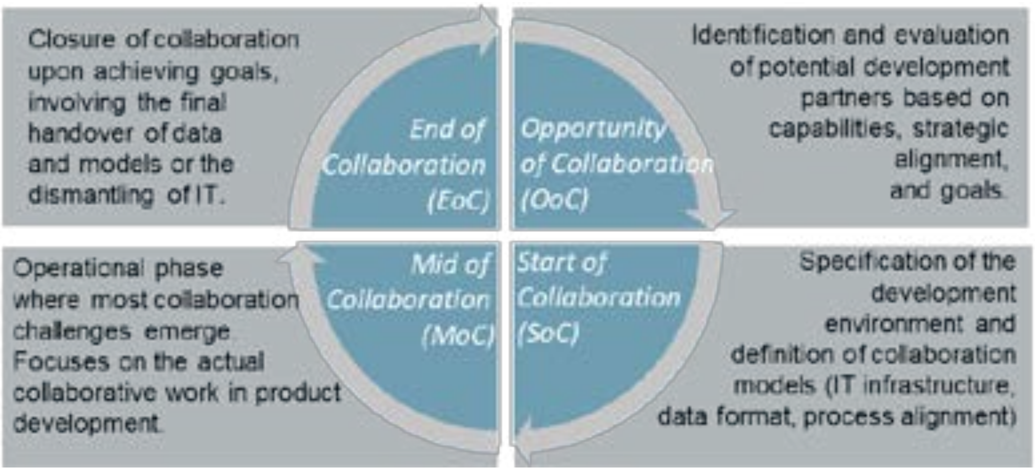

Figure 1 Collaboration life cycle (Wang et al. 2016)

The quality characteristics of collaboration in IT systems and infrastructures include the harmonisation of heterogeneous information systems, compatibility, compliance with standards and adaptability to dynamic cooperation. In addition, clearly defined roles and responsibilities, the commitment and a strategic definition are essential for effective collaboration. Social factors such as trust, conflict management, cultural appreciation and awareness of team members' activities are also crucial. (Randermann et al. 2019)

2.3 Methodical Support for Collaborative Engineering in PBL

Various studies have investigated different approaches to promoting collaboration among students. Du et al. 2020 found a significant relationship between collaboration strategies and team performance, emphasising the importance of strategic planning. Their findings emphasise the importance of planning and structured approaches to improve team outcomes. Mosgaard and Spliid 2011 emphasise reflection and experimentation in the development of process skills and highlight the value of iterative learning. Sumino et al. 2017 found that cross-institutional PBL improves communication skills and students benefit from diverse collaborative experiences. Alves et al. 2021 point out that teachers' collaborative practices serve as role models for students and have a positive impact on their teamwork behaviour. Santoro, et al. 2005 emphasise the importance of planning collaborative processes to foster group engagement and indicate that a well-structured framework for collaboration can lead to more effective teamwork. Hagedorn et al. 2023)investigated into the development of digital twins in PBL setting in a hybrid teaching concept demonstrating the use of IT Tools in PBL.

Despite these findings, there is a notable gap in the literature regarding the methodological support of collaborative engineering using IT tools.

3 METHODOLOGY

3.1 Research Question

The primary research question guiding this study is: *How does task-specific methodological support especially through IT Tools impact engineering collaboration in PBL environments*? The research aims to investigate the role of tailored methodological support in enhancing collaboration skills, focusing on the specific challenges such as communication, time management, resource allocation.

3.2 Presentation of Research Teams

The project analysed for this study took place during the winter semester of 2023/24, spanning from October 2023 to February 2024. Two master project-courses were subjected to the analysis. "Development and Management of Digital Product Creation Processes" (EMP) and "Applications of Industrial Information Technology" (AIIT) modules, further named as AIIT/EMP. In the project AIIT/EMP, each team comprised 2-3 EMP students collaborating with 6-7 AIIT students, creating a dynamic mix of skills and expertise. A total of 44 students, with 11 from EMP and 22 from AIIT, formed 4 project teams with 8-9 students.

3.3 Surveys

The students participated in two surveys conducted at the beginning and end of the project. The surveys contained standardised questions that ensured consistency between the teams and explored key project concepts and collaboration dynamics. By comparing the questions, the study captures the transformation journey of each team and assesses the impact of collaboration.

The first survey focuses on demographic questions that capture the characteristics of the participants, as well as an assessment of prior knowledge and experience in collaboration. Participants are asked to provide insights into any challenges they have experienced in collaboration. This survey aims to gain a basic understanding of the participants' background, experiences, and perceived difficulties in collaboration.

The second survey focuses on participants' current knowledge of collaboration. It aims to gather information on the applied methods, lessons learned and the actual use of collaboration tools and platforms. Participants will be asked to identify the challenges they faced in the project and make suggestions for improvement. This survey should enable a more differentiated and timely assessment of participants' cooperation skills and potential areas for the development of the project itself.

The surveys contained qualitative and quantitative questions. For most quantitative the 5-point Likert scale was used.

3.4 Methodological Support for Student to Facilitate Collaboration

The students were supplied by targeted methodological support aimed at enhancing collaboration within the project. E.g., a specialized seminar was conducted, emphasizing the pivotal role of collaboration in product development. Key principles for successful collaboration, conflict management, and cultivating a culture that embraces failure were elucidated. The seminar also featured a comprehensive presentation on various IT tools and processes designed to bolster collaborative efforts. To streamline collaboration, project roles were thoughtfully assigned, ensuring a clear delineation of responsibilities within the team.

A structured approach was implemented through the formulation of tasks and deliverables, as outlined in Table 1. This served as a roadmap for the teams, guiding them through the intricacies of collaborative product development. The culmination of this support was observed through the meticulous evaluation of team collaboration and working methods during designated design reviews (DRs). DRs are review situations in which decisions can be made and actual results will be interactively discussed (‘Design-Review | KVP Institut GmbH’, n.d.).

4 USE CASES

4.1 Structure of the Semester Projects

The primary objective is to display the product development process from the initial idea to the implementation of a real prototype. All modules were accompanied by lectures on project-relevant topics held by the professor or other experts as well as practical seminars that help the students with the implementation of the projects. Further consultation for individual questions and feedback are offered by the lecturers (see Figure 2). Finaly, the exam performance are deliverables, two DRs and a final presentation.

Figure 2 Structure of the semester project

In total, the academic focus is directed towards equipping students with theoretical and practical engineering knowledge, fostering collaboration in real-world product development projects among students from diverse technical backgrounds. Further, the project is conducted hybrid. Seminars, DRs, and the final presentation are primarily set physical, while the teamwork was left to the individual teams and mainly carried out virtually.

Table 1 Overview of collaboration phase and tasks

No.	Collab. Phase	Short Description
1	OoC	Project Kick-Off
2	SoC	Project plan with task distribution, resource allocation and tool list
3	SoC	Development of a collaboration concept with the other teams based on the collaboration life cycle
4	SoC	Requirement list and solution concept
5	SoC	System design diagrams including technical overlaps with other teams
6	MoC	Operationalisation of the ability to collaborate
7	MoC	Working in digital transformation
8	MoC	Cross-team CAD model and joint physical prototype

9	EoC	Evaluation of the IT tools used for collaboration
10	EoC	Lessons learned on the teamwork and collaboration
11	EoC	Visualisation of the collaboration process throughout the project with the help of the collaboration life cycle

4.2 Tasks and Assessment of Submissions

The product development within the projects is systematically divided into four distinct phases divided by the two DRs and the final presentation.

Phase 1: Idea and Concept Generation (Ooc and SoC) - Teams engage in the initial phase of ideation, exploring creative solutions and conceptualizing their projects.

Phase 2: Design (MoC)- The teams leverage tools such as CAD-Modelling to translate their concepts into tangible designs.

Phase 3: Prototyping and Validation (MoC) – This phase focuses on prototyping and validation, where teams bring their designs to life and test them.

Phase 4: Reflection (EoC) - The team reflect the task and writes a final report.

The two DRs are strategically positioned within this developmental timeline, with specific deliverables and tasks associated with them. These reviews serve as crucial milestones, allowing teams to showcase their progress, receive constructive feedback, and refine their approaches.

In the project, the teams are tasked with developing a smart rollator collaboratively. The project uniquely assigns subsystems (pavement overcoming, obstacle detection, automatic height adjustment, and chassis damping) to individual teams. To add a layer of real-world constraints, conditions for the prototype are stipulated, including a budget of 100€ per team, a requirement for a minimum of 50% reused materials, and the incorporation of mechatronic components.

4.3 Project Results

In the AIIT/EMP project, a fully integrated prototype was successfully developed, showcasing all subsystems, as illustrated in Figure 3.

Figure 3 Final prototype

5 RESULTS

5.1 Presentation of the survey results

The first survey included 34 participants, with an average age of 24. The majority of students studies production technology or mechanical engineering and have an average of 11 semesters of study. Qualitative questions are analysed interpretatively, while quantitative questions are analysed statistically.

The key aspects of collaboration, as the students defined it, included different competences (27%), several participants (57%), common goal (37%), conflict resolution (17%), distribution of structure/tasks (30%), and communication

(27%). 29% had already 1-2 other teamwork, 44% 3-4 and 26% more than 5. The assessment of prior knowledge in various collaboration-related areas can be seen in Table 2. 24% stated that they had a project in which there were guidelines on how to work together. 76% denied being so far supported in the teamwork.

The main challenges on collaboration included coordinating/resource allocation (41%), unequal workload distribution (21%), communication within the team (32%), decision making (12%), different motivation (32%), different skill sets (18%), time management (26%), and planning/structure of the project (44%).

In the second survey, 20 participants revisited their perspectives on collaboration. Collaboration definition included the key aspect of different competences (10%), several participants (80%), a shared common goal (75%), structured task distribution (20%), and effective communication (20%).

The survey also encompassed a comprehensive review and feedback segment focusing on methodological support:

- Survey results indicated that methodological support had proven beneficial for the majority of students, with a notable 60% expressing appreciation for its assistance. However, a significant portion (30%) considered it a helpful addition but not always necessary.
- Seminars received a positive response from 70% of participants, yet constructive feedback suggested a desire for increased practicality and task-specific focus in future sessions.
- DRs were recognized as constructive tools, aiding participants in better task implementation and addressing comprehension problems (60%).

Table 2 Results of the prior knowledge of the students

Prior knowledge	**1**	**2**	**3**	**4**
Collaboration & teamwork area	0%	12%	29%	59%
Use of collaborative tools and platforms	15%	15%	47%	24%
IT tools in product development	6%	47%	35%	12%
Development in interdisciplinary teams	9%	35%	44%	12%
Sustainability	9%	50%	38%	3%
Product development	9%	18%	59%	15%
User-centred development	21%	13%	29%	12%

1= no experience; 2= heard it before;3= first experience gained; 4= experienced

Collectively, the project yielded positive outcomes for the participants. The findings suggested that the students' enhanced understanding of roles and responsibilities in project work reached 53%, and they reported performing collaborative engineering activities more methodically and effortlessly, encompassing collaborative design, knowledge exchange, review, concept development, etc. (60%).

The average feedback on each collaborative task presented in Chapter 3.3 was remarkably positive. This average score underlines the generally positive response from participants, suggesting that the collaborative tasks were well received and contributed effectively to the overall learning experience (see Table 3).

5.2 . Presentation of Employed IT Tools

The utilization of IT tools within the project is categorized into four main domains: Communication, Product Design, Data and Knowledge Management, and Project Management. In each of these categories, predominantly Software as a Service (SaaS) solutions have been employed, characterized by their collaborative features that facilitate effective teamwork (see Table 3).

Table 3 Overview of Employed IT Tools and Used Functions

Team/ Tool	Communi-cation		Product Design		Data and Knowledge Management					Projekt mgmt
1	Whats-App	ZOOM	Fusion 360	Adruino IDE	Microsoft Office	Over-leaf	TUB-Cloud	Trello		
2	Whats-App	ZOOM	Fusion 360	Adruino IDE	Microsoft Office		TUB-Cloud	Microsoft Visio		
3	Whats-App	ZOOM	Fusion 360	Adruino IDE	Microsoft Office	Over-leaf	TUB-Cloud	yED live	Miro	Notion
4	Whats-App	ZOOM	Fusion 360	Adruino IDE	Microsoft Office		Share-point	Lucid-chart		MS Planer

Notably, within the realm of Product Design, similarities are observed among the tools chosen by various teams. This consistency can be attributed to the task descriptions, indicating a standardized approach to product design requirements. Additionally, it is noteworthy that most teams have adopted similar functions within these tools, further emphasizing a shared understanding.

6 Discussion

The survey shows a notable shift in the understanding of collaboration among students over time. There is a clear focus on understanding a common purpose, which emphasises the importance of aligning efforts towards common goals. Students involved demonstrate a deep understanding of their roles and responsibilities within the team.

To promote cross-team collaboration, additional structural guidance from lecturers is critical. This can be achieved through more explicit recommendations for tools to ensure seamless interfaces, scheduled meetings to facilitate coordination and increased methodological support in framing internal discussions.

Furthermore, it is considered necessary to move away from the free choice of team members. Instead, the focus should be on putting together teams with a balanced skills profile. This strategic approach aims to optimise collaboration by utilising different skills within each team, which contributes to a more effective and harmonious learning environment.

Compared to previous studies this study demonstrates a needed methodical support not only in theory but also in the deployment of IT tools in students collaboration.

7 SUMMARY AND ACKNOWLEDGEMENTS

To summarise, the results of this study highlight the importance of methodological support for improving collaboration in projects. While master's students generally demonstrate high levels of collaboration skills, the study emphasises the importance of task-specific methodological support through IT tools to effectively address nuanced challenges. In particular, the delivery of PBL varies significantly across the university, suggesting a need for standardised approaches to improve collaboration consistently.

The realisation that collaboration in both interpersonal interaction and the methodical use of IT tools and building processes is a critical skill for the future underlines the need for a structured approach in degree programmes. This study argues in favour of the introduction of systematic strategies to promote cooperation skills that are geared towards the changing demands of the professional world. It was also intended to investigate the extent to which the perception of collaboration in methodologically supported projects differs from non-supported projects.

The study has its limitations, as the findings were obtained from a sample of 60 students, which does not represent the all students and only covers a period of one semester. Nonetheless, these findings offer valuable perspectives and insights into the collaborative landscape at the university and pave the way for future research and programme improvements. Future research should focus on expanding the sample size and extending the study duration to validate and build upon these findings. Moreover, there is a need to explore the integration of advanced digital tools such as simulation, Digital Mock-Up (DMU), and Virtual Reality/Augmented Reality (VR/AR) technologies in PBL environments. These tools can facilitate virtual prototyping and early-stage collaboration. The chair of IIT should play a pivotal role as a digital integrator. For further exploration of these concepts, readers are recommended to (Stark 2022).

ABSTRACT

The Australian Nuclear Science and Technology Organisation (ANSTO) is the largest concentration of nuclear expertise in Australia and OTJ learning contributes to the development of a highly skilled nuclear workforce. Through a DYD workshop, this paper reports on the OTJ learning and Knowledge, Skills, and Attributes (KSAs) development of a cohort of individuals either whose role has been defined as a nuclear engineer or expected to develop expertise in nuclear engineering at ANSTO.

[1] *Edward G. Obbard*
e.obbard@unsw.edu.au

The OTJ learning revealed the technical tasks including research planning, experimental work, modelling and data analysis form a crucial part of their roles. Non-technical tasks associated with their roles included administration and communication tasks. Analysis of the KSAs associated with each activity demonstrates the importance of experiential and self-directed learning to master nuclear competencies. We find that within this subset of the workforce at ANSTO, specifically nuclear competency predominantly resides in the knowledge domain. As a result, an effective strategy to training could involve a more structured approach to nuclear knowledge development, thereby fast-tracking competency, without compromising overall proficiency.

1 INTRODUCTION

Nuclear engineers conduct research and development activities related to the release, control, and use of energy from nuclear reactions, applicable to nuclear power, nuclear medicine, nuclear waste management, (O*Net, 2024; US Bureau of Labor Statistics, 2022; Townsend et al., 2022). Johnston (2009) affirms that nuclear engineers require expertise in reactor analysis and design, radiation effects analysis, shielding design, radiation utilisation, radioactive materials control and processing, and nuclear energy systems design for constructing nuclear reactors.

There is a growing demand for nuclear skills and expertise in Australia (Commonwealth of Australia, 2006). A nuclear engineer in Australia, could be involved in a wide range of activities, including nuclear fusion, medical applications, health physics, and materials research. The learning of nuclear engineering in Australia takes place both at university and in the workplace (Baradaran et al.,2023). Learning arrangements can be formal, non-formal or informal. Formal learning relates to earning qualifications, certificate training and degrees whereas non-formal and informal learning relates to on-the-job (OTJ) training, mentorships and continuous learning activities (Crouse et al., 2011). Formal, non-formal and informal workplace methods of learning are equally important and complementary.

The University of New South Wales (UNSW, Sydney) offers a formal qualification in nuclear engineering - a Master of Engineering Science in Nuclear Engineering. The Australian Nuclear Science and Technology Organisation (ANSTO) provides OTJ training and professional development opportunities for nuclear engineers and other professionals in the nuclear sector. ANSTO has over 1,300 staff, working in nuclear engineering and reactor operation, safety and radiation protection, waste management, nuclear security and safeguards, materials science, and education and communications (ANSTO, 2022). The workplace clearly plays a fundamental role in educating and training professionals in nuclear engineering in Australia.

Competency, in terms of Knowledge, Skill, and Ability refers to the integrated application of these attributes by professionals in specific contexts to achieve high performance and meet quality standards required by their roles (Warier, 2014).

1. Knowledge –the understanding of technical information necessary to adequately perform job function (Valdez et. al, 2008).
2. Skill – either a demonstration of procedural knowledge or the capability to demonstrate procedural knowledge. Such procedural knowledge usually results from training, i.e. a process of learning and acquisition of proficiencies, including training that may be self-directed (Hlavac, 2023). A skill is something that is

almost always observable and measurable and usually involves a person's interaction with stimuli and/or other people (Hlavac, 2023). Skills can be acquired across various domains and transferred between different contexts.
3. Ability – sometimes called attribute – the power or capacity to act or do certain things in a particular way. In some ways similar to a skill, it encompasses the capacity to do things that are not the result of formal training or instruction (Dweck, 2002). As such, an ability can refer to personal attributes and innate talents that contribute to an effectiveness in performing tasks or roles. These include creativity, adaptability and honesty (Verduyn, 2023).

To meet the needs of the nascent nuclear sector in Australia, the next generation of nuclear engineers must be trained in a timely and efficient manner. ANSTO's current and future engineering capabilities were mapped in the Engineering Capability Framework (ANSTO, 2022) which identified the gaps in capabilities in the workforce and the need to train more nuclear personnel. A thorough understanding of the informal learning and OTJ training at ANSTO is needed to better integrate workplace learning with university programs, and thereby accelerate the training of nuclear engineers.

This research paper aims to uncover the OTJ learning and KSA development of a cohort of people at ANSTO whose role has been defined as a nuclear engineer and, matched to an expectation that they will develop this expertise in the coming years. Through the Define Your Discipline (DYD) process (Dowling and Hadgraft, 2011, 2013), the cohort communicated the tasks and the competencies that constitute their nuclear engineering expertise. By deconstructing this competency into KSA, and comparing with the entry qualifications of this group, we answer how this cohort of people conceptualize their role as a current (or future) nuclear engineer, and how their OTJ training contributes to their KSA development in this discipline.

2 METHODOLOGY

The participants were selected from the Nuclear Fuel Cycle (NFC) Group at ANSTO. ANSTO utilised the US-developed Occupational Information Network (O*Net) online database (US O*Net, 2024), along with its internal specialised knowledge and expertise to categorise roles which correspond to 'Nuclear Science' or 'Nuclear Engineering'. The participants selected from the NFC group were identified in the strategic workforce plan, as nuclear engineers. The group consisted of 9 individuals at various stages of their career, from early career graduates to senior engineers.

During the workshop (Dowling and Hadgraft, 2011, 2013), each participant was asked to write 5-10 technical nuclear engineering tasks and 5-10 non-technical nuclear engineering tasks that they perform in their role on separate Post-it notes. This activity provided information on OTJ learning and the key tasks that participants engage in at work. Participants were then asked to write the Knowledge, Skills and Attributes (KSAs), needed to perform each task, behind each Post-it note. This provides the competency underpinning the activities of the participants at work.

After the participants had written their tasks, they began the second stage of the DYD process, the convergent phase, by performing a cluster analysis. This involved pasting all the Post-it notes with the tasks on the whiteboard and looking for commonalities. The tasks were then grouped into clusters that were named during the workshop.

The workshop concluded when all the tasks were grouped into the clusters and all the KSAs had been recorded. This process ensured that contributions from each individual participant was captured. After the DYD workshop, the clusters were analysed again by the research group to ensure consistency. The KSAs were tabulated, and specific nuclear competencies were isolated from others based on the researcher's knowledge. The competency results (i.e. KSAs) of the DYD analysis were compared to background information for the entry qualification of the cohort at the time of commencing ANSTO employment. This research has adhered to ethical guidelines for conducting qualitative research (HRECS, 2024).

3 RESULTS

The initial data for the cohort of 9 participants working in the NFC group is shown in the Ecosystem Map (Fig.1). This shows the starting level of education and field of qualification of an employee and the upskilling process employees go through in a nuclear organisation.

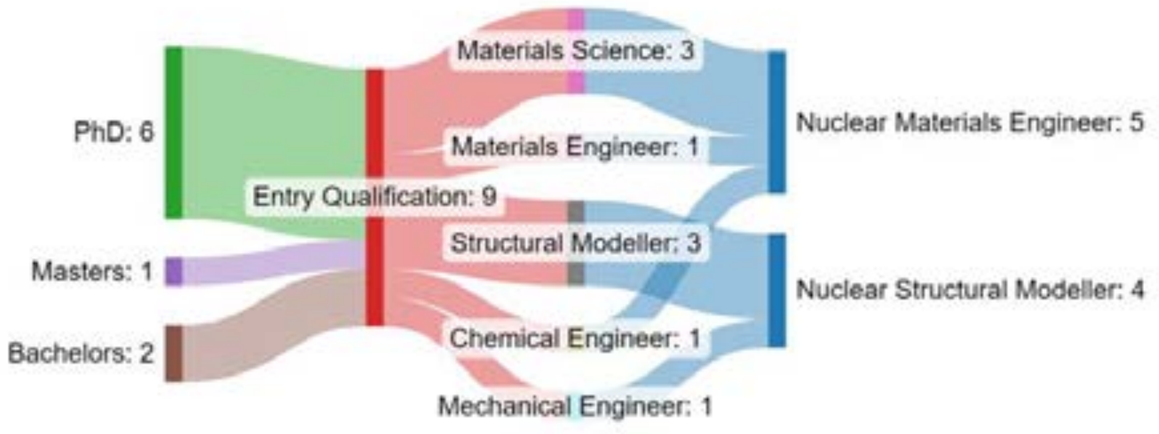

Fig 1. Ecosystem map of DYD workshop participants; people move from left to right.

The workshop comprised of eight males and one female, aged between 24 and 64 years. Among them, two of the participants had a tenure of more than 12 years at ANSTO, while the remaining seven had less than 12 years of tenure.

Table 1. shows the technical and non-technical tasks reported by the DYD workshop participants in the NFC group. Technical tasks are clustered into four main activities: research planning, experimental work, modelling, and data analysis. Non-technical tasks are clustered into two main activities: administration and communication.

Table 1. Technical and non-technical tasks from DYD workshop participants in the NFC group at ANSTO

Activity	Specific activities
Research Planning	1.Conduct literature review of research topic. 2.Contextualise the literature review to determine specific gaps in knowledge and ways to bridge the gaps. 3.Acquire online data on nuclear materials.

	4.Review ASTM standards for nuclear materials testing and simulations.
Experimental work	1.Conduct specific experiments to generate experimental data for testing assumptions and validating the models for nuclear engineering structures of materials used in simulations, including: 2. Conduct corrosion, radiation damage test on materials. 3. Conduct creep, creep-fatigue, tensile and other mechanical testing on various samples. 4. Investigate the structure of materials under TEM or SEM and relate it to properties.
Modelling	1. Generate code in open-source software to build nuclear materials models. 2. Design a model on CAD software of nuclear reactor structures (e.g. pressure vessel, pipe, cooling pipe). 3. Create FEM models to study fracture and plastic behaviour of nuclear materials and engineering systems. 4. Model solid state phase transformations to predict the effect of microstructure changes on stresses in nuclear materials.
Data Analysis	1.Analyse data from mechanical testing of nuclear materials for material models in FEM. 2. Analyse data from mechanical testing to evaluate the performance of nuclear materials in extreme reactor conditions. 3. Analyse data from DIC technique to obtain strain fields of tested nuclear materials. 4. Analyse data of nuclear materials testing, using python to develop figures and plots that can convey information to the appropriate audience
Administration	1. Conduct lab inspections 2.Supervise university students projects. 3.Setup regular meetings for reporting on progress and objectives. 4.Offer internal and external advice on nuclear materials.
Communication	1.Write reports and papers on results of experiments to clients and for publication. 2.Present scientific findings to supervisors, stakeholders, etc. 3.Communicate results to team members. 4.Develop collaborations with external stakeholders (industries, universities and national labs).

Table 2. shows the Knowledge, Skills, and Attributes (KSAs) reported from the participants in the DYD workshop.

Table 2. Key Competencies (KSAs) reported from the DYD workshop participants in the NFC group at ANSTO

The technical activities related to nuclear engineering include research planning, experimental work, modelling and data analysis. Workshop participants highlighted the specific activities that nuclear engineering research planning involves, underlying the need for knowledge of the nuclear fuel cycle, reactor processes and associated technologies (Table 2, Nuclear Knowledge 1 and 2). Participants emphasised the importance of proficiency in various research methodologies, particularly the importance literature review (Table 1, Research Planning 1), to grasp the current state of knowledge and identify gaps for exploration. As seen in Table 2. participants underscored critical skills in data processing and interpretation for undertaking research (Table 2, Skills 1 and 2). Problem-solving and teamwork skills were emphasised as necessary for persistence with research activities (Table 2, Skills 3 and 4). Key attributes like perseverance, critical thinking and adaptability play a pivotal role in defining research methodologies and outlining experimental and theoretical approaches to address specific research objectives in the organisation (Table 2, Attributes 1-3).

Conducting experiments in this group demands knowledge in materials science, particularly in understanding material behaviour under radiation and familiarity with mechanical testing techniques including micro-tensile sample fabrication testing, electron backscatter diffraction imaging, and mechanical testing of structures of materials under Transmission Electron Microscope (TEM) or Scanning Electron Microscope (SEM) (Table 1, Experimental Work 4). As presented in Table 2, participants mentioned problem-solving skills as essential for troubleshooting issues that may arise during experiments (Table 2, Skill 3). Skills in data processing are essential for analysing experimental data and extracting meaningful insights (Table 2, Skill 1). Furthermore, attributes like diligence and attention to detail are indispensable for the rigorous experimental work (Table 2, Attributes 4 and 6). Effective time management is also essential for balancing the various tasks involved in experimental research, from sample preparation to data collection, ensuring efficient progress and timely completion of projects (Table 2, Attribute 5).

For analysing experimental data in nuclear engineering research workshop participants reported needing knowledge of materials science, mechanical testing, physics and chemistry (Table 2, Non-nuclear Knowledge 2-5). Mathematics, computer and programming skills are essential for data analysis (Table 2, Skills 6-8). Analytical and problem-solving skills are also needed for data analysis (Table 2, Skills 3 and 9). Attributes such as critical thinking and attention to detail come into play when determining the most appropriate statistical and analytical techniques to apply to experimental data, ensuring the validity and reliability of results (Table 2, Attributes 2, 6). Additionally, effective time management is crucial for prioritising data analysis tasks and meeting project deadlines (Table 2, Attribute 5).

Other operational duties form a crucial part of their responsibilities, such as project management, supervision, and compliance with regulatory standards. Participants reported administrative tasks and communication tasks to be a regular part of their jobs (Table 1). Given the highly regulated nature of nuclear activities, ensuring proper documentation, reporting and adherence to safety protocols are paramount (Table 1, Administration 1-4). The participants often find themselves engaging in administrative tasks related to compliance (Table 1, Administration 1-4). Effective communication requires knowledge of nuclear materials and regulatory matters (Table 1, Communication 4), for communicating with colleagues, management, regulatory authorities and the public. This may involve tasks such as writing technical reports, delivering presentations, participating in meetings and engaging with media inquiries (Table 1, Communication 2).

4 DISCUSSION

The data collected from the participants in the NFC group at ANSTO shows the process in action as employees become nuclearized or acquire nuclear knowledge and expertise in the workplace. The Ecosystem Map (Fig. 1) shows three of participants in the workshop came to ANSTO with a PhD in materials science, one with PhD in materials engineering, and two with a PhD in structural modelling. There was one participant with a masters in structural modelling and one with a bachelor's in chemical engineering and one participant with a bachelor's in mechanical engineering. Since the starting qualification of the participants were not nuclear disciplines, the competencies (KSAs) in the nuclear field were acquired through OTJ training at ANSTO.

The results in Table 2. shows the nuclear and non-nuclear knowledge required by these 9 professionals at ANSTO. Elsevier's Dictionary of Nuclear Science and Technology defines nuclear engineering as a branch of engineering focused on research and development related to the construction and practical utilisation of nuclear reactors and their products (Clason, 1970). During the DYD workshop, participants reported technical activities in nuclear engineering shown in Table 1. Including research planning, experimental work, modelling, and data analysis, all of which align with the Elsevier definition (Clason, 1970).

Johnston (2009) delineates the expertise expected of nuclear engineers, including knowledge of reactor analysis and design, radiation effects analysis, shielding design, radiation utilisation, radioactive materials control and processing, and nuclear energy systems design for constructing nuclear reactors. The participants in the DYD workshop had knowledge of the nuclear fuel cycle, reactor processes and technologies aligning with Johnston's definition (Johnston, 2009). The participants also noted that non-technical activities in nuclear engineering require knowledge of nuclear legal frameworks, considering the highly regulated nature of nuclear activities. However, these researchers do not have complete expertise in all the aforementioned areas and are therefore more narrowly specialised in materials research than overall nuclear engineering, as outlined by Johnston (2009).

Comparing KSAs reported in the DYD workshop, and the entry qualifications in Fig. 1, it is evident that the cohort must be engaged in experiential and self-directed learning to learn the nuclear component of the competencies in their professional activities. Kolb's experiential learning theory includes engaging in direct experiences to extract meaning and insights and then applying or acting upon what has been learned in practice (Kolb, 1984). Self-directed learning is where the individuals have taken responsibility for their own learning (Knowles, 1968), which is evident in the specific activities reported.

The results from this pilot DYD workshop represent only a very small portion of the organisation, and further data collection is needed to validate the learning process and KSA development. Based on these initial findings, it is evident that the nuclear competencies within this subset of the workforce at ANSTO are primarily concentrated in the knowledge domain. This implies that formal, accelerated instruction in nuclear knowledge could expedite the development of this and similar groups, without compromising overall competency.

5 Conclusion

Through the DYD process, this study uncovered the technical and non-technical activities crucial for OTJ learning in nuclear engineering. Technical activities encompassed research planning, experimental work, modelling, and data analysis, while non-technical tasks involved administrative and communication duties. The analysis of KSAs for each activity affirms that this cohort is engaged in experiential and self-directed learning to learn the nuclear component of their competencies. The results show the nuclear complexities within this subset of the workforce at ANSTO are primarily concentrated in the knowledge domain. This implies a viable approach to expedite their OTJ learning experience could involve intensive, structured instruction approach to nuclear knowledge development, without comprising the overall competency of this group.

ABSTRACT

Tackling the issues of the future will increasingly depend on the dedicated work and creativity of engineers. In addition to the general shortage of skilled workers in the engineering sector, there is a structural under-representation of women in particular, which is reflected in the choice of STEM studies by young women. In addition, the professional fields for future engineers are changing due to global change processes and steadily increasing digitalisation. In order to increase the proportion of female students, motivational projects for the study orientation are seen as a possibility to inspire young women for engineering. With a view to digital and global transformation processes, a central question is: *How should a motivation project for the transition between school and university be designed under today's conditions?*

This paper explores this question in a theory-based manner. After presenting theoretical findings on influencing factors in study orientation, current framework

[1] *Block,*
brit-maren.block@leuphana.de

conditions and requirements are worked out in a two-stage study. First, there is a systematic literature review (SLR) on the state of research in STEM study orientation. Based on this, a qualitative interview study was conducted and evaluated with 25 young women, which identifies the framework conditions for motivational projects to attract young female engineers in today's world. As a result, concrete recommendations for action are given for the design of suitable concepts. In this way, this research work contributes to increasing the efforts of universities to attract young women to study engineering and to strengthen their motivation, self-efficacy and an engineering identity.

1 INTRODUCTION: WOMEN IN ENGINEERING

The engineering sciences have long had to deal with a growing problem of young talent, particularly among young women. This paper aims to make an evidence-based contribution to identifying the challenges, framework conditions and possible intervention strategies. To this end, this section analyses the current framework conditions and theoretical findings on influencing factors in study orientation.

1.1 Lack of young female engineers

The data situation regarding the proportion of women in engineering degree programmes is sobering. The initial situation in Germany is an example: there are currently a total of 300,000 open STEM positions (Anger et al. 2023). Another challenge is the continuing underrepresentation of women in engineering studies. Current statistics show that women currently make up 20% of the engineering professions in Germany (Federal Employment Agency 2023), while only 17.5% of first-semester students in the field of electrical engineering are female (destatis 2019). A variety of projects and initiatives have tackled this problem in the past. There has been a slight increase in the number of young female engineers, but a joint effort is still required from all stakeholders involved to motivate more women to study engineering. In view of digital and global transformation processes (e.g. sustainability), a core question is: How should a motivation project for the transition between school and university be designed under today's conditions? This **research question about framework conditions and strategies for attracting young women to engineering in times of digital and global transformation** is explored in this article in a theory-based manner.

1.2 Theoretical foundation for gender-specific study orientation

The current situation regarding first-year female STEM students points to challenges in study orientation. Evidence-based, gender-specific study choice programmes need to be developed for the engineering sector in particular. In order to analyse the (complex) correlations and answer the research question, theoretical approaches from the various scientific fields are required (e.g. linking the theories of teaching-learning research EER and gender and diversity research). A SLR has revealed the state of research in STEM study orientation, which will be outlined here. In addition to gender, **findings from gender research** point to other factors influencing young women's choice of study and their retention in STEM fields, e.g. (Taskinen and Lazarides 2020, Moote et al. 2020). A large number of research studies on the underrepresentation of women see the prevailing STEM image as well as professional and gender stereotypes as a reason for this, cf. (Hannover and Wolter

2019, Dreisiebner 2019). Prevailing attitudes and images and the "professional image" appear to be of particular importance for young women and may lead to them turning away from a STEM degree programme. This is often due to the fact that young women have little idea of specific STEM fields of activity and the fact that young adults often see STEM activities as "isolated" work with no relevance to their lives, see (Jeanrenaud 2020, Sept et al. 2019). Further studies on the connection between study choice and gender show the great importance of a lack of role models in the STEM field, cf. (Ihsen 2013 and 2019, Makarova et al. 2016) as well as social structural influencing factors, cf. (Jeanrenaud 2020, Makarova and Herzog 2020). The positive effect of role models on the attractiveness of STEM degree programmes has been empirically proven several times, for example (Battistini 2015, Wentzel and Funk 2015). In particular, the research findings that point to the need for "achievable" and "realistic" role models, including (Battistini 2015, Ihsen 2019, Greusing 2018), must form the central theoretical basis of programme concepts. **Educational sociology, psychology and motivation research** see study choice factors in close connection with self-efficacy, cf. (Bandura 1997, Schwarzer and Jerusalem 2010). The particular importance of the theoretical approaches of motivation and self-determination in the STEM context is referred to several times, cf. (Morgenroth et al. 2015, Deci and Ryan 1993, Jerusalem and Hopf 2010). Both theoretical constructs must play a central role in the programme design of motivation projects.

A STEM studies motivation programme should primarily address the causes of the underrepresentation of women in the engineering sector. To this end, theoretical findings on influencing factors in study orientation are presented. These include changes in attitude (e.g. increasing interest in the STEM field, increasing self-efficacy, reducing gender stereotypes) and long-term effective behavioural change, e.g. the intention to take up STEM studies (Brenning and Wolf 2021). Three fundamental factors are identified:

- ***Motivation*** is a significant factor influencing the choice of study. Motivation to choose a course of study is understood to be the force that drives one to choose a subject of study [Janke et al. 2023]. The different facets of study choice motivation are based on the self-determination theory of motivation, (Deci and Ryan 1993),
- ***Self-efficacy*** as personal confidence in one's own abilities, (Goodwin 2016), and
- ***Engineering identity*** as the self-perception of a person as an engineer, (Bandura 1994).

2 METHODOLOGY

2.1 Research on the empowerment of women in STEM fields

The methodological design of the analysis on the framework conditions and strategies for the study orientation of female pupils is carried out in two stages. As a *first step*, a SLR was conducted. The objective was to determine the current state of the art in research on the framework conditions for motivational projects for female students in the STEM sector. In addition to the theoretical findings from Sec. 1, publications from Scopus were selected. The PRISMA statement (Preferred

Reporting Items for Systematic Reviews and Meta-Analyses) was used as a method of systematic literature research (Moher et al., 2009; Page et al., 2021). In particular, the five aspects *Engineering, Motivation, Women, School* and *Programme* should appear as keywords within the title, abstracts or in the keywords of the articles; the document type is limited to scientific articles and conference papers in German and English. Following, the methodology of the analysis is presented in detail. Fig. 1 shows the complete search strings used in the SLR and the inclusion/exclusion criteria. Based on the selection of keywords, 244 contributions were initially identified.

ID	Search	Results
#1	engineering	19.705.099
#2	#1 AND motivation	17.751
#3	female	9.474.629
#4	women	1.504.660
#5	#2 AND (#3 OR #4)	938
#6	#5 AND (student OR school)	625
#7	#7 AND program	244
Search conducted on the 20.06.2023		

Fig. 1. Search strings used in the SLR and the inclusion/exclusion criteria

In the further procedure of literature selection according to the PRISMA statement, the selection of publications suitable for the research question was narrowed down to 18. These publications focus on STEM-related programmes for students at different grade levels and evaluate them with a focus on motivation, self-efficacy and identity. Fig. 2 presents the the data extraction process by using the PRISMA method.

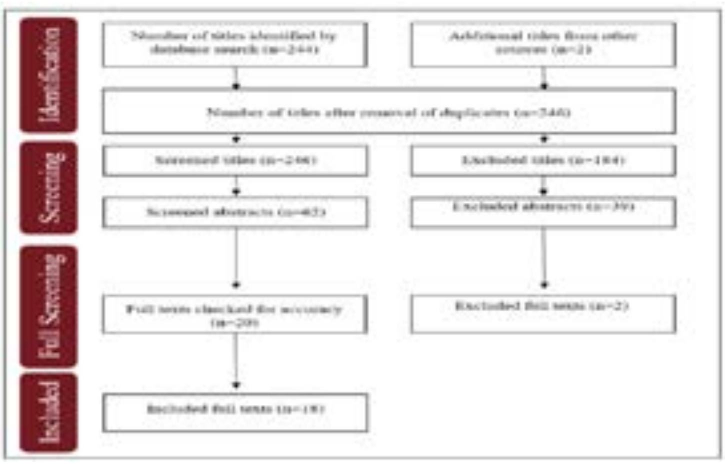

Fig. 2. Further procedure of literature selection according to the PRISMA method, according to (Moher et al., 2009; Page et al., 2021)

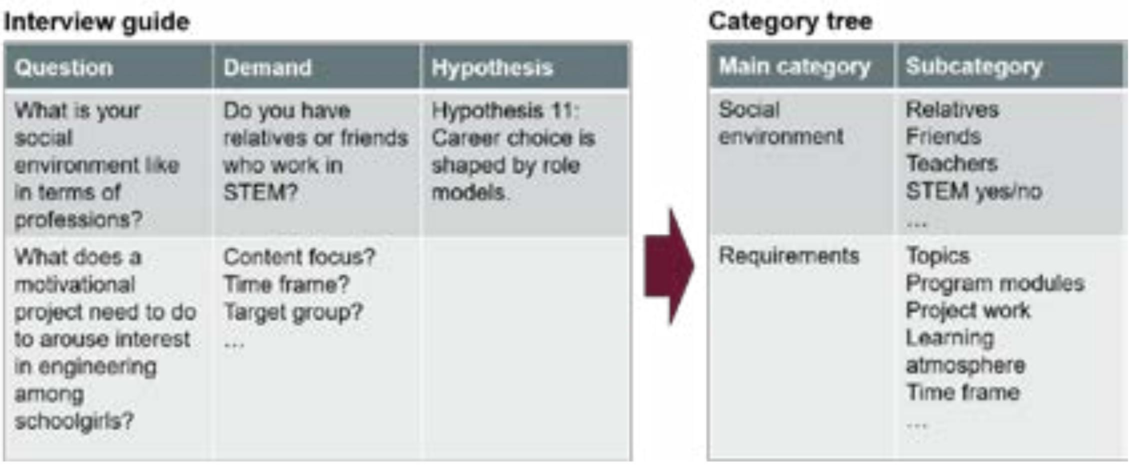
After clustering and inductive categorisation, the following categories were derived from the systematic literature analysis and the theoretical approaches from Sec. 1: *Target group; Topics; Time frame; Programme modules; Project work; Learning atmosphere; Role models*. These approaches form the theoretical basis for the qualitative survey and were incorporated into the development of the theory-based guidelines in Sec. 3. For this paper, the focus is on the qualitative study, as this provided valuable research findings on the fundamental decision-making process for women to study STEM in general and engineering in particular. The reasons for this are analysed qualitatively and barriers and support conditions in this decision-making process are identified based on evidence, see Sec. 3.1. These findings from the qualitative study are formulated as requirements for concepts in Sec. 3.2, which should address the causes of the underrepresentation of women.

2.2 Qualitative Study

As a *second step*, a *qualitative interview study* was conducted. This served to test the hypotheses on study and career orientation in the STEM field and to develop framework conditions for motivational projects for schoolgirls in engineering. Using a theory-based interview guide, 25 young women were interviewed, 14 high school students and 11 students in the initial phase of their engineering studies. Examples from the list of questions included: What is your social environment like in terms of careers? What does a motivational project have to fulfil in order to arouse interest in engineering among schoolgirls? Fig. 3 shows an example of the methodological design of the interview guide and category tree. The interviews were analysed and evaluated on the basis of hypotheses using qualitative content analysis according to (Mayring 2022, Kuckartz and Rädiker 2022). Intersubjective validation was used to increase the quality of the research process.



Interview guide

Question	Demand	Hypothesis
What is your social environment like in terms of professions?	Do you have relatives or friends who work in STEM?	Hypothesis 11: Career choice is shaped by role models.
What does a motivational project need to do to arouse interest in engineering among schoolgirls?	Content focus? Time frame? Target group? ...	

Category tree

Main category	Subcategory
Social environment	Relatives Friends Teachers STEM yes/no ...
Requirements	Topics Program modules Project work Learning atmosphere Time frame ...

Fig. 3. Interview guide and category tree - example of the methodological design

Research findings on the framework conditions and requirements for motivational programmes for young women in engineering have been explored through clustering and categorisation and are presented in Sec. 3.

2.3 Discussion of validity and limitations

At this point, the threats to the validity of the previously presented analysis of the framework conditions and strategies of study orientation programmes for female pupils will be discussed. The main limitation of the systematic literature search is that only one database (Scopus) was used as a source of scientific literature. This could not be realised otherwise for reasons of research economy. This narrow selection may lead to a weakening of the generalisability of the statements. The interview study has a reliably large sample. Nevertheless, limitations can also be identified here that may affect the generalisability of the results. The interviews were conducted and categorised by different people. Subjective categorisations can occur, particularly in the categorisation process, despite intensive discussion within the research team about the categories and their meaning. Another limitation is the selection of the interviewees. On the one hand, the time at which they left school varied and, on the other, all of the selected student interviewees came from the same university.

As the results from two different parts of the analysis were combined in the overall analysis using a mix of methods, the authors assume that the findings are robust.

For this reason, the findings have been adopted for the design of the STEM study orientation programme. A further step in validating the research results will be taken once the orientation programme has been carried out several times and evaluated with regard to the framework conditions and success. It is planned to share these evaluation results in the EER community after three rounds of the programme.

3 RESULTS

3.1 Research findings on the framework conditions of motivation programmes

The interview study shows that female students are aware of the importance of study orientation programmes. The study orientation programmes offered at schools is diverse, but nevertheless insufficient and non-transparent. Furthermore, results show that female students have low self-confidence in the technical field and that the use of role models in motivational projects is of particular importance. By clustering and categorising, findings on the following aspects of general framework conditions have been explored:

- *Focus on content* (e.g. career planning and training paths, future-oriented topics, diverse job profile and gender diversity, awareness of the role of engineering in sustainability, work-life balance),
- *Methodical-didactical design* (e.g. target group, learning atmosphere, type of programme modules, time frame),
- *Incorporating of (female) role models*,
- *Embedding into the school system*.

To assess the effectiveness of motivation projects, the impact of support measures for female pupils in STEM subjects can be assessed in two ways, based on (Brenning and Wolf 2021). As shown in Fig. 4, on the one hand, *short-term effects* can be achieved, which involve changes in attitude and settings. These include an increase in interest in the STEM field, support in finding a study programme and career, an increase in self-efficacy and a reduction in gender stereotypes (Brenning and Wolf 2021). A link can be made here to the theoretical findings from Sec. 1.2, as increasing interest in the STEM field is part of intrinsic motivation (Janke et al. 2023), increasing self-efficacy is described as such (Bandura 1994) and reducing stereotypes favours the development of an engineering identity (Godwin et al. 2023). Measurable indicators can include acceptance of the study orientation programme as a basic prerequisite for effectiveness, satisfaction with the programme, evaluation of the content of the programme and the people involved, as well as potential recommendation or renewed participation (Brenning and Wolf 2021: 115). In addition, *long-term effects* can be achieved, which are reflected in the changed behaviour of the female pupils. These can be determined based on the intention or actual STEM study or career choice, see Fig. 4.

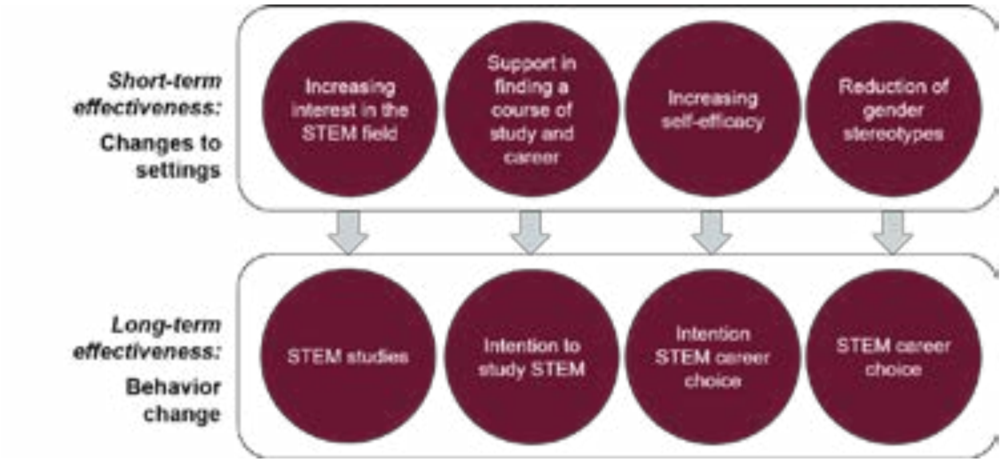


Fig. 4. Impact of measures for the study orientation of female pupils, based on (Brenning and Wolf 2021)

Suitable study orientation programmes for female students in the engineering sciences must therefore strengthen the influencing factors of motivation, self-efficacy and identity in order to have a short-term effect. The long-term effect of such a programme then determines the actual STEM study or career choice of the schoolgirls. The evaluation of the qualitative study has provided valuable insights into the design of a suitable and contemporary orientation programme, excerpts of which are presented next.

3.2 Theory-based recommendations for action for a motivation programme for young women in the engineering sciences

From the interview study, recommendations for action on the following aspects have been explored through clustering and categorising (Fig. 5).

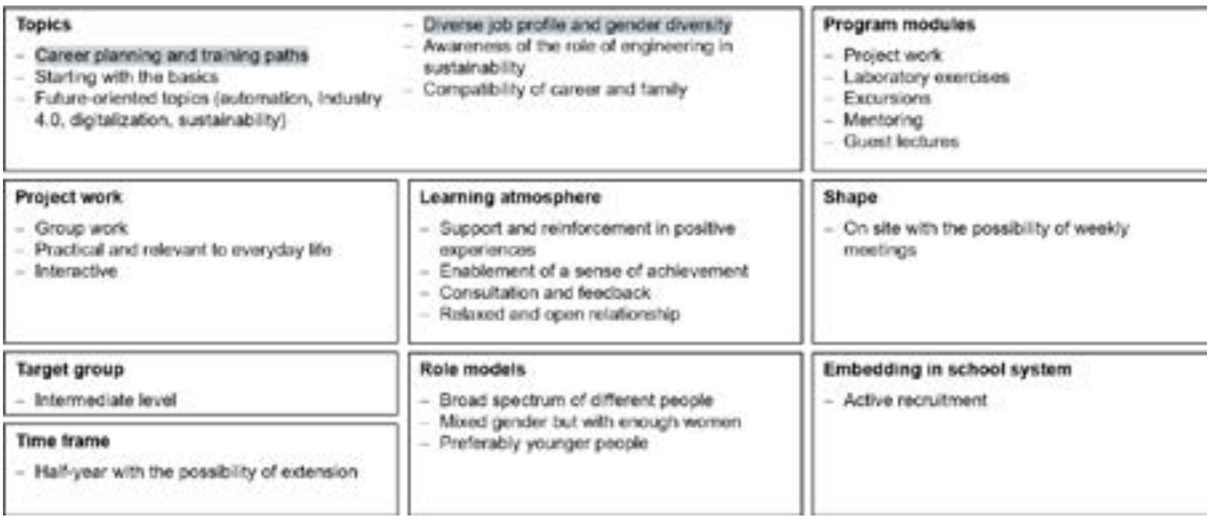

Fig. 5. Overview of recommendations for action

Evidence-based results on all aspects have been obtained from the qualitative study. Statements are listed as examples in this paper. The selected categories are colour-coded in Fig. 5. In the category *"Career planning and training paths to engineering"*, 5 out of 11 female students emphasise that different training paths and career opportunities should be addressed:

“It should be said that you can study there and that there are these and these opportunities, because I don't think anyone knows what opportunities there are in the STEM subjects.” Female student 2

Results in the category *"Diverse job profile and gender diversity"* indicate a diffuse job profile based on gender stereotypes:

“Just talking a bit against this 'women have nothing to do in technical professions' [...], I think that would have helped me a lot.” Female student 6

“So my father also has a technical profession, but because I am the girl, he had shown things to my brother rather than to me.” Female student 2

As outlined in the previous sections, the programmes should also include future-oriented topics such as automation, Industry 4.0, digitalisation and sustainability. The students' statements suggest that modern technology in particular can arouse interest.

4 SUMMARY AND OUTLOOK

The aim of this paper is to provide evidence-based findings on framework conditions and strategies for attracting young women to engineering in times of digital and global transformations.

A SLR on the state of research in general STEM study orientation is first carried out to provide a theoretical foundation. Based on this, a qualitative interview study with 25 female pupils and students in the initial phase of their engineering studies identifies the framework conditions for motivational projects to attract young female engineers today. The results are discussed in relation to the theoretical findings. As a result, concrete recommendations for action are given for the design of suitable concepts at universities.

As a validation approach of the presented study, a project for engineering study choice orientation for schoolgirls was developed as a regional STEM education measure based on the recommendations for action (see sec. 3.2). The aim of the project is to increase the proportion of women in STEM fields through the framework conditions and strategies outlined in this paper (strengthening the self-efficacy, initiative and creativity of female pupils, overcoming stereotypes and prejudices, creating a network of role models for female pupils). The study presented here is therefore to be further validated in practice. To this end, the first round of the project was successfully implemented in January 2024. The next planned steps are further project runs and the review of the effectiveness of the framework conditions presented in this paper by means of the pilot project. In addition, the long-term impact of the motivation project and the influence of the framework conditions on the actual study choices of female pupils will be investigated.

ACKNOWLEDGEMENTS

The authors express their gratitude to the young women involved in the qualitative study for their cooperation and feedback. Thanks in advance to the unknown reviewers for their comments in the early phase of this paper.

Keywords: *Upskilling teachers, teaching approaches*

ABSTRACT

Educating professionals in continuing higher education significantly differs from educating students in traditional university programs. This study aims to investigate the pedagogical approaches of experienced teachers. The insights gained are intended to inform the development of an upskilling program for novice teachers in lifelong higher education, thereby enhancing their didactical skills in this unique educational setting.

This research employed six semi-structured interviews with experienced teachers within a Diploma of Leadership Program, analyzed through a grounded theory approach. The study presents two principal findings: First, teachers who pay close attention to their students' practices often use more experimental teaching methods. Second, the analysis revealed three distinct teaching roles adopted by teachers: Facilitator, Coach, and Challenger. These roles underscore the multifaceted nature of teaching in continuing higher education. While all teachers act as facilitators, coaches, and challengers, they do so to varying degrees.

The conclusions suggest that developing a program to support teachers in lifelong learning contexts should focus on expanding their awareness of educational impacts and outcomes, incorporating experiential learning techniques, and recognizing the value of a diverse learning community.

1 INTRODUCTION

Educating professionals in formal continuing higher education is distinct from teaching students in conventional university programs. Exceptional teaching combines self-awareness, relational skills, and subject expertise to foster critical thinking and problem-solving within a dynamic, supportive learning environment (Cohen et al 2010, Sherman et al 1987). This study aims to explore the teaching methodologies that contribute to becoming an exceptional teacher.

The research question is: How do skilled teachers teach, and what is their reasoning behind their approaches? And assuming the teachers are not all exceptional, looking for differences might help us identify possible lines of progression: What differences do we observe among the teachers?

The findings from this study are intended to guide the creation of an upskilling program for new teachers in continuing higher education, enhancing their teaching capabilities in this specialized educational context.

The study involved teachers from the Diploma of Leadership program, which awards 60 ECTS. To be admitted to the program, students must have an educational background at least equivalent to that of a business academy degree, in addition to two years of relevant work experience. The participants are professionals for whom the integration of practice and theory constitutes the core of the program. The analysis indicates that teachers who successfully blend theory with practice through experiential learning also demonstrate a profound understanding of how to align their teaching with the professional practices of their students.

1.1 The professionals

In the evolving landscape of continuing higher education, the adult learner emerges with distinct characteristics that set them apart from students in regular higher education. These adults, as lifelong learners, come with a rich background of experiences, responsibilities, and goals. They seek education not just for the sake of learning but for practical uses that can boost their careers and professional growth. They participate in different social practices simultaneously, as learners in continuing education and as professionals at work. For them, learning is more than just academic success; it's about improving their practical skills and how they perform in their jobs (Knowles et al. 2020; Knowles 1978, Purwata et al 2022, Illeris 2017).

To join the Diploma of Leadership Program, candidates need at least two years of work experience in their field, along with the necessary academic background. The knowledge and real-world experience these learners bring into the classroom play several vital roles: It deepens theoretical discussions, form a concrete foundation for hands-on learning activities, and demonstrates how theoretical ideas are relevant and useful in real-world practice. Thus, emphasizing the connection between theory and practice is crucial for ensuring that what is learned in the classroom can be effectively applied in professional contexts (Hajian 2019).

1.2 Transformative learning

Transformative learning turns training into a powerful tool for change, opening new ways of seeing one’s work, increasing self-awareness, and broadening the scope of possible actions. Illeris defines transformative learning as "all forms of learning that result in changes in the learner’s identity." (Illeris 2013 pp.67). This perspective shifts the focus towards critically evaluating traditional teaching methods to ensure that learning experiences are relevant and can be directly applied in real-life situations (Mezirow 1997, Kitchenham 2008, Illeris 2013).

Transformative learning involves making tacit knowledge and assumptions explicit, subjecting them to critical scrutiny within theoretical frameworks. It is the teacher's role to foster a learning environment that encourages the exploration and questioning of these underlying beliefs and knowledge.

For adult learners in continuing higher education, collaborative and experiential learning methods are particularly effective. They connect theory with practice and improve the application of classroom learning in professional settings. These methods utilize the vast experiences of adult learners, prompting them to share their insights, question their preconceptions, and collaboratively build knowledge with peers. Experiential learning allows learners to test new ideas and methods in a supportive, reflective space. This practical approach not only deepens their understanding of the subject but also boosts their ability to use this knowledge effectively in their work (Deslauriers et al. 2019, Kolb et al. 2001, Hansman 2001, Wenger-Trayner et al 2014, Mezirow 1990, Gokhale 1995; Kim and Pak 2002).

1.3 Teaching for transformation

Teaching adult learners in continuing higher education presents unique challenges for teachers. While they may design learning activities and possess a deep understanding of the theoretical aspects of a course, less experienced instructors might struggle to establish credibility and authority in classrooms filled with experienced professionals (Holton et al. 2001, Kugel 1993, Eschenbacher 2020, Gravett 2004, Foote 2015, Hatlevik 2018).

A key issue is whether teachers, especially those with limited practical experience in a specific area, can create an environment that supports transformative learning. I argue that these educators can do so. As learning professionals, they can organize collaborative and experiential learning activities that draw on the learners' own experiences and knowledge, fostering a group exploration of practices.

2 METHODOLOGY

2.1 Interviews

To explore how skilled teachers teach, and their reasoning behind, semi-structured interviews were conducted with six teachers from the Diploma of Leadership Program. The head of studies compiled a list of six teachers, representing a diverse mix across the program, and all were invited to participate in the interviews, which they accepted. The group consisted of four women and two men, a blend of both external and internal hires. Their teaching experience ranged widely, from three to over fifteen years, and besides teaching the Diploma of Leadership Program, their professional activities spanned research, teaching in other areas, and consultancy.

The interviews were conducted in a random sequence and analyzed accordingly. The semi-structured format allowed for an in-depth exploration of the teachers' viewpoints, following their train of thought naturally. An interview guide served as a comprehensive checklist, ensuring that by the end of each session, all relevant topics pertaining to the study were discussed. The questions were crafted to shed light on their teaching practices, and were as follows:

- Who typically participates in your teaching sessions?
- If I were to open the door to your classroom on a random day, what would I observe?
- In what ways do the students rely on you?
- How do you prepare for your teaching sessions?
- Could you briefly discuss your teaching career?
- How have you yourself acquired competences to teach lifelong learners?
- If you were mentoring a new teacher in lifelong learning, how would you approach it?

Interviews were recorded on a mobile device and subsequently transcribed using the transcription feature in Microsoft software. The transcriptions were carefully read, coded, and analyzed. To ensure a thorough understanding, the recordings were listened to again, with additional notes taken to enhance the initial analysis as needed.

2.2. Analyzing interviews

The analytical process adhered to the principles of grounded theory (Corbin and Strauss 1990, Corbin and Strauss 1996), ensuring a rigorous examination of the data. To keep a detailed record of each interview, quotes were systematically organized into a program theory matrix (Dahler-Larsen 2018, Frye and Hemmer 2012). This approach provided a structured and comprehensive overview of each interview.

In this study, program theory was utilized to organize and analyze quotes and insights from each interview, with the goal of clearly demonstrating what teachers do and the reasons behind their actions. First, each interview was analyzed separately to treat them as unique stories, ensuring they were understood on their own before comparing them. This step provided a clear picture of each teacher, including how they plan and execute their teaching and the reasoning behind, as shown in table 1. To answer the second half of the research question, 'What differences do we observe among teachers?' the interviews were compared. First, common themes were identified, and then fundamental differences among the teachers were examined based on patterns.

I… (activity)	In order to… (Intention)	The effect in classroom is…	Outcome
Collect, develop and tell stories that illustrate theory	Help the students to understand theory and connect it to practice	Theories become mental tools that the students find meaningful and useful	In practice, the manager must make decisions on a reflected basis

Table 1: A section of a program theory matrix based on an interview with a teacher

3 Presentation and Discussion

How do skilled teachers teach? Initially, data from the various interviews were compiled to outline the teachers' actions in preparing for and conducting their teaching. The data presented in this section, and illustrated in figure 1, details the teachers' activities in both the preparation and execution of their teaching.

The Interviews were coded and condensed. Across interviews, activities fell within four overarching categories:

- Activities to foster a safe and fruitful learning environment
- Activities to link theory and practice
- Activities to facilitate students learning process
- Activities to manage classroom

In addition to these categories, the interviews revealed insights into how teachers prepare, perspectives on teaching roles and how they would mentor new teachers entering the field of teaching lifelong learners.

Fig. 1. Overview of activities teachers carry out related to teaching

Figure 1 represents a comprehensive summary of all the activities discussed individually by the teachers. It depicts the activities conducted by teachers, as identified across interviews, to a) establish a learning environment and define roles, b) ensure student engagement with the content, and c) prepare and evolve their teaching. These activities are arranged according to an intuitive understanding of complexity, increasing from the centre outward.

Differences among teachers manifest in their actions and motivations. The following discussion includes a quantitative analysis of their teaching rationale and a qualitative examination of the differences among teachers.

3.2 Diverse approaches to teaching, quantitative differences

The interviews revealed that teachers have unique traits and engage in various activities, prompting an exploration of these differences. Revisiting the program theories pinpointed variations in activities and revealed an unexpected trend in teachers' views on effects and outcomes (program theories' columns 3 and 4 as in table 1).

All teachers described numerous activities linked to the four main themes identified in the program theory. However, there was a clear distinction in how they discussed the immediate effect of these activities in the classroom and the expected outcomes in students' professional practice.

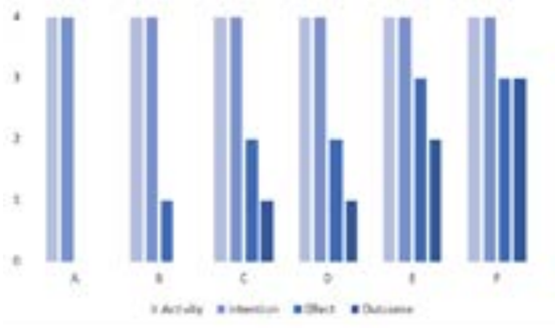

Fig. 2. A numerical representation of the six program theories for each of the teachers A–F.

The chart shows that teachers, labeled A through F, each discussed the four main themes (y-axis). Teachers B, C, D, E, and F talked about the classroom effects to different degrees. Additionally, Teachers C, D, E, and F shared their thoughts on how these activities could influence the students' professional practices.

When comparing the information from Figure 1, Figure 2, and the records from each teacher, it became clear that teachers who focused more on the effects and outcomes tended to use more advanced teaching methods, such as storylines, sociodramas, and action learning.

This analysis suggests that three distinct teaching practices emerge from the data: facilitator, coach, and challenger. The challenger role is observed more frequently among educators who emphasize student outcomes in their practice.

3.3 Characterizing teaching practices –qualitative differences

The six teachers exhibit variations in their approaches, as shown by their activities, how they link theory with practice, the role they assume as teachers, and the value they place on the learning community. These differences are discussed in section 3.3 - 3.6 and summarized in table 2.

All teachers used dialogue and group work in their teaching strategies. However, experiential learning methods like storyline, sociodrama, and case-based teaching were mainly used by teachers C, D, E, and F.

Experiential learning allows learners to gain knowledge and skills through direct experiences. It emphasizes active involvement, tackling real-world problems, and reflecting on these experiences to deepen understanding. This process encourages learners to act, reflect, learn, and apply, thereby building vital skills. Storyline and sociodrama enable participants to engage with real issues in an interactive way, enhancing problem-solving, critical thinking, and adaptability. These methods also help link theory to practice, uncover tacit knowledge, and experiment with new ways of thinking and acting in a safe space (Kolb et al 2001, Lewis and Williams 1994).

While all teachers introduced trial actions, they vary in execution. Teachers A and B ask participants to share their experiences. In contrast, Teachers E and F prompt reflection with questions like "What happened? Did it change anything?"

There is a noticeable difference in how teachers use these learning activities. Although all teachers incorporate elements of the three approaches, the extent and manner of their usage vary greatly. This suggests a link between a teacher's approach to learning and their choice of activities.

3.4 Linking theory and practice

Teachers A and B frequently use a deductive approach, beginning with theory and then inviting students to provide practical examples to illustrate the theory. In contrast, teachers C, D, E, and F prefer an inductive approach in their classrooms. For example, one of them organizes a role-play that immerses students in scenarios related to their leadership practices. This activity helps students see how different strategies can result in varied outcomes and approaches. At times, the teacher steps in as a challenger, pushing students to consider and assess different ways of acting.

The shift from deductive to inductive teaching enables students to not only understand and apply theories but also to address real-life challenges using theoretical knowledge. This method transforms theories into practical tools for making well-informed decisions. As one teacher put it: "Theories become valuable mental tools for students, guiding their decisions in leadership."

Thus, while some teachers focus more on theory, others emphasize the practical application of theoretical concepts.

3.5 The role of the teacher and the learning community

A teacher mentioned: "I sometimes teach very small classes and feel that I can't provide the same quality as when teaching slightly larger classes." This comment sheds light on the difficulties of teaching very small groups. It underscores an inherent understanding of the advantages that arise when students share their knowledge, experiences, and viewpoints in class.

Teachers universally value the input students bring to the learning environment. The diversity of perspectives enriches classroom discussions, serving either as conversation partners in small groups or as a mini society that helps delve into various dilemmas, ideas, and responses. Not surprisingly, teachers who utilize interactive methods like sociodrama and case studies particularly cherish and recognize the significance of a dynamic learning community.

3.6. Classroom management

Teachers have distinct teaching styles, which extends to their approach towards classroom management. All teachers recognize their duty to foster a safe and engaging learning space. They set up a clear didactical contract, define the learning objectives, and establish rules for teamwork and communication.

Some teachers focus more on asserting their credibility and control, while others strive to ensure that every student has equal opportunity to delve into both theory and practice, valuing the varied perspectives and experiences of all students.

Teachers E and F, in particular, face challenges when students struggle to work together or when some students dominate the discussions. They share concerns like "He takes up too much space" and "I mentally keep track of participation to make sure I involve everyone equally." For these teachers, it is crucial to bring into play the diverse perspectives and experiences of all students, acting as a sort of playmaker.

All the interviewed teachers use elements of facilitating, coaching and challenging. However, the reasons, extent, and ways they do it, differ greatly. The three teaching practices as facilitator, coach and challenger are summarized in the table below.

	Teacher as facilitator	Teacher as coach	Teacher as challenger
Focus	Ensure students meet the course objective	Foster the development of each student	Empower students as active practitioners
Teaching approach	Deductive lectures, dialogue-based, group work and time for reflection.	Inductive case studies, storylines, sociodramas, and mirroring exercises.	Experiential Action learning activities
Learning community	Students are viewed as a uniform group.	Each student is addressed individually.	Release of the learning community potential
Classroom management	Establish legitimacy	Clarify didactical contract	Bring diverse perspectives forward

Table 2. Overview of differences between teaching practices.

Table 2 summarizes differences in how teachers approach the students, the content, and the classroom.

4 CONCLUSIONS

Teaching lifelong learners in continuing education demands an approach that takes the participants' professional mindset and applicative perspective into account. This study aimed to answer the questions: How do skilled teachers teach, and what is their reasoning behind their methods? What differences do we observe among teachers?

We have observed quantitative and qualitative differences among the interviewed teachers and identified three distinct approaches where teachers take on the roles of facilitator, coach, or challenger, respectively. While all teachers exhibited elements of these roles, they varied in the extent and way they implemented them. Teachers who are attentive to the participants' practices also challenge participants and leverage the knowledge and experience of the learning community.

The study aims to inform the next phase in creating a training program for new teachers within continuing higher education at an engineering university. Teachers were asked not only about their teaching methods but also how they would guide a newcomer to continuing education. One experienced teacher suggested: "You need to first thoroughly understand yourself and your content." Beyond this, all participants highlighted the importance of watching peers, experimenting, providing mentorship, and building a professional community among teachers. Based on this study's findings, a training program could include expanding understanding of the effects and outcomes of teaching, incorporating experiential learning, and leveraging the benefits of a diverse learning community.

ABSTRACT

The significance of cognitive skills, particularly creativity, for the workforce of today, has been widely acknowledged, with engineering educators and accreditation bodies alike underlining the necessity for integrating and developing creative problem-solving skills in engineering students. Simple ideation techniques have been previously explored to enhance creative problem-solving among students, however measuring their effectiveness is partially masked by whether students employed schema-driven or search-based strategies. Schema-driven strategies, utilising specialised memory structures developed through acquiring expertise are highly effective, while search-based strategies, typically employed by students who do not have a wealth of expertise, are inefficient but can be enhanced through the use of idea generation heuristics. This research evaluates the influence of a particular heuristic, the Eight Fields of MATCEMIB, on idea generation in first-year engineering students through an experiment constructed to separate schema-driven and search-based ideas. Students were exposed to open-ended problems with different prompts and stimuli and assessed on the number, breadth and creativity of the ideas generated. The control group, without any prompting, showed less effective idea generation compared to experimental groups guided by such prompts, indicating the

[1] *G Buskes,*
g.buskes@unimelb.edu.au

heuristic’s effectiveness in improving search-based idea generation for engineering students. No difference was observed in idea generation whether hints were offered as words or images, nor in the sequence of hints provided. By understanding the impact of these heuristics on idea generation, educators can better utilise such techniques to foster creativity in design and project-based subjects.

1 INTRODUCTION

Over the past decade, various entities including governments, technological associations, engineering firms, and global business leaders have recognised the importance of cognitive skills, particularly creativity, for professionals in the 21st century (Deloitte 2017; Aggarwal 2021). For instance, the World Economic Forum surveyed Chief Human Resources Officers and strategy executives from 371 companies, revealing that five out of the top ten essential skills for employment were cognitive: (1) complex problem solving, (2) critical thinking, (3) creativity, (7) judgement and decision making, and (10) cognitive flexibility (World Economic Forum 2016). Engineering educators and accreditation bodies have also strongly advocated for a focus on creative problem-solving skills in engineering education (National Academy of Engineering 2005; Cropley 2015; Valentine et al. 2019). As a result, today’s engineering students often engage in multiple design projects throughout their degree to help develop these skills in preparation for the modern workforce, underscoring the need for effective heuristics to enhance problem-solving approaches and creativity skills (Deckert 2018; Belski et al. 2019).

Problem-solving approaches can be categorised into schema-driven and search-based strategies (Gick 1986). The former are developed through acquiring expertise, while the latter involve following idea generation heuristics. During problem-solving, relevant information is typically retrieved in response to specific cues, which are stored in (limited) short-term memory. These cues are then used to search long-term memory for related information and subsequently retrieved back to short-term memory to be presented as potential solution ideas (Ericsson et al. 1995; Belski et al. 2008).

Over years of extensive professional practice, experts develop special memory structures (schemata) that integrate their specific knowledge. These schemata allow experts to rapidly (and often automatically) search their long-term memory for information and actions that are the most appropriate for the given problem-solving situation (Gobet et al. 1996). In essence, these schemata substantially enhance the operations of their short-term memory (Egan et al. 1979) and reduce its limitations (Kirschner et al. 2006), leading to better performance in recognition and recall. On the other hand, first-year undergraduate students, who can be considered ‘novices’, have not yet built up a sufficient base of expert knowledge and experience and thus have not developed expert schemata, relying on inefficient search strategies (Gobet 1998). Most of the students are likely to develop schemata that are related to their day-to-day experiences (e.g. washing dishes, simple cooking, cleaning shoes).

Previous research has investigated whether several simple ideation techniques (processes of generating and developing new ideas), can enhance students’ creative problem-solving ability and provide insight into simple and effective means to enhance it (Belski et al. 2014; Belski et al. 2015). In these studies, creative problem-solving ability was measured by the total number of ideas generated, the breadth of ideas, and an assessment of their creativity in addressing a given problem. Research established a statistically significant improvement in the numbers and the breadth of ideas generated by students when they were exposed to the Eight Fields of MATCEMIB heuristic through prompts (Buskes et al. 2017, 2018). A true comparison of the influence of these types of heuristics is difficult to achieve, however, due to some of the ideas generated by the students being created by means of schemata. In light of this, the research presented in this paper extends past work to separate schema-driven (developed by acquiring expertise) and search-based (using idea generation heuristics) ideas in order to more accurately evaluate the influence of a heuristic alone on idea generation. The influence on the idea search of changing the sequence of prompting as well as replacing a word prompt by an image was investigated and differences in performance between subgroups of students was explored.

2 METHODOLOGY

Two hundred and thirty-eight students that have just enrolled in a first-year Engineering course in the Bachelor of Science degree at an Australian university participated in this study on a voluntary basis. Seventy-three percent of the participants graduated from secondary school in Australia; 26% were international school students; just one percent of participants did not reveal their country of graduation.

This study utilised the idea generation experiment that was originally conducted by Belski et al. (Belski et al. 2014). Students from five tutorial groups were randomly assigned to five conditions: one control and four experimental. All participants were given 18 minutes of tutorial time to individually generate as many ideas as possible for the same open-ended problem (to remove the lime build-up in water pipes). Participants were shown 26-minute videos that were specifically created for each group. The first eight minutes of the videos were the same for all groups. During these eight minutes participants were introduced to the experiment, entered information on the country of graduation from secondary school as well as information on mathematical and science courses that they studied at school. Australian students were asked to provide their Australian Tertiary Admission Rank (ATAR), a number between 0.00 and 99.95 that indicates a student’s position relative to all the students in their age group. For example, an ATAR of 90 indicates that the high school performance of a student was above 90 percent of all students that graduated in the same year. After this, the problem was introduced to students in a video as an image that contained the problem statement and a photo of a cross-section of a pipe, half of which was covered with lime deposit. This image can be comprehended from Figure 1a if the word “Mechanical” is removed from it. All participants were asked to work individually and to record as many ideas as possible to remove the lime build-up from the pipes. They were asked to record their ideas starting at the top of a page and to draw a line under the ideas they had recorded when prompted to do so. Participants from the four experimental groups were also told that during their idea generation session some additional words or images will be shown on a screen and that they will be told when a new word or image is shown. No explanation of what these words or images would be and what to do with them was given.

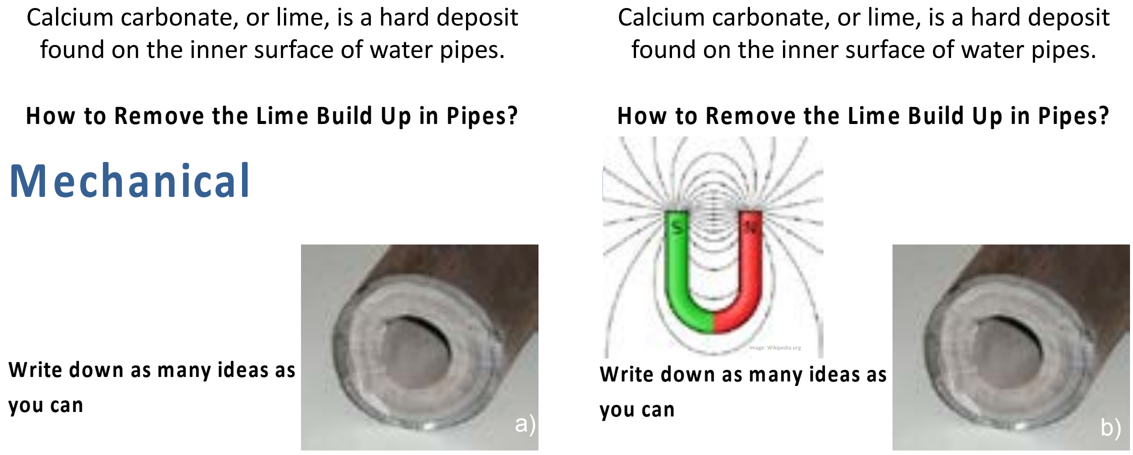

Fig. 1. Screenshots of a video presented to students: a) Word and Reversed Word groups; b) Image and Reversed Image groups.

After the problem introduction, the videos that were shown to groups differed. For the remaining 18 minutes, Control group participants were shown the same 'introductory' image and were prompted to draw a line under the ideas that they recorded every two minutes. Experimental groups were also asked to draw a line under the ideas recorded every two minutes but, after the announcement to draw a line, they were shown a new word or an image and were notified verbally of the change. It is important to note that for the first two minutes of idea generation, students from the experimental groups have not been shown any hints. In essence, for two minutes they generated ideas under the same conditions as the Control group. It was expected that during this time students would use the schema-driven strategies that they have acquired over their day-to-day activities.

Participants from the Word (W) group were shown the names of the Eight Fields of MATCEMIB (i.e. Mechanical, Acoustic, Thermal, Chemical, Electric, Magnetic, Intermolecular and Biological). The Reversed Word (RW) group were shown the same names of the eight fields of MATCEMIB, but in the reverse order (i.e. Biological, Intermolecular, Magnetic, Electric, Chemical, Thermal, Acoustic and Mechanical). Similarly, participants from the Image (I) and the Reverse Image (RI) groups were shown images that were expected to represent appropriate fields of MATCEMIB in an original order for the former group and in a reverse order for the latter. Figure 1 depicts one of the eight screenshots that were shown to participants from different groups: Figure 1a – the Word (W) and the Reverse Word (RW) groups; Figure 1b – the Image (I) and the Reverse Image (RI) groups.

Two independent assessors were trained to evaluate the student idea generation forms using the criteria that were developed for the original idea generation experiment (Belski et al. 2014). To do that, assessors watched a video that explained the assessment criteria and showed the evaluation of ideas proposed by three students. They also evaluated performance of 10 students as an assessment exercise. The inter-rater reliability of their assessment was evaluated with SPSS by establishing the Cronbach's Alpha for the number of independent ideas proposed by each individual student. The Cronbach's Alpha was over 0.9, which suggested excellent internal consistency of assessment of the two assessors. After that, the assessors evaluated all student idea generation forms. Among other items, assessors counted the *number* of distinct (independent) ideas proposed by each student during each of the nine two-minute intervals without necessarily assessing their practicality. Only the ideas to remove the lime build-up were counted, with the number of ideas to prevent build-up or to replace the pipe recorded separately. To judge how broad the independent ideas to remove the lime build-up were, each idea was assigned to a field of MATCEMIB that most closely matched the proposed principle of removing the lime build-up. The number of fields of MATCEMIB present in the ideas proposed by each student during each of the nine two-minute intervals (*breadth* of ideas) was also counted.

Evaluation of internal consistency of assessment of the two assessors for all 238 participants showed that the collected data can be statistically explored: Cronbach's Alphas were 0.948 for the number of ideas and 0.945 for the breadth of ideas. Four participants left their idea generation forms empty and were excluded from statistical analysis. The following statistical analysis was conducted after both the number of ideas and the breadth of ideas generated by each individual participant in each time interval was averaged (sum of numbers by each assessor divided by two).

3 RESULTS

IBM SPSS (28) statistical software was used for the analysis. Table 1 depicts basic information about the groups: group composition (number of Australian students shown in parenthesis), the average number of mathematics and science courses studied by the participants, and average ATAR scores of the Australian students.

Table 1. General Information on Groups of Participants

Group	N(AU)	Mean/SD	ATAR	Math	Science
C(ontrol)	48(37)	Mean	**95.22**	**1.96**	**2.13**
		SD	4.44	0.74	0.87
W(ord)	51(43)	Mean	**88.63**	**1.75**	**1.88**
		SD	20.90	0.80	0.71
RW(ord)	40(27)	Mean	**95.15**	**1.97**	**1.88**
		SD	4.48	0.53	0.72
RI(mage)	56(34)	Mean	**89.33**	**1.86**	**2.04**
		SD	23.10	0.80	0.71
I(mage)	39(29)	Mean	**91.47**	**1.59**	**1.87**
		SD	17.75	0.60	0.86

Table 2 presents the results for the average numbers of independent ideas proposed by the participants in each group during: (i) the first two minutes of the experiment (NB2), (ii) from the third minute until the end of the experiment (NA2) and (iii) the total number of ideas (NAll). It also presents the average values of breadth of these ideas in a similar notation: BB2, BA2 and BAll. Furthermore, it shows the average number of ideas to prevent build-up that were proposed by the participants in each group during the first two minutes of the experiment (PB2) and from the third minute until the end of the experiment (PA2).

Table 2 also contains information on the Standard Deviations (SD) related to the number ideas to clean and prevent build-up as well as to the breadth of ideas generated during the above-mentioned time intervals. It must be noted that when the breadth of ideas proposed by a participant after the first two-minute interval (BA2) was calculated, the fields that were counted towards ideas during the first two-minute interval (BB2) were not counted (e.g. if a participant proposed Mechanical and Chemical ideas during the first two-minute interval (BB2=2) and later on suggested ideas that exploit Mechanical, Chemical, Thermal and Biological fields, only the last two were counted for the breadth during the remaining 16 minutes (BA2=2)). Counting the breadth of ideas in this way ensured that the total breadth of ideas (BAll) will correctly represent the fields of MATCEMIB considered by a participant as ways of removing the lime build-up.

Table 2. Number (Mean) and Breadth of distinct ideas generated by students.

Group	Mean/SD	NB2	NA2	NAll	BB2	BA2	BAll	PB2	PA2
C	Mean	**1.71**	**3.92**	**5.63**	**1.47**	**1.55**	**3.02**	**0.34**	**1.03**
	SD	1.40	3.13	4.00	0.84	1.18	1.42	0.53	1.42
W	Mean	**1.71**	**5.94**	**7.65**	**1.49**	**3.81**	**5.30**	**0.27**	**0.88**
	SD	1.11	2.87	3.27	0.68	1.70	1.71	0.48	1.53
RW	Mean	**1.64**	**6.13**	**7.76**	**1.44**	**3.96**	**5.40**	**0.19**	**0.30**
	SD	1.10	3.00	3.61	0.74	1.67	1.73	0.39	0.83
RI	Mean	**1.90**	**6.05**	**7.96**	**1.68**	**3.67**	**5.35**	**0.12**	**0.18**
	SD	0.90	2.71	2.98	0.70	1.31	1.33	0.38	0.51
I	Mean	**1.89**	**5.78**	**7.67**	**1.59**	**3.90**	**5.49**	**0.14**	**0.18**
	SD	1.04	1.96	2.30	0.77	1.33	1.29	0.30	0.35

The Shapiro-Wilk test identified that the distributions of the number of ideas and the breadth of ideas shown in Table 2 were not normal for all five groups. Therefore, the Independent Kruskal–Wallis 1-Way ANOVA test with Bonferroni adjustment was used to evaluate differences in performance of students from the five groups during different time intervals. The Kruskal–Wallis test showed that the distribution of the number and breadth of ideas during the first two minutes (NB2 and BB2) was the same across the groups (NB2: N=234, Z=5.825, p=0.213; BB2: N=234, Z=3.714, p=0.446). The difference in performance of the participants from the Control group and the other four groups during other time intervals (adjusted by the Bonferroni correction) were statistically significant for the number of ideas (CA2 vs WA2: Z=-50.710, p=0.002; CA2 vs RWA2: Z=-56.877, p=0.001; CA2 vs RIA2: Z=-53.007, p=0.001; CA2 vs IA2: Z=-52.675, p=0.001; CAll vs WAll: Z=-44.834, p=0.010; CAll vs RWAll: Z=-45.973, p=0.015; CAll vs RIAll: Z=-52.180, p=0.001; CAll vs IAll: Z=-50.357, p=0.006). Similarly, the difference in performance of the participants from the Control group and the other four groups during other time intervals (adjusted by the Bonferroni correction) were also statistically significant for the breadth of ideas (CA2 vs WA2: Z=-87.068, p=0.000; CA2 vs RWA2: Z=-91.710, p=0.000; CA2 vs RIA2: Z=-81.689 p=0.000; CA2 vs IA2: Z=-90.720, p=0.000; CAll vs WAll: Z=-83.298, p=0.000; CAll vs RWAll: Z=-87.417, p=0.000; CAll vs RIAll: Z=-84.024, p=0.000; CAll vs IAll: Z=-90.139, p=0.000).

No correlation was discovered between the number and breadth of ideas generated at all time intervals and ATAR, as well as between the number and breadth of ideas and number of mathematics and science courses studied. When groups were considered separately, only a correlation between the number of ideas generated after the first two-minute interval (NA2) and the number of science courses studied for students from the Reverse Image (RI) group (r=0.375, p=0.38) was discovered.

A statistical analysis showed that Australian school students from all five experimental groups generated more ideas than their international counterparts.

The Shapiro-Wilk test identified that the distributions of the number of ideas and the breadth of ideas were not normal for all five groups for both populations. Therefore, Independent Kruskal–Wallis 1-Way ANOVA tests with Bonferroni adjustment were used to evaluate differences in performance of local and international students separately. The results of the Kruskal–Wallis tests were practically the same for local and international students as they were when groups were considered without subdivision (local and international together): no statistical differences in performance were found between the groups during the first two minutes of idea generation and statistically significant differences between the Control (C) group and the other four groups were discovered for other time intervals.

The Mann-Whitney U test was used to more accurately evaluate differences in performance of local and international students for three cases: (i) difference in performance of all local and international students during the first two-minute interval, (ii) difference in performance of local and international students from the Control group after the first two-minute interval and (iii) difference in performance of local and international students from all four experimental groups together (excluding the Control group) after the first two-minute interval. It was established that during the first two-minute interval only the difference in number of ideas to prevent a lime build-up (NP2) was statistically significant (170 vs 62, Z=-2.794, p=0.005) – international students proposed more prevention ideas than their local counterparts. No statistical difference in performance was discovered between local and international students from the Control group after the first two-minute interval. When performance of local and international students from the four experimental groups were compared after the first two-minute interval, their performance differed statistically for both the numbers of ideas to remove and to prevent the lime build-up: NA2: (133 vs 52, Z=-2.237, p=0.025), PA2: (133 vs 52, Z=-2.324, p=0.020).

The number of ideas and the breadth of ideas proposed by local and international students from all groups excluding the Reverse Words (RW) group did not differ statistically. For the Reverse Words (RW) statistical significance was found for NB2 (Z=-2.173, p=0.030), NAll (Z=-1.982, p=0.047) and BB2 (Z=-2.122, p=0.034). It also needs to be noted that local students on average generated more ideas for preventing lime build-up and for removing it than their international counterparts.

4 DISCUSSION

It can be seen from the results of the experiment that the students have not yet developed expert schemata. Most students in the first two minutes proposed mechanical and chemical ideas, which were related to their schemata and were therefore proposed quickly. These schemata have likely developed due to

their day-to-day experiences (for example, schema of cleaning mechanically or with chemicals). Subsequent minutes of idea generation showed that an idea search by students from the Control group was not very effective. At the same time, students from the other groups that were ‘guided’ by hints were able to conduct much more effective searches for ideas, in terms of the number generated and their breadth. The results prove that the Eight Fields of MATCEMIB heuristic, delivered via prompts, is effective in improving idea generation in engineering students by improving their search-based problem-solving methods to generate ideas. It also appears to be unimportant whether the hints are offered as words or images, or the sequence of hints provided.

The fact that there is no practical difference between the number/breadth of ideas generated in the first two minutes between all the five groups is proof that the groups can be considered identical. In previous research, an assumption that the groups were ‘identical’ was based upon random choice of the groups and a similarity in their ATAR. This time there is much more solid proof that the groups can be considered identical in a sense of their ability to initially generate ideas. Although this study did not find any correlation of number and breadth of ideas with ATAR, it is possible that such a correlation exists. The range of ATAR in this study was rather limited, with most students at the upper end of the scale.

Interestingly, there was no correlation found between idea generation performance and number of science subjects studied. This could be possible due to those students having studied, for instance, chemistry in high school, understanding that a chemical removal of a build-up is hardly realistic; consequently, they may not have entered many ‘chemical’ ideas. This may result in a negative correlation between studying chemistry and ideas related to chemical removal. When the data were averaged for all science subjects, this could no correlation to be seen. A further analysis of the data to look for a correlation between ‘subject’ and ‘number of ideas related to this subject matter’ would need to be performed. In this case, it will be necessary to decide which ideas are likely to be related to each subject to then perform a further statistical analysis.

5 SUMMARY

The importance of cognitive skills, especially creativity, in today's workforce is widely recognised, and consequently a focus of development through engineering education. In this research, an experiment evaluating the Eight Fields of MATCEMIB heuristic on first-year engineering students demonstrated its effectiveness in improving idea generation through enhancing search-based strategies. Both the number and breadth of ideas generated by students who were introduced to the heuristic were statistically significantly higher than the control group, which was not provided with anything to assist in idea generation. The heuristic employed also showed effectiveness in not being sensitive to being word- or image-based or to the sequence in which the prompts were shown to the students. Engineering educators can therefore apply this heuristic to support students in idea generation in a broad range of contexts, for example when devising solutions to design problems.

ABSTRACT

In this study a comparative analysis of innovative engineering mathematics courses at TU/e, Netherlands, and HKUST(GZ), China, was conducted to explore distinct educational philosophies and pedagogical approaches that foster unique learning environments. Using a student centered approach, both institutions incorporate a dual focus on knowledge growth and problem-solving skills, employing

[1] *W. Cai*
w.cai@tue.nl

comprehensive evaluation frameworks that integrate peer reviews, assignments, and presentations for a holistic assessment of student learning. [Institution]'s challenge-based learning model in this context emphasizes specific scientific disciplines, while [Institution] focuses on project-based, methodological learning, particularly around design thinking. Despite their common prioritization of student autonomy and engagement, differences emerge in mathematical application, problem themes, student support, and resource allocation. The study highlights the dynamic nature of engineering education, underscoring the need for pedagogical strategies that align with educational objectives and student needs.

1 INTRODUCTION

1.1 Background

Over-consumption, driven by a growing population, climate change, and globalization, necessitates innovative solutions, particularly through engineering education (e.g. Gaskins et al. 2015; Lönngren et al. 2017; Membrillo-Hernández et al. 2021). Mathematics is vital for engineering students' success, with proficiency in mathematics correlating to better engineering outcomes (e.g. Agoestanto and Masitoh 2021; Tsui and Khan 2023). Consequently, there is a push for innovative teaching approaches in engineering mathematics, moving from traditional teacher-centred approaches to student-centred learning. The latter emphasizes active engagement, critical thinking, and application of knowledge (e.g. Baeten et al. 2010; Tangney 2014), unlike the passive lecture-based teacher-centred methods (Emaliana 2017). Innovative pedagogies like flipped classrooms, active learning, problem-based learning (PBL), inquiry-based learning (IBL), and challenge-based learning (CBL) are characterized by student ownership, interdisciplinary learning, collaboration, and real-world relevance (e.g. Hayward et al. 2016; Kock et al. 2021; Van der Wal et al. 2019). This shift also sparks interest in comparing innovative curricular features between different countries, like China and the Netherlands.

This study explores the question: what are the characteristics of innovative engineering mathematics courses in the Netherlands and China from the perspective of the educators involved, including both teachers and teaching assistants?

1.2 Literature review

Mathematics is crucial in higher education, particularly in engineering and STEM, where it supports innovation and technology integration. Mathematics is not only a core academic subject but also a practical tool across various fields, underpinning innovative engineering courses (e.g. Dahl 2018; Liu and Pásztor 2022). The adoption of Problem-Based Learning (PBL) and blended learning highlights the effectiveness of active, hands-on approaches in advancing mathematical understanding relevant to societal and professional needs (Maass et al. 2019). Innovations in mathematics education encompass also technological advancements in curriculum design and novel pedagogical methods, aiming for a deep exploration of these elements.
The integration of technology in engineering mathematics education has revolutionized traditional teaching, with tools like MATLAB enhancing interactive learning and problem-solving skills (Aruvee & Vintere 2022; Soares et al. 2019). Meanwhile, pedagogical innovations, shifting from teacher-centred to student-

centred approaches, promote active learning, critical thinking, and the practical application of knowledge (Elen et al. 2007; Baeten et al. 2010). Methods such as flipped classrooms and PBL emphasize student engagement and real-world relevance, reflecting an educational shift towards student autonomy and interdisciplinary application (Karabulut-Ilgu et al. 2017).
Innovative pedagogical approaches are often characterized by a student-centered orientation. Student-centered learning contrasts significantly with teacher-centered approaches in educational settings. (Elen et al., 2007). In student-centered learning, the focus shifts from the teacher imparting knowledge to students actively engaging in their learning process. This approach emphasizes critical thinking, problem-solving, and the application of knowledge in various contexts, promoting a deeper understanding and retention of material (e.g. Baeten et al., 2010; Tangney, 2014).

A focus on PBL and CBL in engineering education reveals their widespread adoption and effectiveness in addressing socio-technical challenges and enhancing collaboration with industry (e.g. Chen et al. 2021; Gallagher and Savage 2020). Notably, institutions in the Netherlands and Mexico, such as the Tecnológico de Monterrey and institutions in the 4TU Center of Engineering Education, have been pioneers in implementing these models (e.g. Doulougeri et al. 2022; Van den Beemt et al. 2022). In China, the transition from "Made in China" to "Created in China" highlights the importance of innovative skills in national development strategies, with higher education playing a pivotal role in fostering innovation through updated knowledge, innovative skills, and pedagogies (Zhou 2019). Universities are introducing courses like SPOC-based flip classrooms and CBL to address real-world challenges, aiming to enhance student participation and learning outcomes (Yilmaz, 2016). However, despite these efforts, the quality and impact of China's engineering education still lags behind some developed countries, like the Netherlands.

This comparative study aims to identify features of engineering mathematics education in both China and the Netherlands to provide insights into ways to improve the quality of education in China and further contribute to research in this area. Teachers' perceptions of their work and the programs supporting their learning can significantly impact the educational system they operate within (Liu & Goh, 2016). Therefore, examining teachers' and teaching assistants' perspectives can provide valuable insights into the characteristics of courses and the experiences of both students and teachers themselves. However, a review of the existing literature reveals a gap in research specifically addressing this area. Consequently, this study focuses on the teacher's and teaching assistants' perspective of innovative approaches where engineering mathematics is taught or applied.

2 METHODOLOGY

2.1 Learning Settings

The comparative study focuses on engineering education at TU/e in the Netherlands and HKUST(GZ) in China. The primary criteria for selecting schools and courses in China and the Netherlands were the following: 1. Preference for universities that emphasize innovation in science and technology. 2. Engineering courses that involve mathematical content or concepts and apply mathematical knowledge to problem-solving. 3. Courses aimed at engineering students. 4. Student-centered, problem-solving-oriented innovative engineering courses.

The courses considered here were the following:

TU/e, Netherlands

- Sociophysics (SP): This 8-week course is a challenge-based learning (CBL) course facilitated by applied physics faculty. It engages students in addressing real-world problems through teamwork, guided by a teaching assistant. Teams formulate an Essential Question (EQ) and navigate the project with Guiding Questions (GQs), Guiding Activities (GAs), and Guiding Resources (GRs), promoting interaction with lecturers in physics, psychology, and ethics. This is an elective course for students taking programs in applied physics.
- Data Challenge 3 (DC3): This 8-week course is a challenge-based learning (CBL) course. DC3 is the third in a series of Data Challenge courses designed to incrementally introduce students to working with real or semi-real data. Unlike the more structured assignments of DC1 and DC2, DC3 offers greater freedom in applying mathematical techniques, encouraging independent problem-solving. This is a compulsory course for students taking programs in data science.

HKUST(GZ), China

- Cross-disciplinary Design Thinking: This 3-month project-based learning (PBL) course focuses on user-collaborative design methods to create inclusive product solutions, covering design thinking, stakeholder research, and concept development through recursive user feedback. The course utilizes the Canvas platform for distributing lecture notes and materials, emphasizing a varied grading scheme that includes participation, assignments, a final presentation, and peer reviews instead of traditional examinations. This is a university wide course taken by students in different STEM disciplines.

Both courses at TU/e and the program at HKUST(GZ) demonstrate a commitment to fostering innovative thinking, interdisciplinary collaboration, and real-world problem-solving skills among engineering students.

2.2 Methods

Data collection

The research adopted a qualitative approach to data collection and analysis strategies. The study has been granted ethical approval by the Ethics Review Board at TU/e in July 2023. Participants in the study were teachers and teaching assistants involved in the courses described above as follows;

- Five teaching assistants (TAs) (three in TU/e, two in HKUST(GZ)): the graduate or upper-level students who support the lead teacher by assisting with instructional responsibilities, such as facilitating discussions and grading assignments.
- Three teachers (two in TU/e, one in HKUST(GZ)): the educational professional responsible for planning, implementing, and assessing lessons to facilitate students' learning and academic development.

Semi-structure interviews with teachers and tutors were conducted at the end of the courses in 2023. The same interview protocol was used for both institutions. The purpose of the interviews was to provide data to investigate the research questions on student experience and innovative courses from the teacher/tutor perspective. Each interviewee participated in an interview lasting at least one hour. The questions for teachers and TAs covered not only their perspectives on the course and their personal experiences within it but also their views on student and the students' learning experiences. The dataset generated from both institutions helps to build a general perspective of student learning in innovative engineering mathematics settings where both commonalities and differences are evident.

Data analysis

We employed thematic analysis (Braun & Clarke,2006) for data analysis of the orthographic transcription of participant's interviews. The steps followed in the analysis included the following: (1) familiarization with the data, (2) generating initial codes, (3) searching for themes, (4) reviewing themes (5) defining and naming themes, and (6) producing the report. In coding the data results of a previous literature review (e.g. Doulougeri et al. 2022; Kock et al. 2021) were used as concept-driven codes, and through an inductive process also new codes have been identified (marked with an asterisk) as presented in Table 1.

In the analytical phase, we systematically classified the dataset in alignment with the principal categories identified based on the research question and conceptual codes. This classification involved a meticulous coding process, whereby data were organized into predefined categories from the literature, leading to the identification of nuanced subcategories. Subsequently, an iterative examination of the dataset, guided by these categories and subcategories, facilitated the identification of interrelations among them. In addition, an inductive approach enabled the identification of data-driven categories not initially considered in the literature. This iterative analytical process not only underscored the dynamism inherent in the data but also significantly contributed to a theoretical elucidation of the findings, as mentioned by Walker & Myrick (2006).

3 RESULTS

Table 1 presents the result of the coding scheme and framework used to formulate the themes, including examples of instances where such code and category appear in the data set for each of the learning settings (identified with T for the Netherlands and H for China).

Table 1. Codes, categories, and examples identified in the data corpus. Examples coded starting with T refer to the Netherlands while examples starting with H refer to China.

Codes Category/-Subcategory	Codes Definition	Examples (Quotations are from interviewees)
1. Learning Objectives/Course Design		

- Knowledge growth	Development of interdisciplinary knowledge and application of mathematical knowledge	"…the course encourages students to venture beyond their current knowledge boundaries…" (TSP1-1) "This requires students to have broad knowledge and deep thinking abilities when approaching problems …"(HK2-1)
- Problem-solving and skills goals	Aspiration that students solve real-world and complex problems, personal growth, teamwork,…	"Witnessing students' creativity and their approach to problem-solving not only validates the collaborative effort but also…"(HK3-1) " The training primarily focused on general guidelines and specific problem-solving techniques, particularly for addressing conflicts or issues within team dynamics."(TDC2-1)
2. Feedback and Guidance/Course Design		
- Assessment	Types of assessments used e.g. peer assessment, presentation, prototyping, and grading by TAs and Teachers.	"Our assessments focus on the entire journey from problem comprehension to solution implementation…"(TDC1-1) " The evaluation criteria are shared at the beginning of the course, covering assignments, participation, and peer reviews, among others, to ensure transparency and understanding of expectations."(HK1-1)
- Support for Students	Different human resources of support for students i.e. Teachers, Teaching Assistants, Stakeholders	"… we facilitate additional funding, ensuring that students have access to the necessary resources for their projects…"(HK1-2)
- Organizer Role	Different actors take organizational roles i.e. course designer, external stakeholder, teacher, and monitors (teaching assistant).	" Facilitating and observing were the key aspects of my TA role, ensuring students progressed effectively while maintaining their autonomy. "(TDC2-2) " I see my role as a bridge for communication between teachers and students."(HK3-2)
3. Student Learning Experience		
- Transaction of the Problem by Students	Related to the process that students follow to solve a problem, starting with the definition of the problem and subsequently how they tackle the problem and including how they work together.	"… This diversity not only enhances the problem-solving process but also prepares students for the multifaceted nature of solving societal issues..."(TSP2-1)
- Resources Used for Problem-Solving	Physical resources supporting students problem-solving e.g. course materials, equipment (e.g. 3D printers), project budget, and also online resources.	"…if prototyping was needed, students would utilize resources like the school's 3D printing lab." (HK2-3)

- Students' Preparedness	Student academic background and prior knowledge of mathematics or other knowledge and skills.	" The absence of background in these areas is not seen as a hindrance but rather as an opportunity for growth…"(TSP1-3)
- Students' Performance	Associated to results of assessments e.g. grades, achievement of learning outcomes	"…motivation significantly influences one's engagement and appreciation of the course." (TDC2-3)
- Collaboration with Team Members/ Tutors/ Problem Owners	Students working together as a team including communication with others	" … foster a more inclusive and supportive group atmosphere, encouraging participation and collaboration from all members." (TSP2-2) " … this course emphasizes teamwork more strongly."(HK2-3)
- Learning Environment*	Course setting and use of the physical classroom including meeting rooms.	"… as a positive and supportive environment can foster collaboration, creativity, and open communication among students.(HK2-4)
- Challenges in the Learning Process*	Difficulties that students face when working in groups e.g. different levels of motivation, organization, and students from different backgrounds.	"…another group initially struggled with collaboration but improved as they became more accustomed to the course tools."(TSP2-3)

3.1 Comparative analysis between the Netherlands and China

In the comparative analysis of innovative engineering mathematics courses in two countries, the study delineates the overarching characteristics derived from interviews, coding, and textual analysis. The findings are structured into two main themes, reflecting the nuanced aspects of course design and student experience. For the case of TU/e, Netherlands we found the following:
Course Design:

1. Learning Objectives: Emphasis on integrating knowledge growth with problem-solving skills, specifically targeting complex problems within disciplinary contexts. Presents specific, detailed challenges within a disciplinary scope, necessitating a deep engagement with mathematical content.
2. Feedback and Guidance: Utilizes a holistic evaluation framework combining peer reviews, written assignments, teacher evaluations, and final presentations, supported by well-defined roles for teaching assistants and stakeholders. Teaching assistants play a critical role in guiding students through discussions and project work, with responsibility for specific groups.

Student Learning Experience:
Focuses on student autonomy in defining and tackling complex problems, supported by diverse and flexible resources. The learning environment promotes critical thinking, team collaboration, and iterative learning processes.

For the case of HKUST(GZ), China we found;
Course Design:

1. Learning Objectives: Favors a project-based, methodological learning approach across the university, particularly emphasizing design thinking. Focuses on broader, exploratory projects allowing for a wide range of mathematical applications and interdisciplinary integration
2. Feedback and Guidance: Employs a similar multifaceted evaluation strategy but with a broader scope for external collaboration and stakeholder engagement. Focuses on broader, exploratory projects allowing for a wide range of mathematical applications and interdisciplinary integration.

Student Learning Experience:
Encourages broad exploration and discovery, leveraging a "smart campus" for open-ended problem-solving with greater flexibility and autonomy. It's worth noting that the course offers project funding to facilitate the development of prototypes and other project outcomes within a budget.

In this analysis we observe that both institutions, in China and the Netherlands, prioritize innovative pedagogies that encourage autonomous knowledge growth (example TSP1-1 & HK2-1), and problem-solving skills (example HK3-1 & TDC2-1). Likewise, each institution employs a comprehensive evaluation framework that integrates various forms of feedback and guidance to holistically assess student learning (for example TDC1-1 & HK1-1). The importance of student autonomy and engagement is emphasized in both locations, with educational strategies tailored to foster a deep engagement with resources and collaborative problem-solving (for example TSP2-2 & HK2-3).

However, we also noticed differences in both themes. TU/e in the Netherlands adopts a challenge-based learning model with a focus on specific scientific disciplines, requiring deep mathematical engagement and presenting detailed challenges. In contrast, HKUST(GZ) in China utilizes a project-based learning framework, emphasizing design thinking and methodological learning with broader, more open-ended projects (see example HK2-5).

"*Smart campus" is a broad theme, but specific projects require students to focus and expand on their own.*" (HK2-5)

In addition, the role of teaching assistants varies significantly, with TU/e having TAs more involved in direct student guidance and project monitoring, whereas in HKUST(GZ) TAs provide broader, as-needed support (for example TDC2-2 & HK3-2). Finally, resource allocation and provision also differ between the two institutions, with HKUST(GZ) providing specific project funding, in contrast to TU/e, where direct funding for projects is not available (example HK1-2). Despite selected differences in the courses offered by the two universities, likely to be influenced by institutional settings, educational cultures, and backgrounds, there are still valuable lessons to be learned, in particular in relation to TA- approaches and project funding.

4 DISCUSSION

This comparative analysis of innovative engineering mathematics courses in the Netherlands and China demonstrates distinct educational approaches. The study contrasts TU/e's CBL, which emphasizes scientific discipline, with HKUST(GZ)'s PBL focused on design thinking. The findings underscore the importance of diverse teaching strategies, comprehensive assessment frameworks, and adaptable support systems to enhance student learning experiences in engineering education. While the study provides valuable insights into the flexibility and innovation within the field, its conclusions are specific to the unique contexts of TU/e and HKUST(GZ), indicating the difficulty of applying these findings universally across different educational cultures. Similarly, the findings here report only on the teacher perspective which is strongly linked to intended course design and delivery but do not reflect the enacted delivery as experienced by the students. This is an aspect that is important to investigate further to provide a broader picture of the use of these innovative approaches.

5 ACKNOWLEGEMENTS

The authors extend their gratitude to the faculty, staff, and teaching assistants of both institutions who participated in this research. We also thank our institutions for enabling this research and our colleagues for their support and feedback.

ABSTRACT

To foster a more inclusive learning environment, this study implements a quasi-experimental intervention at a university campus of KU Leuven in Belgium. Targeting first-year engineering students (N=88), the intervention aimed to stimulate students' pro-diversity mindset through a brief explanation and reflective assignment. Our hypothesis was that students exposed to this intervention would exhibit a higher pro-diversity mindset. Analysis of pre- and post-tests supported this hypothesis, revealing small, but significant differences in personal attitudes towards - and comfort levels with diversity between the experimental and control group. The findings highlight the importance of integrating diversity topics into engineering education to create a more inclusive learning environment and to emphasize education's role in promoting diversity and inclusivity within the engineering profession.

1 INTRODUCTION

Our rapidly evolving society is heavily influenced by the work of engineers, underscoring the critical importance of diversity in this field. A more diverse representation in engineering teams brings more individual perspectives and experiences together. This does not only enhance inclusivity in developing and implementing innovative solution to society's problems, but also improved problem-solving skills, and enhanced creative thinking, resulting in more ingenious solutions (Page 2017; Herring 2009). However, despite numerous efforts, the engineering field in Western society is still dominated by white men (Charles and Bradley 2009).

If we wish to stimulate a more diverse workforce, it is important to start with the engineering educational programmes. Underrepresented groups in engineering education, such as women and ethnic minorities, often struggle with a lack of sense of belonging, which can lead to higher dropout rates or different study choices in engineering and other educational fields in which women and minorities are underrepresented (Diekman, Clark, and Belanger 2019; Villa et al. 2020; González-Pérez et al. 2022). Previous efforts to overcome this lack of belonging, often include interventions targeting changes in minority groups themselves (Ong, Smith, and Ko 2018; Blosser 2020; Campbell-Montalvo et al. 2022). However, students belonging to a minority group should not bear sole responsibility for fitting in, rather, it is upon the educational system to foster an inclusive environment (Atadero et al. 2018; Moreu, Isenberg, and Brauer 2021).

A mindset that welcomes diversity will foster a more inclusive environment, benefiting the sense of belonging, and by extension the retention, of underrepresented groups, ultimately leading to a more creative workforce (Page 2017; Isaac, Kotluk, and Tormey 2023; Palid et al. 2023). Hence, a quasi-experimental study was set up at a campus of KU Leuven in Belgium, to stimulate first-year engineering technology students' pro-diversity mindset. An intervention was designed to cultivate an inclusive attitude, now, but also for their future careers. We hypothesized that students who are exposed to a brief lecture on the importance of diversity and inclusion in engineering, coupled with a reflective activity related to this, will have a higher pro-diversity mindset than students who are not exposed to this intervention.

This paper first explores the theoretical framework guiding the development of the pro-diversity mindset scale that we generated, followed by a method section detailing the development of the survey and the implementation of the intervention. The results demonstrate the impact of the intervention on participants' pro-diversity mindset. We conclude with a discussion on the implications and limitations of the study, and suggestions for future research on stimulating a pro-diversity mindset in engineering education and beyond.

2 THEORETICAL FRAMEWORK: THE PRO-DIVERSITY MINDSET SCALE

Although several studies address stimulating more positive attitudes, behaviour, or beliefs in the context of diversity, few studies use similar scales, as there is no established standardized scale on this topic (Kauff et al. 2019). However, the Miville-Guzman Universality Diversity Scale (M-GUDS) contributed significantly to assessing pro-diversity attitudes. This scale measures "*an attitude that recognizes and accepts the differences and similarities*" (Miville et al. 1999, 303), and encompasses three subscales: diversity of contact, relativistic appreciation, and sense of connection/comfort with differences (Kottke 2011).

While the M-GUDS is focussed on contact with people and cultures that are different than themselves, the Attitudes Toward Diverse Workgroup Scale (ADWS), is focused on working in diverse teams (Nakui, Paulus, and Van der Zee 2011). The study of Nakui, Paulus, and Van der Zee (2011) found that positive attitudes towards diversity were associated with enhanced creativity and qualitative outputs in diverse team settings. Additionally, the affective dimension of attitudes towards diversity contributed to improved psychological reactions within diverse group dynamics. Studies such as Maestas, Vaquera, and Zehr (2007) also found that supporting affirmative-action goals positively impact students' sense of belonging in diverse academic settings.

Interventions that are focussed on diversity attitudes, beliefs, or behaviours, are often linked to influencing social norms. For example, both Murrar, Campbell, and Brauer (2020), and Bennett and Sekaquaptewa (2014), tried to improve the inclusive social climate, by exposing students to pro-diversity attitudes of their peers at the university, or the university itself. This exposure led to a more positive attitude towards outgroups for non-minority students, while minority students reported an increased sense of belonging and had improved grades.

Several of these studies show the importance of a positive attitude towards diversity when it comes to creating a welcoming environment for minority students. However, many of the existing scales predominantly focus on the specific dimensions of diversity in terms of ethnicity or culture, thereby neglecting other identity dimensions such as gender, age, sexual orientation, or disability. Additionally, it is worth mentioning that most of these studies were conducted in the United States. This indicates a notable gap in European-based research, and even more so for research beyond western contexts, highlighting the need for additional research on this subject matter.

The current study aims to raise awareness among students about the importance of diversity and the consequences of its absence in a demographically relatively homogenous field such as engineering. By focussing on diversity in a broader sense, and recognizing the importance of diversity, we aim to create an environment that embraces differences.

3 METHODOLOGY

3.1 Study design

Context

The intervention took place at a campus of KU Leuven in Belgium and was integrated in a regular course entitled 'Enterprises and Ethics' (3 ECTS). The course consists of three subparts: lectures on enterprises and management (1.2 ECTS); lectures on ethics in engineering (1.2 ECTS); and a practical assignment called ‘day with an engineer’, including an introduction and two workshops (0.6 ECTS). The intervention was integrated in the subpart ‘day with an engineer’, as part of the assignment and first workshop. For their ‘day with an engineer’, the students were tasked with contacting an engineer to plan a day of job observation. Afterwards, students discussed their experiences in small self-organized groups and wrote a group paper about these experiences. The paper consisted of three parts: (1) an individual part, describing and reflecting on their job observation experience; (2) an ethics part, based on a group interview with one of the engineers; (3) a group conclusion, based on the group discussion and reflection.

The intervention

The goal of the current study was to develop an intervention by employing a quasi-experimental study design, using a cluster randomized controlled intervention. Self-organized teams were randomly assigned to the experimental or control group. The intervention was integrated in the subpart ‘day with an engineer’, where both the experimental group and control group received slightly different guidelines for the job observation assignment, as well as different information during the first workshop:

(1) The experimental group focused on the diversity within the engineer’s team and were tasked with checking whether the engineer’s company had inclusive policies. Additionally, the students were tasked with formulating some personal ideas on how they, as future engineers, could contribute to the diversity and inclusivity in the engineering field. During the first preparatory workshop, the students received instructions on the group paper, including a ten-minute explanation on diversity and inclusion. The explanation covered the meaning of diversity and inclusion, why these concepts are important, and what some examples are of the consequences of a lack of diversity in engineering (e.g., women are more likely to die in a car crash, and face recognition software is less likely to work properly for people with darker skin tones).

(2) The control group focused on the influence of external stakeholders on the work of the engineer and the company. They were tasked with formulating personal ideas on how to engage with these stakeholders. In the first preparatory workshop, they received instructions and some supplementary explanations regarding the concept of external stakeholders. However, the required information had already been covered in the preceding lectures on enterprises for the whole group.

The measurement

To assess the effect of the interventions all students were presented with two surveys, one to measure their pro-diversity mindset prior to the intervention (October 2023) and one at the end of the course, after the intervention (December 2023). The pre-test was conducted five weeks before the first workshop, and right before the students received their specific assignments. The pre-test was part of a broader survey, unrelated to the course. The post-test was conducted during the second workshop, three weeks after the first workshop and intervention. This post-test was presented as part of a feedback evaluation survey on the course.

The intervention and surveys were approved by the Social and Societal Ethics Committee, and Privacy and Ethical Review of KU Leuven (G-2022-5665). The students who participated in the surveys also gave consent to use their information for research purposes.

3.2 Participants

The pre- and post-test were administrated across three campuses, including the one where the intervention took place. This means that the pre-test was conducted with 236 participants in total, which is the dataset used for the survey development.

The intervention itself took place on one campus, where all 88 first-year engineering students enrolled in the course 'Enterprises and Ethics' participated. Out of these 88 students, 65 completed both the pre- and post-test (74% response rate), of which 31 students were in the experimental group, and 34 students were in the control group. Among the 65 participants who completed the surveys, 2 (2%) were female, and 7 (11%) had a migration background. The result section is based on the data of these 65 participants.

3.3 Survey development

Test phase

The survey development started by identifying four main themes relevant to a pro-diversity mindset through a literature study: (1) support for initiatives on promoting diversity (Maestas, Vaquera, and Zehr 2007); (2) the importance of working in diverse teams (Bennett and Sekaquaptewa 2014; Kauff et al. 2019); (3) the students' comfortableness with diversity (Miville et al. 1999); and (4) the enjoyment of- or interest in diversity (Murrar, Campbell, and Brauer 2020; Nakui, Paulus, and Van der Zee 2011). Drawing from this literature and additional discussions within the research team, 25 items were included in the study. The items were measured on a Likert scale from 1 (strongly disagree), to 7 (strongly agree) and tested during a pilot study with second-year engineering technology students (N=45). After evaluation, six items were removed due to excessive skewness, or failure to load on any of the factors in exploratory factor analysis (EFA). Additionally, the students gave feedback after conducting the survey, saying that they had difficulty with answering items such as '*to become a successful engineer, it is important to be able to work with diverse people*'; as they felt they could not know if this was true. Difficult to respond items were removed or rephrased to measure opinions. There were 15 items that remained in the survey.

Validating the scales

After the test phase, the 15 remaining items were used for the pre- and post-test. To incorporate the items in a broader study, the Likert scale was modified to a Likert scale from 1 (strongly disagree), to 5 (strongly agree). Additionally, some of the items were reformulated into a negative form. When conducting the survey with the first-year students in the context of the intervention, the positive and negative questions were alternated, to avoid acquiescence bias and socially desirable answers. To minimize the latter, we also added a message stating that a variety of opinions on the topic of diversity exists, and there are no right or wrong answers.

Since the pre-test was part of a broader survey, it was administered across multiple campuses, giving us a larger sample size to validate the scales (N=236). The Kaiser-Meyer-Olkin (KMO) test revealed a good level of intercorrelation among the variables (MSA = 0,81) and the Bartlett's test of sphericity further supported the dataset's appropriateness for factor analysis (chi-square = 980,17; df = 105; p-value = 0). The

EFA with a varimax rotation resulted in three coherent factors after cutting the loadings under 0.4 (cumulative var. = 39,4%; chi-square = 113.54; df = 63; p-value = 0,00) (Field, Miles, and Field 2012). Three items did not significantly load on any of the extracted factors, excluding them from further analysis. After exclusion, the above-mentioned tests were repeated, reaffirmed the findings.

The Cronbach's alpha coefficients indicated an acceptable consistency, after which the three pro-diversity mindset scales were computed based on the average scores of the items per factor. This, to ensure that no individual item disproportionately influenced the results based on one sample. An overview of the scales, their explanations, and an example item can be found in Table 1 *(Detailed scale items are available on request).*

Table 1: Overview of the created pro-diversity mindset scales

SCALE	EXPLANATION	EXAMPLE ITEM
Diversity Initiatives (α = 0,78)	Assesses students' opinion on whether initiatives to improve diversity are required.	Positive: Hiring a diverse team of teachers, should be a top priority of the Faculty of Engineering Technology.
Personal Attitudes (α = 0,73)	Assesses students' individual beliefs and perspectives concerning diversity, inclusion, and collaboration within academic environments.	Positive: I would like to learn more about the benefits of diversity in the engineering field.
Comfort (α = 0,74)	Assesses students' level of comfort and ease in interacting with peers from diverse backgrounds.	Negative: I feel most at ease with people who are similar to myself.

These scales are used to assess the effects of the intervention through a between-group comparison of both the individual mean scores on the post-test, as well as the change score (the difference between pre- and post-score). The Wilcoxon rank-sum test with alternative hypothesis 'greater', is employed to identify significant differences in a small sample size (n=65).

Notably, while these scales were validated within a larger cohort (n=236), it is imperative to acknowledge that the factor analysis resulted in divergent outcomes for the smaller intervention sample (N=88), accompanied by lower Cronbach's alpha coefficients (0,73; 0,59; 0,57 for the subscales respectively). Consequently, caution is advised in the interpretation of the results of the intervention.

4 RESULTS: A BETWEEN-GROUP COMPARISON

To evaluate the effectiveness of the intervention, this section examines the difference between the experimental (n=31) and control group (n=34). First, the post-test scores are compared to assess the difference between the groups in the pro-diversity mindset after the intervention. Second, we compare the change scores (the difference between pre- and post-score) between the groups. Importantly, the pre-test did not demonstrate any significant differences between the experimental and control group, suggesting successful random assignment.

Difference in pro-diversity mindset on the post-test

As shown in Table 2, the scale for *diversity initiatives* did not show any significant differences between the experimental and control group. For the scale *personal attitudes*, the experimental group displayed a small but significantly higher mean score (,.08) than the control group (2,94), with a small effect size (0,21). For the *comfort* scale, the experimental group displayed a mean score of 3.21, which is significantly higher than the control group (2,91), again with a small effect size (0,23).

Overall, there are small, but notable differences in mean scores between groups across the scales, with the experimental group consistently demonstrating higher mean scores compared to the control group.

Table 2: Descriptive data pro-diversity mindset scales: post-test

	Group	*N*	*Mean*	*SD*	*Wilcoxon (W)*	*P-value*	*Effect size*
Diversity Initiatives	Experimental	31	2,92	0,96	REF	REF	REF
	Control	34	2,88	0,70	581,5	0,24	0,09 (/)
Personal Attitudes	Experimental	31	3,08	0,70	REF	REF	REF
	Control	34	2,94	0,52	656,5	**0,04**	**0,21 (small)**
Comfort	Experimental	31	3,21	0,66	REF	REF	REF
	Control	34	2,91	0,50	664,5	**0,03**	**0,23 (small)**

Difference over time

While some differences between the groups were observed during the post-test, it is important to also look at the change in relation to the pre-test to give a more powerful test of actual change.

Figure 1 illustrates the changes in the pro-diversity mindset scales over an 8-week period. These visualisations reveal distinct patterns between groups in participants' pro-diversity mindset. Both the intervention and control group attach less importance to *diversity initiatives* at the post-test, compared to the pre-test. However, while the *personal attitudes* towards diversity declines over time for the control group, the decline for the experimental group is significantly smaller (p=0,03). Additionally, the students in the intervention group show an increased *comfort level* with diversity compared to the decreased observed in the control group (p=0,05).

	EXPERIMENT	CONTROL	EXPERIMENT	CONTROL	EXPERIMENT	CONTROL
N	31	34	31	34	31	34
MEAN CHANGE SCORE	-0,15	-0,12	-0,04	-0,18	0.10	-0.15
SD	0,7	0,64	0,68	0,38	0.75	0.48
W	512		673,5		655	
P	0,58		**0,03**		**0,05**	
EFFECT-SIZE	0,02 (/)		**0,24 (small)**		**0,21 (small)**	

Figure 1: Visual representation of the change between the pre- and post-test

5 DISCUSSION AND CONCLUSION

This study investigated the effectiveness of an intervention aimed at fostering a pro-diversity mindset among first-year engineering students. Results indicate that incorporating a brief lecture and a reflective activity on diversity and inclusion within the regular curriculum, positively influenced students' pro-diversity mindset on two of the three outcome variables. While the impact of the intervention was small, it revealed that the students in the experimental group, compared to the control group, (1) attached more importance to diversity and inclusion in their personal attitudes; (2) and showed a higher level of comfortness with diversity settings. However, there was no significant difference in attitude towards initiatives to increase diversity and inclusion on campus or at the university between both groups. This result was confirmed by both a between-group comparison of the individual mean scores on the post-test, and the change scores (the difference between pre- and post-score).

We can conclude that the short explanation and reflective exercise possibly prompted students to evaluate their attitudes regarding personal diversity mindset in a positive light, resulting in greater comfort and more favourable attitudes. The lack of impact on the attitude with regard to the importance of diversity initiatives can possibly be attributed to the focus on first-year students. Since these students are still acclimating to university life and may have limited familiarity with existing initiatives, and the need for additional initiatives (Johnson 2012).

It is important to keep in mind that this was a small-scale explorative study, however, the observed results are in line with previous research, which showed that pro-diversity attitudes, behaviours, and beliefs, can be impacted by stating social norms. We indeed similarly affected these norms by telling students about the importance of diversity in the engineering field (Bennett and Sekaquaptewa 2014; Murrar, Campbell, and Brauer 2020; Moreu, Isenberg, and Brauer 2021).

The limitations of this study must be acknowledged. Firstly, the small sample size restricts the generalizability of the findings. Secondly, the observed effects were modest and should be interpreted cautiously. To enhance effectiveness, further optimization, validation and reliability confirmation of survey items and additional data collection are necessary.

This opens possibilities for further research. Replicating the intervention and collecting additional data would refine both the intervention and pro-diversity mindset scales and offer deeper insights into related concepts like minority students' sense of belonging. Additionally, more fine-grained analyses as to for whom the intervention was effective, e.g., students who elaborated on the material more or those who followed instructions better, would allow firmer conclusions as to the effectiveness of the intervention. Testing the intervention in diverse settings would also offer valuable insights. For example, programmes or universities that have a more diverse student body, or programmes beyond engineering, like in social sciences. Lastly, longitudinal studies could explore the longer-term impact of pro-diversity mindset changes and their impact on students' academic and professional paths.

While it is crucial to recognize that there is not a one-size-fits-all solution to address a lack of diversity in engineering, it is also important to appreciate the possible power of small actions. The current study suggests that a single intervention can influence students' pro-diversity mindset. It is worth considering the potential impact of systematically integrating this vital topic throughout the curriculum. Such an approach could educate responsible engineers who celebrate and welcome differences by learning from diverse perspectives and experiences.

ABSTRACT

Mentorship is a reciprocal relationship where two or more people are guiding and supporting one another in growth and development. This can be in professional and

[1] *D. Christensen.*
darcie.christensen@mnsu.edu

career development support, role modeling, and/or psychosocial support. Peer mentorship is when this relationship exists between two people that are at a similar level. Peer mentorship is shown to be generally beneficial to both mentors and mentees. To better understand undergraduate engineering students' needs and perceptions of peer mentorship, a mixed-methods research instrument was utilized to retrieve these thoughts from students at a western institution of the United States early in the COVID-19 pandemic.

There were 223 complete responses to the survey and 144 of those students indicated that they did not currently have a peer mentor after being presented with a definition and examples of peer mentorship. These 144 students were then provided a definition of a need and were asked if they felt they needed a peer mentor with four options provided for answer: 1) Yes, I have a need for a peer mentor; 2) No, but I would like and could benefit from a peer mentor; 3) No; and 4) Not sure. Of those 144 students, 78 chose to elaborate on their answer. Those 78 are the responses that are analyzed in this study through qualitative coding means. From this analysis, recommendations for areas of focus are provided on what may be important when crafting a culture of mentorship in undergraduate engineering programs.

1 INTRODUCTION

1.1 Defining Mentorship & its Benefits

Mentorship can be defined as a reciprocal relationship in which a more knowledgeable or experienced person guides and supports the professional development or growth of another, which can be outside the typical co-worker, manager, fellow student relationship, or student-faculty relationship (Lawrence Berkeley National Laboratory 2023; National Academies of Sciences Engineering and Medicine 2019; Kram and Isabella 1985). In other words, mentorship goes above and beyond required training and professional communication to emphasize helping the individual grow and accomplish their goals (National Academies of Sciences Engineering and Medicine 2019). These relationships can either occur organically, which is known as informal mentorship, or be formed through an organization's mentorship program, which is known as formal mentorship (National Academies of Sciences Engineering and Medicine 2019). A mentoring experience provides professional and career development support, role modelling, and psychosocial support (National Academies of Sciences Engineering and Medicine 2019).

Peer mentorship is when two or more people at roughly the same level in some aspect (e.g., age, educational stage, career stage, or hierarchical level) have a mentor-mentee relationship (National Academies of Sciences Engineering and Medicine 2019; Kram and Isabella 1985; Collier 2017). Within peer mentoring, near peer mentoring (i.e., mentor and mentee are at same stage) and step-ahead peer mentoring (i.e., mentor was recently in the same developmental stage as the mentee and is now in the next stage) are the two main types, both of which can be an approachable, comfortable, and valuable alternative to traditional faculty mentorship models found in academic settings (Ensher, Thomas, and Murphy 2001; National Academies of Sciences Engineering and Medicine 2019).

Regardless of type, peer mentorship has been shown to have numerous benefits, especially for promoting academic success in college student populations (Collier 2017). A more comprehensive summary of the benefits of peer mentorship are available in Christensen (2021). Some examples are that peer mentorship provides a way for students to gain emotional competence, build friendship, connect to campus, increase confidence, decrease isolation, and increase satisfaction, performance, and retention for both mentors and mentees (Elegbe 2015; Colvin and Ashman 2010; National Academies of Sciences Engineering and Medicine 2019; Kiyama and Luca 2014; Ghosh and Reio 2013).

1.2 Status of Undergraduate Engineering Mentorship

Christensen (2021) undertook a formal search to determine the prominence of undergraduate engineering peer mentoring programs and found overall there was a lack of formalized research publications on the programmatic characteristics and the associated decision making when designing and facilitating peer mentorship in engineering programs. While programs do exist and tout generally positive outcomes, the documentation in scholarly research is primarily focused on evaluation of existent peer mentorship programs versus focusing on the why of the design of said programs. That reasoning on mentorship initiatives or program design as well as consideration of students' perceptions of needs and experiences with regard to peer mentorship was sparse, calling for the need of Christensen's (2021) design and validation of a mixed-methods instrument to begin considering factors that should be considered in peer mentorship facilitation.

The study for this paper focused on analysing student perspectives from one of the unexplored questions from Christensen's (2021) larger study. The exploration focuses on the perspectives of the need for and benefits of peer mentoring, specifically by those who currently do not have a peer mentor but may have had one in the past. Previous studies by Christensen have focused either on the whole population or just solely on the perspectives of those who do have a peer mentor (Christensen and Villanueva Alarcón 2023; Christensen, Villanueva Alarcón, and Corrigan 2023; Christensen 2021). By studying the student perspectives of those who do not currently have a peer mentor, design of peer mentoring efforts can be more intentional in delivering high quality support to a breadth of students.

2 METHODOLOGY

2.1 Instrument & Rationale

An exploratory mixed-methods instrument was used to collect data for this study. This data was collected from a previous study by Christensen (2021) to explore students' perceptions of the need for peer mentorship. Students first provided consent for the study. Then, they were asked to provide information regarding their experience with peer mentorship after being provided with a definition of peer mentorship with examples (Christensen 2021, 258–59). Depending on the students' responses to whether they have a peer mentor or not, they were presented with a set of questions regarding their peer mentoring needs. The analysis of this paper was focused on one of the questions posed to those who indicated they did not have a peer mentor. The question stated the following:

A **need** is defined as a **gap between your current state and your desired future state. Since you indicated you do not currently have a peer mentor, do you have a need for a peer mentor?** Please explain.

Students were able to answer in one of the following four ways: 1) Yes, I have a need for a peer mentor; 2) No, but I would like and could benefit from a peer mentor; 3) No; and 4) Not sure. In this current study, the researchers focused on the students who elaborated on their answers with open-ended responses.

2.2 Research Question

To better understand how to support students who don't currently have a peer mentor, the following research question was formed: **"What is the perceived need for peer mentors from those who don't currently have a peer mentor?"** It is recognized that for this particular study, just one question's multiple-choice and open-ended elaborations were utilized, which may be a limitation but serves as a foundation for future studies in this space.

2.3 Recruitment

Christensen (2021) describes all recruitment, survey participation, and IRB approval procedures. When asked, "Do you currently have a peer mentor?" 144 (65%) of the participants answered no. Of the 144 participants who answered no, 78 (54%) elaborated on their answers. Demographic information of the participants is shown in Table 1. While the demographic information is not utilized for comparative purposes in responses of this study, it is presented to show that the "no" participants were representatively similar with "all" participants; thus demographic differences were not relevant in this study.

Table 1. Demographic information for the 223 participants (abbreviated "part.") and the 79-participant subset who indicated they currently have a peer mentor (Christensen 2021).

Year in Undergraduate Engineering			**Declared Major**		
Category	**All Part.**	**"No" Part.**	**Category**	**All Part.**	**"No" Part.**
Freshman	19.7%	21.5%	Mechanical	55.6%	54.1%
Sophomore	13.0%	12.5%	Civil / Environmental	18%	21.5%
Junior	40.4%	41.0%	Biological	6.7%	4.9%
Senior	24.2%	23.6%	Electrical / Computer	15.7%	16.0%
Other	2.7%	1.4%	Intend to Pursue	0.9%	1.4%
			Other	3.1%	2.1%
Self-Identified Gender Identity			**Of Hispanic, Latinx, or Spanish Origin**		
Category	**All Part.**	**"No" Part.**	**Category**	**All Part.**	**"No" Part.**
Male	74.0%	75.0%	Yes	3.0%	2.1%
Female	23.8%	22.9%	No	90.0%	91.0%
Prefer not to	2.2%	2.1%	Prefer not to answer	7.0%	6.9%
First Generational Status			**Race**		
Category	**All Part.**	**"No" Part.**	**Category**	**All Part.**	**"No" Part.**

Yes	7.6%	8.3%	White	91.0%	90.3%
No	91.5%	91.0%	Person of Color	3.2%	2.8%
Prefer not to	0.9%	0.7%	Prefer not to answer	5.8%	6.9%

Note: *More options may have been included in the multiple-choice answers, only responses that participants chose are shown in the table. All other options can be found in Christensen* (2021)*. This table was adapted from Christensen et al.* (2022a; 2023).

2.4 Research Team Positionality

The research team aimed to be bias-free in their interpretations through the same procedures that are described in other previous publications surrounding the same instrument (Christensen and Villanueva Alarcón 2023; 2022a; 2022b; Christensen, Villanueva Alarcón, and Corrigan 2023). The first author on this current research team has extensive knowledge of this research topic due to her dissertation work on peer mentorship. The first author collected data from students at a Western institution in the United States, where she was completing graduate studies at the time of data collection. She has since transitioned into an assistant professor role at a different undergraduate engineering institution and remains heavily involved with mentorship. The three student researchers, which include one graduate and two undergraduate students, provided new perspectives in the realm of mentorship and desired to learn more about the need for peer mentorship in engineering education. The final author provides expertise in the realm of mentorship, teaching, and research to support analysis related to peer mentorship.

2.5 Qualitative Analysis Procedures

The qualitative analysis of student's open-ended elaborations on whether there is a need for peer mentorship was coded using a phenomenological approach, which is similar to past studies conducted by Christensen (Christensen 2021; Christensen and Villanueva Alarcón 2023; 2022a; 2022b; Christensen, Villanueva Alarcón, and Corrigan 2023). For the first round of coding, open, in-vivo coding methods (Saldaña 2013) were utilized by the first author. The 78 participant responses from those who chose to elaborate on their answer to "Do you have a need for a peer mentor?" were coded participant by participant. These participants came from the subset of the 144 students that answered no to "Do you currently have a peer mentor?".

Once the first round of coding was completed, coding categories were axially identified from the in-vivo codes to answer the research question (Saldaña 2013). For example, responses like "talk to another peer about struggles" (Participant 8) and "I had a reliable student to bounce ideas and topics off of" (Participant 23) were grouped under a coding category titled "Listener & Sounding Board". After creating these coding categories, two overarching thematic areas that addressed the research question emerged: "A mentor could provide…" and "I don't see a need for a mentor because…". This gave space for student responses to show both the benefits and influence a mentor could have as well as hesitations that students have relating to peer mentorship. The two overarching thematic areas and all associated coding categories were organized in a codebook. The additional three authors proceeded with an intercoder agreement utilizing the codebook to verify the coding directions, draw connections, and gain a consensus on the student responses. Multiple codes, regardless of what thematic area they came from, could be assigned to a single participant response. Through three rounds of coding and discussion, the original coding categories generated from the primary coder were reduced and refined from 16 categories to 11 categories. A consensus was reached on the two thematic areas and 11 coding categories by agreeing 100% on how they applied to each participant response.

3 RESULTS

Table 2 shows the results of the participant's responses to the question, "Since you indicated you do not currently have a peer mentor, do you have a need for a peer mentor? Please explain." As a reminder, this was only asked of the students who answered no to "Do you currently have a peer mentor?" While 12.8% of students did not feel they needed a peer mentor, 62.8% of participants in some way indicated they had the need or could recognize the benefit of a peer mentor as indicated by summing the first two rows of Table 2.

Table 2. Frequency count for 78 participant answers to "Since you indicated you do not currently have a peer mentor, do you have a need for a peer mentor? Please explain."

Response Category	Frequency
Yes, I have a need for a peer mentor	10 (12.8%)
No, but I would like and could benefit from a peer mentor	39 (50.0%)
No	10 (12.8%)
Not sure	19 (24.4%)

The following sections will describe and share examples of student responses in the two thematic areas for each of the 11 coding categories. It should be noted that any participant quotes that are used in the descriptions are direct copies of student responses, and any spelling or grammatical errors that were present are preserved.

3.1 "A mentor could provide…"

The codes and frequencies displayed in Table 3 give an idea of the areas where students see a need that could be addressed with a peer mentor.

Table 3. Coding scheme and frequency counts for those instances when the 78 students stated something that aligned with "A mentor could provide…"

Code #	Code	Frequency
1	Guidance in Pathway, Load Management, & Decisions through Experience, Advice, & Resource Sharing	18 (23.1%)
2	Accountability & Motivation	5 (6.4%)
3	A Support System *(e.g., listening ear, sounding board, friend, relatability, belonging, etc.)*	9 (11.5%)
4	General Positive Influence (*no specifics given, but the response is positive for need of a mentor)*	8 (10.3%)

Representative quotes from each of these sub-codes are shown in Table 4.

Table 4. Representative quotes relating to each of the sub-codes represented in Table 3.

Code #	Representative Quote

1	• I would love a mentor to help a little in the last year of school and research opportunities / club involvement / lab opportunities. (Participant 7) • I would really appreciate having…someone who is farther ahead and can give me an idea what to look out for, show me the ropes, if you will. (Participant 9) • I wouldn't mind having someone that could warn me "hey, this class sucks." (Participant 13) • A lot of engineering homework help is easier understood when it's coming from a person rather than online. (Participant 41) • It would be nice to have someone else have ideas I have not thought of, and advice to help me reach my current goals. (Participant 44) • I think someone to help me figure out where to apply to for internships and jobs would be great. (Participant 63)
2	• It would help me stay on track and keep motivated for the upcoming semesters. (Participant 3) • As I start taking harder classes it would be nice to have someone to help keep me on pace and be able to study with. (Participant 19)
3	• It would be nice to have someone to talk to who has been in a similar situation to me so that I feel like I am not alone in my path. (Participant 5) • I would really appreciate having someone that I can bounce questions off of as we are figuring out how to understand the content within our engineering field. (Participant 9) • A peer mentor is a way to develop a support system and friendship with others who have similar goals as you have. (Participant 30) • It would help me feel like I belong. (Participant 40)
4	• I think everyone needs a mentor in some form. (Participant 2) • I feel like having a peer mentor can only be beneficial. (Participant 6) • Peer mentor would be nice. (Participant 15)

3.2 "I don't see a need for a mentor because…"

The codes and frequencies displayed in Table 5 give a scope of the reasoning why students may not feel that they need a peer mentor.

Table 5. Coding scheme and frequency counts for those instances when the 78 students stated something that aligned with "I don't see a need for a mentor because…"

Code #	Code	Frequency
5	I'm not interested or don't see a need/benefit right now	6 (7.7%)
6	I don't need one, but I can see the benefit/want one *(e.g., not currently struggling but could be at some point)*	22 (28.2)
7	I don't really know what I'm missing out on or don't understand the benefit or process	5 (6.4%)

8	Wrong Timing *(e.g. too late/graduating, don't have time, ready to shift to helping, past being peer mentee, etc.)*	17 (21.8%)
9	I already have a support system	5 (6.4%)
10	I work best on my own or can figure it out myself	4 (5.1%)
11	I don't have access to the peer mentor I need or prefer	3 (3.8%)

Representative quotes from each of these sub-codes are shown in Table 6.

Table 6. Representative quotes relating to each of the sub-codes represented in Table 5.

Code #	Representative Quote
5	• not really interesting in finding someone who is a "mentor". (Participant 50) • I feel like I am doing fine as is. (Participant 67) • I am not sure If a peer mentor would help me more than the other resources already established. (Participant 72)
6	• I don't "need" a perr mentor. If I do not have one I will still be successful but having one would help me enjoy college more. (Participant 34) • I don't feel like I have a need for one, but I do admit it would be helpful. (Participant 39) • No doubt a mentor would help and im sure im missing critical information because i dont have one. Nevertheless im still going to find a way to succeed. (Participant 47) • I believe that peer mentors are certainly beneficial, but are by no means essential for success. (Participant 49)
7	• I am not sure because I am not fully struggling yet and don't know if I really need a mentor. (Participant 62) • I don't know enough about the process to be sure if I need one. I would be interested in trying it out, though. (Participant 76)
8	• I think it would also be good for me to help others. (Participant 11) • Not that I think they wouldn't be helpful but at this point I'm in my senior year, getting ready to graduate and start a career. This probably would have been more applicable prior to now. (Participant 53) • It seems like a great and helpful idea, I just don't know what kind of commitment and time I have towards something like this. (Participant 60)
9	• I have someone I consider a mentor (just not necessarily a peer since he is in industry) who I can turn to when I have questions or need advice, so I don't have the need currently. (Participant 54) • I talked to some friends and learned some from them, though I wouldn't consider them to be peer mentors. (Participant 56) • Also I have a brother who graduated as an engineer so I can ask him for advice. (Participant 59)

	• I have been going through engineering relaying on help from my friends and people that are in my classes. (Participant 75)
10	• Most of the time I can find the answers on my own. (Participant 17) • Although I can see the benefit of a peer mentor, I prefer to work by myself. (Participant 38)
11	• I don't really like formal peer mentors. (Participant 21) • I prefer someone much further down the road that has a greater hindsight perspective (Participant 51)

4 DISCUSSION & RECOMMENDATIONS

Based on the results of this study, three overarching recommendations arose with regard to peer mentorship efforts from those who do not currently have a peer mentor, but it may also be able to apply generally to undergraduate engineering peer mentorship efforts.

First, when combined, codes 1 to 4 and 6 evidence that 79.5% of participants mentioned recognizing some benefit of peer mentorship even though only 10 of the participants originally stated "Yes, I have a need for a peer mentor". This may be directly correlated to a gap recognized by the student or a recognition of the potential for improvement of experience as mentors are involved. This emphasizes that the majority of students recognize the importance of having someone involved in their undergraduate engineering education. That being said, all of these students don't currently have peer mentors. While many students may find great value in a peer mentor, they often do not have the resources or the knowledge to reach out and find one, and many just do not know where to start, which is known to disproportionally affect minoritized students (National Academies of Sciences Engineering and Medicine 2019), though in this study, the "no" participants were a demographically similar subset of the total population. **This speaks to the necessary efforts to create cultures and programmatic efforts in undergraduate engineering programs to help students find the peer mentors they need.** While scholarly literature does generally share that mentoring outcomes are positive (as indicated in the introduction), simply talking about its importance without taking action to provide access and opportunity to all students is not enough.

This is also a note that a friend can be a suitable support system. As stated by some of the participants, many students may already have all the mentorship they need, even if they don't recognize those friends formally as mentors. This means that **undergraduate engineering programs can help create connections in various forms**. This could include student life activities, formal mentorship programs, alumni involvement, study group creation, etc.

Second, it is surprising that 24.4% of the participants were not sure whether they needed a peer mentor or not, which further affirms the importance of not just evaluating outcomes when a student has a mentor but also determining the needs of those who may not fully understand or have access to mentoring (Christensen 2021). While many students showed a drive to overcome challenges by themselves, they may not understand the benefits they are missing out on when collaborating with others. **This speaks to the necessary effort to inform all students of the**

importance of not navigating their educational pathway on their own. This can come with early and intentional effort in first-year programs, which has been shown to be helpful for multiple reasons (Budny, Paul, and Newborg 2010; Meyers et al. 2010), as well as through continual efforts in all years of engineering education. Being a mentor in those later years of undergraduate engineering years can positively affect student experience and growth (Good, Halpin, and Halpin 2000). Students need to be informed of both the importance and mechanisms of mentorship and then provided with the spaces to make that happen as both mentors and mentees.

Lastly, there are strong areas of guidance in how to train mentors given by what students said they do need in a mentor, which was shown in sub-codes 1 to 3. **These areas can help in knowing how to prepare potential mentors and leaders in the roles they may need to fill throughout their mentoring experience in undergraduate engineering programs to help mentees.** Students may be intimidated by what will be expected of them as a peer mentor. Training in these areas will help them to feel better prepared in knowing what to expect in their mentoring relationships and how to handle a variety of situations (Garringer et al. 2015; Eby et al. 2010).

Overall, the responses given by students who currently do not have a peer mentor for various reasons can help undergraduate engineering programs, faculty, advisors, supporting staff, etc., know what efforts can be made to help students be supported on their engineering journey.

ABSTRACT

To create more equitable engineering education, it is essential to understand the adversity faced by students due to their socio-economic status; the impact it has on their academic journey, and how to adapt to overcome it. An aim of the EUniWell "Maximising Academic and Social Outcomes in Engineering Education" (MASOEE) project is to understand student disadvantage and its effect on engineering skill and identity development across 3 European universities. This multiphase, mixed-method research explored the association between adversity through parental education and adaptability through academic self-concept, utilising data from a structured questionnaire and 1-to-1 interviews. We found that students who are first generation in their family to attend university is a common indicator of adversity, and that, on average, their self-concept specific academic skills – communication, networking, and entrepreneurial resourcefulness – is lower compared to other students. The thematic analysis of the 1-to-1 interviews reveals 5 recurrent themes when discussing academic resilience and success with students: social factors, networking, extra-curricular skills development, skill confidence and improvement, and engineering identity fluidity. The findings add to previous research, and the need to develop targeted interventions around these uncovered themes.

1 INTRODUCTION

1.1 Academic resilience

Academic resilience refers to student's capacity to achieve success despite experiencing disadvantage. Within this project we are specifically examining the impact of a student's socio-economic status (SES) through parental education level, which is one of many possible factors affecting resilience. The Organisation for Economic Co-operation and Development reports SES as correlated with academic outcomes, arguing for more equitable higher education (OECD 2018). Students with challenging personal circumstances are less likely to succeed, motivating large-scale international studies to explore this variability and close the attainment gap. Academic resilience is conceptualised in the literature as adversity - representing the level of disadvantage faced by a student, and adaptation - their ability to overcome adversity (Ye, Strietholt, and Blömeke 2021).

1.2 Adversity: disadvantage and social-economic status

Adversity and disadvantage are terms which are used interchangeably in this study, the former relating it to the wider literature of academic resilience, where adversity can also include Diversity, Equality, and Inclusion (DEI) and attitudinal issues like personality traits. Disadvantage is frequently used to describe the narrower consideration of parental and home circumstance. There are many common approaches used by universities to identify such disadvantage. For example, in the UK, universities consider family income and home postcode as reliable predictors of educational outcomes (Jerrim 2020). Furthermore, during the COVID-19 pandemic, Italian families' access to free school meal programs and parental education levels were used to identified disadvantaged students (Gross, Francesconi, and Agostini 2021). Consideration is also given to the impact the status first generation – neither parent attended university - has on student achievement, with (Martin et al. 2020) noting that there are some differences in family support for first generation students who specified a more emotional support system from their families, in contrast to a more academic specific support experienced by those from families with higher education backgrounds. Moreover, a study from Sweden found that parental education not only influences academic achievement, but also the type of education, leading to student segregation (Hällsten and Thaning 2018). Spiegler and Bednarek (2013) also highlighted that within their USA first-generation students, a higher proportion were from lower-income backgrounds and were seemingly less prepared for university level education. Networks can help with being or becoming prepared, particularly in terms of career advice from those they meet in a professional capacity and that some first-generation students face difficulties in identifying and accessing resources available through these networks (Martin et al. 2020) . Finally, differences in academic achievement are attributed to whether a student learns in their native language with those who do not scoring lower (Schnepf 2007). These non-exhaustive examples suggest that despite differences in how disadvantage is identified in education across the European context, there is sufficient commonality to permit a small scale-study of engineering faculties using a shared measure of adversity based on disadvantage.

1.3 Adaptation: academic self-concept and identity

Academic self-concept (ASC) is a helpful measure for the second concept of academic resilience - adaptation. Unlike objective measures of cognition such as test scores and grades, ASC is considered a subjective, non-cognitive measure that reflects a student's self-evaluation of their academic encompassing a student's reflections on their learning and skills abilities (Ye, Strietholt, and Blömeke 2021). ASC has been shown as a reliable predictor of academic retention and progression (Marsh and O'Mara 2008). An important component of ASC is engineering identity - a concept which captures the self-perception and external perception of students in relation to the engineering profession. In a synthesis of work on engineering identity, (Patrick and Borrego 2016) draw parallels to work in science education, noting that the strength identity correlates with performance, recognition, and competence (Carlone and Johnson 2007). Furthermore, identity is linked to persistence, motivation, and the support structures that underpin informed career decisions (Lucas, Claxton, and Hanson 2014). Identity is heterogeneous; the engineer's skill set has diversified beyond technical expertise into other skills. Consequently, emerging identities are associated with the growing necessity for entrepreneurial, sustainability, and professional competencies in modern engineers (Berge, Silfver, and Danielsson 2019). In response, the educator's curriculum development has been facilitated by detailed skill inventories related to these identities, and accreditation bodies have integrated these skill sets to assure quality e.g. (Ward et al. 2021). Furthermore, students use these inventories to reflect on their skill acquisition. Out of the countless skill inventories published, three are used in this work to represent the emergence of corresponding engineering identities associated with entrepreneurial, professional, and sustainability competencies; the EU EntreComp framework (Bacigalupo et al., 2016), the WEF 21st century professional skills (Soffel 2016), and EU GreenComp (Bianchi, Pisiotis, and Cabrera Giraldez 2022) respectively.

1.4 Research aims, objectives, and questions

The "Maximising Academic and Social Outcomes in Engineering Education" (MASOEE) project is an ERASMUS+ University alliance funded project, conducted across three European universities (Cooke et al. 2023). The project's aims to share and develop best practice for skills teaching with ethical approval granted at all institutes. This part of the project explores the relationship between a students' parental education background - SES - and their self-perception as engineers - ASC. In considering academic resilience and its two key elements adversity and adaptation, three research questions are posited:

1. Which common metrics can be used to measure academic resilience (SES and ASC) across the 3 institutions?
2. What is the relationship between SES, ASC, and engineering identity using these metrics?
3. Which methods do students employ to advance their ASC, and how is this progression influenced by SES considerations?

Instead of the more objective common measure of test scores to measure outcome, this work focuses on students' perceptions of themselves as engineers i.e. their ASC. This includes how students rate themselves against the contemporary engineering skill set, as well as how they identify as engineers. This approach is motivated by two reasons: The well-established correlation between SES and academic performance offers limited novelty for further research, and there are inherent challenges in comparing scores across varying year groups, programmes, and institutions. Furthermore, the importance of self-perception of skills and professional identity formation are gaining traction as key themes in engineering education research and carry potential for gaining a holistic understanding of student learning and future success (Lindsay et al. 2023).

2 RESEARCH METHODOLOGY

2.1 Measures of adversity (RQ1)

Partners reported challenges in obtaining SES statistics for student cohorts; enrolment data was typically only available from centralised university functions rather than at faculty level, and its quality and type varied. Consequently, there were 5 types of disadvantage measure reported by partners (Table 1) which are used within faculty, with the number of parents who attended university common to all.

Table 1. SES measures in common use in engineering faculties

Measure of disadvantage	University partner		
	Birmingham(UK)	Linnaeus(Sweden)	Florence(Italy)
Free school meals (FSM)	✓	×	×
Home postcode	✓	×	✓
Parents attend university	✓	✓	✓
First language	×	✓	✓
Government scholarship	×	×	✓

2.2 Multi-lingual survey (RQ2 data collection)

A 25-question online survey was designed to capture students' SES and ASC. To support access and reduce the risk of misinterpretation, the survey was written in each partner's primary language. For SES, it asked if one or both parents attended university. Although there is some variation in the preferred definition of first-generation, for the purpose of this study the definition is based on neither parent attending parent attending higher level education (Spiegler and Bednarek 2013). Six questions captured demographic information including year of study, foundation/pre year, discipline, countries of birth and secondary school education. ASC had 17 Likert-scale quantitative questions measured self-perception of 4 engineering identities proposed in (Berge, Silfver, and Danielsson 2019) 'Traditional engineer'; 'Self-made engineer'; 'Professional engineer'; 'Ethical engineer', with 13 skill levels covering these identities as outlined in section 1.3. More qualitative aspects of ASC were explored using 3 free-text questions. A purposive sampling method (Berndt 2020; Taherdoost 2016) was used to allow the research to target specific engineering student populations as to ensure adequate representation. As advised by Mann (2003, 56), to improve response rates, guidance e-mails were sent out to students with the survey link on a regular basis, with follow up e-mails sent from the team to specific students who met the criteria.

2.3 Interviews (RQ2/RQ3 data collection)

Online interviews with students were semi-structured with prompts based on the DICE approach (descriptive, idiographic, clarifying, and explanatory) (Robinson

2023). The students all signed a letter of participation explaining informed consent (BERA, 2018). This information was repeated verbally at the beginning of each interview, with verbal clarification of agreement received from each participant. All interviews were automatically transcribed, checked, then anonymised in preparation for thematic analysis, which followed six specific steps advised in (Braun and Clarke 2006; Maguire and Delahunt 2017): 1) Data Familiarisation, 2) Initial code generation, 3) Theme search, 4) Theme review, 5) Define themes, 6) Write up. Eight initial codes were generated, and 14 themes identified. Self-selection sampling (Berndt, 2020) was initially used to recruit interviewees who had completed the survey and voluntarily left contact details to take part. However, the availability of respondents who volunteered was lower than expected, and consequently a second sampling method – convenience sampling (Taherdoost 2016) - was used, where the recruited students were identified by faculty programme leads. This introduced representation bias; the interviewees were mostly from later year groups and restricted access to a more representative sample of students. To offset these bias concerns, participants' responses were contextualised within the initial participant criteria such as the year group. As a result, the interviews aimed to explore survey results rather than provide generalisable findings (Florczak 2022).

3 RESULTS

3.1 Survey: The relationship between SES and ASC

The survey was completed by 186 students across the 3 partners: 53, 71, and 59 from Birmingham, Florence and Linnaeus respectively. Only the former two obtained parental background information due to unresolved ethical review issues at the time of data capture. Consequently, 50, 32, and 36 students reported none, one, or both parents attended university respectively (n=124). Whilst these sample counts are different, they are sufficiently large (n≥30) for the central limit theorem to hold and increase the confidence that each group is normally sampled. Fig. 1 compares the average student self-identified skill level for each of the 13 skills. The results indicate that first generation students rate themselves lower for 7 of the skills. In contrast, students with both parents having a university education rate higher for 10 of the skills. These findings suggest that there is a correlation between SES and ASC when measured in this way. For students who have only one parent with a university education, there appears to be, on average, less variation between skills. The largest statistically significant ($p<0.5$) differences between groups were for skills in communication and networking, entrepreneurial resourcefulness, and social-technical responsibility. Parents educational background shows a weak positive correlation with other skills, although the relationship was generally not statistically significant as illustrated in Fig. 1 by the overlapping error bars. Students were grouped according to which of the four engineering identities they primarily related to. There were no statistically significant ($p<0.5$) differences found as to whether parental background correlates with preferred engineering identity. However, further exploration comparing the strongest identity with individual skills (Fig. 2) reveals some trends; communication and networking skills were rated lowest in 3 of the 4 identities, while systems thinking was similarly rated highest.

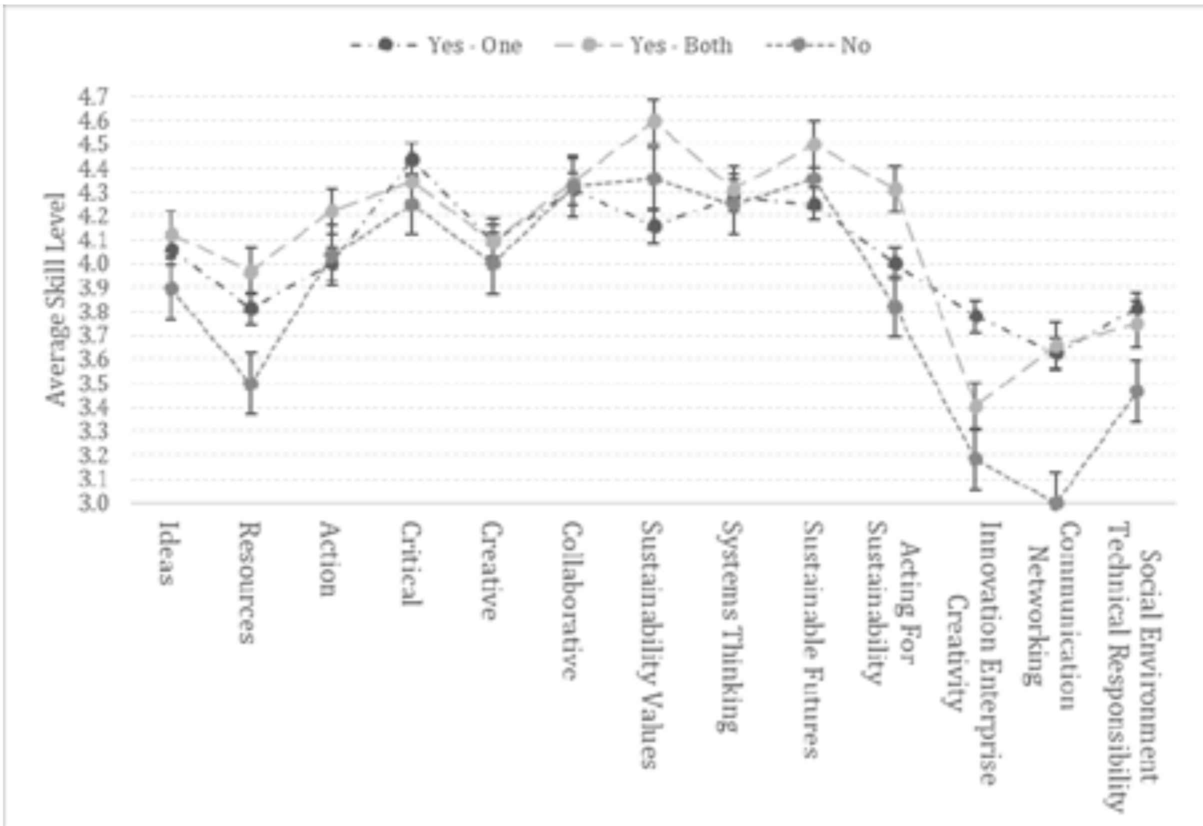

Figure 1 ASC (average self-rating of skill) compared to SES (parents attended university) (n=124)

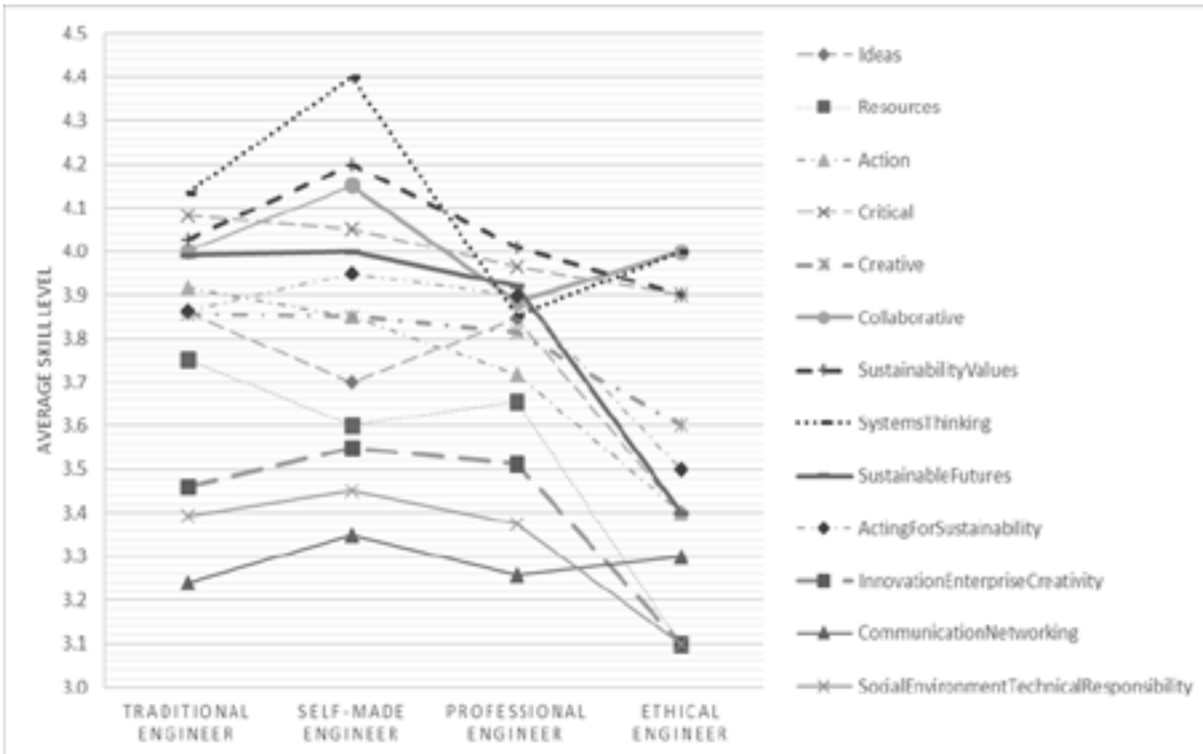

Figure 2 ASC (average self-rating of skill) compared to preferred identity (n=186)

3.2 Interviews: Thematic insights

Seven students were interviewed who are labelled P1-P7 respectively. Interviewees were a mixture of first-generation students (P1, P5, and P6) and those from a family with a higher education background. The thematic analysis generated 14 themes in 4 broad areas: Skills (balance, change, effectiveness of teaching & external skill development, Hard vs Soft, implicit or explicit, improvement, university support), Social factors (work, parents educational background), Networking, and Identity. Five key themes are explored below.

Theme 1: Social factors: parents educational background

40% of students in the survey disclosed that neither parent attended university. P1 and P5 discussed the impact of attending university as first-generation. P1 acknowledged friends who had higher educated parents had advantage: *"… some of my housemates … know what they're getting themselves into … I can't really ask my parents for help… I can't really ask… anyone…" (P1)*. The feeling of uncertainty experienced by P1 is not uncommon e.g. Spiegler and Bednarek (2013). This lack of preparedness is also seen by P5 who said that the lack of guidance impacted their organisation but there was also a higher expectation placed on them: *"my mom…she always told me you have to study more, more and more so you can change your life" (P5),* which might be considered an advantage.

Theme 2: Networking

The importance of networking, as highlighted by Martin et al. (2020) was something also seen during the interviews, with examples shared of the impact networking has had, with P6 sharing their experience of gaining work experience. Additionally, networking is acknowledged as key area of support for disadvantaged SES students (APPG 2017) and this was evident in P1's reflections. P6 – also a first-generation student - reflected on their ability to network through external opportunities, such as sports and student associations, as well as internships which underscores the importance of universities providing access to networking opportunities in the form of practical partner-based projects: *"I've actually worked at a company last summer that I'm going back to this summer and that connection was established during a project course that we had" (P6).*

Theme 3: Extra-curricular skills development

During the interviews, there were discussions around the development of skills independently of, and external to, the university. For some, prior opportunities helped them to develop leadership and team skills: *"I used to do the cadets when I was younger, so that's … helped my leadership … I'm not sure …I would be as effective at uni as I am now" (P1).* P1 believed that the university left *"it to the person to…grow"* the professional skills needed. P2 also felt that it was important to develop professional skills independently of the university, reflecting on joining a boat rowing club. When asked to expand on how this supported skills development, they said feelings of resilience, discipline, and teamwork grew as they trained.

Theme 4: Skill confidence and improvement

Confidence was a topic discussed throughout the interviews as a quality they needed to develop. This differed for each student: P2, P5, and P6 felt the need to develop their ability to communicate effectively, hoping to work on their language skills, supporting the findings of (Obilor 2019) that confidence is a by-product of good communication. Students also identified confidence in leadership and teamwork as desirable, congruent with employer's top desired skills for graduates (Stewart and Wall (2016). P4 expressed the need to develop teamwork skills through extra project work. P1 noted reservations to lead if someone else stepped forward: *"The confidence to lead I think is quite a big one … I'm not sure if I'm good enough." (P1)*

Theme 5: Engineering identity fluidity

Establishing a professional engineer identity is considered to persevere in studying and working in engineering(Lakin et al. 2020). This influence was evident, with all interviewees seeing themselves as a mixture of 2 or more of the 4 engineering identities presented in the study. Most interviewees conveyed that identity as a concept was fluid, anticipating it to evolve alongside career stages e.g. student, young professional, management. P1 shared feelings of uncertainty in terms of feeling like an engineer: *"I think up until the start of this year, I didn't really feel like an engineer. I felt like I was just a student learning engineering."*. P2 and P5 reflected on the importance of the individual personality on the development of an engineer's identity: *"I'm thinking about like it's determined by kind of your personality too, right? … I think nothing is static" (P5)*. P6 conveyed uncertainty over their engineering identity: *"My …kind of engineering is not so defined yet …I need to… maybe understand and do many other things … to finally understand who I am" (P6).*

4 SUMMARY AND DISCUSSION

Several studies show that parental education level affects achievement, type of study, and preparedness (Martin et al. 2020; Hällsten and Thaning 2018;Spiegler and Bednarek 2013). This study narrowed the focus of academic resilience to adversity caused by being a first-generation student, and to adaptability measured through academic self-concept and identity. As expected, and in-line with previous findings, first-generation students spoke of feeling underconfident, uncertain, and ill-prepared in comparison to those with university-educated parents. One interesting result is that lower self-concept of skills in communication, networking and resourcefulness differentiate this cohort, suggesting a targeted approach to closing gaps. An unanticipated finding is that notions of preferred engineering identity do not correlate with parental background or students' self-concept of their underlying skills, underlining the need to exercise caution in future research when characterising students as disadvantaged. A further interesting observation is that students were more likely to conceptualise identity aligned to career status and seniority rather than the entrepreneurial, professional and ecological orientations presented to them in the survey. A limitation of this study is compromises to sampling introduced biases affecting result generalisation. Nevertheless, this contribution highlights the value of applying wider discourse on academic resilience to the engineering education context.

Keywords: *First-generation students, degree choices, study duration, postgraduate education, engineering education*

ABSTRACT

First-generation students (FGS) are traditionally underrepresented in higher education, including engineering education. To ensure equity in access and success in engineering, and thereby ensure that we educate responsible engineers who come from a diversity of backgrounds, we need to understand the unique challenges faced by these students. Using data collected from a survey that was sent to the alumni of our institution we explored differences between FSG and continuing-generation students (CGS) with respect to their choice of postgraduate degrees and time taken for completion of postgraduate education. Our data showed that FGS prefer classical engineering postgraduate degrees, and the difference between their choices is starkest for the domestic alumni. We also found that FGS take longer to

[1] *J. de Lima*
joelyn.delima@epfl.ch

complete their postgraduate education. We conclude by situating our findings in existing literature and discussing possible explanations for the trends we observed.

1 INTRODUCTION

Addressing the diversity of hurdles that lie in the path to building socially and environmentally sustainable societies (United Nations [UN] 2015), requires a diversity of perspectives and expertises (The United Nations Educational, Scientific and Cultural Organization [UNESCO] 2021; Lucena and Schneider 2008). Therefore, to ensure that the engineering field is populated with responsible engineers who are representative of the rich diversity of experiences and perspectives, we need to consider potential barriers to access and success. One of the populations that has traditionally faced issues with both access and success is first-generation students (Seymour and Hunter 2019; National Academies of Sciences, Engineering, and Medicine [NASEM] 2016).

The term "first-generation students" (FGS) refers to individuals entering higher education whose parents did not complete a higher education degree (Council for Opportunity in Education [COE], n.d.). This concept originated in the United States as a response to the changing demographics of students entering higher education, including an increase in women, racial and ethnic diversity, and students from low-income backgrounds (Levine and Associates 1989). When considering demographics (socioeconomic status, ethnicity, migration background, gender etc) these students are not homogeneous (Cho et al. 2008), however, they are underrepresented in postsecondary educational institutions (Cataldi et al. 2018) and face some common challenges.

1.1 University preparation and transition is challenging for first-generation students

FGS face disadvantages compared to continuing-generation students (CGS), including lower levels of knowledge about higher education and family support (York-Anderson and Bowman 1991), lower expectations of academic achievement (Stage and Hossler 1989), and coming from typically lower socio-economic backgrounds (Bui 2002; Kutty 2014). Additionally, their academic preparation is also less rigorous (Warburton et al. 2001). During their transition from secondary education to post-secondary education, in addition to the challenges faced by CGS, these FGS also face social and cultural challenges (London 1989; Terenzini et al. 1994).

1.2 University experiences are different for first-generation students

The variables that influence first generation students' choice of higher educational institution also vary from that of continuing students. With FGS there is much less active “choosing” of institutions (Reay et al. 2009). These choices often revolve around prioritising practical concerns such as financial (Cho et al. 2008; Bui 2002) and geographical (Reay et al. 2001), as well as psychosocial characteristics of the campus including safety, social climate, and social support (Cho et al. 2008; Kutty 2014).

Multiple studies have also shown that first-generation students have higher attrition rates in higher education (Ishitani 2006; Chen 2005; Soria and Stebleton 2012; Billson and Terry 1982; Cataldi et al. 2018). A French longitudinal study on the academic success of over 7.2 million students, of which 3.05 million were FGS, revealed that they are up to twice less likely to succeed in their first year and in university scientific fields as compared to their CGS counterparts (Kasatkina et al. 2020).

Enrolment in programmes differs in these two populations with first-generation students less likely to be enrolled in STEM majors in Europe (Isserstedt et al. 2010; Kasatkina et al. 2020). In their literature review which explored more than 70 research articles and international reports on FGS, Spiegler and Bednarek (2013) found that FSG are less likely to study prestigious subjects and are less likely to be enrolled in academically-selective institutions.

1.3 Research questions

A recent report on the enrolment of first-generation students in institutions across Switzerland showed that, even after controlling for students enrolled only in STEM disciplines, our institution had the lowest percentage of FGS and this percentage has steadily decreased over the last 15 years (Gerster et al. 2023). Therefore, based on an increased institutional focus to increase recruitment and retention of first-generation students, we wanted to get a better understanding of the educational paths taken by our FGS. Specifically, we ask: What are the differences between FSG and CGS with respect to their choice of postgraduate degrees and time taken for completion of postgraduate education.

2 METHODOLOGY

2.1 Settings, Participants, and Data Collection

This data was collected at a large, research-intensive Swiss engineering university, which offers Bachelor's, Master's, and Doctoral degrees in several fields. Data collection was done by sending a survey to the alumni of the institution. Such surveys, which are periodically used by the institution, are aimed at both serving as a quality-control tool as well as a means of identifying scope for improvement in the educational programming. While the questions posed differ slightly based on the year of graduation, the questions that generated the data for this paper remained constant across the graduating classes.

Using an inhouse server, a survey was sent to alumni that graduated from 1980 to 2019. The link to the survey was unique and no identity information was requested from respondents. Of the 29630 alumni that received the survey, 4385 responded. The demographics of this population was compared to the demographics of the graduating classes for the respective years as was considered to be representative with respect to degree obtained, year of graduation, department, and gender (Colzani et al. 2022). However, we do not know if it is also representative of first-generation status.

2.2 Data Analysis

This data was initially filtered to keep only responses from alumni who provided information relating to at least one graduating date (e.g. year in which they obtained their Bachelor's degree). Since gendered diversification of academic paths has been well documented in literature, so as to be able to make generalisable claims, we decided to further filter the data and retain only data for alumni who graduated between 2004 and 2019, as the gender demographics in this population are very close to the demographics of the graduating classes in those years. The final dataset that was used for the further analysis consisted of responses from 1328 alumni, 170 of which were first-generation students.

This data was analysed using Pearson's Chi-squared statistical test and Student t-test comparing FGS and CGS distributions. All analyses were performed using R Statistical Software (v4.3.2, R Core Team 2023). We used the *tidyr* (Wickham, Vaughan, et al. 2024) and *dplyr* (Wickham et al. 2023) packages for data processing, and the *ggplot2* package (Wickham, Chang, et al. 2024) for data visualisation.

3 RESULTS

3.1 First-generation students are more likely to choose classical engineering Masters programmes

We sorted the 26 different Master's programmes offered at our university into 6 categories, based on similarity.

1. Classical engineering: These programmes have existed globally for a long time and are easier for a non-specialist to recognise. 6 programmes (e.g. Mechanical engineering, Civil engineering)
2. Emergent engineering degrees: These programmes have been developed in response to the digital and technological advances in the last few decades, and as such these might not be as easy for a non-specialist to recognise. 8 programmes (e.g. Computational science and engineering, Energy science and technology)
3. Formal & Physical Sciences: 5 programmes (e.g. Physics, Mathematics)
4. Finance & Management: 2 programmes (e.g. Financial engineering, Management, technology and entrepreneurship)
5. Life Sciences & Environment: 4 programmes (e.g. Life sciences engineering, Environmental sciences and engineering)
6. Architecture: 1 programme

Of the 1328 alumni, 1124 provided information about their Master's programme, of these 13.25% were FGS. When we compared the choice of study programme (Fig. 1), we found that FGS were more likely to graduate with a Master's degree in one of the "Classical Engineering" programmes as compared to their CGS counterparts (Chi square - *p* <0.1). 29.53% of FGS graduated with classical engineering degrees while only 19.38 % of CGS did the same. Consequently, FGS were less likely to graduate with Master's in Architecture (5.36% compared to 9.23%), in one of the "Life Sciences and Environment" (14.09% compared to 17.74%) programmes or in one of the "Emergent Engineering" (22.15% compared to 24.41%) programmes. We did not find major differences in their choices for the "Finance & Management" and the Formal and Physical Sciences programmes.

Figure 1. Percentage of all the FGS and CGS who graduated with Master's degrees in the six categories of programmes offered by the institution.

3.2 Domestic students overwhelmingly prefer Classical Engineering degrees

The proportion of FGS was much higher among the domestic alumni (alumni that indicated Switzerland as their first nationality). Among the 564 domestic alumni, 21.28% were FGS. Therefore, to control for Alumni origin as a possible confounding variable, we compared the choice of study programme for domestic alumni (Fig. 2).

Figure 2. Percentage of all the Swiss FGS and CGS who graduated with Master's degrees in the six categories of programmes offered by the institution.

Swiss FGS were much more likely to graduate with a Master's degree in one of the "Classical Engineering" programmes as compared to their Swiss CGS counterparts (Chi square - p <0.05). 31.67% of Swiss FGS graduated with classical engineering degrees as compared to the 17.12% of Swiss CGS who did the same. Consequently, Swiss FGS were much less likely to graduate with Master's in all the other categories of programmes. The biggest differences were observed in the "Formal & Physical Sciences" programmes (15.86 compared to 19.59), "Life Sciences and Environment" programmes (13.33% compared to 16.89%), and in Architecture (4.17% compared to 7.66%).

3.3 Total duration of studies is longer for first-generation students

As an estimation for duration of studies we explored differences in time between successive graduations. On a smaller scale, when examined individually, we did not detect significant differences in time between Bachelor's and Master's graduations, or between Master's and Ph.D. graduations. However, when we look at a larger scale, we find that there is a significant difference (T-test, $p < 0.05$; Fig. 3) in time between Bachelor's and Ph.D. graduations for FGS (n = 50, mean study duration = 8.26 years) and CGS (n = 315, mean study duration = 7.44 years). FGS take approximately 10 months longer than their CGS counterparts.

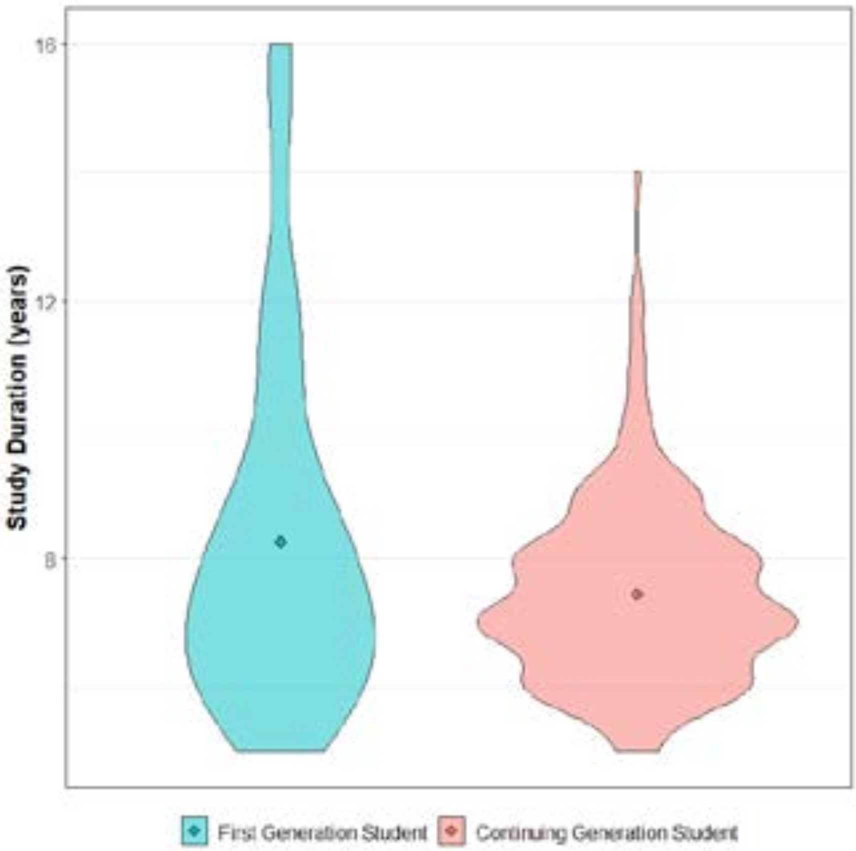

Figure 3. First generation students take longer between Bachelor's and Ph.D. graduations. Mean value indicated by the coloured dot. The width of the plot corresponds to the frequency of data points.

We did not find any difference between the proportions of FGS or CGS who completed a Ph.D.

3.4 Difference in total duration of studies is larger in domestic students

The proportion of FGS who completed a Ph.D. was much higher among the domestic alumni (alumni that indicated Switzerland as their first nationality). Among the 160 domestic alumni for whom we have data related to duration of studies, 23.13% were FGS (as compared to 13.69% of FGS in the total population). Therefore, to control for Alumni origin as a possible confounding variable, we compared the study duration for domestic alumni.

Our results indicated that there is a near-significant difference (T-test, $p = 0.056$; Fig. 4) in time between Bachelor's and Ph.D. graduations for domestic FGS (n =37, mean study duration = 8.19 years) and domestic CGS (n = 123, mean study duration = 7.23 years). Domestic FGS take almost one year (11.5 months) longer than their CGS counterparts.

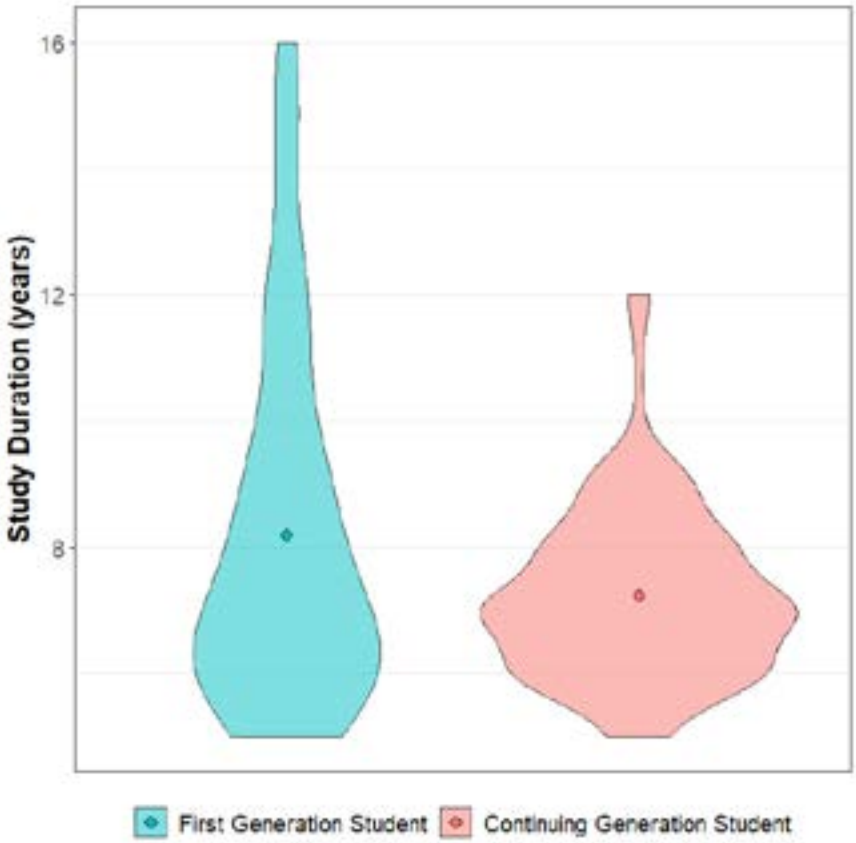

Figure 4. Domestic first-generation students take longer between Bachelor's and Ph.D. graduations. Mean value indicated by the coloured dot. The width of the plot corresponds to the frequency of data points.

4 DISCUSSION & CONCLUSIONS

Based on our data, it appears that there are distinct differences in the choices and duration of post-graduate education between first-generation students and their continuing generation counterparts. At our institution, there is a clear difference in the Master's degree choices with FGS being over-represented in the "Classical Engineering" programmes. These findings are in-line with other studies done in Europe that showed that FGS are under-represented in the more selective higher educational fields (Kasatkina et al. 2020; Isserstedt et al. 2010). One possible explanation for this discrepancy could be that FGS tend to make more 'safe' choices based on the limited information they have access to. The classical engineering fields, and associated job-opportunities better known in the society compared to the new programmes that have emerged with the progression of newer technologies. However, while the classical engineering programmes have been around longer, recent trends show that graduates from the fields that correspond to our emergent engineering programmes earn higher salaries (Michigan Technological University 2024). The lower likelihood of FGS alumni to pursue a diversity of options in their postgraduate education could be influenced by a variety of factors, including access to resources and mentorship. This highlights the importance of providing support and guidance to FGS who may be less familiar with their academic and post-academic options.

The preference for classical engineering degrees is even more stark in the domestic alumni. The domestic FGS are overrepresented in the classical engineering degree programmes and are especially underrepresented in the Formal & Physical Sciences programmes. Other researchers have similarly shown that minoritized students (e.g. low socioeconomic status, FGS) choose engineering degrees over science degrees (Potvin et al. 2009; Godwin et al. 2013; Verdin and Godwin 2015). This could be because of FGSs' interest in engineering as a job rather than the content of an engineering degree (Troiano and Elias 2014) or the perceived job security of engineering degrees over science degrees and a lack of family support to pursue science degrees (Verdin and Godwin 2015). Alternatively, it could be because of the prospects of immediate employment (and earning) after a Master's degree in engineering, as opposed to science degrees requiring additional time investment in education e.g. getting a PhD.

It is not surprising though that FGS are less likely to pursue a Master's in Architecture, a study from Spain showed similar findings (Troiano and Elias 2014). At our institution, the tuition costs for an Architecture degree are the same as any other Master's degree. However, Architecture students have additional out-of-pocket expenses as they are required to purchase the supplies they need to complete their projects and build their models, and since FGS are more likely to come from low socio-economic backgrounds (Bui 2002), and cost of education could be a significant barrier (Troiano and Elias 2014). It should be noted though that Architecture is the programme that is selected the least by both FGS and CGS, and this could be because of the choice of the institution rather than choice of the programme. For example, while there are only two institutions in the country which offer Master's degrees in Mechanical engineering, there are eight institutions that offer Master's degrees in Architecture.

Among the alumni who continued to pursue a Ph.D. after their Master's degree, it is interesting to note that the study duration for FGS was almost a year longer than their CGS counterparts. Similar findings have been reported in a study that showed FGS were likely to take more time to graduate (Ishitani 2006). This could also be attributed to a range of factors, such as the need to balance work and family responsibilities, financial constraints, or lack of access to academic support services (Gardner and Holley 2011). Additionally, FSG experience imposter syndrome (Holden et al. 2024) and a low sense of belonging in academia (McCarthy et al. 2023), which might lead to increases in the time they take to start their Ph.D.

In conclusion, the findings presented in this study underscore the importance of understanding and addressing the unique challenges faced by first generation students in higher education. By examining the study paths and choices of first-generation alumni, we can gain valuable insights into the factors that influence their academic success and develop targeted interventions to support their academic and career goals.

ABSTRACT

Transversal skills (TS) are fundamental to both work effectively autonomously and with others in society. They are key to educating responsible engineers able to assess and proactively respond to issues and opportunities. As evidenced by recent course syllabi and accreditation requirements, TS are increasingly integrated in engineering curricula. However, little is known about students' perceptions of key pedagogical aspects related to skill development and the TS they prioritise. In light of previous work showing that demographics can influence students' perception of curricular experiences, this study reports on perceptions of 244 students on how TS are integrated into their programmes based on demographic information (discipline, year of study, gender) and participation in curricular activities (internships, mentoring programmes). Our data showed that students perceived low levels of receiving information and assessment, and even lower levels of receiving feedback related to

TS. Open questions about the skills they most wanted to develop and which they received least support did not reveal major trends in relation to either curricular experiences or demographic characteristics. This lack of major trends is however a positive result, as it points to reasonably equitable experiences for students in the institution. So, while this study supports the importance of increased attention to developing TS, it also raises questions about how to interest and support students to develop robust TS and therefore prepare them to be responsible engineers.

1 INTRODUCTION

Building a society that is socially and environmentally sustainable requires graduating engineers to be proficient in a wide range of skills (National Academy of Engineering [NAE] 2017; United Nations [UN] 2015). The challenges that engineering graduates face are multifaceted, requiring them to work with other engineers and experts from different fields within complex systems. As they work with others and in communities to co-create future ways of being, transversal skills (TS), especially organisational skills (e.g. project planning, risk assessment) and interpersonal TS (e.g. communication, teamwork) are essential (Kolmos and Holgaard 2019; Passow and Passow 2017; Winberg et al. 2020). Current students understand the importance of well-developed TS (de Lima et al. 2024; Direito et al. 2014; Donald et al. 2019), yet studies with alumni find engineering graduates report insufficient development of TS (Kovacs et al. 2023). Employers have also been explicit about the importance of TS in order to be job-ready (Craps et al. 2022; Robles 2012; Succi and Canovi 2020). Recognising this need, multiple accreditation bodies explicitly include the development of TS in their criteria (Accreditation Board for Engineering and Technology [ABET] 2023; Commission des titres d'ingénieur [CTI] 2023; European Network for Accreditation of Engineering Education [ENAEE] 2023). Engineering programmes are responding by increasing the visibility of TS in their curricula to ensure students become the responsible engineers society needs to tackle a diversity of challenges. Do engineering students' perceptions of priorities and curricular opportunities correspond to institutional objectives and priorities?

1.1 Visibility of transversal skills in engineering curricula

Engineering curricula have become more explicit about the importance and opportunities to develop TS (Crawley et al. 2011; Kovacs et al. 2020) and multiple institutions have launched initiatives to further integrate them into the curriculum. However, enhancing engineering students' development of TS may require adjustments in the pedagogical approaches traditionally used to teach disciplinary knowledge and skills. Researchers have shown that students' perceptions of the content and aims of the curriculum can influence their learning (Kuhn and Rundle-Thiele 2009; Wijngaards-de Meij and Merx 2018). With respect to transversal skill development, teachers often assume that merely allowing students to practise the skill will lead to learning gains (Isaac et al. 2023) although it has been demonstrated that learning gains occur only when skills are explicitly addressed, such as through instruction and assessment (Kovacs, Milosevic et al. 2023; Picard et al. 2022). A recent innovation to assist teachers to integrate TS into the curriculum is the 3T PLAY trident from EPFL (de Lima et al. 2024; Isaac et al. 2024) which highlights three pedagogical aspects for learning skills: *Knowing*, *Experiencing*, and *Learning from Experience*. These aspects are informed by learning sciences research on skill development, as well as making the skill development more visible and explicit for both students and teachers.

1.2 Multiple factors influence students' curricular experiences

Students' perceptions of the relative importance of various learning outcomes (including skill development) can be different from educators' perceptions of the same (Myers 2008; Feldman 1988; Lemos 1996). This can lead to a mismatch between the skills that are integrated into the curriculum, and the skills that students actually prioritise. Multiple studies have also documented that factors independent of the learning experience can influence learning outcomes. These include students participation in extracurricular activities (Chan 2016; Guilmette et al. 2019; Shulruf 2010), as well as demographic factors such as gender (Aeby et al. 2019; Eddy and Brownell 2016) and coming from an immigration background (Joyce and Hopkins 2014; Stewart 2007).

1.3 Research questions

Building from the literature that highlights the importance of explicit incorporation of transversal skills in the curriculum, and the potential for differences in students' curricular perceptions and experiences, we ask the following questions:

- Do students perceive the integration of support for transversal skills development in their engineering studies? What pedagogical aspects (information, feedback, and assessment) are most visible to them?
- Do the skills students personally prioritise/need support to develop change across their studies or due to their curricular experiences? Do their demographic characteristics influence the skills they prioritise/need?

2 METHODOLOGY

2.1 Settings & participants

This study was conducted at a mid-sized European engineering institution. Teachers at this institution are required to specify learning objectives targeting transversal skills in their course syllabi (in addition to disciplinary knowledge and skills), and in general most course descriptions list several such learning objectives.

Student assistants (N = 244) enrolled in Bachelor and Masters programmes responded to a paper-based survey about their perceptions of the degree of integration of various transversal skills (TS) in their curricula. The student assistants (henceforth referred to as students) were participating in a pedagogical training workshop when the survey was administered. The affordances of choosing this population were an opportunistic sampling of students across programmes and years of study, and the ability to leverage their knowledge in distinguishing between the three pedagogical aspects targeted.

2.2 Data collection & analysis

Our first research question is addressed by the quantitative part of the survey asked students about their perceptions of receiving information/training, getting feedback, and being assessed on seven different categories of TS (e.g. Communication skills, Organisational skills). Students were instructed to think about their courses in the current semester (rather than the workshop they were attending) when responding to these Likert-style questions with a 6-point response scale spanning “I do not know (0)” to “in (almost) every course (5)”. We placed “I don’t know” at position zero on our scale, as students not even being able to answer this question corresponds to a serious lack of knowledge of TS. The numerical responses to each of the seven skills were aggregated and averaged to get one mean value per student for each of the three main pedagogical aspects.

Our second research question was addressed when students responded to open ended questions which asked them to list two TS that they were personally most interested in developing (218 responses containing 440 skills), and two for which they perceived receiving the least institutional support to develop (n of responses = 217 responses containing 440 skills). These brief responses were coded using qualitative content analysis (Schreier 2014) to identify 27 skills.

Finally, students were asked about their curricular experiences (year of study, internship, etc.) and their demographics (gender, immigration background etc.). Approval for this study was sought and obtained from the institutional ethics review board (HREC 072-2023).

3 RESULTS

3.1 Students perceive low integration of transversal skills in their curricula

Students perceived little training on transversal skills (TS) in their courses (n = 244, mean 1.89) and reported an equally low frequency of having their TS assessed in their courses (n = 244, mean 1.83; Fig. 1). Their perception of the frequency of receiving feedback was the lowest (n = 244, mean 1.57). Phrased another way, only 10% of students reported receiving information about TS in half of their course or more and 5% reported receiving feedback on their skills in half of their courses or more. Students may not have thought to separate these 3 pedagogical aspects previously, however the high response rates imply that students felt able to distinguish between them.

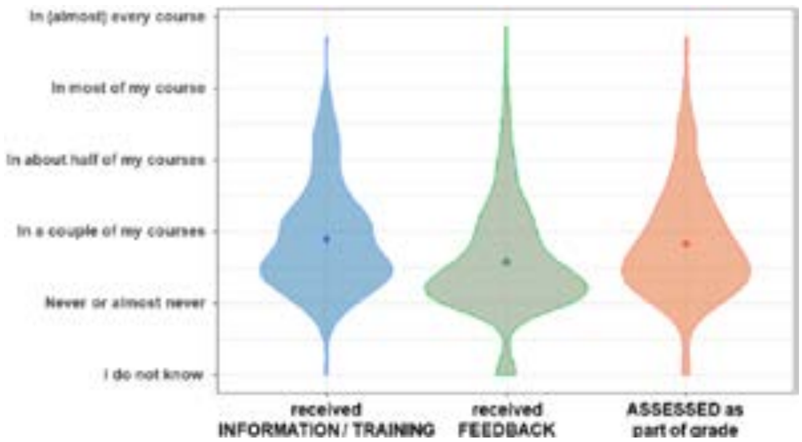

Figure 1. Students’ perception of curricular support for developing their transversal skills is lowest for receiving feedback as compared to receiving information and being assessed (t test 7.650 and -5.908 respectively, both significant <.001 with moderate effect size per Cohen’s d .65-.68)

3.2 Curricular experiences and demographics have little influence on students’ perceptions of transversal skills integration

Using ANOVA, we explored if students’ curricular experiences influenced their experiences of TS in their courses. While neither of the two major curricular elements (year of study & study programme) produced significant relations, several other aspects did show effects. Increased perception of both receiving information and feedback on TS were observed for students who had completed an internship ($F_{1,242}$ = 6.155, p = .014 & $F_{1,242}$ = 4.008, p = .046 respectively) and for students who studied in the UK/EU before EPFL ($F_{2,228}$ = 4.877, p = .008 & $F_{2,228}$ = 3.245, p = .041 respectively). The perception of TS being evaluated was higher for students who had completed individual course projects ($F_{1,241}$ = 7.174, p = .008) and semesters abroad ($F_{1,241}$ = 5.583, p = .019).

We next sought to identify if students' demographic characteristics influenced their experiences of TS in their courses. In our institution, the required courses for each degree leave little space for optional courses. Students' demographic characteristics therefore would not influence what they encounter in class per se but could influence their perception of the integration of transversal skill development in their courses. In our data set few demographic characteristics were relevant, however students with parents/head of household born outside EU/UK/CH perceived less information about TS ($F_{1,227}$ = 4.04, p = .046) and non-gender binary students perceived less evaluation of their TS ($F_{2,224}$ = 3.278, p =.04) than either male or female students.

Although most curricular experiences are outside student control (i.e. course projects), interactions between demographic characteristics and curricular choices could potentially confound our analysis. We identified only three such interactions: (i) Students with recognised neurological conditions were more likely to participate in mentoring programmes (χ^2 = 4.293, p=.038), (ii) Students with long term illness were more frequent in lower years (χ^2 =19.939, p<.001), (iii) Students with a EU/UK parent were more likely to participate in study abroad programmes than those with domestic or non-EU/UK parents (χ^2 = 4.797, p=.029).

3.3 Curricular experiences and demographics have some influence on categories of transversal skills prioritised by students.

Table 1. Count by categories of transversal skills that students deem important and under-addressed in their curricular experiences.

	Communication Skills	Interpersonal skills	Thinking & reasoning skills	Entrepreneurship skills	Intrapersonal skills	Ethics & Sustainability	Organisational skills	Other
Personally develop (PD skills)	122	82	69	62	37	37	23	8
Least supported (LS skills)	123	84	68	60	37	37	23	8

To identify the categories of TS that students deem important and under-addressed in their curricular experiences, we thematically associated their open -ended responses with the 7 categories of TS (Table 1) inspired by those used by our institution (EPFL 2021). Communication skills, such as 'oral communication' and 'written communication', and Interpersonal skills, such as 'networking' and 'teamwork', were cited most often as both the skill sets students wanted to develop and those for which they received the least support. Indeed, there was a tight association between the skills that a student most wanted to develop and those they felt were least supported for all categories. Thinking and reasoning skills, such as ‘critical thinking’ and ‘systems thinking’, and Entrepreneurship skills, such as ‘creativity’ and ‘entrepreneurship’, represent the other most common skills. To explore how students' curricular experiences and demographics influenced their responses, we considered each of the 27 skills individually.

3.4 Curricular experiences and demographics influence specific transversal skills prioritised by students.

We employed likelihood ratio (LR) statistical tests to explore how students' curricular experiences influenced their perception of specific TS. The LR is the likelihood of an unknown experience producing a given outcome compared to a specific experience producing the same outcome. Students’ responses in terms of the skills that they were personally most interested in developing (PD) and those they perceived to have the least support in the curriculum (LS) were highly aligned (Table 2). The strongest effect size is seen between interest in developing ‘systems thinking’ and year of study with the interest shown by second- and third-year Bachelor students dropping in Masters. Doing team course projects and internship experiences both increase the perception that ‘communication skills’ are personally valuable but unsupported. Internships also increase students’ desire to develop ‘intrapersonal skills’. Desire to develop and need for ‘interpersonal skills’ peaks in students enrolled in the third year of Bachelor degree before dropping in Masters students. A desire to develop ethics reported by 18 students in some engineering, physical sciences, and computing programmes; students from these programmes were also more likely to see ‘intrapersonal’ as unsupported. Mentorship programme students report slightly less personal need to develop ‘intrapersonal’ and ‘sustainability’ skills and indeed no students participating in these programmes stated these skills are unsupported.

Table 2. Heat map showing effect size (Cramer’s v) for significant likelihood ratios between curricular experiences with “personally most interested to develop” (PD) and “least support to develop” (LS) skills. Values where n < 10 and/or likelihood ratio was not significant at p <.05 are omitted.

	n	Year of study		Discipline		Team project (course)		Internship		Mentorship	
		PD	LS	PD	LS	PD	LS	PD	LS	PD	LS
Communication	**98**					0.19	0.13	0.17	0.01		
Syst. Thinking	**50**	0.23	0.23								
Interpersonal	**48**	0.19	0.21								
Intrapersonal	**27**				0.22			0.16	0.15	0.12	0.12
Sustainability	**19**									0.10	0.10
Ethics	**18**			0.24							
Project Mgt.	**10**									0.19	

Considering both the frequency of occurrence in students’ responses and effect sizes (measured by Cramer’s V when likelihood ratio *p* value ≤ 0.05), the impact of curricular experiences on students’ interest in specific skills appears fairly random. Further, the relatively low number (combined 17 associations are statistically significant with moderate effect size out of 168 possible) suggests that curricular experiences do not have a major impact on what TS students want to develop nor those they find under supported.

Students' demographic characteristics had some influence on the skills they identified as personally important to develop and those missing in their programs (Table 3). Students who studied in EU/UK before coming to our institution were more likely than domestic or non-EU/UK students to flag 'sustainability' skills and express personal interest in developing such skills. Male students were more likely than other genders to both express an interest in developing and to report lack of support for 'communication skills'. As above, the relatively low number (combined 10 associations of 216 possible) suggests that students' demographic experiences did not have a major impact on the skills students want to develop nor on those they think need more support.

Table 3. Heat map showing effect size (Cramer's v) for significant likelihood ratios between demographic characteristics with "personally most interested to develop" (PD) and "least support to develop" (LS) skills. Values where n < 10 and/or likelihood ratio was not significant at p <.05 are omitted.

	n	non- EU/UK parent		EU/UK parent		Domestic parent		Prior education in EU/UK		Gender	
		PD	LS	PD	LS	PD	LS	PD	LS	PD	LS

Oral Comm.	20			0.14	0.14						
Sustainability	19			0.14	0.14			0.17	0.17		
Project mgt.	10	0.13									

4 Discussions and Conclusions

The importance of transversal skill (TS) development for engineering students is well recognised and TS are increasingly integrated in engineering curricula (Crawley et al. 2011; Kovacs, Milosevic et al. 2023; ABET 2023; CTI 2023; ENAEE 2023). In this study, we examined the extent to which students perceive three key pedagogical aspects for skill development (receiving information about the TS, receiving feedback on their TS proficiency, and assessment of TS contributing to their grades). Further, we investigated the skills students most wanted to personally develop and those they perceived as being the least supported at the institution.

Our analysis of the Likert survey data indicates that students perceive little pedagogical integration of TS in their curriculum. Over ⅔ of students report that, with respect to TS, at most "a couple" of their courses provide them with information (65%), feedback (78%) or evaluate them (69%). This is coherent with previous findings that instructors expect students to spontaneously develop TS exclusively through experience (Isaac et al. 2023). That students perceive feedback as the least developed pedagogical aspect related to developing their transversal skills is coherent with previous work that has identified that students are dissatisfied with the feedback they receive at university (Beaumont et al. 2011; Higgins et al. 2001;

Poulos and Mahony 2008). It would therefore be relevant to explore if students' perception reflects a specific pedagogical lack or a general trend. Curricular experiences of internships, individual course projects and semesters abroad all had small but constructive effects on students' perception of TS in their courses. However, specific curricular elements had little effect on students' perception of TS in their courses. This indicates that efforts to increase teaching of TS are insufficient or are insufficiently visible to students. Future work could consider how the pedagogical conditions that led to increased perception of more feedback (i.e. internships) or assessment (i.e. individual course projects) could be leveraged in other contexts to provide support for students to develop their transversal skills.

As co-curricular and extra-curricular experiences enhance students' academic experiences (Buckley and Lee 2021) and future career prospects (Stuart et al. 2011) but are less available to non-traditional students (King et al. 2021; Stuart et al. 2011), it is relevant to investigate potential inequitable experiences of transversal skill development. It is therefore a positive finding that students' demographic characteristics did not exert a significant impact on their perception of TS in the curriculum. In our institutional context, it is particularly relevant to note that first generation students did not report different experiences.

The TS that students deem important and under-addressed in their curricular experiences align well with the 7 categories inspired by the TS working document. Considering that a recent study mapping TS in syllabi across the institution found that 'Communication skills' had the highest representation in the course documents (Kovacs et al. 2020), it is interesting to note that this was the skill set students were most interested in developing. The current study does not provide information as to whether these skills stand out because students need them now, see them as most relevant to their future careers, or associate them with professional engineering work. It is also possible that students have not (yet) encountered support for communication skills as these skills were addressed more often in non-mandatory and Master's level courses.

Statistical tests between the TS students identified as personally wanting to develop, TS they identified as insufficiently supported, and their curricular and demographic influences identified few interesting associations. The absence of clear patterns between the skills listed by students and their curriculum and demographic characteristics suggests that students' individual, specific experiences inform their perceptions and priorities. While clear trends (e.g. first years are interested in communication skills, architecture students need more support for teamwork), would have provided useful guidance for teachers, our data raises questions about how to effectively support students to develop TS across the curriculum. Students in our study value TS and have self-directed learning goals. Both our qualitative and quantitative data suggests that coherent "across the curriculum" development may be less effective than individualised approaches that offer more flexibility and choice to students for developing their TS.

It is relevant to note that the observations of this small study are limited in several ways. First, the convenience sample of student assistants is likely unrepresentative of the student body (e.g. higher than average grades). It is also difficult to make predictions about the relationships between the variables. For example, we found students with recognised neurological conditions were more likely to participate in mentoring/excellence programmes. This could be because students with such conditions are more likely to participate in such programmes, or because students in such programmes were encouraged to seek formal diagnosis. We also saw students with long term illness were more frequent in lower years. This could either be because such illnesses make it difficult for students to continue to be student teaching assistants, or that they leave the institution entirely. Another limitation is that students' responses to the open questions may have been primed by the Likert questions. Further, by specifying “in their courses” we excluded excellent extra-curricular opportunities that develop TS such as student associations and campus employment.

Overall, our data suggests that students' experience of transversal skills in their curriculum does not meet institutional objectives regarding educating responsible engineers. This could mean that such skills are not being taught, however students’ perspective captured by the methodological approach of this study is likely not an entirely accurate reflection. We can, however, conclude that students are not currently perceiving adequate and relevant opportunities to develop their transversal skills. Thus, we need to consider students’ evolving needs and priorities when integrating transversal skills into the curricula. Additionally, it is important to improve the coherence and visibility of efforts to teach transversal skills by attending to both implicit and explicit aspects of the curriculum. For instance, supporting teachers to incorporate opportunities for skill development in their courses (Kovacs et al. 2023; Picard et al. 2022; Isaac et al. 2023), particularly those that provide explicit information and relevant feedback on the skills themselves (Isaac and de Lima 2024a; 2024b) in (3T PLAY 2024).

ABSTRACT

The presented paper deals with the development and evaluation of a teaching-learning innovation for better student support in the introductory phase of engineering studies. Previous results of a longitudinal study on the study entry phase have shown that there is a strong heterogeneity in terms of prior knowledge of maths and electrical engineering and that there are general deficits in computer skills.

To counteract this, a digitally supported introductory study phase was designed with the help of learning analytics through data acquisition via matlab grader, which enables an effective transition from school to university and improves study skills at the start of the degree programme. In the long term, the implementation of learning analytics should also serve to recognise students at risk at an early stage and enable interventions. This paper aims to contribute to the current discussion on technology in engineering studies, offering both theoretical and practical perspectives. Topics such as the design of an improved introduction phase, agile adaptations to future developments and support for students in the use of technology is addressed, and approaches to evaluation methods for quality assurance and validation will be presented. The evaluation results of the teaching-learning innovation with Matlab Grader show that there is a correlation between the exam grade and the use of

[1] *J. Dethmann*
Jannis.Dethmann@leuphana.de

Matlab Grader. It was also found that the number of tasks completed has a significant correlation on the grade achieved. The feedback from students on the introduction of the new concept indicates that the use of Matlab Grader helps many students to solve exercises and also increases motivation.

1 Introduction

With the emergence of new technologies and the constant development of digital tools and platforms, the way we communicate, work, learn and live has changed fundamentally. Under these changing conditions, graduates should have the ability to identify and describe problems and develop suitable solutions in order to actively participate in future-oriented change processes in a digitalised society (Auer and Kim 2018, Harteis 2018, Uskov and Howlett and Jain 2018). Increasing digitalisation has led to the establishment of e-learning platforms, online courses and digital learning resources that enable learners to learn in a more flexible and individualised way. The use of such tools can help to solve key problems faced by universities. One major challenge for universities, for example, is the early identification of potential dropouts in technical degree programmes, as dropout rates of over 30 % are sometimes reported (Heublein et al. 2017). At the same time, it is increasingly important to facilitate the transition from school to university and to provide students with personalised feedback (Heublein and Hutzsch and Schmelzer 2022). The use of digital tools and learning analytics provides teachers with valuable data on user behaviour. On the one hand, this enables the introduction of an early warning system to identify potential dropouts (Brozina et al. 2019) and, on the other hand, can increase student satisfaction through personalised feedback and have a positive impact on test results (Pardo et al. 2019). The use of evidence-based teaching is particularly important with regard to upcoming transformation processes (Borrego and Hendernson 2014). Prior to this publication, a concept for the evidence-based design of an introductory study phase was already presented, which supports the learning success of students in a technology-based and individualised way (Block and Dethmann 2024). The aim of this article is to implement learning analytics to support student learning success in the first semesters and to present the benefits achieved. To this end, the implementation was analysed and evaluated using the data collected by the Matlab Grader platform and a regular course questionnaire that was supplemented by feedback questions regarding Matlab Grader. The findings are used to derive targeted measures that will positively influence the quality of future teaching. The paper is structured as follows: In Part 2, the research method and the research objectives are defined. Part 3 deals with the implementation of learning analytics using Matlab Grader. In Part 4, the results are presented and analysed. Finally, the paper is summarised and measures for the continuation of the study in teaching practice and EER are presented.

2 Methodology

The aim of this study is the design and implementation of learning analytics using Matlab Grader as well as evidence-based data collection. On the one hand, insights

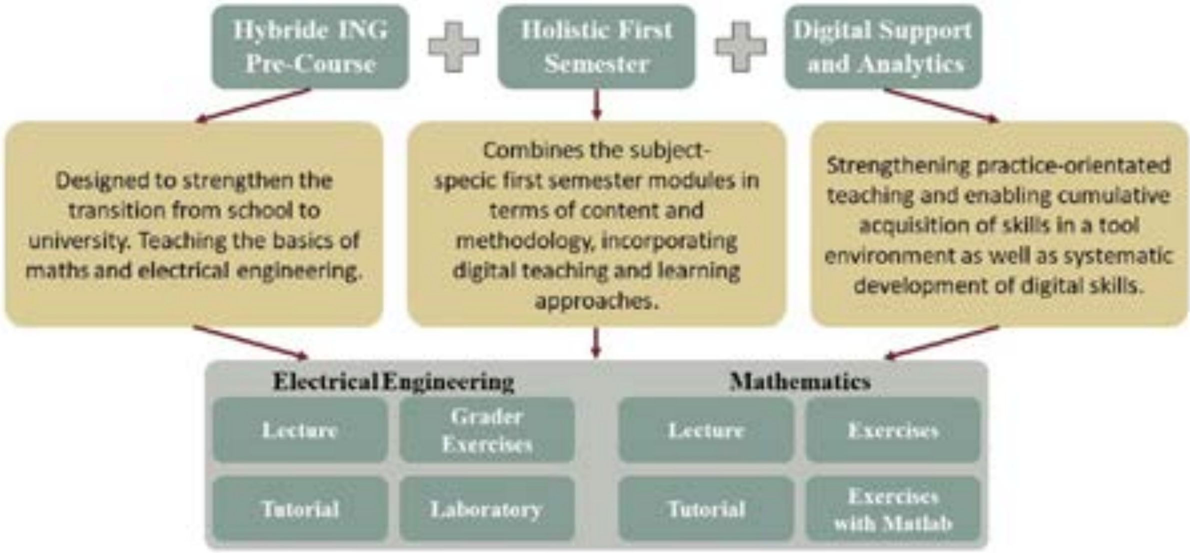

Fig. 1. Structure of the introductory phase

are to be gained for lesson design and, on the other hand, empirical information about the students' learning approaches and success predictors is to be collected in order to enable more targeted and effective support. Design-Based Research (DBR) was therefore selected as the method for the design and investigation within the same research process (McKenney and Reeves 2024). During the *analysis* part, a longitudinal study of the introductory phase of the programme revealed that the students exhibited strong heterogeneity in terms of prior knowledge in the subjects of mathematics and electrical engineering (Block et al. 2023, Block and Dethmann 2024). There were significant deficits in terms of practical knowledge and computer skills. During the *design* phase, an integrative introductory period was created, with its structure illustrated in Fig. 1. The concept for the start of the programme provides for a hybrid preliminary course that facilitates the transition from school to university by teaching the basics of mathematics and electrical engineering and providing introductions to current topics such as energy, electromobility and sustainability. In the holistic subject-related first semester, the subject-specific maths and electrical engineering modules are combined in terms of content and methodology and digital teaching and learning approaches are integrated. By linking electrical engineering and mathematics, synergies can be created that make mathematical training more practice-orientated. The modules consist of lectures, exercises, tutorials and practical laboratory exercises in small groups in which students carry out experiments. The use of Matlab Grader[2] is embedded in the "Digital Support and Analytics" concept. Matlab Grader provides an online-based, interactive environment for creating tasks with automatic evaluation, allowing all students to learn at their own pace and at their individual level. A detailed explanation with an example is given in the following chapter. The *evaluation* and reflection of the implementation of learning analytics through Matlab Grader took place at the end of the winter semester 23/24 and provided new insights that will be incorporated into the redesign of the concept.

[2] Further information on Matlab Grader can be found at https://de.mathworks.com/products/matlab-grader.html.

3 DESIGN AND IMPLEMENTATION OF LEARNING ANALYTICS WITH MATLAB GRADER

The participants in the study were engineering students at Leuphana University Lüneburg in Germany. The Electrical Engineering 1 course is mandatory for all students of the major. 55 people registered for the course at the beginning of the semester, 42 of whom took part in the exam in February 2024. The course took place during the winter semester from October 2023 to January 2024. The course includes lectures, laboratory experiments and tutorials. It is structured in such a way that theoretical content is first covered in the lectures and later deepened through practical experiments in the laboratory. In addition to the lectures, voluntary tutorials are offered, which are led by students from higher semesters. So far, students have been provided with the slides and exercises online in PDF format after each lecture, which they should work on independently at home. Students could contact the tutors during the tutorial if they had any questions or needed help with solving the exercises. For this study, the provision of exercises was supplemented by the implementation of MATLAB Grader. The on-site tutorials continued to take place in parallel. MATLAB Grader is a web-based online platform that is characterised by performance assessments with automatic feedback. As a result, students receive feedback on the accuracy of their results immediately after solving a task. In the event of incorrect answers, students can also be given a hint to help them determine the correct solution. To ensure that all students can use the platform, an introductory course for MATLAB Grader was offered in the first week. Students have access to Matlab Grader throughout the whole semester and can track the status of the tasks (processed, unprocessed, correct, incorrect). Fig. 2 shows an example of a task used in the course. The procedure for creating each task is identical. First, the task must be defined and it must be clear which variables the solutions should contain in order to enable automated checking. Depending on the type of task, images can also be added to make it easier to understand. In the script box, students can assign their solution to the target value. It is also possible to define auxiliary variables, for example to record intermediate results. Students can then test compile the code

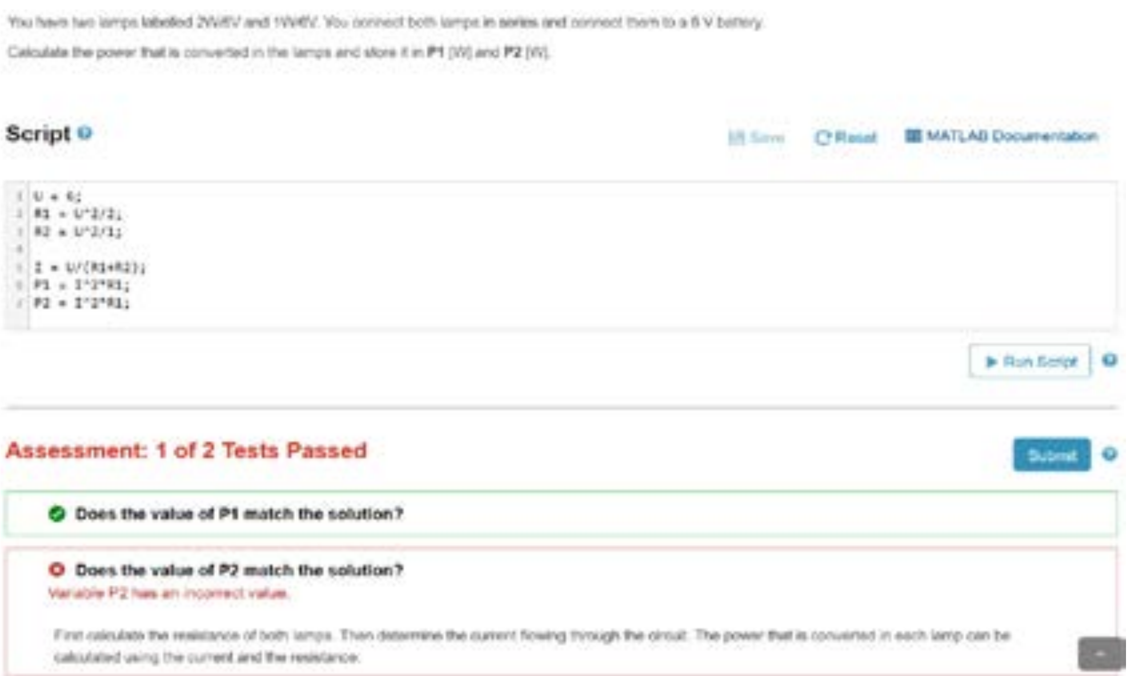

Fig. 2. Example of a Matlab Grader Task

before submitting it in order to recognise errors. After submission, students receive immediate feedback. In the example task, only one of the two variables queried has the correct target value. A message box appears for the incorrect variable, giving tips on how to solve it. The number of possible attempts per task can be set flexibly by the teacher. For this study, the students had two attempts to solve the tasks correctly. The thematically relevant tasks were provided after the lectures in order to avoid an overload of information. It was possible to answer the questions throughout the semester.

4 EVALUATION OF LEARNING ANALYTICS: EVIDENCE-BASED FINDINGS ON STUDENT LEARNING STRATEGIES AND PREDICTORS OF SUCCESS

In order to obtain evidence-based findings on students' learning strategies and the success of learning support for students, two approaches were pursued. On the one hand, data was available from MATLAB Grader (including usage statistics) and the exam results. In addition, data was available from the evaluation of a questionnaire that collected student feedback on the implementation of Matlab Grader at the end of the semester. For the statistical analysis, a value of $\alpha = 0.05$ was assumed for all tests in which a significance level is required. This was adjusted according to the number of groups using the Bonferroni correction. Effect sizes and correlations were categorised according to Cohen (Cohen 1969). The current status of this research work shows limitations with regard to the general validity of the effectiveness of the concept. In subsequent rounds, the population size will increase and possibly lead to an expansion of the validity.

4.1 Correlation between exam grade and utilisation of Matlab Grader

A correlation test according to Spearman was used to investigate whether there was a correlation between the exam grade achieved and the use of Matlab Grader. In addition to the correlation coefficients between the exam grades and the submitted and correctly submitted Matlab Grader tasks, Table 1 also contains the variable of how actively a student participated in the tutorials. The correlation between the exam grade and the submitted tasks (-0.689) and the exam grade and the correctly submitted tasks (-0.710) can be interpreted as a strong correlation according to Cohen. The correlation between the exam grade and participation in the tutorial (-0.417) can be assessed as a medium correlation. The results of the correlation test indicates that a high participation rate in Matlab Grader leads to a better exam grade. The difference between pure participation and answering the questions correctly is very small. Active participation in the tutorials has a smaller influence compared to the use of Matlab Grader.

Table 1. Correlation matrix of exam grade, submitted grader tasks, correct grader tasks and tutorial participation

Variables	Exam Grade 23/24	Submitted Grader Tasks	Correct Grader Tasks	Attendance at tutorial
Exam Grade 23/24	**1.000**	**-0.689**	**-0.710**	**-0.417**
Submitted Grader Tasks	**-0.689**	**1.000**	**0.973**	**0.545**
Correct Grader Tasks	**-0.710**	**0.973**	**1.000**	**0.608**

Attendance at tutorial	-0.417	0.545	0.608	1.000

4.2 Influence of the number of completed Matlab Grader tasks on the exam grade

A total of 168 tasks were available in Matlab Grader over the entire period. The students were divided into five groups to assess whether the number of tasks completed had an influence on the exam grade achieved. The first group did not use Matlab Grader. Groups two to five were each separated in an ascending interval of 25 %. The result of a Kruskal-Wallis test shows that the samples do not come from the same population (p-value=0.004). The output of a Dunn-Bonferroni test is shown in Table 2. In this context, it can be seen that the group of students who did not complete any tasks and those who completed 25 % of the tasks differed significantly from the group who completed more than 75 % of the tasks. The Cohen effect size is 3.19 and 1.80 respectively and can therefore be interpreted as a strong effect. From this it can be deduced that there is a measurable difference in the exam results between students who completed more than 75 % of the tasks and those who completed ≤ 25 %.

Table 2. Dunn-Bonferroni test between five different groups in relation to the number of Matlab grader tasks completed

Groups	$0\,\%$	$0\,\% < x \leq 25\,\%$	$25\,\% < x \leq 50\,\%$	$50\,\% < x \leq 75\,\%$	$75\,\% < x \leq 100\,\%$
$0\,\%$	1	0.414	0.103	0.180	**0.001**
$0\,\% < x \leq 25\,\%$	0.414	1	0.266	0.456	**0.001**
$25\,\% < x \leq 50\,\%$	0.103	0.266	1	0.743	0.048
$50\,\% < x \leq 75\,\%$	0.180	0.456	0.743	1	0.021
$75\,\% < x \leq 100\,\%$	**0.001**	**0.001**	0.048	0.021	1

Bonferroni-corrected significance level: 0.005

4.3 Student´s perception of Matlab Grader

At the end of the semester, the students were asked for feedback on the implementation of Matlab Grader by means of a regular course questionnaire that was supplemented by feedback questions regarding Matlab Grader. To ensure

transparency, students were informed at the beginning of the semester that participation in Matlab Grader is voluntary and that the data will be used for research purposes. The results of the survey are shown in Fig. 3. The evaluation of the statement "I had no difficulties using MATLAB Grader platform" shows that 36 % of students at least disagree. This suggests that the introductory course was not comprehensive enough. "The immediate feedback as to whether I answered a question correctly motivated me to continue" was answered positively by more than half of the students. Only 20 % felt no increase in motivation. Half of the students also agreed with the statement "The additional information in case of an incorrect answer helped me". 16.60 % did not perceive any help. In response to the question "How many submission options for the tasks do you find the most useful", the majority voted in favour of three. Only 12 % are satisfied with the current status of two submissions, while the remaining students would like four or unlimited submissions.

5 SUMMARY AND OUTLOOK

The studies show that the use of Matlab Grader for learning analytics can be useful. It is shown that the use of Matlab Grader correlates with the exam grade and that the group with a very high number of submissions differs statistically significantly from the groups with a very low number of submissions. This implies that students at risk use matlab grader only a little or not at all. Some of the students had problems using the platform and some of them were not helped by the additional hints when they gave an incorrect answer. The evaluation findings are being incorporated into the redesign of the concept for learning analytics with Matlab Grader. The following changes will be made for the continuation of the concept in the coming semester:

1. introduction of bonus system and time limit for submission

In order to increase students' motivation to actively work on the exercises, bonus points will be awarded for the exam. These will be added depending on the number of Matlab Grader exercises completed correctly. In addition, the exercises will only be available online until the next lecture and no longer for the entire semester.

2. individual feedback

There will be weekly evaluations that show how actively each student is working on the tasks. Statistics will be compiled so that each participant receives feedback on how their activity level compares to all other participants. Students with particularly low activity levels are encouraged to participate more actively through personalised messages so that students at risk in particular are addressed.

3. increasing the number of submissions and revising the instructions

Due to feedback that the number of submissions of two is too low and students are sometimes demotivated as a result, this will be increased to three. In addition, the instructions for incorrect answers will also be revised.

ACKNOWLEDGEMENTS

The research work is kindly supported by the Ministry of Science and Culture of Lower Saxony (Germany). The authors would also like to thank the participating students for their co-operation and feedback. The unknown reviewers are thanked in advance for their comments.

ACADEMICS' PERCEPTIONS OF TRANSVERSAL SKILLS: A CASE STUDY IN A NEW ENGINEERING PROGRAMME AT THE NORWEGIAN DEFENCE UNIVERSITY COLLEGE

DOI: 10.5281/zenodo.14254766

ABSTRACT

This case study explores academic staff's perceptions of 'Transversal Skills' (TS) and the impact of educational philosophies on their development within the Civil Engineering Programme at the Norwegian Military Academy, part of the Norwegian Defence University College (NDUC). The study employs Colaizzi's descriptive phenomenology (Beck 2023) to capture academics' views through five interviews, a focus group for reflective discussion on the initial findings, and an analysis of key documents.

The findings highlight an implicit recognition among the staff of the significance of TS for practising engineers. Influencing their perceptions were personal experiences, formal and informal training, institutional frameworks, and governmental regulations. Nonetheless, ambiguity and discrepancies in terminology persist. Challenges in developing TS include achieving a balance between ensuring staff autonomy and providing more structured guidance, better aligning programme elements, and leveraging relatively small class sizes.

Furthermore, this paper delves into the concept of skills, questioning the sufficiency of 'skill' to encapsulate complex practical knowledge, especially against the backdrop of an evolving work landscape driven by technological advancements (Mitchell and Guile 2022). The literature review reveals a lack of research focusing on educators. The findings suggest a need for more explicit definition and integration of TS, guidance in curriculum design, the development of more robust evaluation and assessment techniques and a need for more specific staff support. This aligns with

---

the overarching aim of this preliminary study, which is to enhance the teaching, development, and assessment of TS.

1 INTRODUCTION

The critical role of engineers in addressing societal challenges is universally acknowledged. Various initiatives and reports underscore the necessity of equipping them with 'transversal skills' (TS) for active participation in the global workforce (UNESCO 2021; Jalali et al. 2022). Evidence reveals a positive correlation between the integration of TS in university curricula and graduates' performance in the workplace, yet also often reveals a misalignment between educational outcomes and employer expectations (Souppez 2023; Belchior-Rocha, Casquilho-Martins, and Simões 2022). In response, Norwegian Higher Education (HE), guided by government regulations, emphasises the development of TS without explicitly mentioning the term (Meld. St. 14 (2022-2023)).

This study presents preliminary findings from my doctoral research at the Institute of Education (IOE), UCL's Faculty of Education and Society. My initial focus was on incorporating 'global responsibility' within engineering education (Truslove et al. 2022). However, the accelerating workplace evolution, particularly with the mainstreaming of Artificial Intelligence (AI), redirected my research towards clarifying and cultivating the wider range of skills modern engineers require in the workplace (Mitchell and Guile 2022; Munir 2022). This paper, stemming from an Institution Focused Study (IFS), advocates for an educational paradigm that transcends technical knowledge to enhance skills like communication, cooperation and empathy, fostering a supportive learning environment where students benefit from both their successes and failures.

1.1 Context

Since 1750, the Norwegian Military Academy has educated engineering officers, adapting to evolving professional demands. The conceptual framework of TS emerged from the traditional 'soft skills' concept, originally rooted in US Army initiatives from the late 1960s (CONARC Staff 1973). Despite ongoing debates about the definition of soft skills, their importance has continued to gain acceptance (Joie-La Marle et al. 2022). This has led to the current exploration of TS within the Academy's Engineering Programme. The study leverages insights from the *European Transferability of Skills Across Economic Sectors* report and the ESCO/EQF expert group taxonomy to examine how TS are integrated and perceived in engineering education.

Fig. 1. The transversal skills and competences model (ESCO/EQF TSC expert group, 2021) Hart et al. 2021.

Summarised in Figure 1, TS are defined as essential abilities for effective action in any work, learning, or life activity, encompassing personal effectiveness, relationship, impact and influence, achievement, and cognitive skills (Hart et al. 2021).

This study examines staff perceptions of TS and aligns with the European Commission's Skills Agenda (2020). It distinguishes students' lifelong learning from employability and work readiness, aiming to align educational outcomes with the demands of both military service and the broader engineering profession.

1.2 Aims and Objectives

My study aimed to critically examine the staff's perceptions of TS within the Academy's Engineering Programme, aligning with my belief in the necessity of engineering curricula to extend beyond technical proficiency. The primary research question was: *How do academic staff perceive transversal skills and their development in the new engineering programme at the Norwegian Military Academy?* This was supported by sub-questions addressing the influence of institutional and broader engineering sector factors on TS definition, the emphasis on TS in the programme's learning outcomes, and the integration and support for TS within the educational approach.

The objectives were to understand how past experiences, societal influences, and individual educational beliefs interact with institutional expectations to shape TS development. The study aimed to enhance understanding of how TS are perceived, developed, assessed, and evaluated by the Academy's staff, hopefully contributing to meaningful future improvements. Although the site is a military academy, the engineering component adheres to curriculum regulations, with most staff being civilian educators and engineers. The study hopes to offer broader insights into engineering education and address a gap in current research on TS, particularly regarding educators' perspectives.

2 CONCEPTUAL FRAMEWORK

In writing the IFS, I chose to present a conceptual framework, based on existing theories and research (Maxwell 2022). Given the interpretive paradigm of my study, developing a theoretical framework to address the complex phenomenon proved impractical (Jabareen 2009). Instead, I focused on defining 'skills,' a concept often vaguely treated in soft skills research. Skills are often conflated with related concepts such as attitudes, beliefs, and values (Matteson, Anderson, and Boyden 2016, 80). Further complicating discourse, skills, generally referring to the application of methods in specific tasks, are again conflated with 'competencies,' which encompass broader capabilities in complex situations (Hart et al. 2021). The Norwegian Qualifications Framework (2011) and OECD (2015) highlight this distinction by categorising skills into cognitive, practical, creative, and communicative types. Winch (2010) emphasises that skill development involves more than technique (or technical knowledge); it requires judgment, perceptual abilities, and consistent habits. Schraw & Moshman (1995) add that procedural and conditional knowledge are essential for mastering techniques and understanding their application. This conceptual complexity guided my framework, informing my literature review and subsequent analysis. By grounding my study in a nuanced understanding of skills, I aim to contribute to my own conceptual understanding and provide a foundation for further exploration in my upcoming doctoral thesis.

3 LITERATURE REVIEW

The IFS drew on 40 articles from the ERIC database, exploring the dialogue on the intersection of soft skills terminologies with the domains of 'education' and 'engineering' with only a selection of those articles presented in this paper. There was a notable gender balance in authorship despite predominantly featuring Western perspectives. The review also incorporates pivotal documents such as the *Norwegian National Curriculum Regulations for Engineering Education* (2018). A thematic content analysis (Daley and Baruah 2021) of this document reveals a strong emphasis on problem-solving, analytical thinking and interpersonal skills. This reflects findings from other studies (Saunders and Bajjaly 2022) and suggests that regulations might benefit from a more balanced approach to TS.

The reviewed literature predominantly addresses student development and pedagogical methods, and studies on perceptions offer mainly industry and student views on TS (Groeneveld, Vennekens, and Aerts 2022; Markes 2006; Munir 2022; Rayner and Papakonstantinou 2015; Boelt, Kolmos, and Holgaard 2022; Chan, Zhao, and Luk 2017). The review illustrates a gap in research focusing on teachers' perceptions of TS despite their significant role in shaping educational outcomes. Some studies touch on teacher perspectives but focus on subgroups like pre-service science teachers or investigate specific educational strategies without thoroughly exploring teachers' conceptual understanding of TS (Erdogan and Ciftci 2017; Rahman et al. 2022; Lima et al. 2007; Alves et al. 2016). Saunders and Bajjaly's (2022) survey of over 1000 academic staff across six disciplines was one notable study in which they highlight this oversight and suggest a broader concern in higher education about integrating and teaching soft skills. The review suggests a need for more research into how educators perceive and teach these skills, especially in engineering education, where practice and learning are central (Johri and Olds 2014).

Furthermore, the review highlights the methodological challenges inherent in assessing and evaluating TS, an issue echoed across the literature. While various pedagogical approaches for developing TS were examined, there is an expressed need for robust assessment tools capable of capturing the nuances of these skills (Cruz, Saunders-Smits, and Groen 2020). The selected literature underscores the complexity of defining, teaching, and evaluating TS within engineering education.

4 METHODOLOGY

My experience as an engineer and educator in Norway, shaped by a diverse professional journey through engineering, military, humanitarian, and academic realms, informed the research design (Maxwell 2013). My positionality as both an outsider in Norway and an insider within engineering and military education enriched my perspective, offering a nuanced understanding of the challenges in these fields (Bukamal 2022). Guided by an interpretive paradigm, the study valued personal meaning to understand complex human experiences through qualitative methodologies (Maxwell 2013). Focusing on individual academic lecturers in the Academy's Engineering Programme, this study utilised phenomenology to uncover their perceptions of TS (Larsen and Adu 2022).

4.1 Method

This study adopted Paul Colaizzi's descriptive phenomenology, aiming to reveal phenomena (Beck 2023) and practise 'qualified naïveté' to remain open to new phenomena without preconceived notions (Brinkmann and Kvale 2018). Acknowledging the limitations of completely setting aside biases, as suggested by Merleau-Ponty (1956), the method involved five semi-structured interviews to prompt in-depth reflections on TS, complemented by an ex-post focus group to discuss initial findings collectively (Morse 2006). Colaizzi's procedure guided the extraction and interpretation of significant statements (see Figure 2).

A case study approach enabled an empirical investigation of TS conceptualisation within the real-life context of the Academy's Engineering Programme, incorporating multiple sources of evidence (Robson and McCartan 2016). The flexible nature of qualitative research allowed responsiveness to developments throughout the study (Maxwell 2013). Triangulation ensured a comprehensive exploration, supported by peer debriefing with the doctoral programme cohort (Robson and McCartan 2016, 172). This approach reflected my positionality as an educator-researcher, aiming to scrutinise TS from an educational perspective rather than a practitioner's viewpoint in developing these skills in the classroom.

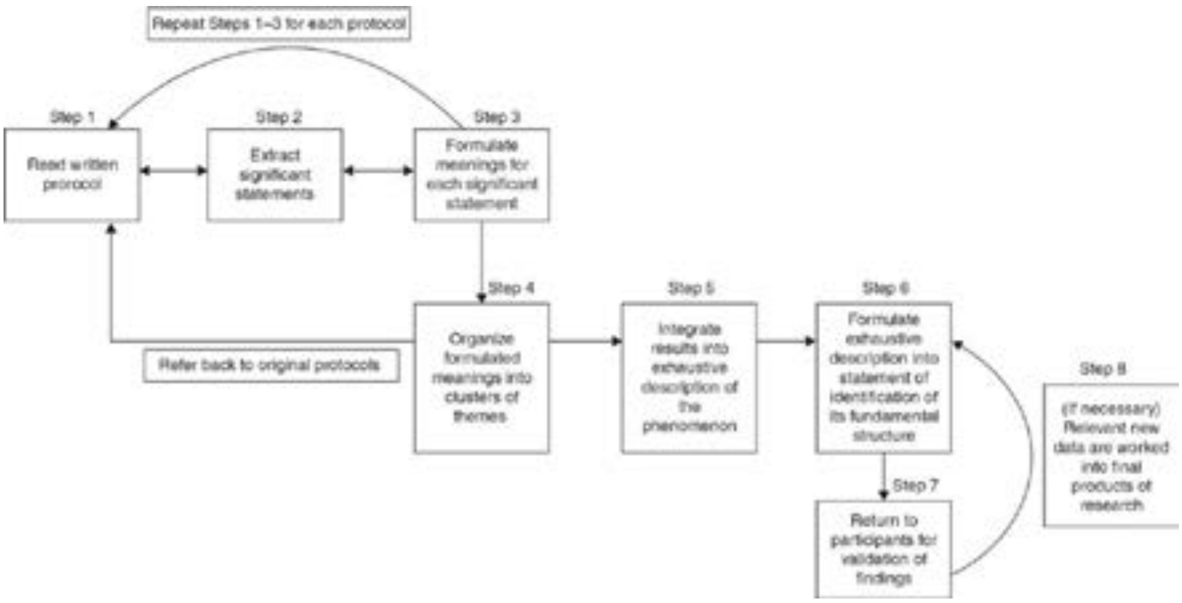

Fig. 2. Colaizzi's procedure and steps for analysing data phenomenologically (Beck and Watson 2008, 231) Used with permission from Wolters Kluwer Health Copyright © 2008.

Gender perspectives were considered to address the traditional male dominance in engineering and military environments (Korsvik and Rustad 2018). Ethical considerations were integrated throughout the research process, from planning to conclusion, with particular attention to potential impacts on participants and the broader educational community (Kara 2018). Ethical standards were maintained by obtaining informed consent, navigating potential conflicts of interest, and securing approval from relevant bodies (BERA 2018; Sikt 2023).

The validity of the research was grounded in a rigorous methodological approach, though further validation was sought through a focus group in step 7 of Colaizzi's procedure. Triangulation, employing multiple data sources (Maxwell 2013, 128), and peer debriefing reinforced the study's aim. These steps aimed to enhance understanding of how academic staff perceive and integrate TS, contributing to meaningful improvements in TS development.

5 FINDINGS

The Academy's Engineering Programme prepares students as professional engineers and military leaders. The objective of the study was to contribute to existing knowledge and provide a basis for programme development and future research. The study uncovered varied perspectives among academic staff on TS, revealing nuanced differences in conceptualisation yet a common acknowledgement of their importance for students' success. Six key themes emerged around the implicit understanding of TS, the impact of institutional structures on their development and integration into pedagogy, and the challenges of aligning these with the Programme's learning outcomes, summarised in Table 1.

Table 1. A summary of key themes and corresponding statements of identification were revealed during the phenomenological study of staff perceptions of TS.

Perceptions and Conceptual Understanding of Transversal Skills	Staff perceive TS as fundamental yet implicitly understood aspects of the Academy's programme and an engineer's future practice. They were defined as competencies developed through practical experience, reflective practice, and teaching-learning interactions. This view frames TS as embedded within educational activities, encompassing, but not limited to, problem-solving, critical thinking, communication, and social skills. Most staff emphasise the acquisition of TS through maturation rather than direct instruction.
Institutional Barriers and Opportunities	Methods for developing TS revealed a tension between the value staff place on autonomy and a need for more structured guidance from the institution. Although all staff appreciate their freedom in choosing teaching methods, there is a visible yet often unarticulated need for more guidance in integrating TS into the curriculum. This situation highlights the challenges of ensuring the programme's outcomes while maintaining diverse pedagogical approaches, further challenged by the limitations of a small professional community, disparate programme components, limited timeframes, and lack of leadership of programme implementation.
Pedagogical Approaches to Developing Transversal Skills	Staff lean towards active learning methods, such as Problem-Based Learning (PBL), for the development of TS with an emphasis on creating a secure and supportive learning environment. Reflection from staff reveal a challenge in balancing teaching theoretical knowledge with practical application, crucial for embedding technical and soft skills engineering education. Achieving this balance involves navigating the complexities, but also opportunities, of incorporating TS into a curriculum that also satisfies the Curriculum Regulations.
Staff's Professional Development and Learning	Professional development and learning among staff are depicted as a personal journey, merging formal education with practical experience and learning. Some staff align their teaching approaches through formal education, while others depend more on practical experience, shaped by personal and professional values. This blend exposes a tension between available formal education opportunities and more informal, experience-based development. A lack of perceived awareness to structured professional development opportunities also was evident.
The Evaluation of Transversal Skills Development	The limited discourse on the evaluation of TS indicates a nascent interest in developing assessment methods that reflect the integrated nature of TS within the Programme. Although efforts to establish TS evaluation strategies are in their infancy, there is a recognised need for clearer, more systematic approaches, aligning with the

	Programme's learning outcomes with the aim of enhancing cadet development.
Education in a Military Context	The educational attitude within the military context seeks to balance individual advancement with collective responsibility, merging technical knowledge with leadership training grounded in the Armed Forces' core values. Insights from staff suggest an educational philosophy that goes beyond traditional engineering instruction, aiming to cultivate responsibility, leadership, and a collective identity further enhancing the development of TS critical for cadets' success in their roles as officers.

The investigation reveals a complex interplay of perceptions and institutional influences on the development of TS. Staff members shared that their professional, cultural, and social backgrounds heavily influenced their implicit and sometimes explicit understanding of TS, aligning with findings from McDonald (2011) on perception as a subjective process shaped by individual experiences. A fragmented perception and a lack of consistent terminology were noted, suggesting a gap between individual concepts and broader soft skills terminologies, as discussed by Markes (2006) and Matteson et al. (2016). This supports the literature on the often-ambiguous nature of soft skills terminology, indicating a need for more precise definitions, at least within the context of the NDUC.

Teaching approaches were often influenced by staff experiences and the belief in the value of experiential learning, with a focus on methods like PBL and reflective activities, pointing to the effectiveness of these strategies in TS development. However, concerns were raised about balancing the technical content with soft skills development, suggesting that TS emerge through maturing, experience, and reflection rather than traditional teaching methods (Mitchell et al. 2019). Institutional structures, including NDUC and Armed Forces guidelines, and the broader Norwegian engineering education sector, play a subtle yet significant role in defining TS and again influencing pedagogical practices. Interviews revealed a disconnect between regulations and soft skills terminology, suggesting room for better alignment.

In conclusion, academic staff at the Academy implicitly understand and perceive the development of TS, while stating their importance for student's success. This is reflected in their approaches to integrating skills like communication and critical thinking into their teaching. Their engagement with pedagogical approaches balanced both technical and soft skill development, while emphasising experimental learning. Staff critically reflected on the resources and development opportunities provided by the NDUC, while highlighting challenges such as balancing teaching autonomy with more structured guidance and leveraging small class sizes. These reflections underscore the need for more precise guidance, focused leadership, and better integration of TS, aligning with the broader goal of this study to investigate the integration of soft skills into teaching, as recommended in the HE literature (Saunders and Bajjaly 2022). Understanding staff perceptions of TS aligns with my belief that engineering curricula must extend beyond technical proficiency and balance theoretical knowledge with a more diverse skill sets needed by engineers in the 21st century. These insights are crucial for exploring improvements to staff professional development, programme content, and evaluation and assessment methods.

6 SUMMARY

This preliminary study delved into the nuanced and complex perceptions of academic staff regarding transferable skills (TS), highlighting both the philosophical discussions surrounding the concept of skills and the practical implications in educational settings. The findings underscore the varied perspectives on TS, reflecting broader discussions on the nature of skill and competence in the literature. Despite the acknowledged importance of TS for students' development, a noticeable gap exists in teacher-focused research, with existing studies primarily concentrating on industry and student perspectives. This study also revealed that while staff recognise the significance of TS, challenges persist in integrating these skills into the curriculum, impaired by the lack of clear guidance and the need for improved assessment methods.

Winch (2010) argues that the term 'skill' is insufficient to describe the complexities of practical knowledge, while Dennett (2018) suggests that competence can exist without full comprehension, indicating that our understanding might be limited by our first-person perspective. This notion extends to the evolving nature of skills in the age of machine learning and AI, where we benefit from advanced algorithms without fully understanding them (Daugherty and Wilson 2018). Despite the importance of comprehending skills, few studies focus on teachers' perceptions, unlike numerous studies on industry professionals, employers, and students. Saunders and Bajjaly (2022) also highlighted this gap, noting that professional development often addresses soft skills without verifying if they are already being taught. This lack of focus on teachers might be due to engineering education research traditionally emphasising practice and learning (Johri and Olds 2014).

To address these challenges, several action points are considered, including defining TS within the specific context of the programme at NDUC, while acknowledging that a universal definition is unlikely; more detailed mapping of the development of TS and competencies within the programme; investigating, developing, and validating robust TS assessment and evaluation methods, potentially leveraging AI and learning analytics; and improving opportunities for professional development and understanding of the Scholarship of Teaching and Learning (SoTL) within the programme.

Reflecting on my findings, it is evident that while academic staff have a sense that their current practices are effective, the mechanisms and reasons for their effectiveness remain unclear, opening multiple avenues for further research. Finally, despite this study being conducted at a military academy, it is believed that the findings are applicable across engineering education in Norway and potentially Europe. These insights contribute to a deeper understanding of TS within engineering education and signal a need for further research, particularly in evaluating and assessing TS development to better align with the objectives of outcomes-based education.

ABSTRACT

E-portfolios offer numerous advantages in engineering education, including the possibility for students to construct their own learning journey. By engaging in this individual learning journey, students acquire the competencies which are essential for lifelong learning (LLL). This study outlines the implementation of an e-portfolio based on the personal development process to support engineering students in the development of these LLL competencies. Using a pre-post design, the effectiveness of this e-portfolio is measured using a LLL attitude questionnaire in the first and second bachelor. Findings reveal a nuanced progression in LLL attitude, warranting further research. Next steps for research and practice are discussed.

1 INTRODUCTION

1.1 E-portfolios in higher education

E-portfolios have been a popular educational tool in higher education for quite some time and have been deployed in a diverse range of disciplines and contexts (Chaudhuri and Cabau 2017; Harun, Hanif, and Choo 2021).

The use of an e-portfolio in higher education has many advantages. First, it allows students to construct their own learning trajectory. Students can have different educational backgrounds, learning experiences, interests, and competency levels. An e-portfolio allows for students to work on competencies which are relevant to them individually and, as such, plays into today's diversity in student groups (Chaudhuri and Cabau 2017; Roger and Kolmos 2020). Second, an e-portfolio can be the common thread in study programmes with integrated learning experiences. It supports educators in seeing the bigger picture of an individual student and students in saving their feedback and reflection for future use (Chaudhuri and Cabau 2017; Alam et al. 2015). Final, the e-portfolio allows students to communicate their acquired competencies to possible future employers or use its content to construct their cv (Alam et al. 2015; Gutiérrez-Santiuste et al. 2022).

This study focuses on the first advantage of students being able to construct their own learning journey by engaging with the e-portfolio. Students not only acquire and record competencies in the context of the e-portfolio, they also gain other competencies by going through this learning journey. For example, students rely on themselves to take charge of their learning process. They have to take initiative and responsibility to learn in a self-directed manner (Alam et al. 2015; Huang et al. 2012). This is strengthened by reflection that takes a central role in effective e-portfolios (Alam et al. 2015; Harun, Hanif, and Choo 2021). E-portfolios oblige students to reflect about themselves, their competencies, the curriculum, their learning approach, their results and other topics depending on the context. Reflection about necessary and acquired competencies relates to the learning competencies of self-assessment and self-evaluation. These learning competencies, and many more such as goal setting, self-regulation, and motivation, can be acquired by engaging with an e-portfolio (Alam et al. 2015; Harun, Hanif, and Choo 2021; Huang et al. 2012).

1.2 Lifelong learning (competencies)

Due to continuous changes in technology, techniques and tools, as well as changes in required professional competencies, engineers need to constantly go through a learning process making lifelong learning (LLL) essential (Galanis et al. 2017; Authors Sankaran and Rath 2021). For engineers, (Cruz, Saunders-Smits, and Groen 2020) identified five competencies that are essential to act as a lifelong learner: (1) locating and scrutinizing information, (2) willingness, motivation and curiosity to learn, (3) self-monitoring, (4) self-reflection, and (5) creating a learning plan. When looking at the learning competencies triggered by e-portfolios, considerable overlap between these competencies and the LLL competencies can be noted. It becomes clear that the use of an e-portfolio and the opportunity to construct a learning journey can contribute to the LLL competency development.

Higher education carries the responsibility to adequately prepare engineering students for their professional career, and thus for lifelong learning (Yap and Tan 2022; Authors 2023). This means that the competencies necessary for LLL need to be part of the engineering programme and the e-portfolio seems a valuable tool to fulfil this role.

1.3 The personal development process

This raises the question of what an e-portfolio can and should look like. Patel et al. (2013) argue that competency development is not achieved through merely filling in a form a couple of times per year. Students have to engage in a learning process, which is dynamic and continuous. This also relates to the discussion on product versus process-based approach in e-portfolios (Alam et al. 2015). A showcase e-portfolio is meant to show accomplishments and competencies to potential future employers and is focused on the *product*. A developmental e-portfolio focuses on the *process* by providing a space where students can reflect on their competencies and competency development. While both are valuable, the latter is the most relevant for preparing students for LLL.

In their work, Patel et al. (2013) define a five-step personal development process (PDP) which can serve as the base of an e-portfolio:

1. **Identifying** gaps in competencies (skills, knowledge, and attitudes).
2. **Prepare** for learning by setting a (SMART) goal and identifying resources and opportunities.
3. **Act** on this plan.
4. **Monitor** the learning process.
5. **Reflect** on how the learning process can be improved and what the future learning needs are.

1.4 The current study

Although the engineering education literature agrees on the importance of lifelong learning and its role in higher education, research on the implementation of interventions for this purpose is limited. This paper aims to answer the following research question: To what extent can an e-portfolio based on the personal development process contribute to an increase in the LLL attitudes of engineering students?

This paper describes the implementation of an e-portfolio, specifically based on the personal development process. The long-term goal of this e-portfolio is to prepare engineering students for LLL by including LLL competencies in the curriculum. First and second year bachelor students are asked about their attitude towards LLL and the LLL competencies before and after a semester of using the e-portfolio. The effectiveness of the e-portfolio as a tool to promote LLL is investigated by comparing the change in students' perceptions before and after the use of the e-portfolio.

2 METHODOLOGY

2.1 Sample and procedure

Students from an engineering technology faculty in Belgium (Flanders) in the engineering technology bachelor programme participated in this study. Data was collected via a survey at the start of the second semester of academic year 2022 – 2023 (pre-test) and at the beginning of the first semester of academic year 2023 – 2024 (post-test). The pre-test was filled in by the first (N = 21, see Table 1) and second year (N = 30) bachelor students. Later for the post-test, the same student groups were asked to fill in the survey and a subset of the first (N = 20) and second year (N = 23) replied. Some students filled in both surveys (N_1 = 14; N_2 = 16). Students were asked by a PhD researcher to participate during a class according to privacy and ethical guidelines (G-2022-5292-R2(MAR)). For example, it was stressed that participation was voluntary and not rewarded.

Table 1. Participating students (N)

	Pre-test	Post-test	Overlap pre and post-test
Bachelor 1	21	20	14
Bachelor 2	30	23	16
Total	51	43	30

2.2 Materials and measurements

The **PDP e-portfolio** was integrated into a project-based learning course and presented as a tool to develop students' professional competencies during the project. An overview of the topics included in the e-portfolio to trigger each of the PDP steps is included in Appendix A.

A **survey** including three questions to measure students' attitude towards LLL was distributed via pre-post testing. In the pre-test students' perceptions were asked about (1) the importance of each of the LLL competencies in engineering practice, (2) the extent to which the competencies are taught in their curriculum, and (3) the extent to which the competencies are assessed. In the post-test the students were asked about (1) the importance of each of the LLL competencies in engineering practice, (2) the extent to which the LLL competencies are present in their curriculum, and (3) how competent they think they are in the LLL competencies. All questions allowed responses on a four-point scale with the following structure: Not important – Somewhat important – Important – Very important. The students answered each question for each of the LLL competencies, namely (1) locating and scrutinizing information, (2) willingness, motivation and curiosity to learn, (3) self-monitoring, (4) self-reflection, and (5) creating a learning plan. In addition, (6) lifelong learning by itself was also added as one of the competencies.

2.3 Research design and analysis

The pre and post-test were first analysed separately using descriptive statistics and correlational analysis. Differences between the bachelor years were tested using a Wilcoxon test after a Shapiro-Wilk normality test indicates a non-normally distributed data. For this analysis the full dataset was used, meaning that, for example for the pre-test, all students who filled in the pre-test were included regardless of whether they filled in the post-test.

These cross-sectional analyses were followed by a longitudinal analysis using the data from the students who filled in both the pre and post-test (see Table 1). The differences between the pre and post-test were tested using a random intercepts model. This is a linear model which allows for a different intercept for each individual and exists of:

- A fixed main effect of the timing of the survey: pre or post (categorical)
- A fixed main effect of the student group: bachelor 1 or 2 (categorical)

- A fixed interaction effect between the timing of the survey and the student group

The random intercepts model is visualised to aid interpretation.

Data analysis was conducted in R Studio using the nlme package for the linear mixed model and ggplot2 for visualisations.

3 RESULTS

3.1 Cross-sectional analysis of the pre-test

Table 2 includes the descriptive statistics of the pre-test. The Wilcoxon test indicates no significant differences between the first and second bachelor.

Table 2. Descriptive statistics of the pre-test

	Importance				Taught				Assessed			
	Ba 1		Ba 2		Ba 1		Ba 2		Ba 1		Ba 2	
	M	SD	M	SD	M	SD	M	SD	M	SD	M	SD
Locating and scrutinizing information	**3.2**	0.6	**3.2**	0.9	**2.9**	0.3	**2.9**	0.6	**2.5**	0.8	**2.5**	1.1
Willingness, motivation, and curiosity to learn	**3.2**	0.5	**3.2**	0.9	**2.1**	0.9	**2.1**	0.8	**1.8**	0.7	**1.8**	1.1
Self-monitoring	**3.1**	0.6	**2.9**	0.8	**2.1**	0.7	**2.5**	0.9	**1.9**	0.8	**2.0**	0.8

Self-monitoring	**3.0**	0.6	**2.8**	0.9	**2.8**	0.6	**2.4**	0.7	**2.5**	0.7	**2.3**	0.7
Self-reflection	**2.8**	0.8	**2.8**	1.0	**3.1**	0.8	**3.0**	1.1	**2.7**	0.9	**2.6**	0.9
Creating a learning plan	**2.6**	0.6	**2.0**	0.6	**2.5**	0.7	**2.4**	0.7	**2.2**	0.8	**2.0**	0.9
Lifelong learning	**3.2**	0.6	**3.2**	0.8	**2.9**	0.6	**2.5**	1.0	**2.8**	0.6	**2.6**	0.7

3.3 Longitudinal analysis of the pre and post-test

In Table 4 the mean scores for the importance variable can be compared between the pre and post test.

Table 4. Descriptive statistics of the importance variable

	Bachelor 1				Bachelor 2			
	Pre		Post		Pre		Post	
	M	SD	M	SD	M	SD	M	SD
Locating and scrutinizing information	**3.0**	0.4	**3.3**	0.7	**3.3**	0.9	**3.4**	0.7
Willingness, motivation, and curiosity to learn	**3.2**	0.6	**3.1**	0.6	**2.8**	0.8	**3.1**	0.8
Self-monitoring	**2.8**	0.7	**2.6**	0.6	**3.0**	0.8	**2.8**	0.9
Self-reflection	**3.0**	0.8	**2.7**	0.8	**2.3**	1.0	**2.8**	1.2
Creating a learning plan	**2.8**	0.8	**2.6**	0.6	**2.0**	0.7	**2.1**	0.6
Lifelong learning	**3.5**	0.8	**3.2**	0.6	**3.1**	0.9	**3.3**	0.8

The random intercepts model indicates a significant main effect of the student group for *creating a learning plan* ($t = -3.03$; $P < .01$) is found and can be recognised as the horizontal distance between the lines on Figure 1. This means that the students in bachelor 2 find *creating a learning plan* less important than the students in bachelor 1.

Further, a significant interaction effect of the student group and the timing (pre vs. post) for *self-reflection* ($T = 2.17$; $P < .05$) which can be recognised by the intersecting lines on Figure 1. This means that the attitude change for *self-reflection* from the pre to the post test depends on the bachelor year. In bachelor 1 there is a decrease in the perceived importance of self-reflection, but in bachelor 2 there is an increase.

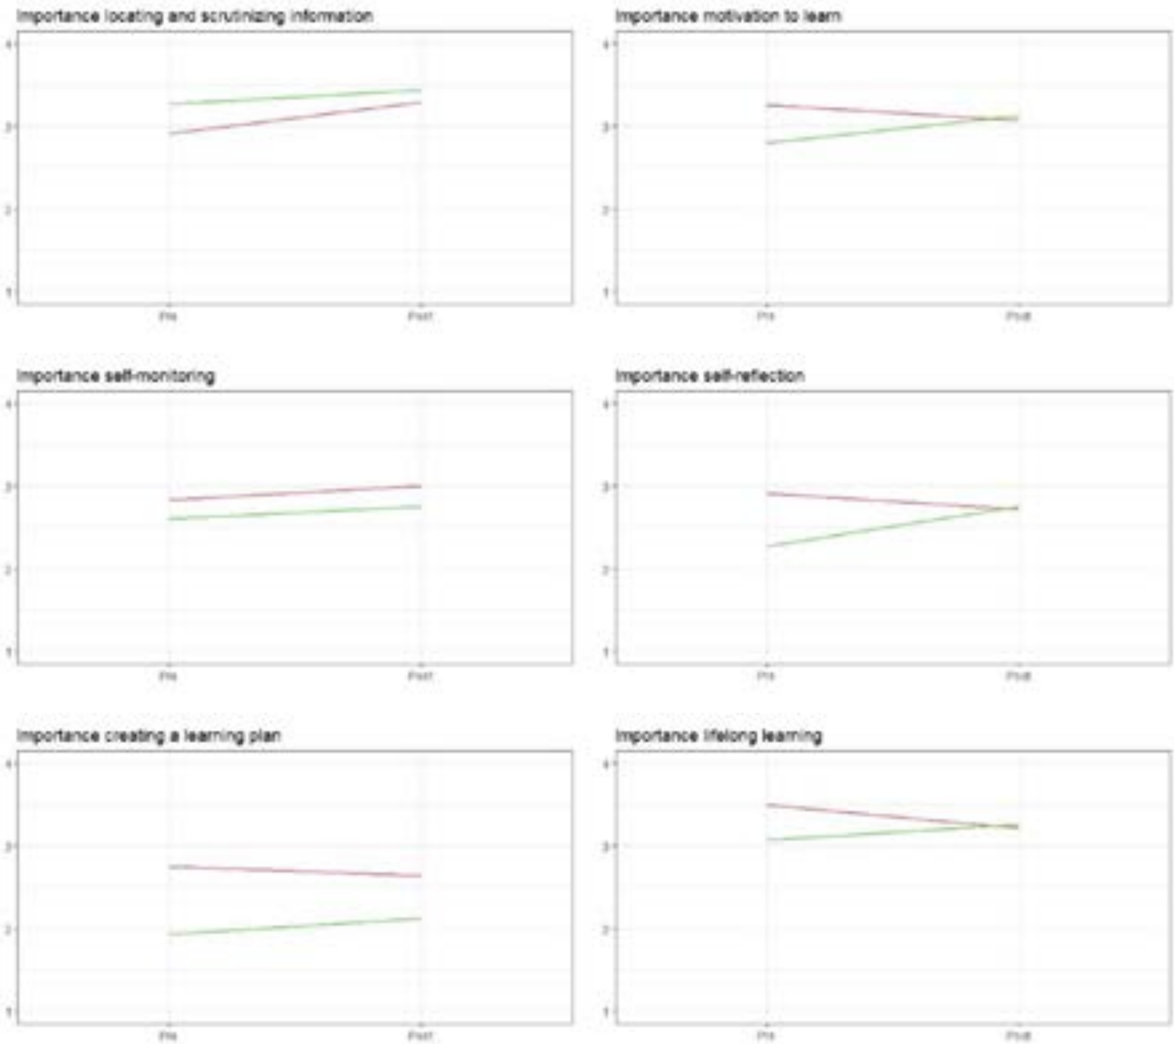

Fig 1. Visualisation of growth of importance. Pink = bachelor 1; green = bachelor 2.

4 DISCUSSION

4.1 Discussion of the results

To support the development of LLL competencies, an e-portfolio based on the PDP was implemented in an engineering technology programme. The effectiveness of this intervention was measured using attitude measures in a pre-post design.

In the pre-test, students of the first and second bachelor were asked about the LLL competencies and their importance, the extent to which they are taught and the extent to which they are assessed. The first bachelor students perceived the general lifelong learning competency to be the most important (M = 3.5), but not that extensively taught (M = 2.4) and assessed (M = 2.1). This decrease in scores from the importance to taught to assessed variable can also be identified for the LLL competencies. The data from the second bachelor contains a similar relationship between the variables, however, LLL is indicated to have the same importance as the LLL competencies. When zooming in on the taught and assessed variable it can be seen that locating and scrutinizing information as well as self-reflection are taught and assessed the most for both the first and second bachelor. This is in line with the fact that these competencies are included the most explicitly in the curriculum.

Analysis of the post-test shows similar results. Lifelong learning remains one of the most important competencies in engineering practice but is less present in engineering education. A new variable here is competency level variable (how competent do you think you are?) where the relatively modest answers of the students stand out (bachelor 1: 2.2 – 3.1; bachelor 2: 2.0 – 2.6). These means are around the midpoint of the scale and lie between ‘somewhat competent’ and ‘competent’ on the response scale. In previous research at the same university, the lifelong learner scale (Authors 2023) was used to measure LLL preparedness and this measurement painted a more positive picture with a mean score well above the midpoint of the scale (M = 3.44; Min = 2.57; Max = 4.57). Two different measures which aimed to measure a similar idea – LLL attitude vs. LLL preparedness – thus paint a slightly different picture.

The longitudinal analysis of the data points out that the second bachelor students find being able to create a learning plan significantly less important than the first bachelor students. It is notable how they find creating a learning plan to be only somewhat important while they indicate lifelong learning to be the second most important competency in the list. This finding aligns with other (currently unpublished) observations of ours on how students conceptualize lifelong learning as being open-minded and curious, and associate it with informal and unintentional learning, and thus without a learning plan. Meanwhile professionals seem to have a more formal idea of lifelong learning with employees taking on courses or doing direct self-study where a learning plan becomes more relevant. If this is the case, the discrepancy between students’ and professionals’ conceptualisation of lifelong learning can cause a misunderstanding between recent graduates and their employers. This line of research needs to be further inspected within our data and evaluated for generalizability.

A main effect of the time point – pre versus post testing – is not present in the data. Inspection of the visualisations in Figure 1 point out that a more complex effect might be at play here. The first bachelor students seem to go through a drop in attitudes between the pre and post test while the second bachelor students go through an increase. Only for self-reflection, this interaction effect is significant, but visually it can be identified for most other variables as well. This decrease in the first bachelor can be a consequence of students initially having less experience with these competencies and perceiving their importance to be very high. By engaging with the e-portfolio they initially become more critical (post-test, first bachelor), while the second bachelor’s are starting to recognize the importance of LLL and LLL competencies. This progression is similar to what is called the Dunning-Kruger effect (Dunning 2011) where people initially overestimate themselves because of a lack of knowledge and experience, but later, when they are more experienced, underestimate themselves.

4.2 Next steps

This final section includes some next steps in the implementation of the e-portfolio based on the results, including (1) changes to the e-portfolio for next academic year, (2) the measurement of LLL competencies, and (3) the research design of the next e-portfolio.

Currently, the PDP is present in the e-portfolio (Appendix A), but student go through multiple cycles in one semester. The time in between the cycles is too short to fully engage in self-monitoring. In a next version of the e-portfolio, students will go through only one PDP cycle per semester to increase the time for monitoring one's own learning process. Additionally, the different steps of the PDP as outlined by Patel et al. (2023), as well as the idea of the PDP as a process, will be made more explicit for students. Making competencies explicit seems to work, as can be seen in the higher scores for self-reflection and locating and scrutinizing information for the taught and assessed variables (as seen in section 3.1 and 3.2).

The competency level variable aimed to capture how students would estimate their competency level and the slightly different results we have found previously using a survey (LLS; Authors 2023) raise questions about their validity. Future research will have to point out which measures are better at predicting actual LLL behaviour or an increase in their actual mastery of the LLL competencies. A first step here will be to compare the self-reported measures with (1) grades on relevant assignments such as self-reflection exercises or learning plans in the context of the e-portfolio, and (2) interviews with students giving insight in how they answer these questions and how it relates to their competencies.

The effectiveness of the e-portfolio in this study is inconclusive because of a lack of a control group. Future studies using the more explicit PDP e-portfolio, as described above, will include a control group to compare the natural growth in LLL attitudes to the growth in a student group with an e-portfolio. Qualitative data collection will be used to further underpin conclusions.

Keywords: *mental models, think-aloud protocol, mechanical objects, conceptual understanding, thermodynamics*

ABSTRACT

This study employed a think-aloud methodology to delve into the intricacies of student cognition and problem-solving behaviors in the context of thermodynamics education, specifically focusing on the challenging domain of psychometrics. By elucidating the cognitive strategies employed by students with and without the use of physical objects, the study aimed to provide valuable insights into the efficacy of tangible learning aids in enhancing conceptual understanding and problem-solving proficiency in thermodynamics. The study findings reveal that the presence of a simple physical object facilitated the development of robust mental models in the participants from the group with the object, enabling a more intuitive grasp of problems and alignment with scientific principles. Suggestions for implications for engineering education and further research are shared in the conclusion of this paper.

1 INTRODUCTION

The use of physical artifacts in STEM education has become a significant teaching strategy for demystifying complex and abstract concepts. By providing tangible representations of complex ideas, these artifacts offer students hands-on experiences that enhance understanding and memory (Koretsky et al., 2018; Mitropoulos et al., 2024). Especially in subjects like mathematics and physics, where learners often confront abstract theories, physical models, manipulatives, and simulations become critical for linking theoretical knowledge with practical application (Bain et al., 2014; Rogers, 2023). For example, in mathematics, tangible tools such as geometric shapes and algebraic manipulatives allow students to interact with abstract concepts in a visual and tactile manner, thereby promoting active learning and deeper comprehension (Kuhn, 2022).

Furthermore, these artifacts are essential for situating STEM concepts in real-world scenarios, making the theoretical knowledge more relevant and applicable (Koretsky et al., 2018; Kuhn, 2022). By mimicking real-life situations or natural phenomena, they help students bridge the gap between classroom learning and practical applications, emphasizing the real-world utility of STEM education (Mitropoulos et al., 2024). In the context of engineering education, the deployment of physical prototypes and lab equipment enables students to apply theoretical principles in the creation and testing of actual systems, fostering essential skills such as problem-solving, critical thinking, and experimentation—all crucial for success in STEM fields (Nottis et al., 2018; Rogers, 2023).

In engineering specifically, the abstract and complex nature of thermodynamics presents a considerable challenge for many students (Bain et al., 2014). Nevertheless, integrating physical artifacts into the learning process can significantly enrich students' educational experience in this area (Kuhn, 2022). Utilizing tangible objects like pistons and phase change models allows educators to concretely demonstrate key thermodynamic principles such as energy transfer and entropy. These physical models not only facilitate the visualization of abstract concepts but also enable hands-on exploration of variables and their effects, deepening students' understanding of thermodynamic principles (Bain et al., 2014; Rogers, 2023; Saricayir et al., 2016). Through these practical tools, educators can successfully bridge theoretical knowledge with its practical applications, preparing students to navigate the complexities of thermodynamics in real-world engineering contexts.

This paper discusses a portion of a broader study focused on evaluating the impact of physical artifacts on the learning experience within thermodynamics education. Specifically, it examines how these tools influence student cognition and the development of mental models during problem-solving tasks. Utilizing a think-aloud protocol, the study explores the cognitive strategies employed by students when faced with thermodynamics problems, with and without the aid of physical artifacts. The investigation centers on problem-solving sessions related to critical topics in thermodynamics: heat and work, entropy, and psychometrics. This paper particularly emphasizes the findings from sessions on psychometrics, aiming to uncover how tangible learning tools affect students' mental models and problem-solving approaches. Through this detailed analysis, we seek to highlight the value of physical artifacts in enhancing students' understanding and mastery of complex thermodynamic concepts, contributing to the literature on effective teaching strategies in STEM education.

1.1 Abstract and difficult topics in engineering thermodynamics

Thermodynamics is the branch of physics that deals with the relationships between heat, work, energy, and the properties of matter, explaining the principles governing the behavior of systems undergoing thermal processes (Drake, 2021; Steane, 2016). Abstract and difficult topics in engineering thermodynamics often present formidable challenges for students (Bain et al., 2014). Concepts within thermodynamics delve into the fundamental principles governing energy transfer, heat exchange, and the behavior of complex systems, posing significant cognitive hurdles due to their abstract nature and mathematical intricacy (Bain et al., 2014; Kuhn, 2022; Saricayir et al., 2016). Topics such as entropy, which quantifies the disorder or randomness of a system, and thermodynamic processes involving heat and work interactions, require students to grapple with theoretical frameworks that can be challenging to visualize and comprehend (Foroushani, 2019). Additionally, psychometrics, which deals with the properties of moist air and their applications in air conditioning and refrigeration, introduces complexities stemming from the non-linear relationships and multifaceted interactions inherent in air-water vapor mixtures (Foroushani, 2019; Steane, 2016). The abstract nature of these topics, coupled with their inherent complexity, underscores the need for innovative pedagogical approaches and effective instructional strategies to facilitate students' understanding and mastery of thermodynamic principles.

1.2 Conceptual understanding

Conceptual understanding lies at the core of effective learning in thermodynamics, providing students with a robust foundation upon which to navigate the intricate landscape of this discipline. Unlike mere memorization of formulas and procedures, conceptual understanding entails grasping the underlying principles, relationships, and phenomena that govern thermodynamic systems (Foroushani, 2019; Saricayir et al., 2016). It involves the ability to interpret and apply abstract concepts in diverse contexts, discern patterns and trends within complex data, and make connections between theoretical knowledge and real-world phenomena (Saricayir et al., 2016). A strong conceptual understanding enables students to not only solve problems algorithmically but also to reason critically, analyze situations holistically, and devise innovative solutions to novel challenges in thermodynamics. Through engaging in activities that promote conceptual understanding, such as inquiry-based experiments, modelling exercises, and collaborative problem-solving tasks, students can develop deep insights into thermodynamic principles, fostering enduring comprehension and proficiency in this intricate discipline (Ertikanto et al., 2023; Nottis et al., 2018; Rogers, 2023).

1.3 Mental models

Mental modelling is a cognitive process wherein individuals construct internal representations or mental simulations of external phenomena, systems, or processes to understand, predict, and interpret their behavior (Johnson-Laird, 1995). In the context of thermodynamics, mental models play a crucial role in how students conceptualize and make sense of complex phenomena such as heat transfer, entropy changes, and thermodynamic cycles (Ertikanto et al., 2023). By mentally constructing simplified versions of thermodynamic systems and processes, individuals can explore the relationships between variables, anticipate system behavior, and formulate hypotheses about outcomes. Mental models serve as cognitive frameworks that facilitate problem-solving, decision-making, and the interpretation of experimental data within the domain of thermodynamics (Hsu &

Thomas, 2002; Kirschner & Van Merriënboer, 2013). As students engage in learning activities, they continuously refine and adapt their mental models based on new information, experiences, and feedback, leading to a deeper understanding of thermodynamic principles and their applications.

Through the iterative refinement of mental models, students develop metacognitive awareness and self-regulation, enhancing their ability to transfer learning to novel contexts and apply acquired knowledge in practical situations (Nilson, 2013). Overall, the deliberate integration of mental models in education fosters active engagement, conceptual understanding, and metacognitive development, empowering students to become lifelong learners equipped with versatile cognitive tools for navigating the complexities of the world around them.

2. METHODOLOGY

This study employed a think-aloud protocol to investigate the cognitive processes and problem-solving strategies utilized by students in understanding and solving psychometrics problems in thermodynamics. Sixty students overall participated in the think-aloud protocol study. For the purpose of this study, the researchers worked with the transcripts of ten students who sat down for a think-aloud session that was focused on understanding the problem-solving mental models when students engaged in solving psychometrics-related problems. The think-aloud sessions were conducted a week later after the problem-solving section on psychometrics. Five students were selected from a group that used physical objects as aids during problem-solving sessions, while the other five were chosen from a group that did not utilize any objects. Each student engaged in a step-by-step verbalization of their problem-solving procedure while tackling the psychometrics problems. The think-aloud sessions were audio-recorded to capture the students' verbalizations in real-time and lasted approximately 45 minutes each.

Subsequently, the audio recordings were transcribed verbatim, and the transcripts were cleaned to remove any extraneous speech or irrelevant content. Thematic coding was then applied to the transcripts to identify emerging themes and patterns in the students' problem-solving approaches. The coding process followed Mettes et al. (1980, 1981) an established procedure tailored to the step-by-step method commonly used in problem-solving and recently adapted to the context of statics in Taraban et al. (2008). The codebook was further augmented to include student experiences and resource usage based on previous work done by McNeil et al. (2016). This systematic approach ensured consistency and rigor in the analysis of the think-aloud data, allowing for the identification of key insights into students' mental models and cognitive processes during psychometrics problem-solving.

This study’s codebook was based on the phases and subphases developed by Mettes et al. (1980, 1981) referred to as the Program of Actions and Methods (PAM) for systematic problem solving in science. The PAM is divided into 4 phases as illustrated in figure 1. Mettes et al. (1980, 1981) divided each phase into subphases that were used as 28 codes in this study, similar to what was done in Taraban et al. (2008). Figure 2 illustrates the conceptual model of student’s belief about engineering problem solving developed by McNeil et al. (2016). This study used the

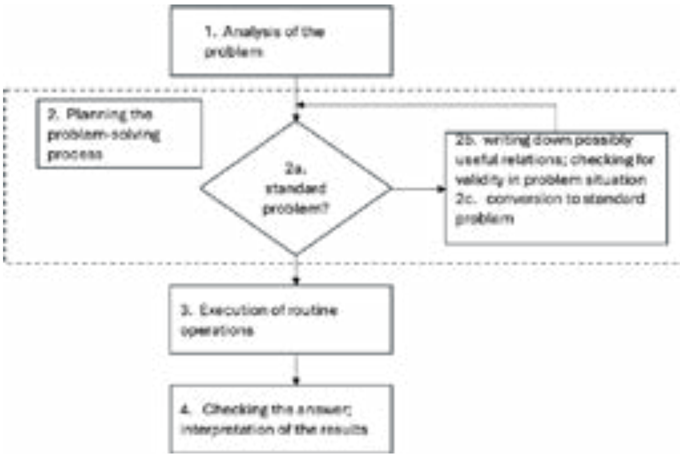

Fig. 1. Principal Phases of the PAM for systematic problem solving (Mettes et al., 1980)

elements of this model as 17 codes to further analyze the think aloud session transcripts.

3 RESULTS AND DISCUSSION

For this study, as well as the larger study, the researchers use Dedoose to code the think aloud session transcripts. The team looked into the code application tables as well as the co-occurrence matrix to investigate the potential themes arising from the coding process. Figure 3 represents the packed code cloud generated by Dedoose as a weighted representation of the codes present in the studied sample. It is important to mention that not all the codes have been observed in this first set of coding for this specific exercise given the nature of the posed questions.

The study results indicate that all participants present at the problem-solving session related to psychometrics engaged initially with the problem statements, an action likely influenced by the directive nature of the interviewer's prompt. This finding

Fig. 2. Student's Belief About Engineering Problem Solving (McNeill et al., 2016)

Fig 3. Packed Code Cloud

parallels the systematic problem-solving approach delineated by Mettes et al. (1980) and Taraban et al. (2008), which emphasizes the importance of the problem representation phase in the cognitive process of problem-solving. Moreover, analysis revealed a slightly more pronounced inclination among control group participants to draw upon personal and life experiences. This approach aligns with Johnson-Laird's (1995) mental models theory, suggesting that individuals rely on analogical reasoning, applying known experiences to unfamiliar problem contexts. Such strategies underscore the complexity of mapping personal experiences onto scientific principles.

The results also highlight that a subset of experimental group participants referenced mechanical objects during problem-solving, which corresponded with an enhanced use of intuition. This observation is supported by Koretsky et al. (2018) and Mitropoulos et al. (2024), highlighting the potential for tangible learning aids in fostering a deeper conceptual understanding. The reliance on intuition suggests a cognitive shift towards conceptual and principled reasoning, indicative of a deeper engagement with the material. For instance, one participant remarked, “I've always been a pretty conceptual learner, so when I can relate things to something tangible, or even just some fundamental concept, then I get it. I've never been good at remembering things at all. I can't just memorize things, so I have to really understand them.” This personal account vividly illustrates the study's findings, emphasizing the significant role that physical objects play in enhancing the intuitive grasp of complex principles for individuals predisposed to conceptual learning.

Participants from both groups eventually recognized key relationships among the variables, albeit with varying degrees of accuracy. This behavior demonstrates the cognitive effort to integrate provided information into a coherent understanding of the problem, as suggested by the coding rubric based on Mettes et al. (1980, 1981) and the conceptual model developed by McNeil et al. (2016).

Furthermore, it could be noted that participants in the experimental group sought to correlate the provided information directly with the problem or its model. This finding underscores the potential of physical artifacts to enhance the application of scientific principles to problem-solving, supporting the pedagogical value of tangible objects in abstract domains (Kuhn, 2022). Echoing this sentiment, one participant shared, “I had physically experienced all these things, so it just made a lot of sense. I think physical explanations of things have always been easier for me than, say, mathematical explanations of things." This reflection reinforces the value of experiential learning through physical artifacts, underlining how tangible experiences can demystify complex theoretical concepts, thereby catering to students who find abstract mathematical explanations challenging."

Moreover, both groups demonstrated a capacity to articulate conceptual understanding and identify key relationships. Notably, the experimental group exhibited a pronounced tendency to discern and articulate law-like principles. This distinction underscores the role of physical artifacts in promoting a more nuanced engagement with and application of fundamental scientific principles, echoing findings from Bain et al. (2014) and Rogers (2023).

Finally, the coding highlighted distinct patterns in how each group approached the psychometrics problems, revealing the potential influence of tangible learning aids on their cognitive processes. Participants from the group without objects predominantly leveraged personal or life experiences in their problem-solving endeavors, indicative of a reliance on analogical reasoning. This strategy suggests an attempt to bridge abstract thermodynamics concepts with familiar real-world contexts, a method that can offer intuitive insights but also risks inaccuracies when analogies do not fully align with scientific principles. Furthermore, these participants often resorted to guessing and subsequently recognizing mistakes—a hallmark of a trial-and-error approach. This behavior points to less developed mental models, where uncertainty in problem-solving steps is prevalent. Despite occasionally making assumptions to simplify problems and identifying key relationships and equations, these strategies were not predominant, suggesting a less systematic approach to understanding thermodynamics problems.

In contrast, the group with access to mechanical objects exhibited a more structured approach to problem-solving. Frequent references to conceptual understanding and intuition were observed, indicating that the presence of tangible aids likely facilitated a deeper, more intuitive grasp of thermodynamics concepts. This group demonstrated a strategic approach to problem simplification and a systematic

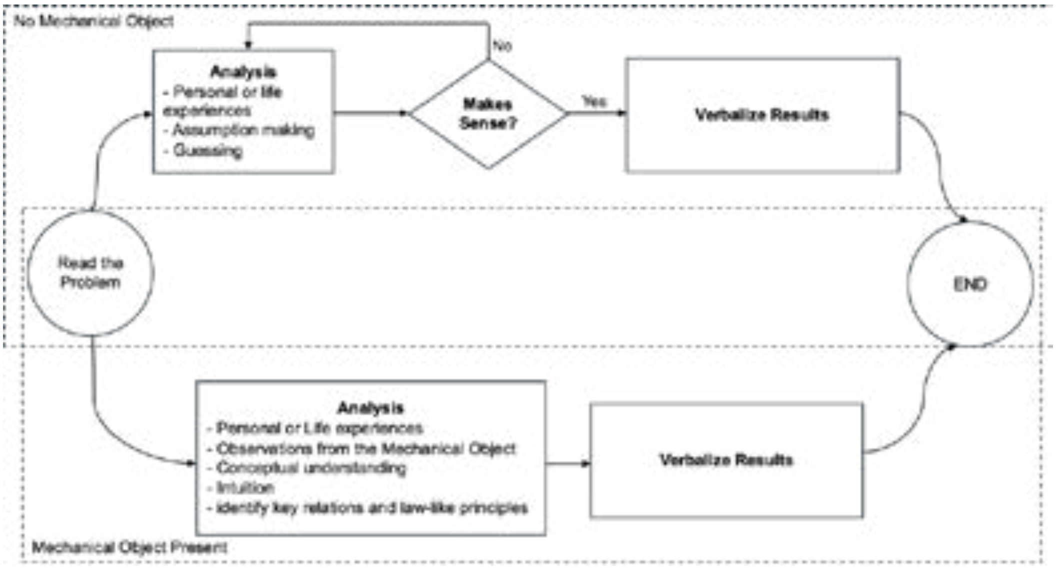

Fig 4. Simplified Student Mental Models of Problem-Solving for Each Group

breakdown of problems, behaviors that suggest well-developed, robust mental models capable of navigating complex problems with greater efficacy. The ability to identify key relations and law-like principles more frequently and accurately suggests that these participants' mental models were closely aligned with the scientific principles of thermodynamics, enabling a direct and effective approach to problem-solving as illustrated in Figure 4.

4 Conclusions and Future Works

This study, focusing on a set of ten students engaged in solving psychometrics problems, provided detailed insights into how the presence or absence of a simple physical object could influences individual problem-solving strategies and their mental models. Through the meticulous application of a think-aloud protocol, we captured the cognitive processes underpinning students' approaches to these challenges, revealing the nuanced impact of tangible learning aids on their problem-solving efficacy.

For the participants who had access to a physical object during the problem-solving sessions, there was a notable facilitation in the development of robust mental models. This select group of students demonstrated a more intuitive grasp of the problems at hand, aligning closely with scientific principles in their problem-solving efforts. Their strategies were characterized by a direct and strategic navigation through the complexities of psychometrics, contrasting markedly with their peers without such aids.

The group without physical objects leaned more heavily on personal experiences and analogical reasoning. Although creative, this approach led to a less structured problem-solving process. It was marked by a reliance on trial-and-error tactics and an observable uncertainty in applying abstract thermodynamics concepts.

This investigation's findings, while rich and informative, are contextualized within the experiences of these ten students and the specific domain of solving psychometrics-related problems. It draws attention to the potential benefits of integrating tangible objects into educational practices, suggesting that such aids could significantly impact students' understanding and problem-solving strategies. However, the observations and implications derived from this study are specific to this particular cohort and the unique set of problems they addressed.

Acknowledging the limited scope of this study—centered on a singular object and a focused problem-solving session—it was crucial to refrain from broad generalizations. The intention was to provide a detailed account of how tangible objects might influence problem-solving within a narrowly defined context. Future research is planned to extend beyond this preliminary exploration, aiming to code and analyze all think-aloud activities conducted across a broader array of topics and with a larger group of participants. This subsequent work will seek to validate, refine, or expand upon the findings presented here, offering a more comprehensive understanding of the role mechanical objects play in engineering education, specifically within the realm of thermodynamics and beyond.

ABSTRACT

Teacher burnout can be a severe problem in higher education, as it can affect the quality of education. In 2022, we started a career planning course based on Stanford's Design Your Life course (BurnettB and EvansD 2016; 2018; 2020), supplemented with positive psychological exercises, for the teachers and researchers of the Budapest University of Technology and Economics. 4 courses have taken place so far, in two types of organization (classic or intensive), with 53 participants. In the study below, we asked the previous participants to participate in a follow-up research, in which we asked about the usefulness of the course in terms of their well-being and burnout. We asked them for a subjective estimate in both areas and used an objective measurement. Their well-being was measured using the PERMA Questionnaire (ButlerJ and KernML 2016), and Maslach's Burnout Inventory (Maslach et al., 1996) was used to measure burnout. The PERMA Questionnaire was already known to them, as they filled it out at the beginning of the course and three months after the course, and it also showed positive results in the short-term follow-up (Authors 2023). One year later, based on the sample's responses (n=22), the course is particularly effective in terms of well-being, which is supported by medium and significant solid correlations. Based on this, we can conclude that the course is effective both in the short and long term, thus suitable for permanently improving the mental state of teaching colleagues.

1 INTRODUCTION

In these challenging times, the competitiveness of a higher education institution is crucial. National and international rankings of universities deal partly with the staff's academic performance metrics, such as teaching excellence and rate of publications. The other indicators related to graduates also depend on the effectiveness of the faculty. After all, only prepared and dedicated teachers can train excellent professionals. We see in the literature that the burnout of employees works against the above process, while well-being supports it (RahmT and HeiseE 2019; BallantyneJ and RetellJ 2020; Smetackova et al. 2019).

1.1 Programs targeting decrease teachers' burnout and increase well-being

As Watts and Robertson (2011) emphasized in their review article, a decade ago, burnout among academic staff was spread out. Mironova and Slokta (2021) found in their recent meta-analysis that burnout among academic staff is a common state because university teachers face many stressors that can lead to burnout syndrome. To solve the situation, we must better understand the demands and resources of higher education staff, especially teachers (Khan et al. 2017). The stressors have changed and multiplied over the last few years. However, we see a lack of techniques that can solve the situation and improve academicians' well-being (HyattK 2022).

These two phenomena are interrelated (Kolomitro et al. 2020). Programs targeting the development of critical elements of well-being are complex to study empirically. Researchers focus on specific aspects of well-being in terms of the PERMA model, a widely accepted and well-known framework (Donaldson et al. 2022; Linton et al. 2016). According to Seligman's (2011) updated model, people have to fulfill five different components to reach the state of flourishing. These are positive emotions, engagement, (positive) relationships, meaning, and accomplishment (SeligmanM 2011). Furthermore, well-being considers other factors, such as physical health, absence of negative emotions and loneliness, and presence of the experience of happiness (ButlerJ and KernML 2016).

Several studies found that engagement, dispositional optimism (Barkhuzien et al. 2014), resilience (Johnson et al. 2019), more commitment, and better work-life balance (Fontinha et al. 2019) seem to be necessary for being well (KinmanG and JohnsonS 2019) and reduce burnout in direct and indirect ways.

1.2 A possible solution: The Designing Your Life program

Our Designing Your Life Program (DYLF) is based on Burnett and Evans's "Designing Your Life" and "Designing Your Work Life" methodologies (BurnettB and EvansD, 2016; 2018; 2020). Regarding the authors' idea, a well-designed life is the key to a well-lived life and well-being. The idea came up first as a class at Stanford University designed for design students. In this approach, they used techniques that fit designers' mindsets, which means it is suitable for people who like to solve problems (BurnettB and EvansD, 2016; 2018; 2020). We expected that the design thinking mindset would also fit in with the original thinking patterns of the Budapest University of Technology and Economics teachers (Authors 2023).

Without pretensions of completeness, the most crucial Design thinking mindset elements that we touched on in the DYLF program were (based on BrownT 2008; 2009):

- Empathy: Understanding the needs, desires, and motivations of others is fundamental to design thinking. In the DYLF program, the tasks helped the participants to be empathic about themselves.
- Creative Confidence: The significance of instilling confidence in individuals to unleash their creative potential and innovate.
- Iterative Thinking: advocates for an iterative approach to problem-solving, where ideas are continuously refined through prototyping and testing. In the DYLF program, for example, we organized Living Library with participants who have worked or worked at our university and have already achieved attractive results in several career segments.
- Mindful Observation: design thinkers cultivate the ability to observe the world around them keenly, uncovering insights and opportunities for innovation.
- Collaboration: design thinking is a team sport. Bringing diverse perspectives together and fostering collaboration is critical to unlocking innovative solutions.

We had exciting results based on the data we measured during the program and the short-term follow-up (Authors 2023). First, we saw a statistically positive effect at the short-term follow-up. As relationships are essential for well-being (SeligmanM, 2002; SeligmanM, 2011; KhawD and KernML, 2014) and the program has its' effect on the relationship scale, we could say that the Designing Your Life program seems appropriate for engineering university teachers. At the end of the course, the participants had concrete plans for the following months. They have tools to use daily and planning to be more accurate and flexible simultaneously. These tools and plans can lead them through the difficulties of academic career building so that they can set more appropriate achievements. Participants gave feedback from growing social networks and felt that the university cares more about them than they had felt before the program. We also found that the workshop design is familiar to engineers' thinking, and with these small changes, we adapted it to our university's circumstances (Authors 2023).

1.3 Research questions

Our previous research confirmed that the effect of the design thinking-based career planning course on the well-being of the participating teachers can be felt in the short term (Authors 2023). In the present research, we examine the long-term effects.

Burnout is a syndrome to avoid, while well-being is a generally desirable state. The course provided the tools to achieve and maintain this dual goal. After one year, we were curious to see if the participants used the knowledge they perceived and experienced a positive change in terms of their well-being along the PERMA factors.

This study aims to explore whether the course mentioned above is an appropriate tool for engineering educators in the stressful context of higher education to reach a state of well-being and avoid burnout in the long run, i.e., i.e., can the results of the course be felt 1-1.5 years after the program.

2 METHODOLOGY

2.1 Study design

We planned a follow-up study for those who participated in the carrier (re)planning course. In an online questionnaire, we asked for demographic and carrier-regarded data, attitudes about the efficiency of the course, their experiences about the course in the long run with extended text answer possibilities, and some retrospective opinions about their mental state in terms of burnout and well-being.

In addition to the qualitative part, we used quantitative tools. To measure former participants' well-being, we used the PERMA Profiler (ButlerJ and KernML 2016), which they already knew, and the Maslach Burnout Inventory (Maslach et al. 1996).

We shared the questionnaire with each former participant in February 2024, 0.5-1.5 years after they finished the course.

Before starting the course, we informed the participants that the program also has a research purpose. By voluntarily participating in the program, they gave informed consent, which they had the right to withdraw at any time. The participants anonymously filled out the course and follow-up questionnaires, but their data was not processed this way.

In this study, we only focus on one part of the data.

2.2 Sample description

We asked 53 former participants to complete the online survey, and 22 responded. In this section, we describe them.

Twelve were female and ten male, which is similar to the distribution of the courses. One was a professor and one associate professor, 10 were senior lecturers, four assistant research fellows, one technical assistant, and 5 PhD students.

Participants work at the university for an average of 8.27 years with a 5.08 years SD.

16 participated in a classical course setting, i.e., 5 times in a 6-week long period, and 5 participated in an intensive course setting, i.e., in a 2.5-day long weekend training.

After the first 3 run courses, we offered former participants a 2.0 course to develop themselves, and among our respondents, 11 attended that course too.

50% of the respondents attended the first course (May 2022), 22,7% participated in the second course (October 2022), 13,6% attended the third course (April 2023), and 13,6% participated in the fourth course (September 2023). That means that 53% referred to more than 1.5-1-years effects, 14% to short one-year effects, and only 13% had less than 1-year impact. The data is retrospective and self-reported based on former participants' memories and everyday experiences. In this sense, researchers have to trust respondents as psychological changes are the best experienced by the person themselves.

3 RESULTS

3.1 Effectiveness of the course – descriptives

Half of the sample (n=11) said they had significantly shifted their career since the course ended. Many of them got their degrees or started their doctoral plot (n=6), have successfully won tenders of excellence (n=3), and reached higher or better positions (n=4). However, it is interesting that there is no difference in any of the examined indicators between the participants who achieved progress and those who did not. From this, we can conclude that the later described changes in well-being are not the results of material changes associated with progress but the totality of the internal changes induced by the course.

On a 10-point Likert scale, participants reported the course's general efficiency at 8.32, which means excellent. We also asked them about the usefulness of the PERMA factors because the course tasks were related to the different aspects of well-being (see Authors 2023) on the same 10-point scale shown in Table 1.

Table 1. The usefulness of the course in terms of the PERMA factors

Well-being aspect	Mean	SD	Range
Positive shift in the emotional life (more positive and less negative emotions)	7.27	2.41	1-10
Engagement (finding the intrinsic motivation and one's own goals in work)	7.77	1.95	3-10
Relationships (better and more satisfying network, less feeling of loneliness)	6.55	2.32	2-8
Meaning (finding coherence, meaning, and long-term goals)	7.32	2.01	2-8
Accomplishment (reframing of challenging situations, setting SMART goals with higher demand level)	7	2.05	1-8

In addition, we asked participants to guess how much they were burnt out before attending the course. They referred, on average, 7.27 points on a 10-point Likert scale where one was not at all and 10 was completely burned out. In these terms, the participants were highly loaded and close to complete burnout.

Based on our data, we see that there are positive correlations between work experience (measured in years) and usefulness in positive emotions ($r=.473$, $p<.05$) and motivational changes ($r=.446$, $p<.05$).

3.2 Good practices are taken from the course

Participants shared the three words that came to mind regarding the course. In our translation, these were their primary cognitive and emotional experiences from the course. In Figure 1. we show the diverse answers.

Fig. 1. Answers to the question "What are the three words that come to mind concerning career planning?" The bigger the word is, the more people say it.

We asked the participants what practices or tasks they have used since the course ended. 17 of the respondents mentioned tasks from the original Carrier (re)planning course that they used (i.e., planned in the frame of Designing Your Life Program and directly related to PERMA factors) and pick-up tasks (i.e., come additionally to the tasks) too listed in Table 2. Many of the respondents mentioned more tasks.

Table 2. The usefulness of the course in terms of the PERMA factors (n=17)

Task	Type	Well-being aspect
Odyssey plan (to plant at least 3 different lives)	DYL	meaning
Good times diary (to collect flow activities)	DYL	positive emotions
Concrete action plan (to choose one goal and plan the way to reach it)	DYL	negative emotions
Work-life attitude (to write essays about values)	DYL	engagement
SMART goals (to learn how to write a SMART goal)	pick-up	accomplishment
mind-map making (to learn how to group ideas and tasks)	pick-up	meaning
physical to-do and done list (to feel success and capacity)	pick-up	accomplishment
breathing exercises (to learn physical techniques to cope with stress)	pick-up	health
5-minutes rule (to learn time management)	pick-up	engagement

From the advanced course, they referred to deeper self-knowledge tasks, such as DISC personality classification. However, the whole 2.0 course was a networking event, which weighted the relationship well-being factor.

Based on these results, we can say that they used the tasks as expected and extended the tasks to each well-being factor.

4 SUMMARY AND ACKNOWLEDGMENTS

At the beginning of the DYLF program, the university's main objective was to support colleagues in various critical career stages at a leading national technology university. This is based on preventing burnout and increasing well-being, according to Rahm and Heise (2019), Ballantyne and Retell (2020), and Smetackova and his colleagues (2019).

Critical stages are most often characteristic of periods around the transition of different career stages, for example, before a step forward and at the same time a more significant challenge, or after the step forward, entering a new unknown stage. One of the biggest challenges of the university career is that it typically consists of more significant milestones, with each stage spanning 3-10 years.

Awareness and appropriate human relations are necessary to maintain motivation. During the DYFL course, participants also practice planning short, mid, and long periods. If they become more successful, their commitment and awareness will also increase. The university is interested in providing a long-term perspective for its employees to reduce career-related stress. A better and more satisfying network and less loneliness give inspiration at the critical points.

This follow-up study shows that the DYFL course can support the university's primary goal of keeping and developing employees. So, it can answer the poor toolkit that Hyatt (2022) stated.

We consider the main result of the course that they felt burned out, but based on the follow-up study results', they experienced a positive shift in all areas of well-being elements, according to Seligman (2011), especially in engagement, which allows colleagues to find their intrinsic motivation and look for such goals that lead them to flow experiences as an essential aspect according to Berkhuzien and his colleagues (2014). They are more able to see the big picture, which helps them know the meaning of their huge efforts, strengthening resilience (Johnson et al. 2019; Fontinha et al. 2019). A motivational change appeared as a parallel, mutually reinforcing effect among colleagues with more work experience.

A remarkable result is that they use well-being techniques and exercise what they learned, which is a key to success, according to Kinman and Johnson (2019). This feedback means that they find the course valuable, and the practices fit into their original mindset, so they are familiar with it. This result strengthens the idea that the DYLF-based program is appropriate for the engineering field of higher education, strengthening the main idea that this Designing Your Life program was first dedicated to design students (BurnettB and EvansD, 2016; 2018; 2020).

Last but not least, a good quality of social network and increased collaborative skills are crucial. They mentioned various forms, and almost every time in the follow-up study, the teams at teamwork experiences which are crucial for well-being (SeligmanM, 2002; SeligmanM, 2011; KhawD and KernML, 2014).

However, the ecological validity of the results is limited to our university our former (Authors 2023), and current results are impressive and suggest that the modified DYLF program is a potential and innovative tool to strengthen the psychological capital of engineering educators.

4.1 Acknowledgments

We are grateful to the Budapest University of Technology and Economics, especially the Talent Support Council, for enabling and supporting the organization of the course.

The National Talent Program (NTP-HTTSZ-23-A-0004) project supported some of the program's courses.

4.2 Limitations and Further Research Directions

Participation in the course was voluntary by the university lecturers, so in a certain sense, motivated staff participated in the study. Hence, the generalizability of the results is limited. It is also important to emphasize that we worked explicitly with teachers participating in engineering education at a university, which may limit the validity to other fields of higher education.

Since the sample size was relatively small, it was just enough for statistical tests; the conclusions are currently valid in our narrow area, i.e., engineering education. As a further research direction, it would be worthwhile to test the program's scenario widely initially with higher education instructors who volunteer and then expand it into a generally available university well-being development program. Our results are positive and perspectival. The empirical impact assessment of both programs is the task of the future.

ABSTRACT

The rise of new teaching formats poses opportunities and challenges for educators. While promising enhanced content transfer and engaging learning experiences for students, they also bring added responsibilities and risks for educators, accountable for student outcomes. Podcasts, a novel tool in engineering education, illustrate this trend. Despite studies on student agreement, teachers' perspectives are often overlooked. This paper bridges this gap by examining educators' experiences with podcasting. Beyond assessing its didactic potential, it explores practical challenges and educational adjustments required. Recognizing teaching quality's reliance on educators' capabilities and resources, the study underscores the importance of holistic considerations in integrating podcasts. By highlighting educators' viewpoints, this research aims to guide successful incorporation of podcasts into education, informing future strategies and supporting pedagogical innovation.

1 INTRODUCTION

New teaching formats are popular. They promise teachers a better transfer rate of their teaching content and students a welcome change in their everyday learning routine. Such new formats are often discussed in terms of their didactic potential for increasing learning outputs (Colis & Moonen 2001; Indahsari 2020). However, from the educators' point of view, who feel responsible for the learning success of their students, they always represent a risk, a great deal of effort in addition to the usual research and teaching load, and often also a personal challenge if the new formats require them to leave their comfort zone of familiar and proven roles and routines. Podcasting is a new format that is currently being experimented with in engineering education. A podcast is a digital audio or video program that is made available on the internet for downloading or streaming. A good podcast can serve as the basis for decision-making or as a synopsis for a listener to gain knowledge on a specific topic (Spina et al. 2017). Similar to screencasts and learning games, a medium traditionally associated with private use and entertainment is now being harnessed for targeted knowledge transfer within the realm of higher education. Initial studies on the acceptance and learning success of students as well as descriptions of different didactic objectives and integration into the course sequence are emerging (Peters, Hagedorn & Stark 2021; Engzell & Norrman 2023). What has not been considered so far is the perspective of the educators, whose professional background generally qualifies them neither as media producers nor as journalistic talk show hosts. Thus, this is the main focus of this paper. Past research has prioritized the perspective of students over that of educators (Cooper 2008; Farshi & Mohammadi 2013; Sabrila & Apoko 2022). However, learning success depends on the quality of teaching, e.g. teaching materials. This quality, in turn, depends on the educator and resources of the educator, especially in the case of newly developed formats. This paper therefore examines the experiences of educators, or teachers, who have ventured into podcast production as a teaching tool to find out what should be considered apart from the didactic potential when considering integrating this new format into teaching. This paper seeks to explore the issues of (a) *How do educators perceive the effectiveness of podcasting as a pedagogical tool in enhancing learning outcomes in engineering education? and (b), What practical adjustments and resources are necessary to support effective implementation?*

2 FRAME OF REFERENCE

Students learn in different ways, a fact that has been observed by e.g. Kolb (1984) among others, hence teacher need to take this into account when designing their lessons and learning materials. The term "blended learning" (cf. Garrison & Kanuka 2004; Ginns & Ellis 2007; Lopez-Perez et al. 2011) is a way to meet this as it integrates traditional face-to-face lecturing with digital learning platforms. Besides this, teachers also need to create (cf. König 2021; MacInnis et al. 2012; Zimba et al 2021) among the learners. Several studies show the importance of active learning designs (cf. Biggs 2003; Politis 2005; Gibb 2002) as they encourage deeper understanding. The "flipped classroom" model (Bergmann & Sams 2012) entails that the theoretical input is acquired by the students through e.g. literature, video lectures or podcasts ahead of a teacher-led activity. The benefit of this is that the students can acquire the knowledge and understanding needed at their own pace and then deepen their knowledge during the teacher-led activity. According to our experience, so-called podcasts, by means of pre-recorded audio tracks where course content is treated in the form of a dialogue between two or more parts, can be a great tool for teachers, both to enhance knowledge and understanding and to create inspiration to learn and understand more.

3 METHODOLOGY

The usage of case study methodology is a viable approach for delving into complex and less-explored subjects (Yin 1984). Various scholars have embraced case studies to explore podcasts in higher education from diverse angles (Cartney 2013; Lewis & Francis 2020). This study employs a multiple case-study approach to investigate the distinct differences and similarities among podcasts at two different universities. Our study comprises three different podcast cases. Multiple-case studies are known as more robust compared to single-case studies, as they offer the opportunity to observe and analyze a phenomenon across multiple contexts (Yin 1984). Thus, this approach not only facilitates comparison among different cases to yield similar results (literal replication) but also enables the exploration and validation of patterns identified in initial cases (theoretical replication). Hence, this methodology does not prescribe a fixed number of cases required to fulfill the replication strategy; rather, cases are chosen based on theoretical criteria established to identify podcasts for higher education (Laing & Wootton 2007; Sprague & Pixley 2008). These criteria, gleaned from the literature, are demonstrating the various perspectives of why students prefer them and how they are used in learning (Chester et al. 2011; Knowles 1975; König 2021). Cases were selected based on diversity and university (providing technology and engineering programs).

The data collection methods employed was in line with the multiple case-study approach. To ensure the validity and reliability of the study (Yin, 1984), diverse sources and extra materials were gathered for all three cases. These sources included university publications such as magazines, publications and websites, as well as podcasts and related audio materials that could be found at the universities.

Regarding data analysis, the cases were analyzed using variables such as e.g. didactic goal, didactic integration, role of the teacher, personal challenges, and practical challenges, thus enhancing reliability across all cases (Yin 1984).

Analysis was conducted searching for patterns, differences, and similarities. The authors did comparative reflection rounds in addition to doing a comparative analysis of the podcast material. In sum, this methodology enabled us to do triangulation of perspectives, evaluations, and other data through a comparative and inductive analysis (Eisenhardt 1989; Jick 1979).

Besides these, all the authors have produced podcasts and used them in their teaching. This have benefited our analysis.

3.1 Potential of podcasting: Three Case Studies

3.1.1 Case 1: Interviewing befriended scientists for making students experience effective learning strategies

In the first case, a teaching podcast at TU Berlin funded by ”Qualitätspakt Lehre” by the Z for Y, a cross-sectional bachelor course on ”Fundamentals of Industrial Information Technology for Engineers ” was chosen (for more detail see Peters, Hagedorn & Stark 2021). This course is mostly taken by young students during their first semester who in Germany usually start their studies with little experience in effective and self-organized learning after the strictly pre-structured learning routines of their school vitae. The podcast was intended to provide these students with learning experiences that would improve their self-learning skills by experiencing that 1. preparing oneself helps following the lecture and thus makes attending it more effective, 2. listening is not the same as active listening and learning, and 3. the effects of distributed learning over time. To accomplish this, a podcast episode relevant to the upcoming lecture topic was released one week prior to the lecture and was paired with a mandatory quiz that students needed to complete before attending the lecture. This way, the students went into the lecture prepared, were able to follow it more easily and were less likely to drift off. Continuous engagement with the topics made learning easier at the end of the semester. In addition, they learnt to recognize if they were actively listening or if they were listening but not processing information, as in the latter case they failed the quiz even though they had listened to the episode.

The podcast featured an assistant teacher, chosen for their familiar rapport with students. Research assistants from a partnering Fraunhofer Institute, well-versed in relevant topics through their PhD research, were selected as guests due to their close working relationships with the podcast producers. Their similar age to students and informal rapport with the interviewer aimed to cultivate a relaxed podcast atmosphere. Additionally, their proximity to TU Berlin's podcast studio facilitated easy participation and integration into existing collaboration routines. Collaboratively, a rough script was prepared for each episode to ensure alignment with lecture content. Five episodes were produced, initially recorded at TU Berlin 's studio and professionally edited. Later episodes adhered to COVID-19 regulations and were recorded via Zoom. Access to the podcast was restricted to TU Berlin's online platform, as some interviewees preferred limited accessibility, a deviation from the initial agreement.

3.1.2 Case 2: Engaging academia experts to offer theoretical insights to students from varied scientific backgrounds, disrupting conventional learning routines

The second case, from TU Berlin and funded by the "Freiraum" programme of the Foundation for Innovative University Teaching, addresses Master's students in a module on transdisciplinary technology development in the context of sustainable and fair urban mobility. The challenge here lies in the broad interdisciplinary composition of the participants with their heterogeneous learning habits. In order to favor no disciplinary group over the others, a format for providing theoretical input was needed that was equally unfamiliar and low-threshold for everyone. Thus, the podcast format was chosen. Interviewees were chosen according to their outstanding expertise on the episodes topics from other departments and other universities, some of them international. Thus, the teachers could expand vastly the sources of expertise that contributed to the course input and even integrating first-hand multiperspectivity. Also, the search for qualified dialogue partners resulted in a rapidly growing network of experts for the teachers and their departments that greatly facilitated access to the scientific community of "transdisciplinary research".

Extensive planning preceded the podcast's development, addressing various media aspects including interviewer role, audience relationship, language use, and interview structure, all aligned with didactic goals. The interviewer, also the course teacher, adopted an approachable persona, fostering student engagement through relatable dialogue devoid of technical jargon. This carefully crafted role aimed to establish a relaxed atmosphere, facilitated by the informal German "du" form of address. Pre-interview meetings were crucial in overcoming hierarchical barriers, ensuring a trust-based environment. However, logistical constraints led to remote interviews, with sound editing undertaken by the teacher using Audacity. Despite efforts, the lack of professional conditions extended editing time, indicating a need for improved post-processing in future endeavors. Two episodes were double-interviews with two interviewees at the same time, other interviewees contributed to more than one interview, so that eight interviewees were involved but not necessarily one per episode.

3.1.3 Case 3: Experimenting with academic colleagues for innovative teaching approaches

"The Auditory Classroom" was a one-year explorative project on how to create podcasts to complement and broaden the teaching in Linköping university courses and make the teaching more accessible and flexible. The incorporation was to meet the demands of modern learners and the dynamic nature of academic studies. Pedagogically, the project was based on the idea of the "flipped classroom" and the division into pre-, during, and post-teacher-led activities. By listening to a podcast before a specific course moment, students' learning is facilitated (Kelly et al 2022). The opportunity to listen afterwards can also deepen understanding. Students can take greater responsibility for their studies as they have already absorbed the material in advance, thus using classroom time to build on their knowledge, ask relevant questions, and thereby progress in their learning. The teacher can therefore more quickly delve into analysis/deepening of the subject in the learning process. The goal of podcast episodes was to create different episodes covering topics, theories, and models within the subjects of project, innovation, and entrepreneurship. The idea was also to inspire and motivate students. In total, 6 episodes were created in the project covering: entrepreneurship & intrapreneurship, NABC, Challenge-based-learning, business model and BMC, pitch, and environmentally driven innovation. Participating teachers edited and edited the episodes themselves, and the music was created by an external person; Teodor Miciol. Finally, this project has emphasized the importance of incorporating student input when selecting pedagogical tools for teaching. Podcasts are just one of many educational tools that can enhance blended learning approaches.

4 DISCUSSION

Comparing the three cases reveals significant differences in didactic objectives and integration, yet similarities in project conditions and experiences. Despite variation, each podcast produced a similar number of episodes: 5, 6, 8. This highlights the importance of meeting the minimum episode requirements to maintain consistency and engagement in a recurring podcast format. While maintaining regularity demands a minimum number of episodes, the extensive production process, alongside teaching and research commitments, constrains maximum episode output. Also, a limited number of episodes of a podcast can effectively deliver focused content, keeping listeners engaged without overwhelming them. This concise format also ensures manageable production, allowing for consistent quality and the opportunity to evaluate the podcast's impact before committing to a longer series. As confirmed by previous studies e.g. Yeh (2021) and McCarthy et al (2021), guest engagement involves familiarization, preliminary meetings, and format discussions. Additionally, logistical aspects such as studio bookings and scheduling coordination are crucial. All episodes require recording, editing, and integration into online platforms, often including supplementary information and links. For a teacher with little experience in audio editing, doing all of these things on his or her own can mean 15-20 hours of work for a 30-minute episode with guests. Thus, an effort such as podcast production is only possible with additional funding, which also has been confirmed by previous studies (Sellan & Solá 2019). This leads to the further commonality of the three cases in that they were all created as part of specifically funded projects aiming at developing innovative educational formats, although the level of funding varied greatly. Depending on the equipment available at the university, there are also costs for equipment and editing software. In two of the three cases, an external music producer was hired to produce a jingle to give the podcast a professional look. In Case 1 a research assistant got sponsored for three years to develop innovative approaches to teaching of which the podcast was one result. In Case 2 the didactic development and iterative testing of a new teaching module with new teaching methods was funded, paying two research assistants for two years, also covering the 3 months of podcast production and a little equipment. In Case 3, the production was supported as a pedagogical project.

The three cases discussed are also similar in the sense that the teachers had no prior experience in this area before engaging in podcast production. Therefore, in addition to the time commitment, such a project is also fraught with uncertainty due to the number of new roles that teachers must fulfill simultaneously. In addition to their roles as researchers and teachers, podcast producers are asked to act as journalists, producers, and entertainers ~~(see Fig. 1),~~ which is not usually part of their job description. For teachers and researchers, podcast production therefore means leaving their comfort zone, increasingly so the less familiar they are with the invited guests. If colleagues are interviewed, as in Case 1 and Case 3, only the new role of a journalistic interviewer is a challenge. If, on the other hand, external experts are sought, as in Case 2, it is necessary to make contact with actors who may be higher up in the hierarchical university system. Asking unknown, senior colleagues for something without any apparent quid pro quo can cause great internal tension. On the other hand, it can pay off to withstand the potential conflicts, as proven in case 2, where the teacher and her department could build a network of top experts on the podcast topic within four months. In Case 3, the multiple roles sparked diverse discussions and highlighted the necessity of prioritization to yield meaningful outcomes and avoid potential conflicts.

In all three cases, the instructors had at least partial professional support for the technical implementation. It is an advantage if the university has a central institution for digital teaching, which may even run a podcast studio. To produce a technically high-quality podcast, professional technical support is helpful and was actively sought in all three cases. However, the sound editing was only done by professionals in case 1. In cases 2 and 3, the teachers themselves learned to use editing programs.

From a didactic point of view, the three cases show the variety of possible uses of podcasts in teaching, which also has been outlined in previous research (Laing &

Wootton 2007). In case 1, the podcast is intended to create learning experiences for first-year undergraduate students that will encourage them to develop effective learning methods. In case 2, the podcast is intended to make theoretical input equally accessible to a large interdisciplinary group of students with very different learning habits typical of their discipline. In case 3, the podcast is intended to introduce students to cross-curricular themes and serve as an inspiration for the use of new teaching formats. Cases 1 and 2 are geared to a specific course and are therefore integrated into the course in terms of time and content, while case 3 is available as a permanent offer. Podcasts can therefore be used in the classroom for both general and very specific educational purposes. In the former case, there is a great deal of freedom in the production process in terms of topic selection and preparation. However, if the podcast is to cover course content, it is necessary to check the content for compatibility with learning goals, course structure, and exam content. Didactically, in cases 1 and 2, it has proven useful to couple such podcasts with subsequent quizzes to ensure that students have absorbed the content. As confirmed in previous studies e.g. Peters, Hagedorn & Stark (2021), this is one effective way of using podcasts in teaching to improve students learning. After all, most students listen to podcasts incidentally in their everyday lives, with divided attention, e.g. while exercising or on the move. If such an everyday medium is to be integrated into the classroom in a way that is relevant to exams, it is important to ensure that users develop appropriate usage patterns. Thus, for teacher the task of producing a podcast might be linked to further tasks of producing even more new learning materials such as quizzes, lists of show notes, graphic illustrations or scripts to embed the podcast in the course didactically.

5 RESULTS AND CONCLUSIONS

In the modern educational landscape, podcasts have emerged as multifaceted tools, offering educators various possibilities for enriching teaching methodologies. Drawing from our three cases, this study delves into the multifaceted uses of podcasts in teaching, emphasizing resource needs, personal commitment, and incentives for guest participation from the educators' perspective.

One main finding is that becoming involved with podcasts as a teaching medium presents educators with new challenges (e.g. using new structures or being more entertaining), significantly diverging from their professional identities as teachers and researchers. Educators embarking on podcast production must also actively cultivate expertise in new professional domains, including both journalistic practices and technical aspects of media production. This requirement introduces psychological, social, and professional dimensions that educators must navigate. The endeavor demands considerable resources in terms of time, energy, and even financial investment – i.e. it requires a substantial effort. ~~Consequently,~~ The educators may also find themselves pushed beyond their comfort zones. Yet, despite the challenges, engaging in educational podcast production offers manifold benefits, not least through the broadened palette of reaching out with their message. Through packaging the teaching in new formats, educators gain new experiences and competencies, which can enrich their personal growth. Podcasts may also extend their network and improve their collaborative skills. Finally, teaching effectiveness and expansion of the teachers professional networks, thus augmenting their impact within the educational sphere, can also be a result. Thus, while the undertaking demands substantial effort and adaptation, the rewards in terms of personal and professional development can be profound.

Also, the integration of podcasts in teaching requires educators to embrace self-reflection and personal commitment. Stepping out of one's comfort zone and embracing innovative pedagogical tools demand a willingness to adapt and evolve.

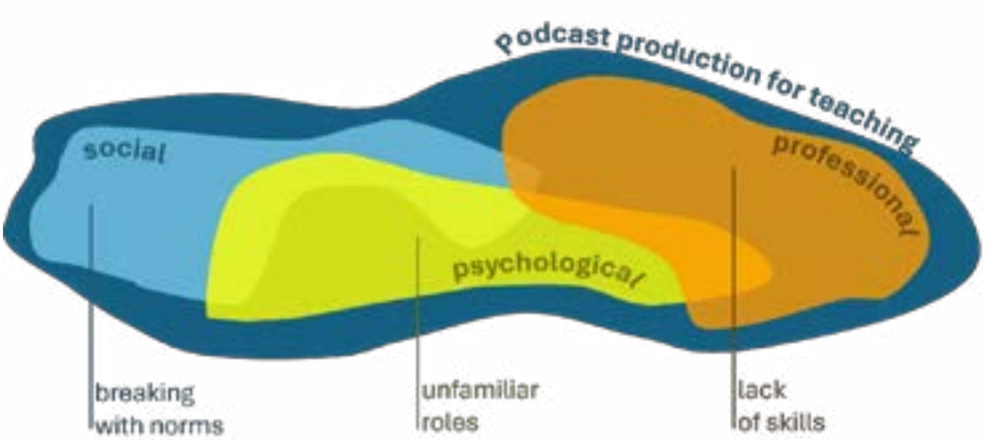

Fig. 1. Dimensions to consider when getting involved with podcasts as teaching medium

In conclusion, integrating podcasts enriches educational experiences dynamically. The comparison of podcast methodologies illustrates educators’ capacity to develop diverse episodes independently. It's crucial to recognize the considerable effort educators invest in content creation and podcast design tailored to their courses. However, the time-intensive nature of content creation, recording, and editing poses challenges, especially for educators balancing multiple roles. The article emphasizes educators’ capability to produce podcast episodes independently, with varying purposes across courses or contexts. Collaboration with podcast production and technology experts significantly enhances material quality and production efficiency. This collaborative approach played a pivotal role in improving podcast engagement and user-friendliness in the described cases.

APPENDIX

Variables	Case 1	Case 2	Case 3
Level of experience teachers? students?	No experience of neither teachers nor students to use podcasts in edu	No experience of neither teachers nor students to use podcasts in edu	Little previous experience of teachers Little experience of students to use podcasts in edu
Format of podcast	One Podcast, 5 Episodes	One Podcast, 8 episodes planned to be expanded	One podcast, 6 episodes
Purpose	To create learning experiences for freshmen to implicitly collect experiences with important learning	To replace classical disciplinary media for providing theoretical input in a broadly interdisciplinary course to provide just	To introduce students to a certain topic

	techniques without addressing it as such	accessibility to all students	
Didactic plan	Bi-weekly with additional online quiz Didactic Goals Content: Illuminating and deepening the topics of each lecture from a different perspective Competence: implicitly showcasing useful short-term and long-term learning strategies	Synchronization with the students' project working phases 90% of theoretical input via the podcast pluralization of knowledge sources on the teachers' side	Not included in the didactic plan, extra resource
Who is the receiver of the podcast	Early bachelor students	Advanced master students	Students e.g. engineering programs
Who is the speaker	Teacher (research assistant, not professor)	Teacher (research assistant, not professor)	Teachers
Guest(s) in the podcasts	Colleagues from a partnering Fraunhofer-Institute	Highly experienced (external) scientific experts on the respective topics	Teachers
Relationship between speaker and guest	Colleagues	Strangers	Know each other since before
Ambitious level of group			Vary depending on the role
Level of professionalism Quality of sound etc.	Project as Experiment accompanied by professional technical assistance but inexperienced staff; main focus: avoid discrepancies with the lecture while	Main focus: content and atmosphere (journalistic professionalism)	High expectations on sound, quality and content

	providing new learning experiences		
Funding and resources	Funded by the national Ministry for Education and Research (one educational researcher for 3 years, no equipment funds)	Funded by the German Foundation for Innovation in Higher Education (one educational researcher to develop the didactic for a module on transdisciplinary for 2 years)	Pedagogical project, very limited resources
Content	Specific topics related to Industrial Information Technology	Theory and practice of transdisciplinary research for sustainable urban mobility	Broad topics related to entrepreneurship, innovation and project management
Role of the moderator	1 moderator Interviewing colleagues from the field as additional teaching input	1 moderator identifying with the students, going on a quest to understand the topics together	Rotating the role as moderator
Dynamics of people in the studio			Structured and flexible at the same time
What can we gain? Is podcasts worth the effort from a teacher perspective?	Offer learning experiences, especially with “deep listening” vs. just being physically present	To provide students with different learning backgrounds (interdisciplinary student group) with material equally accessible to all reach students with specific learning styles or disadvantages (e.g. reading disorder or impaired vision) Offer expert knowledge from the best instead of the best knowledge of one teacher (distributed first hand knowledge resources) scientific network	To formulate and package content, to provide students with knowledge in another format

***Conference Key Areas**: Engineering skills, professional skills, and transversal skills; The attractiveness of engineering education*

ABSTRACT

Early-career engineers encounter various surprises in engineering practice when they transition from being students to becoming early-career professionals. Studies on employability identify transition issues, and in our present study the guiding research question is: what can come as a surprise to early-career engineers when

[1] *D. Friedrichsen*
friedrichsen@plan.aau.dk

entering engineering practice? In this article, we analyse qualitative data collected from interviews and identify several aspects that surprise early-career engineers. Our findings indicate that generic competences, and the importance of generic competences, may be surprising to early-career engineers. This raises questions about engineering education and whether degree programmes should take steps to better prepare students for engineering practice. Although technical competences remain the bedrock on which engineering practice rests, generic competences are identified as central in order to successfully collaborate and communicate, and therefore remain a vital component of employability alongside of areas such as the multiple roles an early-career engineer will take on, the parallel projects they must navigate, and the mutual dependency they will experience. As this article will show, these areas of concern play an important role in ensuring that early-career professionals are able to do their jobs satisfactorily.

1 INTRODUCTION

Employability is a journey, not a destination. This is the fundamental characteristic of employability, and (much like journeys) employability can be changed and developed by proactive choices as well as other factors, including personal attributes and attitudes. Employability encompasses a wide field of potential areas of interest; in this context, we use Yorke's definition to establish a baseline understanding, not least since it considers different interests:

[…] a set of achievements – skills, understanding and personal attributes – that makes graduates more likely to gain employment and be successful in their chosen occupation, which benefits themselves, the workforce, the community and the economy. (Yorke, 2006)

In line with this, Clarke (2018) insists that there are six key dimensions to a broad framework of employability: human capital, social capital, individual attributes, individual behaviors, perceived employability, and labor market forces. While some aspects relevant to an applicant's professional background may be tangible (i.e., does the applicant know the relevant software or programming language?), other central skills may be less easy to identify, and/or difficult for graduates themselves to articulate in a manner that assists their own employability. Some of these include adaptability, curiosity, proactivity, conscientiousness, goal-orientation, and more.

Furthermore, there is an expanding list of desirable competencies that employers look for, and many of these depend on a mix between professional skillsets and personal attributes. These skills are also reflected in Yorke's oft-cited employability definition which highlights the combination of both professional capabilities, disciplinary knowledge, and gainful personal attributes.

Many research projects have explored the attributes and capabilities that members of the workforce are required to demonstrate. These include teamwork, conflict management, written-, verbal and non-verbal communication, confidence, resilience, flexibility, and stress management skills (Stagnitti, School & Welch, 2010; Walker et al., 2013, Friedrichsen et al, 2023). Recent research has listed an additional set of contemporary proficiencies that graduates require, including a design mindset, virtual collaboration skills, cross-cultural competency, novel and adaptive thinking, new media literacy, social intelligence, epistemic fluency and emotional intelligence

(Davies, Fidler, & Gorbis, 2011; Goodyear & Ellis, 2007; Little, 2006; Higgs, 2009) Furthermore, it is noteworthy that transversal skills and self-awareness are highlighted as key areas, particularly given the fact that these may not immediately seem as crucially important for an engineer (Craps, 2017).

In a similar vein, Creasey stresses the importance of being able to reflect in an effort to showcase how one's experience, achievements, and skills positively influence employability. Improving employability skills, "requires students to record their achievements and to reflect on these." (Creasey, 2013, p. 18). This is a pertinent reminder that numerous skills and competences exist that influence employability, but self-awareness and reflection are required to create a realistic representation of an individual's current abilities and their employability. Whether several of these areas can or should be taught at universities is a complex issue. It is clear, however, that graduates are expected to perform on parameters beyond just the technical, and that employability relates to several different and expanding areas – some of which are surprisingly intricate and rely on personal development as much as on professional competences.

A Danish study on engineering students' perception of what is important at different stages of their studies showed a kind of instrumental turn with an increased focus on mono-discipline related engineering skills such as engineering analysis, engineering tools, and data analysis (Kolmos & Holgaard, 2019). This study indicates a situation where engineering students becomes oriented towards the disciplinary; this resonates badly with calls for generic competences and personal attributes in more differentiated employability contexts, e.g. as proposed by Clarke (2018).

In this study, we aim to characterize some of the areas related to employability in engineering education by asking early-career engineers to elaborate on their expectations about work while studying compared to their actual experience after being employed. Our research question is as follows:

What can come as a surprise to early-career engineers when entering engineering practice?

2 METHODOLOGY

2.1 Data collection

This study is based on 8 interviews with early-career engineers. The study is inductive in its approach which allows the interviewer to explore unexpected and relevant aspects of the conversation. The interviews are based on probing questions as well as emerging questions (Kvale & Brinkmann, 2009). The qualitative data was collected in October 2023. The following table (Table 1) details the educational backgrounds of the participants. Each interview was collected individually and was approximately one hour in duration. The interviews were semi-structured (Creswell, 2017) and explored the experiences and understandings of early-career engineers cf. engineering practice and their expectations in this context. The qualitative methodology (Patton, 2015) provides insights that help clarify experiences; this helps researchers' understanding based on actual experiences and subjective framings.

All interviews except one were conducted in Danish and any quotes have been translated by the authors. Participants were from three different universities: one

Japanese university, and two Danish universities. One of the Danish universities uses a PBL model, the other does not.

Table 1. Educational backgrounds, years of experience, and gender of participants

Particip ant ID	Country in which degree was obtained	Educational background	Years of experience	Gender
P1	Japan	PhD, polymer science & organic chemistry	3	M
P2	Denmark	Civil engineer (chemistry)	6 months	F
P3	Denmark	Materials technology & nano technology	3	M
P4	Denmark	Chemical engineering	10 months	M
P5	Denmark	Civil engineering (chemistry)	2	F
P6	Denmark	Chemical engineering	2	M
P7	Denmark	Chemical engineering	5	M
P8	Denmark	AP Automotive Technology	4	M

The interview data was transcribed using Whisper and afterwards double-checked and corrected by the authors. The interviews were coded in Nvivo, and the coding was guided by the following themes: generic competences, interdisciplinary, experiences, transition, and employability.

3 RESULTS

In the following we outline four surprises experienced by early-career engineers in the transition from engineering education to work. Although the interviews contain much interesting and relevant data, the scope of this article is limited to the following surprises.

3.1 Surprise number 1: The value of generic competences

The first citation describes the value of generic competences and highlights how P7 was specifically surprised at how crucial it is to develop strong generic competences.

I think it is quite clear that it is the generic skills that have the greatest impact. As in, when we actually get to work. Those are the ones I have used the most, and they are probably the ones that have had the least direct focus on in my degree programme. I definitely think it's something that develops over time, and it's a bit hidden, but they come as part of a lot of other things at university. But they are *definitely the ones I feel are the most important. [...] So those generic things about how you learn. (P7).*

It is noteworthy how P7 also mentions *how* a person learns, stressing the importance of the ability to learn in new situations. The impact of generic competences as described here is an interesting phenomenon, and the following quote specifically highlights communication and teamwork.

Yes, but there is clearly much more communication than one is accustomed to at university. Also with people from other companies or other countries. (P2).

P2 was surprised at the extent to which communication, and people generally, influence engineering practice, and how this differed from their experiences at university. Furthermore, P2 highlights intercultural competences, and this is noteworthy because cultural competences are not a significant part of many engineering programmes.

Inclusion of generic competences in engineering education does not only mean that generic competences is to be known and acted on by the students. Boelt et al (2022:1415) argued, based on a literature review of studies of generic competences in a problem-based learning environment (PBL), that even though generic skills and competences are seen as a remedy for increasingly complex and interconnected world and highly integrated in the PBL approach, the movements towards inclusion of these competences in engineering education is instrumental rather than critical and reflective. In engineering education, it would be beneficial for course content and the overall education to transcend the purely instrumental.

As mentioned in the introduction, generic competences are strongly emphasized in relation to the employability discourse. In the following, we point to other surprises that engineers got in their transition from education to work.

3.2 Surprise number 2: The many different roles

The following surprise focuses on different roles and how engineering practice turned out to be different from the interviewee's assumptions. P3 describes the small disconnect between their expectations and the reality of their many roles.

I had expected that I would sit somewhere and do some office technical work, do a lot of calculations on things that I learned at university, and then test them in reality, and figure out how it all practically fits together, and then be involved in implementing it. Making some documentation updates and talking to some project managers who poke at me. I hadn't expected that I would have to be both an advisor and project manager, and purchaser and engineer and documentation [specialist]… that's not how I expected it to be. (P3)

The surprise mostly concerns the sheer number of different roles and the different tasks involved with each role. This particular interviewee had anticipated to primarily use what Ravensteijn et al (2005: 67) call instrumental competence which requires thorough technical knowledge and capability. Instrumental competences are seen in contrast to strategic competences which embrace social know-how, and in contrast to communicative competences which are related to the necessity of creating a social consensus for innovations. However, engineering practice turned out to involve more tasks – several of which are not strictly instrumental engineering.

The same pattern emerges from the next quote in which the interviewee was unsure about what a career even is or includes, and we see surprise expressed at how few engineers focus solely on stereotypical engineering work.

For me, I wasn't really aware of what a career was, or what it would mean, or whether one is a specialist, or a project manager, or a manager, etc. It's only something I learned later, after entering the workforce, that there's actually a whole aspect of this that some people focus on called motivation, etc. And then I think… at least from what I've seen, what I've learned, is that what I consider classic engineering work is not something that many engineers do. (P8)

Another early-career engineer (P6) also said that they definitely expected more "hardcore" engineering work, with more calculations and sitting by oneself and solving problems related to a larger project. The reality turned out to be slightly different.

3.3 Surprise number 3: Work across multiple projects

One way in which engineering practice may surprise concerns projects and collaboration across projects. As the following will highlight, project work plays a significant role in engineering practice, and an engineer may be involved in several projects at the same time instead of focusing solely on one big project.

I believe that the group work we use out there is insanely important, but it's also what we use a lot to explain how we work. It's not the same, because you're not just working on one project for six months, and that's it. It's often several things where you're involved in ten different projects, and some of them get stopped, and some of them run for five years. (P7).

This sentiment was shared by other interviewees who also mentions that an engineer may not simply work across multiple projects, but also collaborate with multiple different project managers. This necessitates specific generic competences in other to manage one's workload and the different situations involved.

I feel that there has been a lot of interdisciplinary work in terms of putting things into perspective, the projects one had, especially projects at the university. But I don't think there has been as much in terms of... What do you call it? Yeah. I mean, there hasn't been specifically as much collaboration across projects. (P4)

In an engineering education context, Kolmos et al (2024) stress the need for cross-group work in what they identify as inter-team, system and M-project (which includes mega- or mission driven projects).The three project types include a higher degree of interdisciplinarity: from cross team collaboration within an engineering program (inter-team); across engineering programs (system); and across engineering and humanities and social science programs (M-projects). This is an example of a framework that can help engineering education institutions prepare students to work across multiple projects.

3.4 Surprise number 4: The degree of mutual dependency

Mutual interdependence is an interesting topic because, as early-career engineers learn, their own progress and ability to conclude tasks will depend on other people, other departments, and many factors more or less outside of their control, including time, money, and resources. The following quote highlights this, paying particular attention to the influence other people's work has on one's own work.

Yes, and then there are all sorts of factors with time and money and resources and colleagues, and it matters in a different way than as a student. [...] The thing is, one thing is that I have to deliver the piece of work that I now have to, but the quality of that piece of work also depends, as most often as not, on others' work. (P5)

The same interviewee goes on to describe the transition from one project to the next, and how the quality and overall result of one project will influence other projects. This relates to Mathieu et al (2018) and their work on multi-team systems. This is an interesting difference compared to sequential university projects. Furthermore, these other projects are linked to other people, and this influence of other people is a recurring theme. Another interviewee describes how engineering practice is influenced by the interests of other people and stakeholders.

I always ask this question myself, because when we are a student, right, we always think about professional. So it's more like how quick, how deep, how creative idea, how good idea you can think about it. Right. Back to a reality right now, I don't think like in the job, in the society, there's so many different people. There's so many people. Right. And sometimes even you have good idea, but in reality, it's really hard to put it to you to use it (P1).

This is related to what P3 also argued, namely their surprise that they could not simply work on what they wanted, but had to ensure that their work always creates some kind of value for the company. While this may seem self-evident, it was nevertheless described as a surprising change from life as a student where projects more easily initially can be based on personal interest.

4 CONCLUSION

This study points to four surprises that early-career engineers identify when comparing their study life with work life (see figure 1). As illustrated, each surprise addresses the need for coping strategies to prepare graduates for work and positive influence their employability.

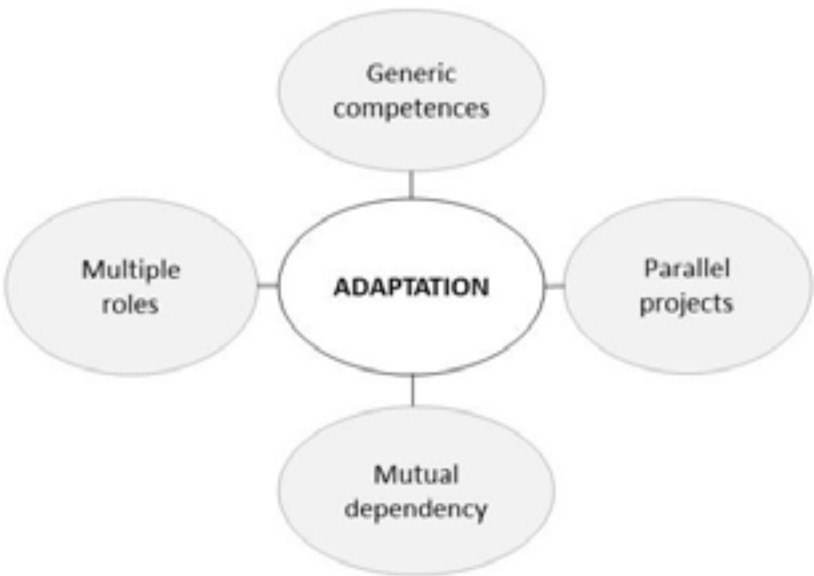

Fig. 1. Adaptation strategies

There are limitations to the study, parly connected to the number of interviewees. Our hope is that this will inspire further research into the transition to work. Additionally, more surprises can arise from other contexts of study (such as gender perspectives), but it is our hope that the simple framework presented in Figure 1 leads to reflections on the educational design in different engineering institutions. The question is whether such coping strategies are needed in the different educational contexts and, if so, whether this should lead to a redesign of engineering education programs. More fundamentally, which surprises should engineering education allow engineering graduates to encounter in their transition from engineering education to work?

5 ACKNOWLEDGEMENTS

This research project was made possible by the Poul Due Jensen Foundation and the Obel Family Foundation. The authors are grateful for these contributions.

Conference Key Areas: Teaching foundational disciplines of Mathematics and Physics in engineering education
Keywords: *Concept Inventory, Differential Equations, Undergraduate Mathematics, Formative Assessment, Validity*

ABSTRACT

Differential equations (DEs) are an important mathematical concept for a wide variety of disciplines in engineering. Hence, students need to develop a good understanding of the basic concepts of DEs. To assess student conceptual understanding, Concept Inventories (CIs) are commonly used in engineering disciplines. They also serve to evaluate instruction especially when new teaching methods are tried out.
The Differential Equations Concept Inventory (DECI) was developed to be used to evaluate the average basic understanding. In a first stage it shall be used to compare the impact of different teaching methods. Existing frameworks were used to develop the DECI and statistical methods to assess its validity and reliability for the given purpose.

The DECI shows a good level of support to measure students' overall understanding of the concepts addressed by the DECI. It is not yet recommended to determine individual students' understanding of specific concepts, their difficulties or common errors. For this purpose, higher statistical standards would need to be met and individual influencing factors like gender or ethnicity would have to be investigated.

[1] *TA Fuhrmann*
tina.fuhrmann@hs-merseburg.de

Hence, the DECI can be used by instructors to examine the impact of their teaching and new teaching methods on the conceptual understanding of students in the field of differential equations.

1 INTRODUCTION

Differential equations (DEs) are an important mathematical concept for a wide variety of disciplines in engineering. Students must not only acquire (some) procedural skills but also a deep understanding of the basic concepts of DEs and their solutions. They need to be able to assign meaning to DEs, use them in the correct way and utilize their knowledge for complex problem solving. However, there is substantial research showing that many students have conceptual difficulties and do not achieve these goals (Zandieh and McDonald 1999; Habre 2000; Rasmussen 2001; Rowland and Jovanoski 2004; Trigueros 2004; Rasmussen and Kwon 2007; Raychaudhuri 2008; Mallet and McCue 2009; Arslan 2010; Camacho-Machín, Perdomo-Díaz, and Santos-Trigo 2012a; 2012b; Czocher, Tague, and Baker 2013; Camacho-Machín and Guerrero-Ortiz 2015; Hyland, Van Kampen, and Nolan 2018; 2021; Sijmkens et al. 2022; Habre 2023).

The term *difficulties* and not *misconceptions* is deliberately used, as students might not have conceptions about some of the addressed concepts at all. The difficulties are subdivided in those connected to (i) a severe lack of prior knowledge from algebra and calculus, (ii) the DE itself and (iii) the solution to the DE (Fuhrmann and Kautz 2022). For lecturers it can be challenging to successfully address students' difficulties in their teaching and provide for a good basic conceptual understanding.

To evaluate both, instruction and individual students' performance, Concept Inventories (CIs) are becoming increasingly popular in different fields of STEM education (e.g., Force Concept Inventory (Hestenes, Wells, and Swackhamer 1992)). CIs make one or more of the following claims about students' conceptual understanding and common student difficulties (Jorion et al. 2015): Students' CI scores can be used to indicate their overall understanding of all concepts identified in the CI, to indicate their understanding of specific concepts, and / or to indicate their propensity for difficulties or student errors. In this paper we discuss the design, reliability and validity of the Differential Equations Concept Inventory (DECI).

2 METHODOLOGY

2.1 Design of the DECI

The DECI was designed along the ten-step process laid out by Crocker and Algina (1986) which are in agreement in the essential aspects with Adams and Wieman (2011) and the AERA-Standards (2014).

Table 1. Ten-Step process for the design of the DECI (Crocker and Algina 1986)*. The steps are discussed in detail in the results section.*

Step 1	Define the purpose of the test
Step 2	Identify the concepts to be tested
Step 3	Define the test specifications

Step 4	Create an initial pool of items
Step 5	Have items reviewed by experts
Step 6	Hold preliminary item try-outs
Step 7	Field-test the items on a large representative student sample
Step 8	Conduct item analysis
Step 9	Design and conduct reliability and validity studies for the final test
Step 10	Develop guidelines for administration, scoring, and interpretation of the test scores

2.2 Statistical considerations

The most fundamental considerations for developing and evaluating a CI are its validity and reliability. The *Standards for Educational and Psychological Testing* (2014) define validity as the degree to which evidence and theory support the interpretations of test scores for the proposed uses of the inventory. They use the term reliability (precision) in the more general notion to denote consistency of the scores across instances of the testing procedure. Validity and reliability of the inventory can be tested through quantitative statistical and qualitative methods, e.g., external measures like interviews, measures from classical test theory (CTT), and item response theory (IRT).

Validity can only be assessed for the specific proposed interpretations of test scores and therefore for the given purpose, target population, and setting. Qualitative measures were used to examine the four types of validity (face, content, criterion, and construct validity).

To asses reliability the following measures (table 2) were used (Direnga 2021):

The **average of score** $\bar{x}$ is calculated using equation (1) and the **standard error of the average** σ_{mean} is given for experimental data with unknown mean and standard deviation by (2). **Cronbach's-**α is a measure of internal consistency of the inventory and calculated using (3). Only given answers were included in the calculation of the variance, i.e., if an item was not answered by a student, it was not included rather than classified as being wrong. The **difficulty index** diff_j is a measure of "easiness" and ranges between 0 (always answered wrong; "difficult" item) and 1 (always answered correctly, "easy" item). The **discrimination index** disc_j compares the subgroup difficulty indices $\mathrm{diff}_{\mathrm{j,H}}$ of the 27 % high scorers (H) of that item to the one $\mathrm{diff}_{j,L}$ of the 27 % low scorers (L) and is defined by (5). Here, again, only students that answered the item of interest, are included in the calculation.

The **ability** of a student is defined as a (normalized) measure that predicts (or explains) the students' performance on the inventory (Hambleton, Swaminathan, and Rogers 1991). It also depends on parameters of the items, e.g., their difficulties and abilities to discriminate between students. Since the item parameters are not known and since not all items are in their final form yet, it was decided to calculate the **normalized score** ϑ as a simplified method to estimate a students' ability (6). ϑ does not take into account characteristics of the items. It therefore has a midpoint of 0 and a standard deviation of 1. The **probability** of answering an item correctly increases

Table 2. Equations used to calculate statistical measures.
n - number of test takers, x_i - score of each test taker, k - number of items on the test, $Var(\chi_j)$ - variance of item j, $Var(\chi)$ - variance of the entire test, $n_{j,correct}$ - fraction of test takers who responded to item j correctly, $n_{j,correct} + n_{j,incorrect}$ - pool of students that answered item j, x_n - score of individual n, σ_x - standard deviation of scores.

$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$	(1)	$\mathrm{diff_j} = \frac{n_{j,\mathrm{correct}}}{n_{j,\mathrm{correct}} + n_{j,\mathrm{incorrect}}}$	(4)
$\sigma_{\mathrm{mean}} = \sqrt{\frac{1}{n} \cdot \frac{1}{n-1} \cdot \sum_{i=1}^{n} (x_i - \bar{x})^2}$	(2)	$\mathrm{disc}_j = \mathrm{diff}_{j,H} - \mathrm{diff}_{j,L}$	(5)
$\alpha = \frac{k}{k-1} \cdot \left(1 - \frac{\sum_{j=1}^{k} \mathrm{Var}(\chi_j)}{\mathrm{Var}(\chi)}\right)$	(3)	$\vartheta = \frac{x_n - \bar{x}}{\sigma_x}$	(6)

monotonically as the level of ability increases. This relationship can be shown in the item characteristic curve.

3 RESULTS

In the following, the relevant data for the DECI is presented along the steps of the design process as stipulated by Crocker and Algina (1986) and shown in table 1.

3.1 Definition of the purpose of the test

The Differential Equations Concept Inventory (DECI) was designed to measure students' basic conceptual understanding of DEs and their solutions. In a first stage it is intended to assess the success of instruction and instructional methods, meaning that the test scores indicate an overall understanding of all concepts identified in the DECI. Test score interpretation for individual students' learning is limited, since construct-irrelevant components (e.g., gender, ethnicities, or age) could influence the total score and were not investigated up to now. Also, higher levels of validity and reliability would have to be met. The DECI shall not be used as a placement tool, formative assessment tool, or to discover unknown difficulties. However, it can inform about the frequency of certain false ways of reasoning.

3.2 Identification of the concepts to be tested

Student difficulties and key concepts with DEs were identified through literature, and complemented and partially confirmed by semi-structured interviews with 9 students (Fuhrmann and Kautz 2022). They were grouped, when necessary, and six concepts were chosen for the inventory based on the following criteria:

- **Completeness**: If all of the concepts covered by the inventory are understood by a student, the student may be considered as having gained a basic conceptual understanding of DEs. The inventory encompasses all essential concepts of DEs.

- **Parsimony**: If even one of the concepts covered in the inventory is not understood, one may not conclude, that this student gained a basic conceptual understanding of DEs. The inventory contains only essential concepts of DEs.

- **Testability**: It must be possible to test for the concepts with a multiple-choice questionnaire. E.g., it is hard to test for difficulties concerning the differences and similarities between functions, DEs and solutions of DEs with multiple choice questions since there has to be one definitely correct answer and four definitely incorrect ones with no room for interpretation.

The concepts included in the DECI are:

1) Recognition of DEs from a text-based problem

Students decide whether a text-based problem can be described by a DE and base their decision on correct arguments.

2) Formulation of a DE from a text-based problem

Students can formulate a DE from a text-based problem or associate the problem with an appropriate DE.

3) Understanding the meaning of variables and terms involved in the DE

Students are able to interpret the variables and terms involved in a DE, such as y, $\dot{y}$, x, and constants.

4) DEs and graphical representations (diagrams)

Students relate DEs and graphical representations of functions in diagrams. They interpret and draw conclusions from the graphical representation of a DE or its solution.

5) Application of solution methods and verification of solutions of DEs

Students decide for and use a correct solution method to solve basic-level DEs. They provide proper justification, using mathematically correct arguments, for determining whether a given solution can correspond to a given DE.

6) Prior knowledge

Students understand basic mathematical concepts that are considered to be important for the topic of DEs. Our choice was the understanding of functions, derivatives, infinitesimal quantities and graphical representations / diagrams.

Concepts regarding the topics of equilibrium solutions or homogeneous and inhomogeneous DEs were not considered by the test designers to be very basic concepts but themselves require a basic conceptual understanding of DEs. Therefore, they were not included in the DECI.

3.3 Definition of the test specifications

The DECI is designed to be administered as a post-test and should be paired with an appropriate pre-test as a reference for students' prior knowledge. It cannot be used as a pre-test, as the concepts are unlikely to be familiar to students from prior mathematical courses or everyday life experiences. When administering the DECI, students are expected to have covered the relevant materials on DEs in their study programs, but it can be implemented at any subsequent point in time.

Any CI that covers basic mathematical skills, including the understanding of functions, limits, derivatives, infinitesimal quantities, and integrals can be used as a pre-test (e.g., the Calculus Concept Inventory (Epstein 2013; Gleason et al. 2019) when ensured that the relevant concepts have been covered in the university courses beforehand).

The implementation is similar to other CIs (Madsen, McKagan, and Sayre 2017). The DECI has to be performed during class time (!) and lasts 30 min. An online form is possible, e.g., to ensure easy handling, comparability and data transfer between institutions. No tools are allowed except the test environment in the electronic device if administered online.

The DECI is a multiple-choice questionnaire for various reasons. In this way it is highly objective, allows for automated and fast scoring, enables assessing large student groups, and is feasible for the application of test-theoretical methods for validation and reliability checks. The concepts 1) to 5) relating to DEs are assessed with three items each, prior knowledge with four items, resulting in 19 items. The number of items per objective was guided by the principle of providing at least three items per concept (Engelhardt 2009) for a reliable and valid inventory while ensuring that the DECI remains within reasonable length constraints.

3.4 Creation of an initial pool of items

The questions were inspired by existing multiple-choice and open-ended questions from literature and online resources (e.g., http://mathquest.carroll.edu/de.html). For each of the concepts 1) to 5), three items were developed. The creation of distractors was based on known difficulties and students' typical thought patterns from literature and semi-structured interviews. The distractors may be more strongly linked with one of other concepts tested for in the DECI rather than the specific concept intended in the question. Prior knowledge was assessed with four items taken from the Calculus Concept Inventory.

3.5 Item review by experts and item revision

Four experts (i.e., professors and lecturers of mathematics) reviewed the items with a focus on ensuring mathematically correct wording and completeness of the items. They assured that the items encompassed all relevant concepts and were solvable with a basic conceptual understanding of DEs. Additionally, the authors strove to minimize complexity and facilitate understandability of the items for students.

3.6 Preliminary item try-outs and item revision

This step was omitted because we found it to be of limited value in this development process due to the greatly diverse target group at Universities of Applied Sciences. Therefore, a first field test followed the item review with more field tests to come.

3.7 Field-test of the items on a large representative student sample

The DECI was used at different Universities of Applied Sciences in Germany. In contrast to traditional Universities or Technical Universities, the students' background is often more heterogeneous concerning their educational background and mathematical knowledge. We strongly believe, that the DECI is also valid in other types of universities, but did not yet test for it.

The DECI was carried out in six mathematics courses at five Universities of Applied Sciences with second semester students (Darmstadt, Landshut, Merseburg, Rosenheim, Regensburg). 121 students participated. No bonus points or rewards were given to students for participation.

3.8 Item analysis and item removal or revision

Based on the statistical analysis in section 3.9, test items will be rephrased and slightly rearranged before unrolling the 2nd version of DECI.

3.9 Design and conduct of reliability and validity studies

Reliability and validity of the DECI are assessed as far as possible in section 4.

3.10 Develop guidelines for administration, scoring, and interpretation of the test scores

Administration is equivalent to other CIs, as shown in section 3.3. Comparative scoring values need to be assessed for the final version.

4 RESULTS OF RELIABILITY AND VALIDITY STUDIES

General Statistical Considerations

The distributions of the total scores and of the number of answers are shown in Fig. 1 and Fig. 2. On average, 18.65 ± 0.12 items (out of 19) were answered and 7.30 ± 0.33 correct answers given (with standard errors of the mean as indicated). Fig. 3 and Fig. 4 show the percentage of test takers that did not answer each item and the percentage that answered an item correctly, respectively.

Reliability Considerations

Cronbach's-α is 0.728 and therefore larger than 0.7 which indicates that the DECI is sufficient for group measurements (Engelhardt 2009; Jorion et al. 2015). For each item of the DECI, α was also computed for the entire test without the given item. α should then be lower compared to the entire test. For items 1, 6, 10, 15 and 18 it was greater ($0.73 < \alpha < 0.74$), indicating the need for revision of these items.

In Fig. 5 the scatterplot of item difficulty and item discrimination is shown. Most of the items meet the recommended criteria for CIs intended for instructional (as opposed to individual) use, with the difficulty ranging between 0.2 and 0.8 and the item

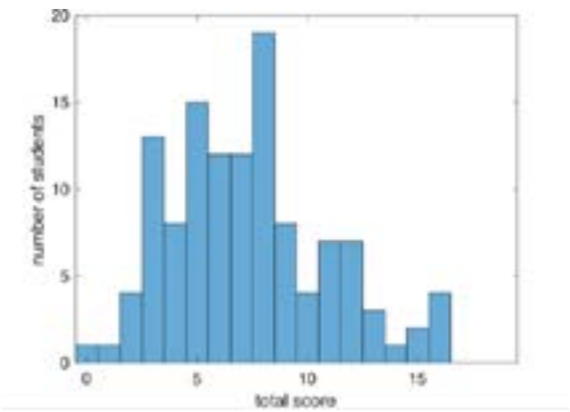

Fig. 1. Distribution of students based on the total scores, which is equal to the number of correct answers.

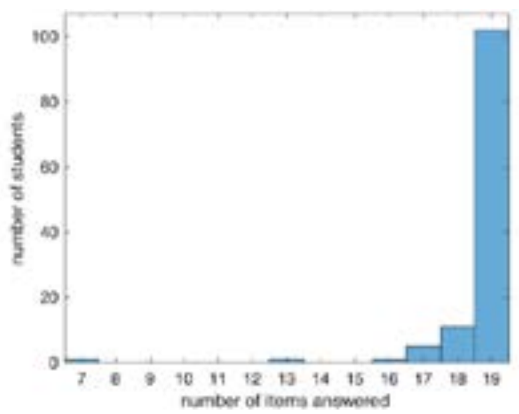

Fig. 2. Distribution of students based on the number of answers given in the DECI.

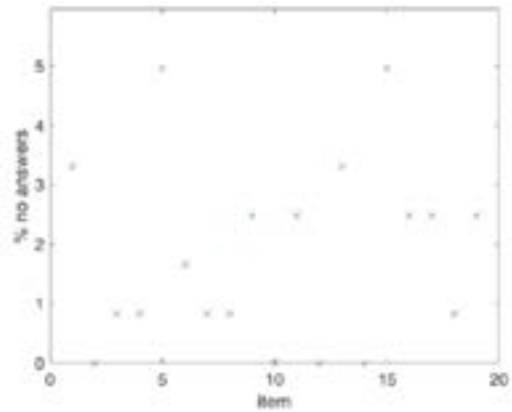

Fig. 3. Percentage of students that did not give an answer for each item.

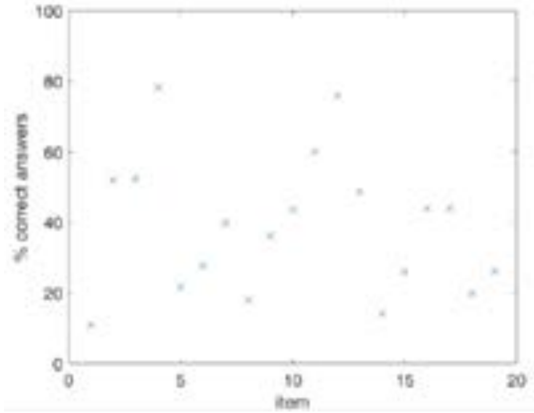

Fig. 4. Percentage of students that gave correct answers in relation to the number of students answering each item.

discrimination being larger than 0.8 (Jorion et al. 2015). The diagram indicates the need for revision for items 1, 8, 14 and 18. A rarely chosen option in item 6 will be removed leaving 5 answering options and leading to a better alignment with the other items with mostly five options.

For each item, the item characteristic curve (ICC, e.g., Fig. 6) and the distribution of chosen answer options was assessed. ICCs were constructed by grouping students in 10th percentiles (i.e., aggregating 12 to 13 students per data point on the ICC). This methodology facilitated the collection of 10 data points for each ICC and allowed for a comprehensive examination of item quality. The observed slopes for the correct answers across all items were positive, showing that students with a higher total test score were more likely to answer each item correctly. Despite attempts at curve fitting and model validation, such as utilizing a 3-parameter logistic model, these efforts were impeded by the limited amount of data available as well as the necessity for slight adaptions in certain items.

The process of assessing the ICC and the given answers is illustrated using item 3. The question and answer options are shown in Fig. 6. Even though the correct option a) is the first response option and the only one with a derivative of y, only 52 % of students chose this answer. Option b) was chosen by 26 % of students and may result from two possible ways of thinking. First, for some students, DEs are inextricably linked to exponential functions. Second, some students do not or not

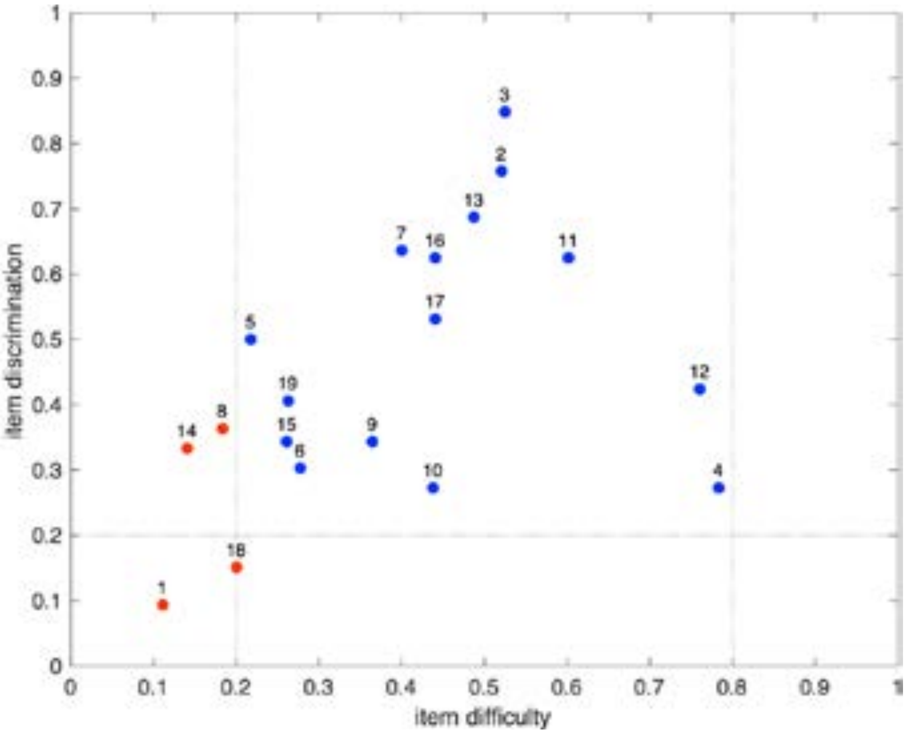

Fig. 5 Scatterplot of item difficulty and item discrimination. Recommended minimum and maximum values are denoted by the dotted lines. Three items (1,8,14) did not meet the recommended minimum item difficulty of which two had a good discrimination index.

sufficiently distinguish between a DE and its solution. Option b) is a very well-known solution for students to the stated problem. Option c) (7.4 %) might be selected by students who do not have a deep understanding of the meaning of the variables and terms involved in a DE. They may see that the rate of change, which they think of as the dependent variable, is proportional to the number of rabbits, which they consider to be the independent variable. Therefore, a linear function results. Option d) (6.6 %) was included as an option for students who reason similarly but might additionally think that the answer must be more "complicated" than a linear function. Option e) was designed to attract students who build an isolated, completely decoupled knowledge about DEs and think of them as something "totally different" to what they have learned before. For those students it can be nonsensical to write down a DE (part of the new knowledge) for an everyday, well-known phenomenon (part of the previous knowledge).

If the following problem can be described by a differential equation, which differential equation can correspond to the problem ($a, b \in \mathbb{R} \setminus \{0\}$)?

A small number of rabbits are located in a very large open area without predators. The rate of change in the number of rabbits is proportional to the number of rabbits present.

a) $\dot{y}(t) = a \cdot y(t)$

b) $y(t) = a \cdot e^{bt}$

c) $y(t) = a \cdot t$

d) $y(t) = a \cdot t^2$

e) The problem is not described by a differential equation.

Fig. 6: Item 3 with the correct answer being a).

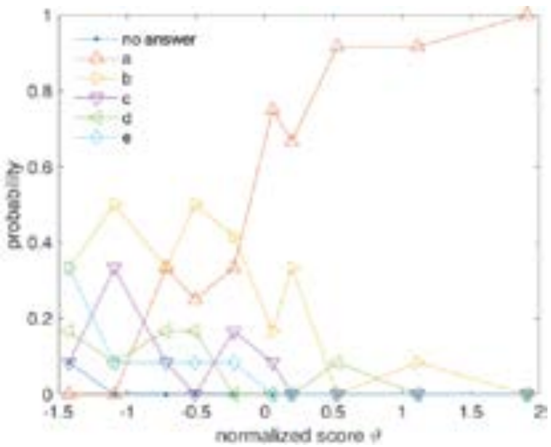

Fig. 7. Item Characteristic Curve of item 3. The probability of giving a specific answer is shown for all answer options. The correct answer is a.

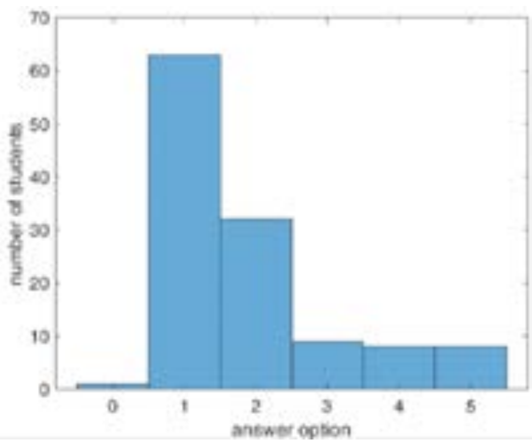

Fig. 8. Distribution of student responses: index 0 indicates the count of students who did not respond to the item, indices 1 to 5 correspond to options a to d.

In Fig. 7 it can be seen, that the probability for answering item 3 correctly increases for students with a higher normalized score. This is the preferred characteristic for an item in a Concept Inventory. Fig. 8 shows, that the correct option is the preferred one, but also, that all options were chosen by students. Therefore, all options appeal to students and no option has to be exchanged.

Validity Considerations

***Face Validity**:* Mathematicians (experts) verified that the DECI appears to measure the intended constructs.

***Content Validity**:* During steps 2 and 5 of the design process, attention was devoted to ensuring that the concepts and items of the DECI fully represent the overall construct, namely, the basic conceptual understanding of DEs. However, for a final version of the DECI, interviews with experts should be conducted.

***Criterion Validity**:* The results of the DECI cannot be compared to other quantities since there is no "gold standard" inventory available (concurrent validity). Due to strong data protection regulations in Germany, the DECI was performed anonymously, asking students only for self-generated identity codes (SGICs, (Timmermann et al. 2016)). Therefore, it cannot be correlated to e.g., exam results (predictive validity) or other measures.

***Construct validity**:* Construct validity assesses whether the DECI and its individual items measure the intended overall construct. Some questions were given to students in semi-structured interviews in a modified form. The students' reasoning was then observed and analyzed, suggesting that the questions were correctly interpreted by the students. However, the exact questions of the DECI were not given to students in interview settings.

5 CONCLUSIONS

The Differential Equations Concept Inventory (DECI) is not in its final form yet, but our data indicate that it is a valid and reliable instrument to assess students' basic conceptual understanding of DEs and their solutions. Accordingly, it can be utilized to compare the effectiveness of different teaching methods.

ABSTRACT

This paper examines the application of Generative AI (henceforth GenAI), specifically OpenAI's advanced Large Language Models (LLMs), in evaluating student reports within challenge-based courses with focus on Sustainability and Ethics (S&E). Traditional grading methods, heavily reliant on manual effort and subject to human biases, present a significant workload for educators and often lack consistency. By integrating LLM into the grading process, this study explores the

[1] *S. Garcia-Huertes*
saul.garcia@upc.edu

feasibility of automating assessment tasks, aiming to achieve more objective and efficient evaluation while reducing evaluators' workload. The research method entails preprocessing and anonymizing student reports, *promptifying* existing rubrics for LLM compatibility, and analyzing the AI-generated assessments against human-graded benchmarks. Preliminary findings suggest that LLMs can complement human grading by providing consistent evaluations under certain conditions, such as when reports are text-based and rubrics are clearly defined. However, limitations such as the model's reasoning capabilities and handling of non-textual information indicate areas for future research. This research contributes to ongoing discussions on the potential of GenAI in education, underscoring the need for further exploration into AI-assisted assessment tools that could enhance the transparency and efficacy of grading practices in engineering education.

1 INTRODUCTION

The rapidly growing field of Generative AI (henceforth GenAI), particularly in the development of Large Language Models (LLMs), catalyzes a range of potential applications across diverse sectors, including Healthcare, Business, Finance, Banking, Sales, Marketing, Content Creation, and Education (Bahrini et al. 2023; Ray 2023). The integration of Gen AI into the evaluation process of student reports presents a novel pathway for enhancing educational assessment methodologies (Tobler 2024). This paper explores the use of Gen AI to assess student reports on Sustainability and Ethics (S&E) topics, utilizing a custom methodology to emulate the grading approach of course professors. By incorporating contextual knowledge in the form of a rubric into the LLM, the study seeks to explore whether the assessment process could be streamlined, thereby supporting evaluators in reducing the time spent on grading and minimizing human errors and unconscious biases.

Challenge-based courses, especially those with group work, present unique assessment challenges. Fair assessment for individual students in capstone projects requires criteria beyond the final output to meet project objectives (Farrell et al. 2012). One method is determining the final grade by consensus in department meetings (Schramm and Chan 2013), although rubrics and IT tools are commonly used (Schramm and Chan 2013; Tio et al. 2014). Evaluations typically include class participation, peer assessment, group presentations, and final reports, which are often unrestricted in format and length. This freedom, while pedagogically valuable, increases the assessment workload for faculty (Valenti, Neri, and Cucchiarelli 2003), as the open-ended nature of assignments demands considerable time and effort in grading, especially with many students and complex reports.

Recent literature on AI for student assessment highlights its application to specific topics or domains (González-Calatayud, Prendes-Espinosa, and Roig-Vila 2021). AI has been used to assess English report quality with non-linear regression models (Liu et al. 2017) and evaluate programming exercises by measuring answer similarity with edit distance, categorizing answers, and identifying errors (Grivokostopoulou, Perikos, and Hatzilygeroudis 2017), among others. These approaches highlight the limitations of applying AI to broader domains without precise assessment tool design.

GenAI has shown exceptional ability in synthesizing extensive texts (Sallam 2023), responding to specific questions based on the text or integrating contextual or broad knowledge bases through techniques like Retrieval Augmented Generation (RAG) (Nashid, Sintaha, and Mesbah 2023). These systems offer a consistent approach to interpreting and evaluating text, presenting a solution to the subjective nature of essay grading, which often results in students perceiving unfairness due to grading variability by different human assessors (Valenti, Neri, and Cucchiarelli 2003). Utilizing automated assessment tools could improve consistency in grading and decrease the workload associated with the comprehensive evaluation of student reports. This shift towards automated systems seeks to reduce the risks of human biases and errors, which are likely when grading a large volume of submissions.

Exploring GenAI’s potential to streamline assessment in challenge-based courses is logical and promising. The application of LLMs in this domain could extend beyond reducing faculty's grading workload. It also has the potential to offer valuable feedback for refining and iterating existing rubrics. Such enhancements to the grading criteria can improve transparency and understanding for students, providing them with clearer expectations and requirements before they complete their reports. Ultimately, the incorporation of GenAI into the academic evaluation process heralds a substantial advancement in engineering education, promising a more efficient, objective, and enriching learning and teaching experience.

2 METHODOLOGY

This research uses GenAI, particularly OpenAI's advanced LLM, to simulate standard human grading processes. Subsequent sections detail the workflow from report selection to ground truth validation. This process is illustrated in Figure 1.

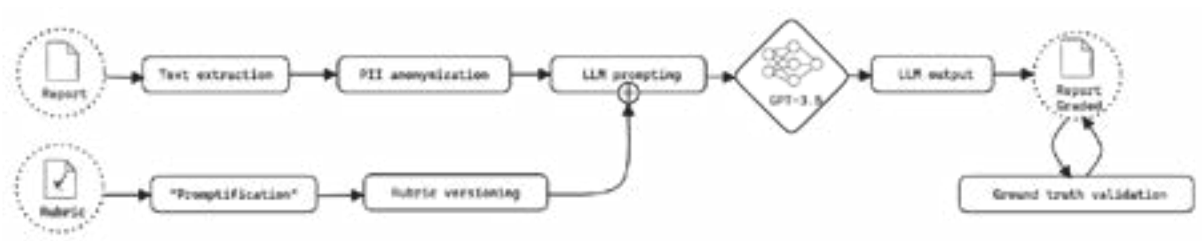

Figure 1. Methodology diagram

2.1 Reports Preprocessing and Anonymization

The initial stage of our methodology involves the compilation and preparation of student reports from the “Advanced Engineering Project" course, a capstone requirement for final-year ICT Engineering students at Telecos-BCN, the ICT Engineering School of Universitat Politècnica de Catalunya (UPC) in Barcelona, Spain. This is the third project-based course of our curriculum and follows the Product Development Project (PDP) model, which can also be assimilated to the New Product Development model (Cobb et al. 2016). In this course, relatively big students’ teams (8-12 students) carry out the design of a complete product or service, including its business model. They also perform the S&E analysis and an intellectual property search and patent proposal. The teams generate the requirements and specifications of the product or service from the initial interaction with the stakeholders, define the system block structure and the work packages and then distribute them among subgroups of 2-3 students. They must design, implement and test the subsystems, integrate them, define a business model based on the product or service and perform the S&E analysis. Since 2011, more than 1650 students have passed this compulsory course, working in more than 170 different projects. Currently, 75 % of the challenges are proposed by external agents: companies, hospitals, foundations, NGOs,… A more detailed description can be found in (Bragós Bardia, Aoun, Charosky Larrieu-Let, et al. 2022) and a comparative study of the performance of the student teams according to the kind of stakeholders (internal/external) and other features of the projects has been reported in (Bragós Bardia, Aoun, Bermejo, et al. 2022).

Bridging the academic framework with our analytical approach, over the course of three semesters from September 2022 to January 2024, we gathered a collection of 18 reports. We extracted the chapters focusing on S&E from these reports and these amounted to 156 pages to be assessed, averaging 9 pages per report. We used a Python script with regular expressions to preprocess the reports, removing escape characters and formatting issues for cleaner analysis. Following the extraction and cleaning, we utilize the Presidio library[2], an open-source tool, to perform the anonymization of Personal Identifiable Information (PII). This step was executed locally to ensure that sensitive information, such as personal and organization names or email addresses, would not be part of the prompt to the LLM. The result was a sanitized dataset ready for interaction with the LLM without compromising the privacy of any individual or entity involved.

2.2 Rubrics Promptification and Versioning

The rubrics for the “Advanced Engineering Project” course, originally formatted in a spreadsheet, underwent a process of *promptification* to make them suitable for use with an LLM. This term refers to the conversion of the existing rubric into a text-only format that encapsulates the grading criteria in a manner that is self-explanatory and it is able to properly instruct a LLM. This step was needed so the rubric would seamlessly integrate into the LLM operational framework as a part of the prompts used, as depicted in the next section.

To examine how rubric specificity influences the LLM's grading reliability, we developed two versions. The detailed v1 provided explicit grading instructions for each report section, while the less prescriptive v2 allowed for broader interpretive leeway by the LLM, Table 1 highlights the contrast. This comparative approach aimed to measure grading variance with repeated assessments, shedding light on the stability and dependability of the LLM's grading influenced by rubric design.

2.3 LLM Prompting and Output Parsing

The core of the assessment process involves prompting the LLM with the anonymized report text alongside the *promptified* rubrics. Upon receiving the prompts, the LLM generated assessments for each report. These outputs were then carefully parsed to separate the grading and feedback into formats that could be analyzed both quantitatively and qualitatively.

Table 1. Comparison of rubric versions for a given question

Rubric v1	Rubric v2
F.EN.D. (Environmental Design) **Question:** Evaluate the project's approach to environmental sustainability, including the quantification and reduction of environmental impacts, the use of sustainable materials, supplier compliance with environmental standards, and the application of the cradle-to-cradle philosophy. **Criteria to grade from 0 to 10:** - Assign 2 points for specific quantification of environmental impact reductions. - Assign 2 points for detailing actions taken to reduce impacts with measurable outcomes. - Assign 3 points for using sustainable materials and ensuring supplier compliance with environmental standards. - Assign 3 points for incorporating the cradle-to-cradle philosophy with clear examples.	**F.EN.D. (Environmental Design)** **Question:** Evaluate the project's approach to environmental sustainability, including the quantification and reduction of environmental impacts, the use of sustainable materials, supplier compliance with environmental standards, and the application of the cradle-to-cradle philosophy. **Criteria to grade from 0 to 10:** Consider the depth of environmental impact analysis, efforts to reduce those impacts, the integration of sustainable materials, supplier compliance, and the cradle-to-cradle philosophy's application.

For our experiment, we used the *gpt-3.5-turbo-0125* model, known for its balance of performance and cost-effectiveness. Although OpenAI offers more advanced models like gpt-4, gpt-3.5 was sufficient for our task and more economical, crucial for large-scale research. The model's token window of over 16,000 tokens accommodated our combined prompt, which included the student's report S&E sections, the rubric, and framing instructions.

We provided clear instructions to the LLM to present grades in brackets "[ ]" for easy tabulation, with any deviations triggering a reiteration of the grading process. Extensive trials were needed to refine this response format. The final Python script, shown in Table 2, illustrates how we interacted with the OpenAI API and handled non-compliant responses.

```

2.4 Results Summarization and Ground Truth

In the final stage, we compared LLM-generated results with human evaluator grades to gauge accuracy. Additionally, we aimed to examine the level of consistency across multiple assessments of the same report. The generation of the final dataset for this study was completed on April 1st. To avoid potential rate limits, the dataset was processed sequentially in blocks of five reports, which translated to a minimum of 100 API calls, assuming no repeats were necessary due to incorrectly formatted LLM responses. The entire operation spanned approximately 1 hour and 15 minutes, entailing 559 API calls. It used 1,075,000 tokens—795,000 for prompting and 280,000 generated by the LLM in responses—and incurred a total cost of $0.82. On average, each report required 31 API calls, indicating a 50% increase over the ideal scenario with no retries.

With the collected data, we aimed to detect any significant grading deviations using boxplots. These visualizations, as depicted in Figure 2, were designed to quickly pinpoint reports with notable discrepancies in grading across iterations for either version of the rubric. By averaging the grades assigned per question, we could aggregate a score that reflected the LLM assessment behavior.

Further, in Table 3, we presented the aggregated data of all reports, segmented per question and rubric version. This granular approach allowed us to spot potential deviations in how the LLM assessed specific questions, which could indicate areas where the LLM setup in our experiment was more or less adept at grading.

3 RESULTS

The comparative analysis of rubric-based grading shows that Rubric v1, with its explicit criteria, results in more consistent grading than the less explicit v2. In 11 out of 18 reports, the interquartile range (IQR) was narrower for v1, indicating a tighter consensus across iterations. Additionally, the overall grading range was smaller for v1 in 13 out of 18 reports, highlighting the impact of clear criteria on grading consistency. However, a 46% overlap in IQRs between the two rubric versions suggests that other factors besides rubric design also affect grading outcomes.

These findings emphasize the value of detailed rubrics in achieving consistent evaluations and indicate the need for further work to minimize subjectivity in grading.

Other factors contributing to the lower percentage of overlap and the presence of outliers in the boxplots include the limited content in some reports (e.g., report 16, which is less than 3 pages) and content embedded in tables or images within the reports that cannot be extracted from the PDF format (e.g., report 11 and 16).

The data in Table 3 reveals that the 'Resource Utilization and Efficiency' question has the lowest average grade, suggesting students may find this topic more challenging or the grading criteria might be more stringent. Additionally, higher standard deviations for 'Economic Reevaluation' and 'Social Reevaluation' indicate varied interpretations of these questions, hinting at potential ambiguity in the rubric or diverse student approaches to these topics. This underscores the necessity for clearer guidelines or enhanced focus in teaching these areas.

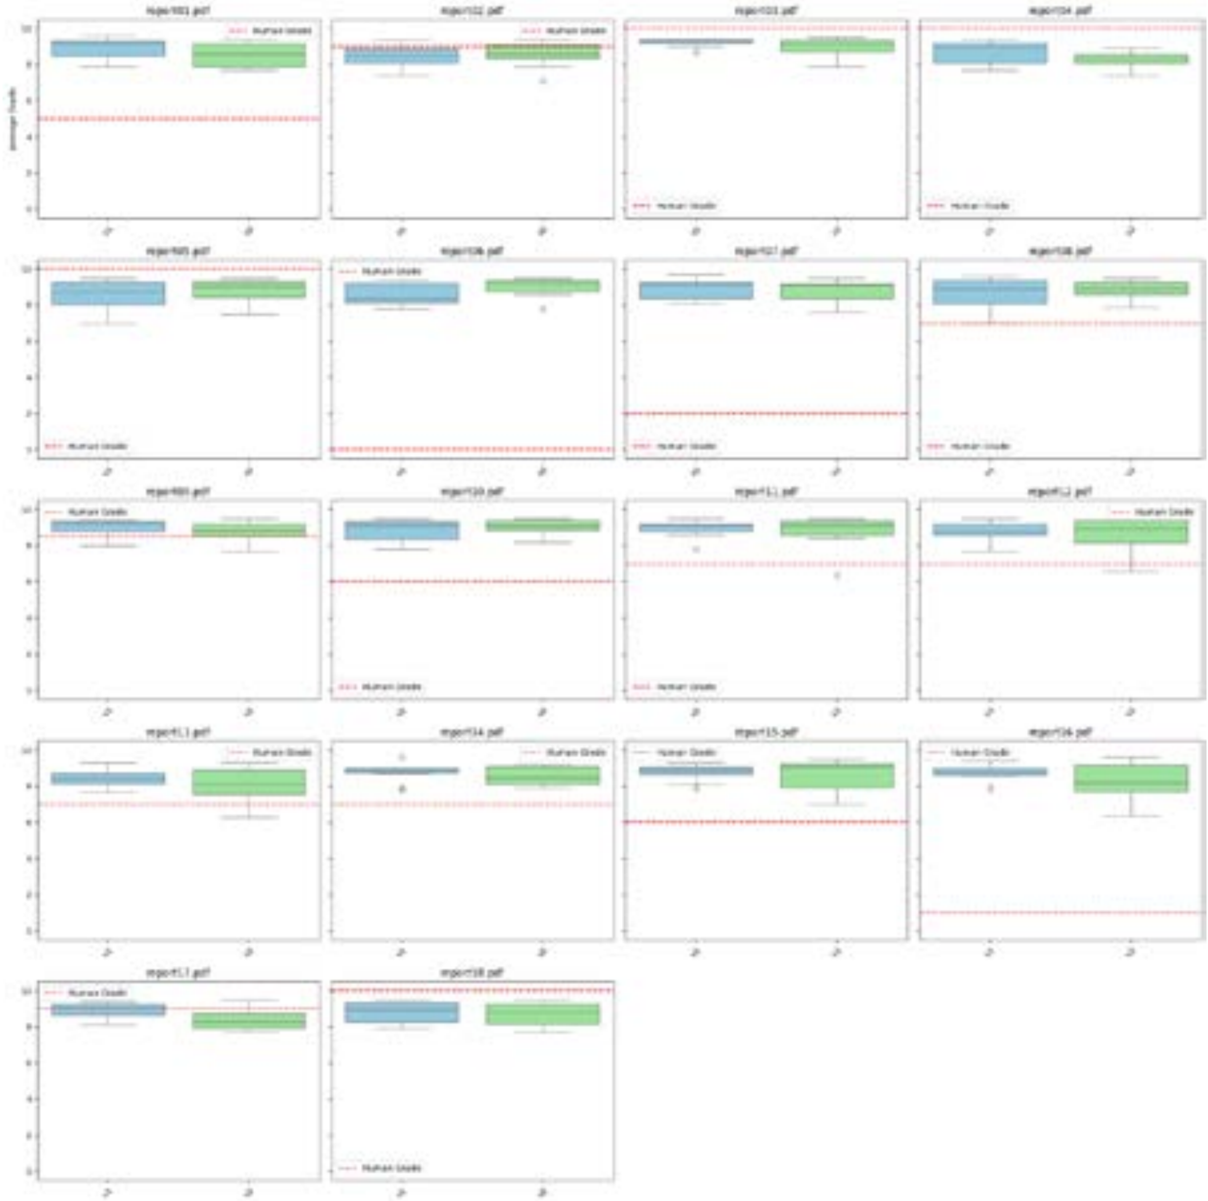

Figure 2. Boxplot grid for each report grades across the 10 iterations per rubric version

When it compares to actual human grading, reports 6, and 17 represent an outlier that should be further included in subsequent iterations of this automatic assessment fine tuning as in those cases, the human evaluator introduced values that are far from the tool assessed. The main reason behind, is that the evaluator used several threshold concepts (Baillie, Goodhew, and Skryabina 2006). There were some basic calculations and report formats that were basic requirements of the course and were not met. Those requirements were not reflected in the rubrics we used in the automatic assessment due to limitations on their definition. This issue helped us to realize that the rubrics may lack some requirements that are just assumed. This is not a problem if there is only an evaluator but would be if there is more than one. Therefore, the process of validating rubrics to be used in LLM-assisted assessment may help to make them more robust.

Table 3. Aggregated data statistics per question.

Question	RubricVersion	Grade mean	Grade std	Grade min	Grade max
F.EN.D. (Environmental Design)	v1	8.37	0.69	5	10

	v2	9.01	1.18	5	10
ETH (Ethical Considerations)	v1	9.82	0.46	8	10
	v2	9.73	0.57	6	10

3.1 Conclusions and limitations

While our experiment revealed variations in grading across multiple iterations by the LLM, it's important to note that such fluctuations also happen when multiple human evaluators grade the same reports using an identical rubric (Brookhart and Chen 2015; Tio et al. 2014). In essence, discrepancies in final grades among evaluators are to be expected. This observation underscores that, under specific conditions—namely, when rubrics are clearly defined and objectively detailed, and when student reports are structured primarily in text (as opposed to non-textual formats like images)—an LLM-based tool can effectively serve as a co-pilot. It offers a means to cross-check and validate grades assigned by human evaluators. However, it is fair to state that this AI tool is not positioned to replace human judgment in the grading process, at least not in the current state of technological advancement.

The limitations of this experiment highlight significant areas for further research and underscore the current constraints of technology. Refining the integration of rubrics with prompt generation for greater specificity remains a challenge, including improving prompt strategies for more accurate LLM responses and the LLM's inability to interpret non-textual content, indicating the potential need for computer vision models. Additionally, the current LLM's lack of reasoning skills, especially its inability to perform basic calculations, reveals a crucial gap in assessing certain concepts that human rubrics can, which state-of-the-art LLMs cannot yet bridge without the use of external tools as an addon to the LLM (Zhuang et al. 2023). These challenges point to the need for ongoing development in GenAI, suggesting that consistent grading with detailed rubrics and the successful application of GenAI in educational assessments require careful consideration of report content and format.

ABSTRACT[1]

This article presents the initial results of theory-based concepts for an innovative study orientation program designed for female 11th and 12th grade students in Germany. The focus is specifically on motivating young women for engineering and strengthening their self-confidence and creative potential. Using the design-based research (DBR) method, the first step was to analyse possible requirements with the help of a systematic literature review and 25 qualitative interviews. Based on the results a concept was designed and successfully transferred into practice. The program was tested for the first time in January 2024 with 61 grade 11 and 12 students at Leuphana University. A variety of technical workshops were developed,

[1] M. G. Guerne
gillian.guerne@leuphana.de

whereby the modular structure of the Virtual Reality (VR) and Augmented Reality (AR) workshop is presented in this paper. Initial results show that the program was very well received by the students. Further runs of the intervention as well as an effectiveness analysis of the program are pending.

1 INTRODUCTION

Digitalization, decarbonization and demographic change are creating strong pressure for transformation worldwide. Qualified professionals with different skills are needed. However, the current developments show otherwise. In April 2023, a labour shortage of 308,400 people in the STEM sector was reported in Germany (Anger et al. 2023). STEM expert occupations representing the largest bottleneck group. This is further boosted by demographic change, which results in 64,700 STEM academics leaving the labour market in Germany every year. The trend is rising (ibid.). As a result, demand and the labour shortage are increasing significantly. The simultaneously declining number of new STEM graduates will further exacerbate this problem. Educational measures to increase skills and motivation in the STEM sector are urgently needed to counteract. A closer look at the gender distribution in STEM professions show a strong underrepresentation of women (ibid.). Furthermore, it is notable that women do leave the STEM sector more frequently than men (Solga and Pfahl 2009). According to Anger et al. (2023), in order to master the structural challenges of the future, opportunities in the education system must be improved, digitalization in educational institutions must be promoted, STEM education must be strengthened and the potential of women must be raised through stereotype-free career and study orientation (ibid.).

This is where this contribution links in. This paper is intended to provide initial insights into the design of a study orientation program for female students in grades 11 and 12 in Germany in order to increase the proportion of women and strengthen the creative potential and self-efficacy of women in the STEM field. After discussing the research goals and methodology, chapters 4 and 5 deal with the results of the analysis of requirements of a STEM study orientation program as well as the design and implementation of a designed program. Chapter 6 describes the exemplary structure and implementation of a module on the topic of "Virtual and Augmented Reality" as an example of a game-based approach to introducing the field of new technologies. The orientation program was carried out for the first time in January 2024 with 61 female students. Initial results will be presented.

2 RESEARCH GOALS

The design, implementation and evaluation of a study orientation program for female high school students is part of a three-year research project of the German Federal Ministry of Education and Research (BMBF) titled "Hybrid STEM study orientation program for women in the context of digital transformation". The design-based research project aims to provide evidence-based and transferable findings on successful STEM study choice orientation for women in the context of digital transformation and, at the same time, a sustainable implementation as a regional STEM education measure. In addition, the development of self-efficacy, initiative and creative potential of young women is considered. Further positive effects are expected with regard to actively shaping the transition from school to university. The existing network between universities and schools is to be further expanded in order to contribute to securing the next generation of skilled workers in the technical sector. Three implementations of the program and an evaluation of its effectiveness are planned within the three-year term. This paper is intended to provide initial insights into the theory-based concept of the program and explain the structure and implementation of an exemplary workshop. Initial results and feedback from the first participants will be presented.

3 METHODOLOGY

Design-based research (DBR) according to McKenney and Reeves (2013) was chosen as the methodological approach for the research project. This is a methodological approach that aims to gain research-based insights into both the theoretical understanding of teaching and learning and pedagogical practice (McKenney and Reeves 2013; Kelly 2013). The model is shown in Fig. 1 and illustrates the three main stages of the process model for DBR: analysis, design and evaluation. The three stages are interdependent and require the implementation of the respective approaches. The results are delivered in two ways, both for theoretical understanding and for intervention in classroom practice. Feedback loops enable continuous improvement and adaptation (McKenney and Reeves 2018).

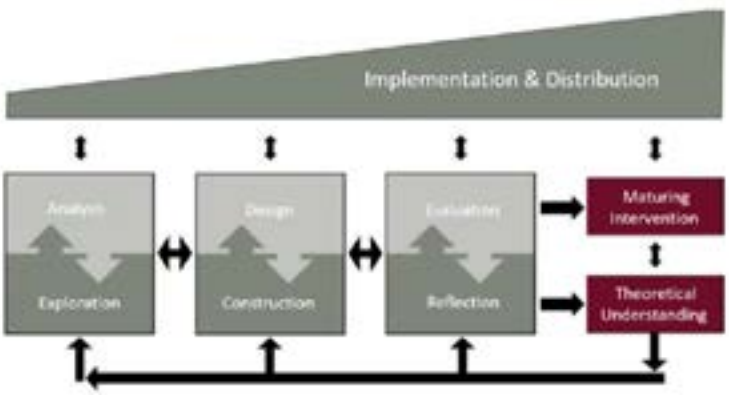

Fig. 1. DBR approach, illustration based on McKenney and Reeves (2013)

In the *analysis phase*, the problem is analysed and defined (McKenney and Reeves 2018). In this phase of the research project, a total of 25 qualitative interviews were conducted with female high school students, bachelor and master students from the field of engineering (Mayring 2022 and Kuckartz 2018). A systematic literature review was conducted (Moher et al. 2009). The aim was to collect recommendations for the ideal concept design in a theory-based manner. The results of the analysis phase are briefly outlined in Chapter 4.

In the *design phase* of the DBR approach, a solution is designed. A concept for an educational intervention or a learning environment is created, which must be implemented and tested. Based on the results of the analysis phase, two theory-based program proposals were developed. Eight schools in the region were contacted, three of which agreed to a rapid implementation. This enabled the final design and development of the program, incorporating digital tools, future technical fields (e.g. Sustainability, Industry 4.0, AI) and suitable remote units for a one-week program including a project phase of several weeks.

Finally, a complex effectiveness analysis is planned in the *evaluation phase*, in which the data from the three interventions will be evaluated. The program will be examined for its influence on the decision to study, the strengthening of self-efficacy and the initiative of the participating students. In addition to pre-post surveys, interviews and learning diaries, accompanying observation will be used (Mummendey 1999; Kromrey 1995).

4 RESULTS OF THE ANALYSIS OF THE REQUIREMENTS OF A STEM STUDY ORIENTATION PROGRAM

To generate a theoretical basis, a systematic literature review and qualitative interview studies were conducted in order to draw up recommendations for motivational projects for female students in engineering. In addition to the systematic analysis of 18 research papers (Moher et al. 2009), 25 qualitative interviews were carried out and evaluated (Mayring 2022 and Kuckartz 2018). For the interviews, eight female Bachelor's and three female Master's students from Leuphana University as well as 14 female pupils were interviewed. The aim of the systematic literature review was to filter previously researched framework conditions for motivational projects in the STEM field. The qualitative interview study aimed to obtain further individual opinions and the current status quo of the region. Both studies were analysed under the main categories "Target group", "Integration into the school system" "Timeframe and format", "Topics", "Teaching methods" "Role models", and "Learning atmosphere". Figure 2 shows the most important results and recommendations of the analyses.

According to the results of the analysis, the design of a six-month program is recommended. The program should be carried out in presence and be designed to be multifaceted. It should address topics relevant to the future, such as automation, digitalisation, Industry 4.0 or sustainability, and include a diverse range of teaching methods, such as laboratory experiments, excursions or mentoring programs. Addressing career planning and possible training paths to engineering proved to be an essential topic. In addition, a supportive and encouraging learning atmosphere as well as space for consultation and feedback should be created. A further component of a motivation program should be the presentation of the very diverse occupational profiles and in particular the demonstration of gender diversity and the countering of stereotypes in engineering. Finally, the inclusion of role models from different professions is recommended, preferably involving young female role models.

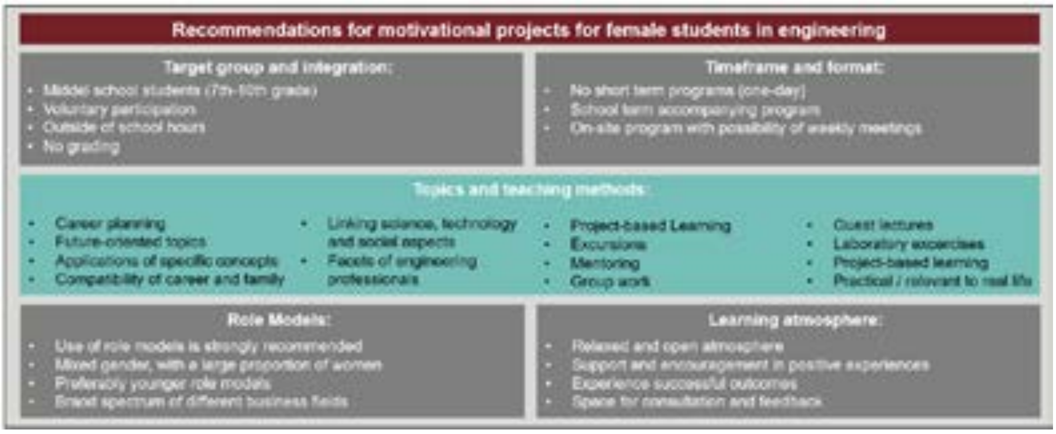

Fig. 2. - Recommendations for motivational projects for female students in engineering, own illustration

5 DESIGN AND IMPLEMENTATION OF THE THEORY-BASED CONCEPT

A suitable program was developed based on the results of the analysis phase. Contrary to the recommendation to design the program for the middle school, the upper school was chosen as the transition from school to university is imminent and the project funding was aligned to it (Stringer et al. 2020). A one-week program was developed at Leuphana University followed by a project phase, resulting in a total duration of about three months (Salto et al. 2014; Christensen et al. 2008). Figure 3 shows the timetable and the main topics of the individual days of the project week consisting of the future-relevant topics “New Technologies”, “Industry 4.0”, “Insights into Professional Practice”, “Sustainability” and “Student Orientation”. Different workshops on the respective main topic are planned for each day. This means that a wide range of topics can be covered within a week, such as VR/AR, robotics, excursions or study orientation offers. Section 6 presents an exemplary technical workshop on VR/AR. In addition, female engineering students and female professionals are involved as role models to demonstrate the variety of opportunities and career paths in STEM professions (Stringer et al. 2020). In the subsequent project phase, further workshops, panel discussions and the implementation of individual projects are planned.

Project - Week - Schedule

	Monday	Tuesday	Wednesday	Thursday	Friday
8 am - 3 pm	Main topic: New technologies	Main topic: Industry 4.0	Main topic: Insights into professional practice	Main topic: Sustainability in Engineering	Main topic: Study orientation

Fig. 3. Schedule with main topics of the project week at Leuphana University, own illustration

The developed program was tested for the first time in January 2024. A total of 61 students from three different schools visited Leuphana University for one week between 15.01.24 and 26.01.24 to take part in the program. Most of the participants were in grades 11 and 12. Four students from a vocational school also took part, resulting in an age range of 16 to 24 years.

6 PRESENTATION OF THE DESIGN AND IMPLEMENTATION OF THE "VIRTUAL AND AUGMENTED REALITY WORKSHOP"

The workshop on the topic of VR and AR, which was used as one of three modules on the "New Technologies" day, is presented below. The approach of game-based learning in combination with a modular structure was chosen.

The aims of the workshop included learning about the development of VR, familiarising participants with various theories and areas of application and autonomously learning the difference between VR and AR using game-based learning.

VR is a computer-generated reality with images (3D) and, in many cases, sound. It is transmitted via large screens, in special rooms (CAVE) or via a head-mounted display (Bendel n. D). As the technology evolved, the term "virtual reality" was coined to describe devices that create an immersive, interactive environment with visual realism (Boyles 2017). AR is a hybrid form of visualisation that combines the real and virtual worlds (Choi 2016). The study of Silva et al. (2017) concluded that immersive educational gaming experiences have great motivational potential. As one of many studies, it shows that the use of VR is an effective educational tool that increases motivation.

The VR and AR workshop is designed for a maximum of 25 participants and can be flexibly adapted depending on the number of participants, available headsets and further materials. For this workshop, there were six VR headsets available, which were used as the primary basis for the structure of the concept. The duration of the workshop is 120 minutes as standard, but can be adapted flexibly.

Figure 4 shows the structure of the workshop for participant groups with fewer than twelve (1) and more than twelve (2) participants. Version (2) in particular is explained below, with possible adaptations for a smaller number of participants (1).

The workshop was started with a short introduction and explanation of each activity. The participants were divided into four groups, which rotated to a next station every 25 minutes.

Station 1: Presentation
Station 1 included an introductory presentation on the topic of "Virtual reality, augmented reality, mixed reality - theory and areas of application". The differences between VR, AR and MR were explained and their historical development, functions and areas of application, such as industrial production, medicine and entertainment media, were discussed. The aim of this station is to provide participants with theoretical knowledge and to differentiate between the various concepts. Participants should become aware that VR & AR is already part of their everyday lives and that many of them have already used various functions of it in apps and games such as *Snapchat* or *Pokemon Go*. The potential of these new technologies should be explored.

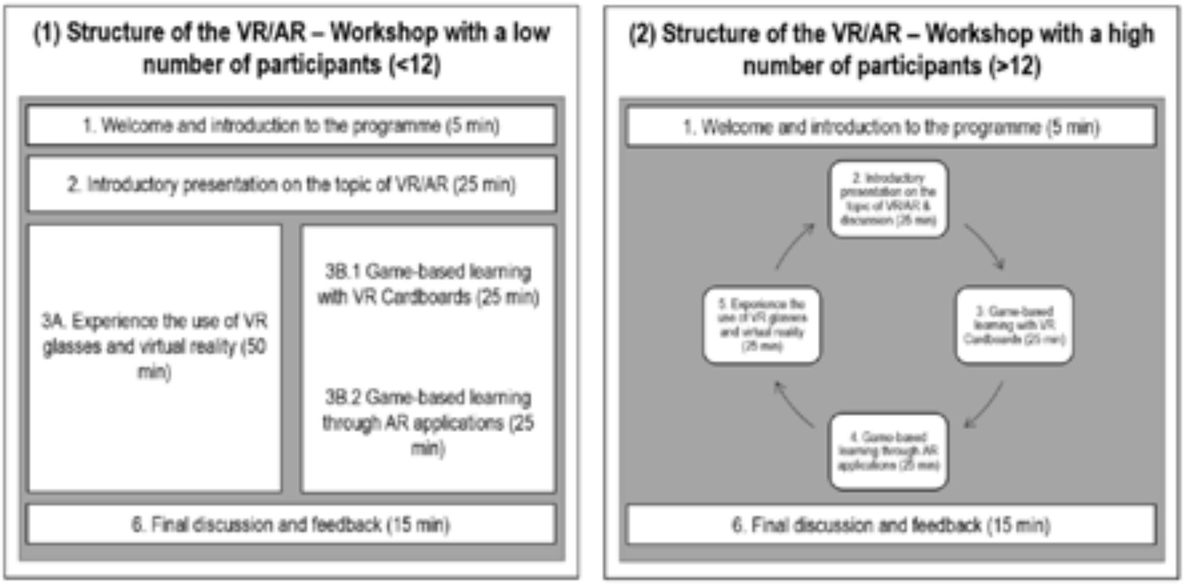

Fig. 4. - Structure of the VR/AR Workshop depending on the number of participants, own illustration

Station 2: VR Cardboards

At station 2, participants have the opportunity to learn selected content in greater depth through game-based learning and at the same time experience virtual reality with the help of cardboards and smartphones. The applications *"VR Tube (for iOS)"*[2] *a*nd *"YouTube (for Android)"* are used for this purpose. The videos can be selected from a variety of videos, ranging from engineering lab tours and city tours to popular skydiving experiences. After watching the videos, a short "*Kahoot"* survey follows to check understanding.

Figure 5 - Station 2 Cardboards and Station 3 Merge Cubes

[2]VR Tube:
https://play.google.com/store/apps/details?id=com.canturkgames.vrtube&hl=gsw&gl=US&pli=1

Station 3: Merge Cubes
Using Merge Cubes and the *"Merge Object Viewer"*[3] application, this station illustrates the difference between virtual and augmented reality. Participants can choose from various categories, such as Genetics, Human Anatomy, Solar System, Viruses, Space Science and many more, and take a closer look for example at the human heart or the James Webb Telescope. Predesigned exercises ensure that the participants understand and can apply these new concepts.

Station 4: VR headsets
Participants have the opportunity to test real VR headsets and try out various games at this station. In our case, the applications *"Beat Saber"* (rhythm game), *"IEYTD - Home Sweet Home"* (a virtual escape room) or *"Wooorld"* (a journey to different places in the world) were offered. The number of headsets influences the structure of the workshop and the amount of time the students have to try out one or more of the games. With 25 participants, each person had around 25 minutes to test the headset, whereas with only ten participants, each person had 45 minutes.

The structure and modular division of the workshop depends on the number of VR headsets available. In our case, six VR headsets were available. Structure (1) was chosen for a group with twelve or fewer participants (see Fig. 3). In this case, station 1 is an introduction and presentation for everyone. Two subgroups are then divided. While one group tests the VR headsets at Station 4, the other group works on Stations 2 and 3 simultaneously. The groups then switch before having a final discussion and feedback. If there are more than twelve and up to 25 participants, the group is divided into four subgroups and rotated until each group has been to every station. Appropriate supervision is particularly necessary for Stations 1 and 4, while Stations 2 and 3 can also be carried out as self-study, depending on the age of the participants.

The game-based workshop was successfully tested twice with 25 students each and once with a group of ten students from grades 11 and 12. The first evaluations of the feedback shows a positive perception of the workshop by the participants. On a Likert scale of 1 to 5, they rated the workshop with an average of 4.2 and 4.5 respectively in terms of their knowledge gain, which indicates a high level of satisfaction. The entire week was also rated very positively, as evidenced by the fact that 95.65% (N=46) would recommend participation to their friends.

7 RESULTS AND OUTLOOK

This contribution presents the initial results of theory-based concepts for an innovative study orientation program designed for female 11th and 12th grade students in Germany. The concepts developed were successfully transferred into practice. A variety of technical workshops were developed, whereby the modular structure of the VR/AR workshop is emphasized in this paper. The implementation of the project week met with an extremely positive response from the students, with 95.65% stating that they would recommend participation to their friends or want to participate again themselves. The effectiveness of the program will be evaluated after the project is completed, focusing on the development of skills and orientation

---

[3]Merge Object Viewer:
https://play.google.com/store/apps/details?id=com.MergeCube.ObjectViewer&hl=de&gl=US

for STEM studies. At least two further interventions are planned in order to optimize the concept.

ACKNOWLEDGEMENTS

The design and implementation of the motivation program is made possible by the BMBF program "Hybrid STEM study orientation program for women in the context of digital transformation". The authors express their gratitude to the young women involved in the program for their feedback. We would also like to thank the school representatives for their co-operation and support.

ABSTRACT

Education is an instrument for cultivating innovative methods, practices, and skills. Higher education is undergoing significant transformations, necessitating changes in educational institutions as well. Strategic management principles are one of the most common ways to manage transformation. Within the realm of strategic management, it is crucial to identify not only the imperative for change but also the internal and external environmental factors shaping current and future operations. Furthermore, the strategy formulation process must consider the interests of stakeholders, along with the means and resources to enact the strategy at the operational level. Active engagement of staff members holds particular significance.

This article presents the process how LAB UAS's circular economy education is responding the observed shifts in the operating environment and UAS´s strategic principles. The analysis is centred on two degree programmes: Environmental Technology (in Finnish) and Sustainable Solutions Engineering (in English). During the development process, a PESTE analysis, which encapsulates the key political, economic, social, and environmental drivers influencing circular economy education, was conducted. The PESTE environmental analysis served as the foundation for competency-based curriculums and has been instrumental in shaping the content and pedagogical framework of the examined study programmes to meet evolving adaptive competency requirements and aligning them with UAS´s strategic objectives.

1 INTRODUCTION

1.1 Strategic Management in Higher Education: Navigating Change and Complexity

The central objective of strategic management is to guide the organisation and its personnel towards the desired strategic direction, enabling the achievement of profitability, continuity, and developmental goals in a changing internal and external operational environment (Tirronen 2014; Kamensky 2014, 15; Faulkner and Campbell 2009). The importance of strategic management increases as the operational environment becomes more complex (Faulkner and Campbell 2009; Hassanien 2017). The starting point for the strategy should be an understanding of the changes in the organisation's operating environment (both internal and external), based on which strategic objectives and action plans are selected and prioritised. (Yüksel 2012; Kamensky 2014, 16, 19).

In strategic management, an organisation should primarily be viewed through an individual and human-cantered lens, emphasising processes, individuals, and the actual activities, in what is known as the "*strategy-as-practice*" approach. This approach strongly emphasises extending strategic thinking beyond the organization itself and integrating it into everyday operations (Tirronen 2014). This is crucial to consider because, particularly from the perspective of the organization's employees, understanding the significance of strategies and their direct impact on practical tasks is often found to be limited (Kamensky 2014, 15–16, 18).

We are living in a rapidly changing world where global megatrends such as climate change, sustainability crises, digitisation, and globalisation have already had and will continue to have a significant impact on the principles of organisational operation and the skills required in the workplace (Ministry of Education and Culture 2017, 7; Dailey-Hebert and Dennis 2015; Tirronen 2014).From the perspective of an organisation's success, it is crucial to proactively prepare for changes so that they can be anticipated before they become mandatory (Kamensky 2014, 32–33). Strategic management and setting a course for the future, where very little is certain, represent one of the most challenging yet essential tasks for leadership. The complexity of the strategy process is further heightened by the interests, assumptions, and perspectives of various stakeholders and experts who have different objectives related to teaching, research, and service activities (Faulkner and Campbell 2009; Kamensky 2014, 33; Tirronen 2014; Williams 2020). Successful strategic dialogue, in line with the theory of a learning organisation, involves trust, commitment, and perceived fair treatment (Ranki 2016, 28).

The changes are so extensive that individual and organisational transformations alone are insufficient; systemic changes are required in all aspects of society (Sitra 2019). Various levels of political and economic control mechanisms are significant tools for directing activities and resources. Societal goals related to education, entrepreneurship, and sustainability have been outlined in Finnish, European Union, and global action programmes and objectives. These should be considered in the strategic work of organisations, leadership, and, consequently, directed operational activities. (Dailey-Hebert and Dennis 2015; Frølich et al. 2018). All these factors will reshape the traditional, relatively stable role of universities in regional development, as well as the pedagogical methods, models of education delivery, and contents.

Higher education policy instruments also aim to promote the effectiveness of education as part of competence-based economic growth. Higher education institutions are expected to contribute more to societal competitiveness, impact, adaptability, higher quality, and internationalisation (Dailey-Hebert and Dennis 2015; Kolmos et al. 2016; Kamp 2020, 3–4). Future professionals are expected to have not only strong subject-specific knowledge but also a sufficiently broad interdisciplinary competence (Dailey-Hebert and Dennis 2015). Changes should not be seen solely as threats but also as opportunities to leverage the good reputation and relatively dynamic adaptability of the Finnish education sector thus far.

1.2 Trends in Higher Education and the Utility of PESTE Analysis

Strategic management in higher education is characterised by a long-standing culture rooted in discipline-specific goals and values (Tirronen 2014). Therefore, it is essential to consider not only the personnel but also environmental factors, as well as the numerous perspectives, interests, needs and demands of students, personnel, and stakeholders. Changes in the external operational environment affecting the higher education sector include requirements related to knowledge-based economies, digitalisation, globalisation, and government means of control. (Tirronen 2014). At both individual and organisational levels, one of the key prerequisites for success is the ability to innovate both in terms of operations and skills. Micro-work, advanced revenue models, organisational forms, shifts in values, and networked activities are also increasingly shaping the future of the workforce (Ministry of Education and Culture 2017, 7). In the future, success will require greater adaptability in work that is independent of time and place, as well as an entrepreneurial attitude and approach (Miller 2015), including engineers (Byers et al. 2013). Future skills needed should be an integral part of education development since they directly affect how work is done, the sources of income and the structure of industries (Pucciarelli and Kaplan 2016). The need to implement sustainability, environmental and circular economy aspects into the education and curriculums is also highlighted (UNESCO 2016, Memon et al. 2015, Mulá et al. 2017)

At a general level, the trends affecting higher education, according to Pucciarelli and Kaplan (2016), include increased internationalisation and global distribution of knowledge, the mismatch between education and the workplace, diverse learning needs of millennials and the workforce, growing student numbers, student heterogeneity, the need for external funding, and reduced regulation. Changes in the education market and skill requirements have brought new competitors into the field. Additionally, information and communication technology and digitisation have significantly transformed the landscape of education. (Pucciarelli and Kaplan 2016.) Competition of skilled students and workforce is increasing, while at the same time public funding is under economic pressure (Frølich et al. 2018). Therefore, higher education institutions should invest even more in enhancing educational content and implementation methods (de Haan 2013).

One of the most common tools for observing the external business environment is the PESTEL or PESTE (Political, Economic, Socio-cultural, Technological, Environmental, and Legal) analysis, which provides organisations with information about the state of the environment, especially at the macro level (Yüksel 2012). It is suitable for various purposes and organisations of different sizes. PESTE analysis can also be used as part of other strategic processes. Through PESTE analysis, factors affecting the attractiveness and market potential of a product or service can be identified, and factors and trends that influence market success can be predicted. (Perera 2017.)

2 Methodology

2.1 Aims of the study and PESTE environmental analysis

LAB University of Applied Sciences (LAB) was established in 2020 by merging the two universities of applied sciences located in different cities in Finland. The complexity of the work was increased by the extensive transformation process taking place at LAB, which involves merging the practices and cultures of two universities of applied sciences in a changing operational environment. Dozens of teams have been involved in this transformation, and numerous workshops have been held to ensure the implementation of the strategy as part of the measures taken by the units, RDI focus areas, various target groups, and the personnel.

At the same time, as structural and cultural change, the development of two new study programmes began. The author actively participated in different development workshops arranged for internal and external stakeholders and reviewed guiding documents and research. During this work, efforts were made to identify globally and regionally influential change and environmental factors affecting higher education, particularly in engineering and circular economy education. These factors include, among others, macroeconomic and political factors, industry environment, stakeholders, and various networks. In the applied PESTE analysis, special attention was paid to factors influencing the content of curriculum: political and economic, social/societal, technological, and ecological environmental factors. The analysis also considered key players in the industry (customers, competitors) and other stakeholders (such as owners, public sector, network partners). The PESTE analysis thus encompasses a multitude of different subject areas, perspectives, and components, of which the most relevant ones for this work are presented in Figure 2.

One of the objectives of this work was to increase, through participatory action research, the knowledge at both individual and organisational levels about existing information, regulations, and plans. Through this knowledge, models and content can be developed to enhance the competence in these themes for Finnish and international degree and continuing education students.

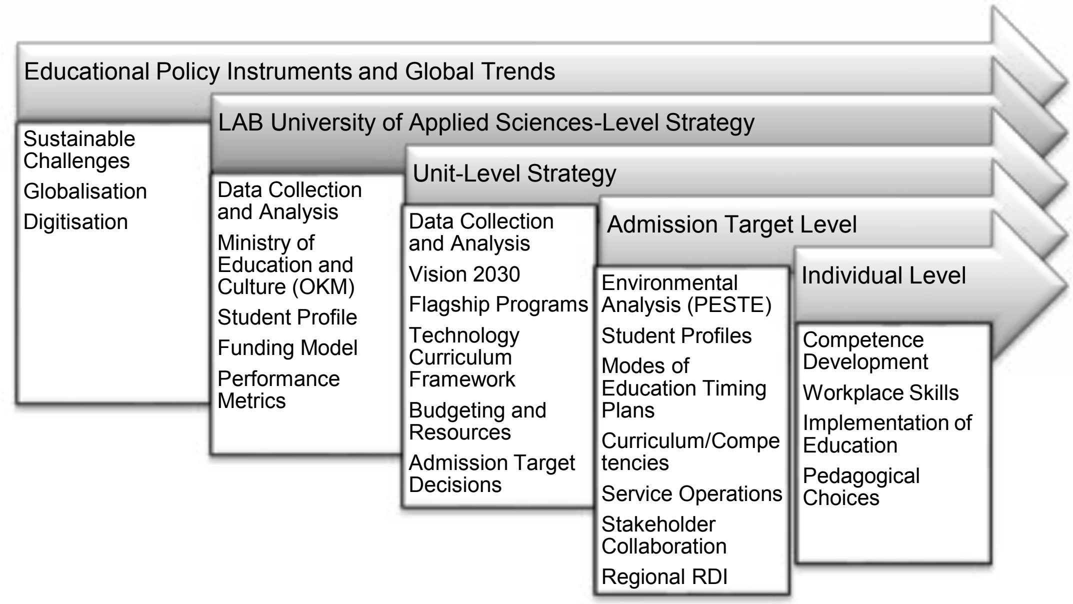

Fig. 1. Reviewed strategic levels and main influencing factors evaluated during study.

2.2 Profiling and Curriculum Work Related to Circular Economy Education

The process to develop the competence-based curriculums and the coordination of network-based collaboration for the English-taught Sustainable Solutions Engineering and Environmental Technology blended-learning programmes along with its competence objectives lasted about half a year, each.

The planning of a curriculum involved various stages and components (Kolmos et al. 2016). These methods included gathering information from various written sources, actively participating in seminars and workshops related to the topic, conducting internal and external workshops. The curriculum development process requires a multidisciplinary and multidirectional approach (du Toit et al. 2010). To gain a comprehensive understanding, the author consulted various national and international reports and forecasts, alumni surveys, thesis and clients, as well as engaging in discussions with industry representatives through interviews conducted over several years as part of futures study courses. Additionally, EU, national, regional, and organisational-level research and development strategies and supporting projects played a crucial role in supporting the curriculum development work.

Furthermore, the curriculum planning process considered organisational and national-level strategies, technology unit guidelines, collaboration with other universities, competitor analysis, network collaboration with various entities within the organisation, nationally, and internationally. It also considered continuing education needs and offerings, student´s and student organisation´s statements, existing online offerings, integrating expertise gained through organisational RDI projects into teaching, implementation possibilities, and existing learning environments (including laboratories). All these factors assisted in determining the competence needs required for the future labour market and the constraints that need to be considered in the curriculas. Each of LAB´s engineering study programmes´ curriculas were self- and cross-evaluated during workshops arranged among study programme coordinators. The aim was to figure out how the curriculas and the implementation methods align with LAB´s educational and technology unit strategic guidelines. The results of these evaluations for circular economy education programmes are presented in Tables 1 and 2.

In curriculum development, it was also necessary to consider the profiles of two parallel study programmes. The skills required for graduates of international, English-language programme, and for Finnish-language students, were identified. Cost-effectiveness was pursued by avoiding duplicate courses with the same content in these two study programmes. This approach provides students with more freedom to deepen their expertise by taking courses from other study programmes as part of their complementary studies.

3 RESULTS

3.1 The most Significant Environmental Factors Confirmed in the PESTE Analysis

The most important factors influencing the circular economy curriculum work, as observed during the completion of this work, have been compiled in Figure 2. Many environmental factors identified in the analysis are relevant across multiple categories or have mutually reinforcing and supportive significance. Overarching themes in all areas of the environmental analysis include requirements for change, digitalization, and the green transition. LAB's circular economy education aligns with the findings of the environmental analysis conducted. Additionally, the actions taken within the technology unit to implement the strategy and define future guidelines are in line with the environmental analysis.

Political and Economic Environmental Factors

Ministry of Education and Culture's Outcome Control: Increased emphasis on external funding's
EU Directives, Action Plans, and Financing: Alignment with policies, programs, and funding opportunities.
Entrepreneurship Policy Guidelines: Entrepreneurship education, initiatives by the Ministry of Economic Affairs and Employment, Business Finland's programs.
Environmental Policies: Internationalisation and cross-cutting societal functions, holistic examination of emissions, systemic change.
Trade Policy Measures: Harmonisation, regulations, standards, common rules, growth of digital services
Economic Instruments: Allocation of subsidies towards circular economy and green transition, shifts in taxation focus, emissions trading, and carbon tariffs.
Educational Policy Measures: Internationalisation, increased competition, raising the educational level, lifelong learning, strengthening RDI, innovation, collaboration, entrepreneurship education.
Government Program Values and Interests: Alignment with the values and interests outlined in government programs.
Competition for Talent: The competition for skilled professionals.
Green Transition and Circular Economy: The government's focus on sustainable and circular economy practices.

Social and Societal Environmental Factors

Sustainability Crisis, Digitalisation, Globalisation: Shaping societal challenges.
Changing Work and Learning Environments: Emergence of new professions, obsolescence of old ones, continuous learning, general and specialised skills, transdisciplinary skills, metaskills, teamwork, systems thinking.
Foresight, Shared Objectives, Collaboration, and Networks: Anticipatory actions, common goals, cooperation, accessible education, informal-non-formal-formal learning.
Open Recognition of Learning and Competence: Decentralised learning, shared learning, diverse learners
Perception of Work, Lifestyle, and Consumption: Evolving views on work, lifestyle, and consumption patterns.
Uncertainty and Complexity: Navigating through
Values and Interests: Societal values and interests.
New job opportunities due to Circular Economy

Technological Environmental Factors

Digitalisation: A pervasive factor influencing all areas.
Integration into Engineering Education: Incorporation of digitalisation in engineering education.
Significance of Green Transition and Circular Economy Strategies: Critical role in green transition and circular economy strategies, as well as educational transformation.

Ecological Environmental Factors

Climate Change and Adaptation: Minimising and preparing for climate change, biodiversity loss, and overexploitation of natural resources
Shift from Linear Growth to Circular Economy: Emphasis on material and energy efficiency, ecodesign.
EU Green Transition and Circular Economy Programs: Supporting instruments, investments, life cycle thinking and analysis.
EU and Finland's Leadership: Leading positions in sustainable practices.
Business Model Transformation and Preparedness: Adaptation of business models and readiness for changes.
Renewable Energy Sources, Environmentally-Friendly Materials, Technological Advancements: new resource efficient technologies, value chain thinking.

Fig 2. Summary of the most significant environmental factors confirmed in the PESTE analysis.

3.2 Implementation of LAB's and the Technology Unit's Strategic Directions in Circular Economy Education

Comparing LAB's strategy with the PESTE environmental analysis conducted during the study, it can be observed that they align closely in nearly all areas. Tables 1 and 2 provide a summary analysis of how the curricula and competencies of Sustainable Solutions Engineering and Environmental Technology programmes align with the general principles underlying competence in this work. They clearly show that the new programmes are well align with LeAB's and the technology unit's strategic guidelines. While the assessments are subjective, even cross-evaluated and includes various assumptions, the summary gives a good overview of areas that may still require development and further strengthening.

Both programmes aim to better reach students from diverse backgrounds (age, employment, parenthood) and enable multi-location, as well as time and place-independent, studying. Purely online education currently offers limited opportunities for collaboration with the working world, which needs to be developed in the future, as well as cooperation with secondary vocational education.

Table 1. Internal (and implementation) alignment of Sustainable Solutions Engineering and Environmental Technology programmes with LAB's educational strategies (- = does not align; + = partial alignment; ++ = substantial alignment; +++ = complete alignment)

4 SUMMARY

Strategic management is the most common way to address challenges faced by higher education institutions due to globalisation, digitalisation, and sustainability. The need to align education and research activities with the demands of the business sector and learners in a complex and dynamic environment should be emphasised. Various factors such as new work and learning trends, revenue models, organisational innovations, and collaboration networks are trends for future of education. The vision, dialogue among stakeholders, and government measures in supporting strategic work is important. Successful strategy implementation is seen as contingent upon leadership culture and the competency of the workforce.

This study showed that organization strategy should be consider in the curriculum development process. The PESTE environmental analysis, as observed in this work, is suitable for future competency-based curriculum planning and supports the gathering of background information. The author strongly believes that it is a useful tool for developing any education alongside with strategic guidance. It will also help to adapt organisations and individuals in the higher education operating environment, emphasising the increasing importance of knowledge, entrepreneurial attitudes, and practices, as well as the influence of globalisation and digitalisation on education. The importance of multidirectional and multilevel cooperation among different actors is emphasised even more.

Conference Key Areas: *Teaching technical knowledge in and across engineering disciplines. Improving higher engineering education through researching engineering education*
Keywords: *Variation theory, Cognitive theory, engineering education, student achievement*

ABSTRACT

This study aims to test the usefulness of an integrated pedagogical approach (combination of variation theory and cognitive theory) to teach complex engineering problems in face-to-face classroom environments. 36 undergraduate students in their third year of the 4-year electrical and electronic engineering program were purposively selected who participated voluntarily in this study. Also, a course teacher

[1] *M Hasan*
m.hasan@iut-dhaka.edu

of associate professor level from the same discipline participated in this study and conducted classes following traditional and theory-driven methods. Students were divided into a control group (where the traditional method was applied) and an experimental group (where an integrated pedagogical approach was applied). An observation protocol was used during the application of the treatment to the experimental group to ensure that the integrated approach was utilized as intended. A test was conducted with both groups, and their quiz scores were considered as the outcome of the methods applied. It was revealed that, overall, there is no significant difference in student achievement between the control groups and the experimental group. The findings have implications for engineering educators such as inadequate teacher training may obstruct expected outcomes. Priority attention is recommended to be facilitated to female students and those with low academic performance.

1 INTRODUCTION

1.1 Variation theory and student achievement

Variation theory, a pedagogical approach rooted in the principles of variation and contrast (Ference Marton 2014), has shown remarkable efficacy in enhancing students' learning experiences across diverse educational disciplines that deal with building concepts such as mathematics (Kullberg, Runesson Kempe, and Marton 2017), physics (Wang and Wang 2021) and in engineering education (Thuné and Eckerdal 2009; Hasan, Khan, and Ahmed 2024). Variation theory supports deeper understanding and promotes meaningful connections between ideas by systematically presenting concepts in multiple contexts and highlighting their differences. Ference Marton and Pang (2006) argue that “to learn something, the learner must discern what is to be learned (the object of learning)”, and it is the responsibility of the teacher to create the conditions required for learning to facilitate discernment to take place. Recognizing its impact, the European Association for Research on Learning and Instruction (EARLI) subsequently organized its annual conference: one in 2022 with the theme "Phenomenography and variation theory in practice – addressing educational challenges in a changing world" and another this year, 2024 with the theme *"Phenomenography and variation theory – the core, the diversity and the potential,"* where educators highlight the effect of variation theory on students' cognitive growth, problem-solving abilities, and academic success (The European Association for Research on Learning and Instruction 2022). Variation theory has also been used to teach complex engineering concepts, where students are expected to possess an interrelated set of intellectual skills of creative thinking, critical thinking, and innovative problem-solving abilities (Hasan et al. 2022).

1.2 Cognitive theory and student achievement

Cognitive theory-driven instruction has transformed classroom teaching methods and provided a deep understanding of students' learning (Mayer 1998). The cognitive theory of learning is a theoretical framework that focuses on understanding the internal mental processes, including memory, perception, and problem-solving, to improve how humans gain and utilize knowledge. By examining the complexities involved in brain functions like memory, concentration, and problem-solving, cognitive theory provides teachers with useful tools to use in classrooms to improve students' learning outcomes (Moreno 2009). By utilizing concepts such as metacognition and schema theory, educators can create learning activities that foster their students' more profound comprehension and critical thinking abilities. This method is necessary in engineering classrooms to encourage active involvement and long-term retention of the content, going beyond conventional rote memory (Hadie et al. 2018). Therefore, Engineering students are better prepared to understand complex engineering concepts and apply their knowledge in various situations, opening the door to academic success and work-integrated learning (Karim, Campbell, and Hasan 2019).

1.3 Positionality statement

Previous research has mostly reported the advantages of using either variation theory or cognitive theory in single empirical research. Utilizing both theories simultaneously in face-to-face teaching is a unique idea, particularly in engineering, which may have potential opportunities and challenges.

Combining cognitive theory and variation theory provides an integrated approach to education that uses each theory's advantages to improve student learning. While cognitive theory explores the mental processes underpinning learning, variation theory emphasizes the value of providing a wide range of situations and viewpoints to promote a deeper understanding. When combined, they create an engaging educational atmosphere that strengthens critical thinking abilities and profound conceptual knowledge.

However, merging cognitive and variation theories may be challenging from different perspectives. For example, educators may struggle to balance each theory's instructional practices. Adaptable lesson planning and collaboration between educators may be needed to align both theories for use in classroom settings. Thus, integrating variation theory with cognitive theory may improve student learning, but its complicated nature raises concerns regarding the usefulness of such integration. This study particularly investigates to what extent this integrated pedagogical approach provides benefit (or not) to engineering classrooms by seeking answers to the following two research questions:

1. *How does the teaching method (integration of variation theory and cognitive theory) influence students' achievement in engineering education?*
2. *Do students' academic background and gender influence their conceptual development and learning outcomes after applying variation and cognitive theory in engineering classrooms?*

2 METHODOLOGY

2.1 Research Design

As this research aims to investigate the influence of the proposed integrated pedagogical approach on students' achievement, the researchers followed the guidelines of a design study. The steps involved in designing this research are shown in Fig 1. The first step was to train the course teacher who taught a complex engineering topic in a face-to-face classroom.

Fig 1: Steps involved in the research design

Following the training, the course teacher prepared a lesson plan based on the learning study, which was then verified by the other authors of this study (Ling, Chik, and Pang 2006). The third author of this study was the course teacher and taught a topic of electrical engineering named *Properties of Various Optical Fibers* in the course *Optoelectronics* (*Sub Code: EEE 4671*). The intended learning outcome of the class varies from *knowledge to create* of the Cognitive domain of learning. The first and the third author, experienced in variation and cognitive theory, had several meetings to train the course teacher. However, this training session was held after the teacher had already taught one group of students (control group) and before teaching another group (experimental group) of the same cohort. A test was then administered for both groups of students together. The score of the test was considered as their achievement. In order to answer the research questions, the following hypotheses were developed as a guide for this research.

Hypothesis 1:	*Application of an integrated pedagogical approach in engineering classrooms influences students' achievements.*
Hypothesis 2:	*Gender influences student achievement.*
Hypothesis 3:	*Academic background influences student achievement.*

2.2 Ethical Considerations

This study was approved by the Department of Research, Extension, Advisory, Services, and Publications (REASP) of the university (Ethical Clearance number: 24-001). All participants provided informed consent after receiving comprehensive information about the study's purposes, methods, possible risks, and benefits. Participants were informed that their involvement was voluntary and that they had the freedom to withdraw from their participation at any point without facing consequences. To ensure confidentiality, all data collected were anonymized and stored securely, accessible only to the research team. Participants' identities were protected in all reports and publications.

2.3 Participants

36 undergraduate students studying 3rd year from the Electrical and Electronic Engineering department were chosen purposively as the sample for this study. A control group of 19 participants was taught in the traditional method, and an experimental group of 17 was taught following the integrated pedagogical approach. An experienced teacher from the same university, who is the third authors of this study, conducted these classes. A summary of the participants is presented in Table 1.

Table 1. Summary of the participants

		Gender		Academic Background		
Groups	Total	Male	Female	Good CGPA	Average CGPA	Below-average CGPA
Group A (Control Group)	19	18	01	11	04	04
Group B (Experimental Group)	17	11	06	7	06	04
Total	36	29	7	18	10	8

Note: Good CGPA (>3.74), Average CGPA (3.74 to 3.50), Below-average CGPA (<3.5)

2.4 Data Collection

The necessary background information (gender, academic background) of the students for both groups was collected by the course teacher, who is also one of the authors of this article. Students' achievement scores were collected after taking the test. An observation sheet was developed in consultation with the experts to ensure the integrated pedagogical approach was used. One of the authors of the article observed the class and took notes.

2.5 Data Analysis

For data analysis, SPSS software version 26 was used. Students' achievements (quiz marks) were not normally distributed. Due to the nature of the data, only non-parametric tests were used to test the hypotheses, which are discussed below.

1. For hypotheses 1 and 2, the dependent variables are categorical (methods of teaching in hypothesis 1 and gender in hypothesis 2, and the dependent variable was in ratio measurement (students' achievement). The sample size of each group was also less than 30. Considering the nature of the variables and group size, the Mann-Whitney U test was the good fit to test hypotheses 1 and 2.
2. For hypothesis 3, the independent variable "students' academic background" consisted of three categories: Good CGPA, Average CGPA, and Below-average CGPA. The dependent variable was measured at the continuous level. Considering the nature of the variables and small sample size, the Kruskal-Wallis non-parametric test was used.

3 RESULTS

3.1 Testing of Hypothesis 1: Application of an integrated pedagogical approach in engineering classrooms influences students' achievements.

Table 2. Two-tailed Maan-Whitney Test for Student achievement by pedagogical approach

Variable	Mean Rank		*U*	*z*	*p*
	Group A Control Group	Group B Experimental Group			
Student achievement	19.97	16.85	133.500	-.891	0.379

Note: *p>0.05*

A Mann-Whitney U test was performed to evaluate whether students' achievement differed by the pedagogical approaches applied. There were 19 students in the control group where the traditional teaching approach was applied and 17 students in the experimental group where the integrated teaching approach (combination of variation theory and cognitive theory) was applied. The result indicated that there was no significant difference between the achievement of students in both groups, z = -0.891, p = 0.379. It can be concluded that applying an integrated pedagogical approach in the engineering classroom does not influence student achievement.

3.2 Testing of Hypothesis 2: Gender influences student achievement.

Table 3. Two-tailed Maan-Whitney Test for Student Achievement by Gender

Variable	Mean Rank				
	Male	Female	*U*	*z*	*p*
Student Achievement	20.48	10.29	44.00	-2.30	0.020

Note: *p<0.05*

A Mann-Whitney U test was performed to evaluate whether students' achievement differed by gender. There were 29 male and 7 female students. The result indicated a significant difference between the achievement of male students and female students, z = -2.30, p = 0.020. It can be concluded that gender influences student achievement and male students' achievement is significantly higher than female students. If there were fewer female students in Group B (Experimental Group), the positive effect of the integrated teaching method would be realized. In other words, it is not only the teaching method, but also other associated variables, such as gender may influence students' achievement.

3.3 Testing of Hypothesis 3: Academic background influences student achievement.

Table 4. Kruskal-Wallis Rank Sum Test for Student Achievement by Academic Background

Levels	Mean Rank	*λ2*	*df*	*p*
Good CGPA	23.08	7.926	2	0.019
Average CGPA	11.65			
Below-Average CGPA	16.75			

Note: *p<0.05*

A Kruskal-Wallis test was conducted to evaluate the differences among the three categories of students based on their academic background (Good CGPA, Average CGPA, and Below-Average CGPA). The test revealed a statistically significant difference between the students' achievements and their academic background (p<0.5). They indicate that students with good CGPA yield the highest score (23.08). Also, Students with below-average CGPA performed better than those with an average CGPA, suggesting that third-year students in this category are dedicated to improving their academic performance.

3.4 Potential factors influencing the implementation of variation theory on student learning.

3.4.1 Students' Psychological State

The classes were conducted just after the semester-final exam result was published, which could affect student attentiveness to participate in class activities. Eventually, the implementation of cognitive they may not work with such students.

3.4.2 Time Frame between the class conducted and the test taken

The test was taken two weeks after the class was conducted (for the experimental group) and three weeks after the class was conducted (for the control group). It may have caused students to forget information and fail to achieve the desired test result.

3.4.3 Lack of adequate training for teachers

Lack of proper training and understanding could affect a teacher's teaching method, which may result in no change in students' learning; rather, in some cases may obstacle learning. Given the long-standing reliance on traditional methods, changing the classroom environment by implementing a new methodology would have been challenging.

3.4.3 Student's readiness for a new method of learning

Similar to the case of the teachers, students have been experiencing the traditional way of teaching. Teachers need to provide guidance to students regarding the intended conditions of learning in the classroom to ensure that students grasp the concept and derive benefits from integrated theory-oriented teaching.

4 SUMMARY AND ACKNOWLEDGEMENTS

The result shows that the integrated pedagogical approach (combination of cognitive and variation theory) in engineering classrooms does not influence students' achievements. However, this pedagogical approach provides better learning outcomes for male students and high academic background students. We need to acknowledge the limitations of this study having a small sample size that performs non-parametric tests. Moreover, the achievement test with one test is not adequate to generalize the findings. The second phase of this research will explore the qualitative understanding of students on engineering topics as a basis for evaluation. To achieve this, the phenomenographic approach will be adapted (F. Marton and Pong 2005), which will allow us to investigate deeper into students' understanding of specific engineering concepts. Therefore, well-trained teachers will be employed who will conduct classes using the integrated method and take several tests with a much bigger sample balancing male and female students.

ABSTRACT

The internationalisation of higher education has led to a surge in the number of international students enrolled in UK universities, particularly in one-year postgraduate taught (PGT) engineering courses. Another significant change is the recent shift in engineering education towards a more project-based approach, which means that teamwork is increasingly becoming a key skill that influences the success of student learning. However, many international students show deficiencies in basic teamwork skills due to insufficient attention to developing these skills during their undergraduate studies. In addition, most of these students have limited or no relevant work experience before the PGT course. Hence, emphasising and helping them to improve their teamwork skills during their academic year will not only improve their academic performance but also strengthen their future career prospects. Recognising this necessity, this study introduces an inclusive workshop framework and team-building games designed to provide PGT students with the opportunity to develop teamwork skills by engaging in team role plays where they

learn how to behave, contribute and interrelate with others in a team within an engineering educational setting.

1 INTRODUCTION

1.1 Teamwork in Engineering Education

With the recent shift towards project-based engineering education, the impact of teamwork on the academic journey and future career development of engineering students has become increasingly important. The integration of teamwork into the higher education curriculum necessitates educators to adopt and implement effective teaching, learning, and assessment methods, ensuring that students acquire indispensable soft skills alongside technical proficiency. Teamwork is indeed a crucial aspect for engineers and engineering students, and it can lead to improved problem-solving abilities, increased innovation, and enhanced project outcomes in engineering practice.

Collaboration among team members allows for the pooling of diverse skills, knowledge, and perspectives, which can result in innovative solutions to complex engineering problems (Campion, Papper, and Medsker 2006). A study by Smith-Jentsch, Salas, and Baker (2006) also underscored the importance of teamwork in enhancing decision-making processes within engineering teams. By working together, team members can leverage their collective expertise to analyse problems from various angles and arrive at well-informed and responsible decisions. Salas et al. (2014) emphasised the significance of teamwork in engineering projects, highlighting that collaboration among team members with diverse skills and expertise can result in more creative solutions and better decision-making processes.

In addition to project outcomes and decision-making, teamwork plays a crucial role in the professional development of engineering students. Johnson, Johnson, and Smith (2014) found that engaging in team-based projects helps students develop essential skills such as communication, leadership, and conflict resolution. Moreover, teamwork in engineering education aligns with the Accreditation Board for Engineering and Technology (ABET) criteria, which has long prioritised teamwork and communication skills as common skills that engineering graduates must possess (ABET 2023). Thus, it is clear that by learning teamwork in classrooms, engineering students can leverage the skills and expertise of their peers to tackle complex problems, drive innovation, and ultimately achieve better project outcomes in their studies and work.

1.2 Efficient Curriculum Design to Promote Teamwork in Engineering Education

An efficient curriculum design in engineering education can significantly promote teamwork among students through strategies such as project-based learning, team-building exercises, peer assessment, and faculty support (Bronson, Ng, and Wong 2007; Korkmaz and Kalayci 2019; Oladiran et al. 2011; Van den Beemt et al. 2020). Knight and Novoselich (2017) suggested that purposefully incorporating professional skills development in the curriculum can effectively nurture leadership skills among undergraduate engineering students. Research conducted by Suckarieh and Krupar (2005) also presented a course design called "Leadership and Teamwork from Within," employing experiential learning, community service, and problem-based learning strategies, which aligned with traditional frameworks of American applied engineering education to impart leadership and teamwork principles to engineering and technology students. Chen et al. (2011) introduced a novel assessment approach combining students' team performance and learning styles for teaching and assessing teamwork among software engineering undergraduates. Furthermore, Jiang et al. (2017) demonstrated a "joint assignment" project wherein biomedical engineering students collaborated with peers from diverse disciplines, enriching their teamwork capabilities. Takai and Esterman (2019) proposed a conceptual design of a team effectiveness model to augment teamwork in engineering education, with a particular emphasis on team member collaboration and the design process. Beddoes (2020) introduced a typology aimed at fostering successful interdisciplinary teamwork and enhancing awareness of teamwork among engineering graduates. In brief, integrating experiential modules, emphasising professional skills development, and providing structured teamwork training are essential strategies to enhance teamwork among students and better prepare them for the demands of collaborative work environments.

1.3 Gamification to Promote Teamwork

Gamification in higher education has also gained significant attention in recent years. It has emerged as a promising strategy to promote teamwork among students (Langendahl, Cook, and Mark-Herbert 2017). Previous research findings into improving students' learning outcomes and performance via incorporating game elements and combining teamwork and collaboration have been reported consistently (Diaz-Ramirez 2020; Forndran and Zacharias 2019; Sailer and Homner 2019; Rakhmanita, Kusumawardhani, and Anggarini 2023). Studies by Su and Cheng (2014) and Alsawaier (2018) also highlighted the positive impact of gamified learning activities on student motivation and engagement, which are essential components for promoting teamwork among students. The development of new digital methods, tools and games to be applied to teaching and learning was also critical to promote in promoting the integration of education into industrial practice (Markopoulos et al. 2015). Paciarotti, Bertozzi, and Sillaots (2021) introduced the Learner-Designer Approach to Serious Games (LDASG) as a new approach to gamification to promote inclusivity among engineering student groups. Furthermore, Maraffi and Sacerdoti (2018) reported the successful implementation of a Computer Classroom Role-Playing Game (CCRPG), emphasising the importance of user-friendly tools that promote teamwork in teaching and learning STEM subjects. Gamification is still in the developmental stage in higher education, but it can play a positive role in facilitating student learning outcomes and developing soft skills by combining it with traditional classroom teaching.

2 METHODOLOGY

2.1 Project Overview and Research Questions

This study applies a mixed-methods research design to investigate the teamwork performance and team dynamics of international chemical engineering postgraduate taught (PGT) students in a workshop setting. In recent years, an increasing number of Chinese students have opted to pursue a master's degree at UK universities. Although there has been a significant amount of previous research on students' teamwork, most of it has originated and been conducted using an existing business teamwork test (Aranzabal, Epelde, and Artetxe 2022; Aritzeta, Swailes, and Senior

2007). This test does not specifically address the learning and practical characteristics of students, and therefore, this leaves a gap to investigate teamwork performance and enhancement strategies in academic settings, particularly for Chinese students studying in UK universities.

This study primarily examines Chinese students' strengths and weaknesses in team-based learning in UK education settings and explores potential approaches to enhance their skills by engaging them in inclusive workshops, in-depth interviews, and focus groups. Based on the findings, we will further design diversified teamwork games and a team role test that are more suitable for application in educational contexts, with the aim of improving students' understanding of teamwork and their teamwork skills in future professional development. The complete research sequence is summarised in Table 1.

Table 1: Research Sequence of Designing the Inclusive Workshop and Team-building Games.

Phase	Activity	Data Type
1	Design the workshop process and team-building board game.	Desk research
2	Conduct the workshop	Practical
3	Investigate students' teamwork behaviours by engaging them in inclusive activities.	Quantitative data
4	Students fill out a post-activity questionnaire.	Quantitative & Quantitative data
5	Students are invited to participate in semi-structured interviews and focus group studies after the workshop.	Qualitative data
6	Improve the design of the team-building game and transfer it into a digital format.	Desk research
7	Develop and test a new team role test for educational settings.	Desk research, qualitative and quantitative data

2.2 The Workshop Study Design

This inclusive workshop study was conducted among PGT students on MSc Environmental and Energy Engineering and MSc Environmental and Energy Engineering with Industrial Management at the University of Sheffield during the autumn semester of the 2023 -2024 academic year (according to the internal admission data, the average annual enrolment rate of Chinese students in these two programmes was 63% from 2021 to 2023). It comprised a board game (Activity 1) adapted from a traditional team-building activity, "Lost at Sea" ("Lost at Sea - a team building game") and a project simulation activity, "Create Your Project" (Activity 2). Before the workshop, students were grouped into groups of 5-6 individuals, with the group formation predetermined by the departmental academic staff. Fig.1 presents the general schematic plan of the workshop study process to be conducted and the learning objectives expected to be achieved. Students will collaborate in groups during the workshop to complete various tasks. By engaging in team-building games, activities, and role tests, the students can learn about teamwork skills and strategies, and further understand their own collaborative abilities. The workshop will be followed by semi-structured interviews and focus groups to gain deeper insights into international students' perceptions of teamwork within the UK educational environment. Therefore, the research aims to support international students in forming better and continuously developing the teamwork skills and strategies essential for their life-long learning growth based on understanding the students' teamwork characteristics and improving the teamwork teaching approach at UK universities.

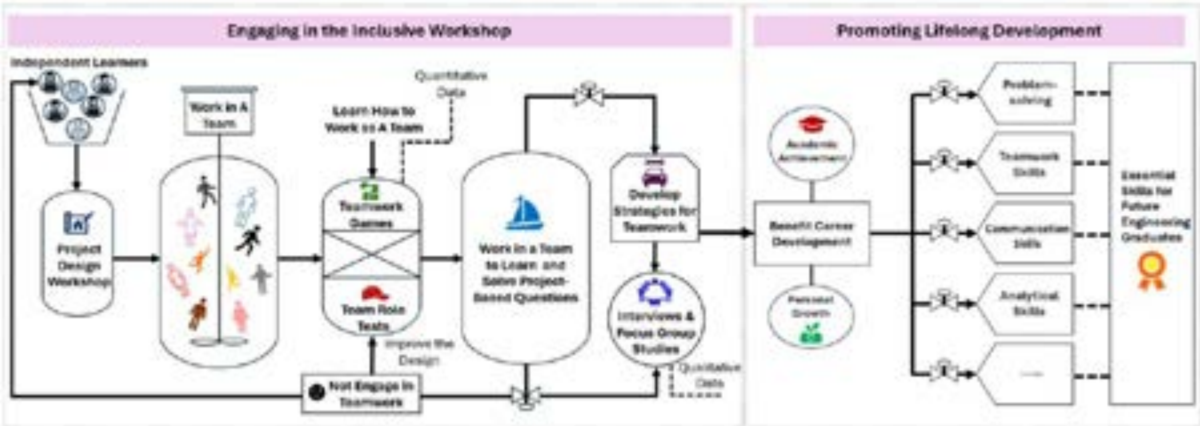

Fig. 1: The schematic diagram of the process of the inclusive teamwork workshop.

2.3 Team-building Game and Project-based Simulation Design

The team-building game used in Activity 1 was modified and redesigned based on the traditional team-building activity "Lost at Sea". The general game objectives and flow still followed the main logic of the original game (the game instructions mentioned in section 2.2 contained a detailed description of the content and process of the game). However, the original game design contained massive textual descriptions of the background and survival items, which required participants to have good English reading, reasoning and communication skills. But this setting may make it challenging for students who lack teamwork experience and English skills to be included and play the game smoothly. International students, especially, may experience language barriers when they first enter a Western educational environment, as they might tend to switch between languages (e.g., Chinese students translate English into Chinese and then into English again) while learning technical expertise. This additional presence of language switching may impact their ability to learn and accept new information or distract them from paying attention to the language rather than the learning content.

Therefore, to maximise the participation of a diverse range of students in the learning activities and to facilitate a smooth transition and adaptation of international students to the English teaching environment, we added simplified text descriptions and corresponding images for each survival item in the design to help students understand the game. Fig.2 illustrates the design template of the clue cards and the playing board for the team-building game applied in Activity 1.

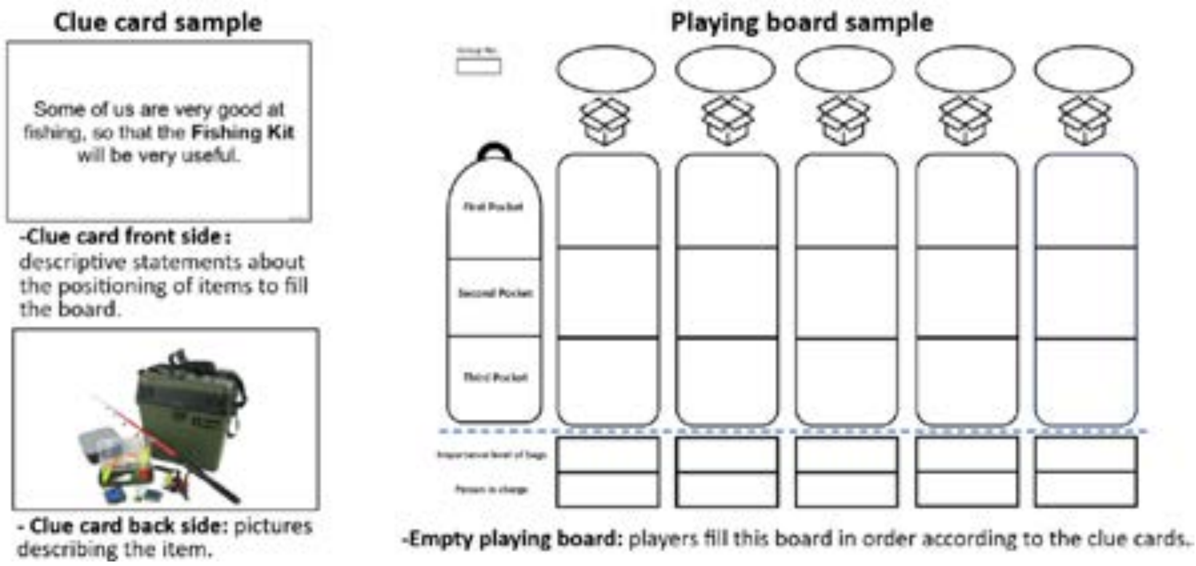

Fig 2: The design template of the clue cards and the playing board for the team-building board game. The left side of the figure shows a sample of a game card; the top left shows the front of the card containing a textual description to help students understand the importance level of the item, while the bottom left shows the back of the game card, which is an image of the item associated with a written description. The right side shows the playing board, divided by a dotted line into two parts: the upper part is filled with items to be put into different backpacks according to the cards' contents, while the lower part is filled with the importance levels and participants in charge of the different backpacks.

In Activity 2, we improved and redesigned a project design-based simulation game derived from the business simulation models (Baruah and Mao 2021; Levant, Coulmont, and Sandu 2016). Table 2 outlines the principle for assigning roles in the project-based learning Activity 2. The theme of the project-based design was the development of sustainable energy applications and devices, enabling students to make connections between the simulation and their professional knowledge. The detailed task responsibilities were described in each role's learning materials to promote collaboration with different roles.

Table 2. The role and task assignment principle for Activity 2.

If the bag you choose to take in Activity 1 is*:	The role you can consider to be in Activity 2 is:	Role description & task:
1st rank survival bag	Leader	Learning material pack 1
2nd rank survival bag	Responsible for calculating work	Learning material pack 2
3rd rank survival bag	Responsible for hands-on activity	Learning material pack 3
4th rank survival bag	Generating ideas	Learning material pack 4
5th rank survival bag	Making slides	Learning material pack 5

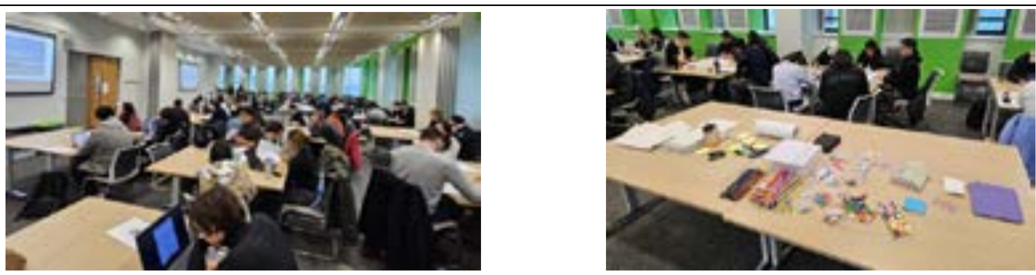
**At the end of Activity 1, the workshop facilitators will inform students about the importance of the backpacks. Students will then have a group discussion about who is responsible for the different backpacks. The backpacks students choose after discussing will be used as a basis for playing different roles in Activity 2.*

3 RESULTS

3.1 PGT students' engagement

A total of 83 students, including both home and international participants, formed 18 groups for the inclusive workshop. Among these, 86% were international students, with 83% of this international cohort originating from mainland China. This highlights the highly international nature of the learning environment within these postgraduate programmes. Notably, the group formations were organised by departmental staff to avoid homogeneity and ensure diverse team compositions (16 groups were mixed with Chinese, other international and home students; only two groups were completely Chinese). The deliberate pre-formation of diverse groups enhanced both the cultural diversity within teams and the potential for rich exchanges of communication and collaboration. This setup allowed for a broader range of perspectives and problem-solving approaches, facilitating a more inclusive and practical teamwork experience.

However, this arrangement also presents certain challenges. For instance, due to English proficiency, international students might face difficulties adjusting to different communication styles and collaborative patterns among their peers from various backgrounds. Most of the groups participating in the workshop consisted of students from different nationalities and cultural backgrounds, but the majority of each group still consisted of Chinese students (e.g., in a group of five students, four were from China, while the other one was a home student or from another country). Due to the limited team diversity, it may impact the efficacy of teamwork and the overall learning experience. Such a composition of the student cohorts is becoming more prevalent in UK master's programmes. Thus, providing adequate support and varied resources is necessary to enrich students' learning process and promote the effective achievement of learning outcomes, which will be an essential strategy to be adopted in teaching practice research. The complete process of the PGT students' participation in the workshop is shown in Fig.3.



Introduction and Learning Materials

Engaging in Activities and Presentation

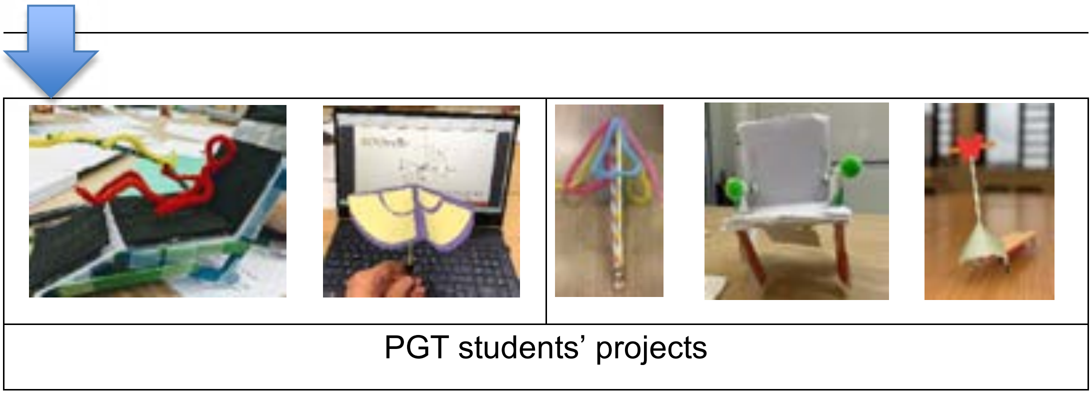


Fig. 3: PGT Students' Participation in the Workshop: The top shows the beginning of the workshop, where the facilitators explained the main content, process, and rules of the workshop; the middle shows the main component of the workshop, where students participated in activities and did hands-on work; and the bottom shows the prototypes of a sustainable energy device/application designed and built by the PGT students themselves.

3.2 PGT students' team performance

At the end of the workshop, we asked the students to give feedback and obtained preliminary insights into students' perceptions of the workshop. The results of the feedback showed that 87% of the PGT students who participated in the workshop felt that they were more of a collaborator in the team, while the other 13% felt that they were mostly in a leadership position (data presented in Fig.4). The students were also asked if they felt that their participation in the workshop had improved their knowledge and understanding of teamwork. For international students, their responses were distributed as follows: the majority of respondents (78%) indicated a certain level of agreement with the statement, with 33% agreeing and 45% strongly agreeing, while 18% expressed neutral. The remaining 4% disagreed, and 1% strongly disagreed (data presented in Fig.5). For home students, the results revealed that most of them also exhibited positive perceptions towards the workshop. 72% of respondents either agreed (54%) or strongly agreed (18%) that they gained insights to enhance their understanding of teamwork. Conversely, 28% of participants expressed disagreement, with 10% strongly disagreeing, 18% disagreeing with the statement, and no respondents were neutral in their stance (data presented in Fig.6).

The above data results show that a high percentage of students perceiving themselves as collaborators suggests that the workshop effectively fostered a sense of teamwork and collective participation. In contrast, the smaller proportion of students identifying as leaders indicates a potential area for further development in leadership skills within team settings. Furthermore, the positive feedback from most international students underscores the effectiveness of the team-building games to promote communication among group members. Yet, the neutral and negative responses also suggest that the workshop design may not holistically meet the learning needs of different students, and we will follow up with interviews to further investigate the perception of international PGT students to learn teamwork skills at UK universities.

It is worth noting that the majority of home students also viewed the workshop positively, but the relatively higher percentage of disagreement compared to international students raises questions about the differing expectations and experiences of home students in mixed-cultural settings, particularly in PGT programmes. This suggests that while the workshop was generally beneficial, better understanding and addressing the distinct perspectives and challenges faced by diverse students in such internationalised environments is needed to ensure students' overall effective learning experience.

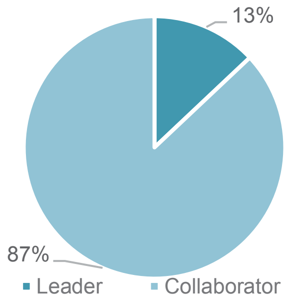

Fig. 4: The role preference of PGT students in group work. (87% preferred to be collaborators, while 13% intended to be leaders).

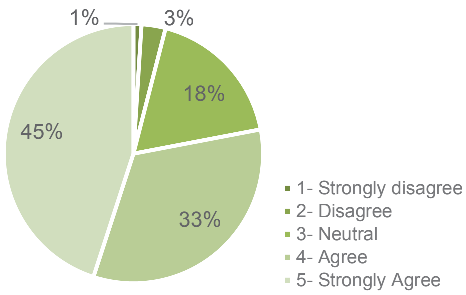

Fig. 5: Self-assessment of international students' improved understanding of teamwork after the workshop. 78% of international students agreed (45% strongly agree and 33% agree), 18% were neutral, and 4% disagreed (1% strongly disagree and 3% disagree).

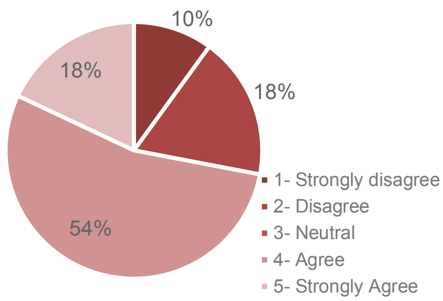

Fig. 6: Self-assessment of home students' improved understanding of teamwork after the workshop. 72% of home students agreed (18% strongly agree and 54% agree), and 28% disagreed (10% strongly disagree and 18% disagree).

4 SUMMARY

This study presented an inclusive workshop framework and team-building games designed to provide international PGT students with the opportunity to develop teamwork skills. This research is driven by the observed inconsistency between international students' team performance during collaborative work and the results of the commercial team role test they completed, such as the Belbin questionnaire. The commercial team role tests are typically designed for experienced professionals in business environments, not for university students with limited work experience. Therefore, this study seeks to develop team games and tests tailored to the academic context, reflecting the team behaviours of university students, particularly international students at UK universities. Currently, the prototype team games have been developed and tested with one PGT cohort. The early results and feedback have been positive and welcoming. In the following research phase, we will refine the inclusive workshop design, develop the team role test further and apply it to digital platforms to accommodate diverse learning needs, with the aim of improving the teamwork skills of international students in UK higher education institutions.

ABSTRACT

Universities are adopting more comprehensive teaching methods in an effort to prepare engineers for complicated problem solving. By engaging in Problem Based Learning (PBL) and Challenge Based Learning (CBL), students not only acquire content knowledge, but also encounter intricate settings where they collaborate with stakeholders, cultivate professional skills, and adapt to transdisciplinary situations. At the University of Twente, students were provided assistance in cultivating transdisciplinary competency through the CBL based semester project. Upon conclusion, participants were instructed to assess their personal learning experience and conduct a Q survey to rank the aspects they deemed most and least significant in this process. The results indicate that transdisciplinary learning is a personal journey, and students will find certain components more difficult and more beneficial based on their prior professional development. However, the trend indicates that

[1] *J Jezdimirovic Ranito,*
j.jezdimirovicranito@utwente.nl

they highly prioritize contacts with stakeholders and view teamwork as a means to effectively achieve this. They deem individual learning to be of lesser significance, as well as the act of reflecting on interactions with stakeholders and the process itself.

1 INTRODUCTION

To address issues such as climate change, sustainability threats, and inequality, fostering collaboration is necessary not only across different academic fields but also with non-academic stakeholders like industry and broader society (Ramachandran et al., 2022; Roysen and Cruz, 2020; Ward et al., 2019). Meeting market demands (labour or otherwise) requires recognizing the need for a new type of engineer. This enhanced engineer would not only prioritize the knowledge need to excel but also the competencies required to tackle societal challenges effectively (Mulder et al., 2012). Worldwide is consensual the need to educate engineers for unpredictable, volatile professional contexts and equip them with required competences and skills such as complex problem solving, communication, collaboration, interdisciplinarity, critical and creative thinking, etc. This calls for problem oriented, student-centred, collaborative, and contextual learning environments such as Problem Based Learning (PBL), and Challenge Based Learning (CBL).

University of Twente has adopted the CBL approach to develop students' skills beyond basic knowledge during their studies. University College Twente (UCT), part of the University of Twente, offers an Honors Bachelor of Science program that provides students with a comprehensive education in mathematics, natural sciences, and social sciences. Engaged in CBL environment, students in this program work with various stakeholders (e.g., peers, teachers, staff, external partners) to address societal challenges. Through CBL projects, students collaborate with, for example, government and industry partners to develop sustainable technology solutions and devise market introduction strategies. However, learning through transdisciplinary collaboration with external and non-academic partners might trigger student emotions which impacts their learning experiences and achievements. For example, it can trigger apprehension and uncertainty about how to interact and communicate efficiently with stakeholders, balance the hierarchical approach where stakeholders are regarded as experts and students as apprentices. Another example is how to effectively handle, and integrate knowledge learned in the challenge solving process. Students might achieve results expected, albeit in an instinctive manner, but this not necessary secures the needed attaining confidence in how to interact in transdisciplinary settings (see for example, Horn *et al.*, 2024)

In overall, it is fundamental understand in which ways student experience transdisciplinary learning (socially, emotionally, and cognitively) and what do they consider most important to support their transdisciplinary learning (see for example, Horn *et al.*, 2024; Akkerman, & Bakker, 2011). To support student transdisciplinary learning in a CBL environment, UCT in collaboration with Aalborg University (AAU), designed and implemented a tool based with aim to support students transdisciplinary learning. The tool design took the point of departure on Guliker and Oonk (2019) transdisciplinary learning model. It comprises seven stages, named learning mechanisms, and each stage provided prompt questions to guide students on what to consider when engaging and learning from, and with, stakeholders. The evaluation of the tool comprised two phases: (i) pre- and post- focus groups interviews and (ii) a Q study. This paper reports the results of the Q study and explores the following research question:

What do engineering students consider most important to support their collaboration with external stakeholders?

Guliker and Oonk (2019) transdisciplinary learning model revolves around four key stages: Identification, Coordination, Reflection, and Transformation. These stages are recognized as pivotal in facilitating collaborative learning across disciplines and in co-creating sustainable knowledge and practices, including in transdisciplinary environments. They encompass: (1) Identification, gaining insights into diverse current practices at disciplinary boundaries; (2) Coordination, collaborating with others to tackle shared challenges; (3) Reflection, gaining a multifaceted understanding of problems through diverse perspectives; and (4) Transformation, jointly developing novel knowledge or practices.

2 METHODOLOGY

2.1 Q methodology

Q methodology is a research approach used to systematically study subjective viewpoints and perspectives on a particular topic or issue. It combines elements of both quantitative and qualitative methods to capture individual beliefs, perceptions, and viewpoints while considering the subjectivity of study participants. Through a structured process involving steps such as developing a concourse (the range of statements representing viewpoints), constructing a Q set (a set of statements representing the concourse), conducting participant Q sorting (participants rank-order the statements according to their agreement or preference), and performing factor analysis, Q methodology aims to identify underlying patterns or factors in subjective viewpoints. This methodology is particularly useful for exploring complex concepts or issues where multiple perspectives exist, such as learning mechanisms to support student learning in a transdisciplinary environment.

Concourse development and Q-set construction

In this study, the concourse is draw from Guliker and Oonk (2019), two UCT tutors empirical experiences in facilitating students learning in their CBL projects. The initial concourse collaboratively crafted by first and second authors, both seasoned research experts and educators in CBL and PBL. Several rounds of discussion and revision of initial concourse led to first Q set comprising 32 statements. To enhance study validity, two international experts on PBL and CBL reviewed the initial Q-set draft, which consolidated the final 32-item version. Table 1 (available in annex) presents the Q set items, grouped according to learning mechanisms.

P-Set

P-set is composed by 13 students in 2nd semester of ATLAS, the UCT honours Bachelor program, with ages ranging between 18 and 23 years old. Additionally, P-set comprises students from different nationalities, namely Dutch (n=8), German (n=2), US/Dutch (n=1), Spanish (n=1) and Iranian (n=1), whereas six are males, four are females and three refer to other genders, or did not disclose it.

Q. sorting and post-sorting activities

After securing ethical approval from the University of Twente, the Q sorting process commenced, with participants physically conducting the sorting. Each participant received an informed consent form detailing the study's aims, format, procedure, and data management strategies to aid their decision to participate, followed by the Q set and sorting grid. Participants were prompted with the question: “Based on your experience in using the tool for transdisciplinary collaboration, what did you consider most important in supporting your collaboration with external stakeholders?” and tasked with individual ranking the Q set items based on what they consider most important. All 32 statements must be ranked hierarchically from -5 to +5, indicating their importance, where each grid allowed only one. Fig. 1 provides an example of a grid used to collect students’ responses.

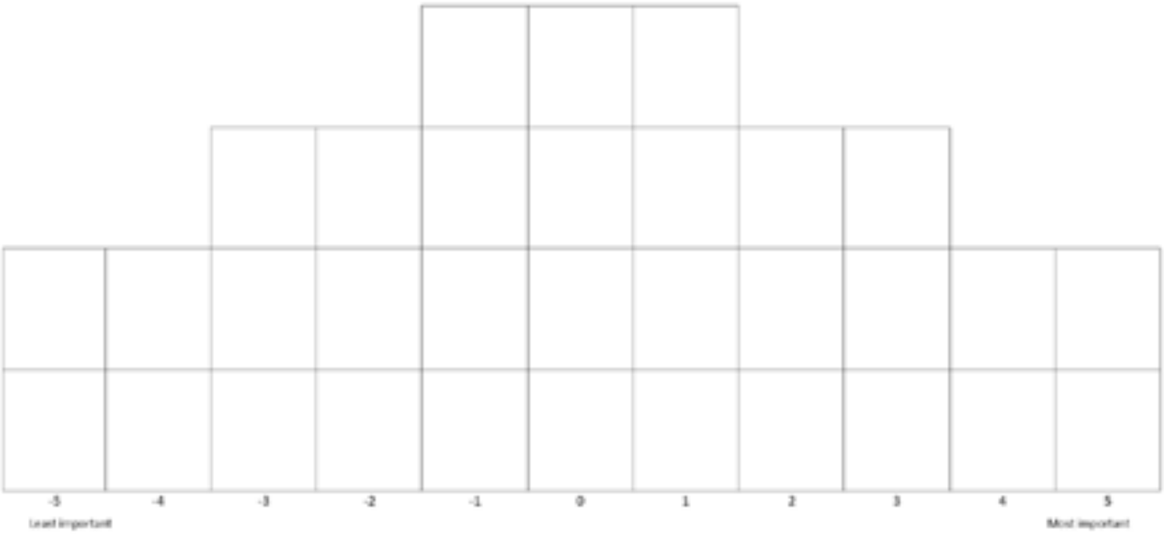

Fig. 1. Example of Q sorting grid.

In the post-sorting activities, each participant is asked to elaborate on reasons why they ranked given statements as most important (+5) and least important (-5).

Q. factor analysis and interpretation

The Q-sort correlations and inverted factor analysis involved inputting and reviewing raw data by the first and fourth authors before importing it into KADE, a Q analysis tool known for condensing data and identifying the most informative factor solution through Principal Components analysis and Varimax Rotation (Banasick, 2019). Four factors were chosen based on statistical criteria (eigenvalues ≥ 1.00 and significant loading participants per factor) (Watts and Stenner, 2012). After discussions and several rounds of KADE analysis, the research team agreed on the factors' theoretical significance and the most informative solution (Lundberg et al., 2020). Twelve participants significantly leaned towards one of the four factors (factor loading< 0.456), and one confounded sort occurred (Du and Lundberg, 2021).

3 RESULTS

In overall, all participants subjective opinions were significantly loaded in four factors. The four factors are described, combining the quantitative attributes, i.e., items ranked highest and lowest, and respective qualitative justifications provided by the participants. Each statement is referred to by its item number, correspondent learning mechanism and rated on a scale from +5 to -5 (e.g., '#5(R)/3' refers to statement 5, learning mechanisms reflection, with a rate value of 3). For distinguishing statements, 'D' ($p < .05$) is used after the value to emphasize statements in which the viewpoints significantly differed, and D* is used to indicate 'significantly distinguishing statements' ($p < 0.01$). Table 2 provides an overview of the results.

Table 2. Overview of results

	Factor 1	**Factor 2**	**Factor 3**	**Factor 4**
n	6	2	2	2
Gender	M: 3; F: 2; Other: 1	F: 1; Other: 1	M: 2	M: 1; Other: 1
Eigenvalues	4.1974	1.8438	1.6093	1.1625
% Explained variance	32	14	12	9
Highest-ranked items	#4(T): 5 D* #10(T): 5	#17(pre-I): 5 D* #1(C): 5	#1(C): 5 #7(pre-C): 5 D*	#10(T): 5 #12(I): 5 D*
Lowest-ranked items	#20(R): -5 #13(pre-I): -5 D*	#16(R): -5 #22(R): -5 D	#5(R): -5 #6(pre-I): -5	#8(post-C): -5 D* #19(pre-C): -5
Distinguished items	#4(T): 5 D* #32(T): 3 D #11(pre-I): -2 D* #21(pre-I): -4 D* #13(pre-I): -5 D*	#17(pre-I): 5 D* #18(I): 0 D #2(I): -2 D* #26(C): -3 D #10(T): -3 D*	#7(pre-C): 5 D*	#12(I): 5 D*; #5 (R): 2 D* #27(I): 0 D* #24(pre-C): -2 D* #29(C): -3 D #8 (post-C): -5 D*

3.1 Factor 1. Multi-perspectives and co-creation of solutions as true value in collaborating with stakeholders.

Six participants consider as most important to support their transdisciplinary collaboration the ability to "combine of different perspectives to generate new perspectives" (#4(T): 5 D*) and to "assess if the knowledge gathered is relevant to the challenge being addressed" (#10(T): 5). Both statements refer to transformation dimension of transdisciplinary learning, and students associated it by "what real means" to collaborate with stakeholders and the "true value" that brings to the development of solutions. As students F1-8 and F1-11 state respectively:

"*In my eyes, they (the items) define what collaborating with external stakeholders really means. To combine different perspectives on a challenge and obtain a solution through the process*" (student F1-8).

"*Collaborating with a certain stakeholder is only relevant if they can provide value. It is therefore crucial to identify these with important knowledge*" (student F1-11).

For these students, the least important aspects to support their transdisciplinary learning is to evaluate if the "individual learning goals are achieved" (#20(R): -5) and the "Set up individual learning goals" (#13(pre-I): -5 D*). Students perceived collaboration with stakeholders require focus and excel in other competences like communication as student F1-7 individual learning goals become less relevant. For this student, individual learning goals are important when it comes to team dynamic, as following states:

"*I think the individual learning goals are not as relevant as other concepts detailed here. In our group, individual learning goals more pertained to group dynamics and working in the challenge itself*". (Student F1-7)

3.2 Factor 2. Safe and good team work as pre-conditions to promote positive stakeholders' collaboration.

Two participants consider "Create openness to share my individual thoughts about the project (e.g., important tasks, uncertainties, etc.)" (#17(pre-I): 5 D*) and "Set up team plans to prepare oneself before engaging with stakeholders" (#1(C): 5) as most important when learning in transdisciplinarity environments.

For these two students, create a work environment that is safe and open is a pre-condition create positive engagement with stakeholders, and consequently the project, as Student F2-2 states:

"*I choose 1 and 27 specifically since I think a good knowledge base and a good safe/ good working team help a project tremendously*" (Student F2-2).

In opposition, they ranked lowest the ability to "Reflect on collaboration with stakeholders as the driver to create positive impacts on society" (#16(R): -5)

and to "Reflect on collaboration with stakeholders as the driver to develop innovative solutions (#22(R): -5 D). They explain that "*stakeholder contact is the driver behind innovation and positive impact on society*" (F2-2), or that even though it is important to reflect in overall, it is not "*specifically the driver to creative and positive impacts*" (F2-4).

3.3 Factor 3. Plan and strategize to gain the most from stakeholders' engagement.

Defining "strategies to engage with stakeholders" (#1(C): 5) and setting "up team plans to prepare oneself before engaging with stakeholders" (#7(pre-C): 5 D*) are consider most important by two students. Students have referred that being ready "*to meet the stakeholder in short time they have available*" (student F3-1) is most important so you can take most of the meeting and engagement. Therefore, strategies like "*proposing and discussing question for stakeholder meeting beforehand in the team made a difference*" (student F3 -1), so then the time came the team knew what is needed to address the challenge and how. This position is shared by student F3-5, who refer preparedness as important strategy to "*gain the correct knowledge*" from experts.

On the other hand, they consider "set up plans for future development of professional skills" (#5(R): -5) and "develop a sense of belonging to the team" (#6(pre-I): -5) as least important. They justify their positions by stating that "*the background of experts was similar to their own, so I don't understand what the professional differences*" could be (student F3-1), and that "*sense of belonging did not influence the context with experts, since I feel that the tools have contributed to developed the sense of belonging*" (student F3-5).

3.4 Factor 4. Identify and assess the “right” knowledge.

“Assess if the knowledge gathered is relevant to the challenge being addressed” (#10(T): 5) and “Identify sources (e.g., books, scientific articles, etc.) necessary for the required knowledge” (#12(I): 5 D*) significantly loaded in factor 4, grouping two students’ opinions which highlight the knowledge and sources as most important to support their transdisciplinarity learning. Both students emphasise the role of knowledge from an individual perspective, like student F4-6 who states that by identifying their weaknesses they can improve and address them throughout the learning process. Student F4-13 also emphasise on knowledge by stress the importance of being able to critically reflect on its “nature” and suitability to apply in building arguments on decisions made.

On the other hand, “evaluate on team experience when engaging with stakeholders” and “develop coping mechanisms to deal with negative emotions such as anxiety and nervousness, when engaging with stakeholders” are the two items considered as least important by these two students. Main reasons relate with lack of experience in performing the tasks as part of the project (student F4-6) or in meetings with stakeholders (student F4-13).

4 DISCUSSION

Based on the results that have been provided, certain patterns stand out. It is evident that the individual learning is given less weight in the transdisciplinary process. Instead, students value more to work in teams and engage with stakeholders together. Involving stakeholders and obtaining, selecting, and integrating knowledge to produce new knowledge are the most crucial aspects of transdisciplinary learning that they identify. They consider that to succeed, strong teamwork is a prerequisite, and that working in teams is the most effective way to complete tasks involving stakeholders since it enables them to organize and discuss their own ideas prior to meeting with stakeholders. It is believed that this preparation is essential for productive stakeholder participation since it enables students to identify their knowledge gaps and be ready for discussions on subjects. It is also emphasized that a key element influencing effective transdisciplinary learning is their own disciplinary learning and preparedness.

They argued that thinking back on stakeholder interactions had less of an impact on society. Based on their feedback, the general reflection is favourable; nonetheless, the influence comes from the engagement with stakeholders, not reflection on it. Given that debates and information exchange are considered as advances to already existing knowledge, this can be understood as a result of those events. Furthermore, they believe that thinking back on "sense of belonging" and "further development of professional skills" is less significant. They discovered that's the process's natural course for development.

5 CONCLUSION AND FINAL RECOMMENDATIONS

This explorative study examined what do engineer students consider most important in supporting their learning for transdisciplinary. Here, transdisciplinarity is defined as collaboration with external, non-academic stakeholders from whom student collect, select, transfer, and integrate knowledge with aim to solve a real and authentic societal challenge (Gulikers & Oonk, 2019). The theoretical framework underlying the Q set is based on four learning mechanisms for transdisciplinary learning referred by Gulikers & Oonk, 2019, adjusted to UCT context by its practitioners and researchers. First, the Q analysis provided four factors, where the subjective opinions from 12 students are grouped. This indicates an emergent pattern that students where potentially students have different needs and prioritize different aspects of transdisciplinary learning mechanisms. Additionally, such knowledge can enable educators to better scaffold students in their transdisciplinary learning. Second, the student sample is small, only 13 participants, with 12 loading significantly in four factors. For this reason, no inferences can be made but nonetheless it is indicative of diversity of subjective opinions students have concerning the meaning and value of transdisciplinary learning in engineering formal education. The study comprises other limitations besides the small sample of students. For example, the construction of Q set could be revised and improved through a pilot by involving student; comprise a more systematic literature review on transdisciplinary learning which complete the work of Gulikers & Oonk (2019). That said, several recommendations can be made, from a research perspective (e.g., enlarge sample, compare several semesters), and from an educational perspective (e.g., organize workshops and tailor-made activities which address students' needs and apprehensions).

Table 1. Learning mechanisms and corresponding statements, which compose the items of the Q set.

Learning mechanism	Statements	Q item
Pre-identification (**pre-I**)	1. Develop a sense of belonging to the team	6
	2. Set up individual learning goals	13
	3. Create openness to share my individual thoughts about the project (e.g., important tasks, uncertainties, etc.)	17
	4. Identify my individual strengths (e.g., knowledge, skills and/ or competences)	21
	5. Identify my individual weaknesses (e.g., knowledge, skills and/ or competences)	11
Identification (**I**)	6. Identify the knowledge the members of the team have in connection with challenge.	23
	7. Identify what knowledge is lacking to solve the challenge	27
	8. Identify sources (e.g., books, scientific articles, etc.) necessary for the required knowledge	12
	9. Identify which stakeholders hold the knowledge needed to solve the challenge	18
	10. Identify ways to acquire the needed knowledge	28
	11. Develop criteria to assess the appropriateness of the knowledge obtained from stakeholders in relation to the challenge being solved	2
Preparation for cooperation (**pre-C**)	12. Set up team plans to prepare oneself before engaging with stakeholders	7
	13. Prepare to act professionally when engaging with stakeholders	24
	14. Develop coping mechanisms to deal with negative emotions such as anxiety and nervousness, when engaging with stakeholders	19
Cooperation (**C**)	15. Define strategies to engage with stakeholders	1
	16. Accept cultural, social, and/or professional differences of stakeholders when engaging with them	25
	17. Be able to establish agreements with stakeholders for continuous collaboration	29
	18. Be able to communicate effectively with different groups of stakeholders	3

	19. Be open to different perspectives on addressing the challenge when collaborating with stakeholders	26
Post-cooperation (**post-C**)	20. Evaluate on team experience when engaging with stakeholders	8
	21. Be able to improve the strategies used to engage with stakeholders based on previous experiences	15
Transformation (**T**)	22. Assess if the knowledge gathered is relevant to the challenge being addressed	10
	23. Assess the implications of the obtained knowledge for developing solutions	32
	24. Select the knowledge to be integrated in developing new solutions	30
	25. Be able to combine different perspectives to generate new perspectives	4
	26. Be able to integrate new knowledge in the existing collective one (i.e., the knowledge that already exist among the team members)	31
	27. Be capable of influencing one's preconceived view	14
Reflection (**R**)	28. Evaluate if the individual learning goals are achieved	20
	29. Set up plans for future development of professional skills	5
	30. Reflect on collaboration with stakeholders as the driver to develop innovative solutions	22
	31. Reflect on collaboration with stakeholders as the driver to create positive impacts on society	16
	32. Reflect on the shortcomings of the solutions given the strategies used to collaborate with stakeholders	9

USING DELIBERATE DISCUSSIONS TO DEVELOP A RESPONSIBLE ENGINEERING MINDSET AMONG STUDENTS

ABSTRACT

In this research paper, we present a study of how deliberate discussions among students can guide the development of a responsible engineering mindset. We used a role-play case study intervention to teach students about the responsible and ethical dimensions involved in the use of facial recognition technology (FRT) on a college campus. Role-play discussions are a productive mechanism for teaching responsibility given the central role of deliberation in this process. From the literature we synthesized a framework (PAIR) that has four dimensions corresponding to the responsible use of technology: ***P***ractice, ***A***nticipation, ***I***nclusion, and ***R***eflexivity. We used this framework to analyze student responses at the group-level. The data was collected from 38 students enrolled in an undergraduate course on 'Technology and Society' at a US university. Two researchers conducted a thematic analysis of student responses to a range of prompts following the discussion. We found evidence of all elements from the PAIR framework in student discussions. We discuss the implications of our findings.

1 INTRODUCTION

Engineered products and services directly or indirectly shape many aspects of how people live and work. Being cognizant of the sociotechnical aspects of engineering is therefore important for students and professionals alike (Martin et al., 2019), and inculcating values of responsibility towards society is a common goal within engineering education (Lathem et al., 2011; Zandvoort, 2008). Often through standalone courses on technology and society, or through an embedded approach, where responsible engineering is introduced through design or technical courses, engineering educators strive to provide students with a holistic mindset to guide their work (Rea et al., 2021). In this paper, we present a study on the use of deliberative discussions to inculcate a mindset of responsible use among students. We designed a role-play case study on the use of facial recognition technology (FRT) and students read the case and subsequently engaged in a dialogue on the merits of using the technology to make a college campus more secure. In the rest of the paper, we first briefly review prior work, followed by a description of our implementation and methodology. We then present the findings and discuss the implications.

2 PRIOR WORK

2.1 Deliberation

Much of the work in the literature on responsibility within engineering and technology comes from the field of responsible innovation. Within that literature, deliberation has been recognized as a central component of designing technology that takes societal considerations into account (Parkhill et al., 2013). Primarily, by engaging different stakeholders and having a comprehensive dialogue, diverse issues, concerns, and opinions about the potential use of technology are brought to the table. The important elements are representation of different voices, the opportunity to state a case, and openness to other ideas and perspectives (Shen et al., 2021). Within emerging technologies such as AI (Weerts et al., 2022), scholars argue that deliberation is important in “finding optimal solutions” and “this process should satisfy conditions of inclusiveness to various stakeholders, ensure the reciprocity of actors, and facilitate diverse and well-informed arguments and viewpoints (Buhmann and Fieseler, 2021, pg. 1).” Using role-play case studies, as we discuss later, we replicate these conditions of deliberate discussion for students.

2.2 PAIR Framework

In addition to the process of deliberation, prior work on responsible innovation and engineering points to several factors that are essential for evaluating a new technology. These include the following four dimensions that form the framework we use for analyzing the data (Frigo et al., 2021; Stilgoe et al., 2020; Stone et al., 2020; van Grunsven et al., 2023): a. *Practice* - This dimension refers to practical concerns associated with the use of an engineered product or service that preclude or support its use more broadly and in the specific context of implementation. For the context of our analysis, we use this dimension to assess the practical viewpoints of stakeholders and specific concerns they focus on if the technology is in use, e.g., cost of implementation. b. *Anticipation* - This dimension refers to a forward-looking stance that considers different contingencies and what is plausible and possible. Within responsible innovation literature, this dimension can often refer to hypothetical future use as well, a more sci-fi approach, so to say, but in our analysis, we use it to evaluate future aspects of technology in use that students anticipate, e.g., data security needs once personal data is collected. c. *Inclusion* - This dimension refers to the representation of different stakeholder voices, including those not in power, and the nature of overall participation within the deliberation. In our study, the inclusion of different viewpoints is already designed using role-play and a discussion script that requires each stakeholder to voice their opinion. Given the focus on responsibility, for our analysis, we have used inclusion also to explore specific concerns such as racial bias in algorithms. d. *Reflexivity* - This dimension refers to trade-offs in decision-making based on different relevant factors and self-reflexivity in terms of understanding that one's perspective might differ from others and might not be universally held. In our analysis, reflexivity is present both in terms of changes in personal viewpoints and evaluation of pros and cons related to FRT.

Although we have analytically separated these dimensions, in conversation and discussion, they are often intricately linked with each other, and more than one dimension is often present in a single stakeholder statement or viewpoint.

3 DELIBERATION AND ROLE-PLAY CASE STUDIES

Role-playing case studies promote an active learning environment beyond what is possible in a traditional classroom and encourage students to contextualize the case or scenario they are working on in a situated manner and engage in sensemaking and perspectival thinking (Brummel et al., 2010; Loui, 2009; Herzog et al., 2024). Role-plays are commonly used in teaching engineering and technology ethics Martin et al., 2019; Shapiro et al., 2021). Role-plays serve as an instrument to guide students to engage with, debate, and evaluate decisions from the perspective of different roles. By making students aware of other perspectives, they better understand pressures and influences that would otherwise have been hidden. Furthermore, role-plays provide a collaborative learning pedagogical approach that is effective for deliberation because 1) collaboration triggers cognitive processes associated with learning, including perspectival thinking; 2) collaborative activity allows learners to strengthen understanding of material they have already learned and repair mental models that maybe fragmented or incomplete; and, 3) a cognitive-elaboration approach within collaborative learning requires actively processing information, and aims to elaborate basic information-processing activities such as encoding, activation of schemas, rehearsal, metacognition, perspective, and retrieval. In addition to the discussion aspect of role-plays, the other effective element is the “relatability” that can be designed in them in the sense that the narrative can focus on both a technology and context that students find interesting and relatable (Mehta et al., 2023). This makes recognizing ethical issues convenient and facilitates decision-making. Therefore, due to its situated learning element, case studies, particularly role-plays, allow students to explore many sides to a problem and develop multiple perspectives facilitating decision-making through collaboration and consensus with peers.

4 FACIAL RECOGNITION TECHNOLOGY (FRT) ROLE-PLAY CASE STUDY

The role-play scenario we designed follows a fictional situation involving the stakeholder's decision to use FRT to help monitor university campus security (Andrejevic et al., 2020). In this scenario, facial recognition is a method of identifying or verifying an individual's identity using the features of their face. Facial recognition systems can identify people in photos, video, or real-time. Prior work has shown that face recognition data can be prone to error, which can, for instance, implicate people for crimes they have not committed (Brey, 2004). Recent research has also shown that facial recognition software is particularly erroneous at recognizing African Americans and other ethnic minorities, women, and young people, often misidentifying or failing to identify them, disparately impacting certain groups' outcomes (Raji & Buolamwini, 2019; Williams, 2020).

In the case, Trisha Brown, Chief of Safety and Emergency Management (SEM) at the University, has put together a cross-functional committee (played by participants of the role-play activity) to provide a recommendation on the use of the technology along with the pros and cons of adopting facial recognition technology or a different solution. The committee is charged with identifying barriers to adopting the technology that the campus would face. The committee's composition is such that different stakeholders from the campus community can have a voice in a decision that will likely affect everyone. Table 1 depicts the roles. Details are available online (Hingle & Johri, 2024; Johri, 2024).

Table 1: Roles for FRT Role-Play Case Study

Role	Role Title	Role Description
A	Vice President of Information Technology Software and Services	A is has recently moved to AHU after a successful career in the industry. He is an unabashed technology optimist who believes that IT can solve almost any organizational problem, and once a solution has been implemented problems can be addressed.
B	Undergrad psychology; VP student senate	B represents students' welfare on this taskforce. B is a frequent user of social media and has used it to drum up support for causes such as the safety of women on campus.
C	Professor of History and a member of the faculty senate	C represents the faculty on this taskforce. As a historian, he often takes a long-term perspective and is cicumspect of technology-based solutions.
D	Associate vice-president in the provost office at AHU	D looks at student admissions and retention and is worried that a perception that the university is not doing enough for student safety might impact admissions. D thinks FRT would put AHU at the forefront of technology use and safety.
E	Senior Director, Equity and Inclusiveness (OEI) at AHU	E manages a range of efforts that can assist with advancing AHU's mission to admit and support a broad range of students. E is skeptical of any effort that might undermine inclusiveness on campus and this includes technology-driven projects.
F	Director, FaceAware, a non-profit consultancy in the field of FR	F is providing consulting for the taskforce pro bono. F is a renowned expert on FR and was responsible for creating one of the first deployable applications of facial recognition. F has been a proponent of facial recognition but is cognizant of problems with FR technology.

5 IMPLEMENTATION

The findings in this paper come from a study conducted at a large public university in the United States with undergraduate students majoring in computing technology-related fields. The study was conducted in a technology and society course with 39 predominantly junior and senior-level (3rd and 4th year) undergraduate students majoring in computer networking, information technology, and cybersecurity. Students participated in the role-play in groups of 6-7 students. Students were given the readings based on the case study to prepare for the role-play. Pre- and post-class assignments helped students prepare for the exercise and helped articulate their learnings, respectively. Participants were provided the role-play outline a few weeks before the role-play activity and given specific roles ahead of time to allow for preparation. In addition, participants were also provided reading materials and articles (both peer-reviewed and news-focused) related to the use of FRT to supplement their understanding of the scenarios. The role descriptions outlined the stance each role could take, but also left space for improvisation. The role-play activity was conducted in class, where participants were asked to take the perspective of their assigned role and engage with the other role-play participants. The role-play discussion was facilitated by a moderator, who provided some initial questions to focus the conversation. Participants were then asked to explain their role-based recommendation before leading into debating and negotiating with the other participants.

6 METHODOLOGY

6.1 Data

Data was collected in Spring 2024 and consisted of textual responses to open-ended questions. The study was approved by the Institutional Review Board (IRB), and only data from participants who consented (38 out of 44) was included. All participants completed a pre-discussion assignment focused on understanding students' perspectives on the case material presented. The pre-discussion assignment tasked students with outlining an individual recommendation to the committee lead based on their understanding of their role and the context of the scenario. Participants were also asked to identify any ethical issues and barriers that their role may be presented with while establishing their chosen recommendation. Finally, a post-discussion assignment captured the final consensus of the group and collected feedback on the participant's experience in the role-play scenario. Prior to this course, the students had one class period on ethics in an introductory course.

6.2 Analysis

Students understanding of responsible use and their decisions for the case study were analyzed qualitatively by the two authors using thematic analysis of responses to pre/post-class assessments (Braun and Clarke, 2012). Themes were drawn inductively and deductively in consultation with the literature review. Students' responses were coded to identify ethical themes, identify dilemmas in the case study, and demonstrate a multidimensional approach to making decisions about responsible use. A decision was made, after examining individual students' data, to undertake a group-based analysis to reach an understanding that reflected the deliberation process more accurately.

7 FINDINGS

After reading individual responses, we analyzed the data at the group level to better understand the outcomes of the deliberation process. Overall, of the seven groups that participated in the discussion, one group recommended that FRT be used, three groups recommended that FRT use be phased in slowly so that its usefulness and harms can be tested in a smaller setting, and three groups rejected the use of FRT completely and described alternative routes forward. Although each group fixated on some concerns over others, each group discussed many factors, and almost all relevant issues related to responsible use were brought up. Privacy and security were the most discussed issues, which is not surprising given the case topic and the fact that many students were majoring in cybersecurity.

Table 2: PAIR Framework applied to student responses.

		PAIR Dimensions			
Group	**Group Decision**	*Practice*	*Anticipation*	*Inclusion*	*Reflexivity*
1	FRT can be used but slowly phased in.	“**Collecting and storing biometric data**, raises privacy concerns.” “The privacy of students is an issue…**cameras** will have biometrics of all the students on the campus.”	“Users may not be fully **aware of the extent of data** being collected or how it will be used, leading to **potential breaches of privacy**.”	“**I partially agree** with the group decision that the school could implement the FRT **slowly but not everywhere**…I will only agree with this idea **if the school provides a clear consent form** of how they will use the students' data before they do the work.”	“The case study discussion **deepened my understanding of the complex interplay between privacy, cybersecurity, and ethics** in technology deployment…**I have a better understanding** that before doing any technology implementation **we have to always consider the privacy of the users… ensure responsibility** in case anything happens.”
2	FRT should not be used.	“**Data collected** must be checked regularly to verify it's **accuracy by utilizing automated auditing system** to detect any updated features change from the images data/info.” “**Updating the databases**, maintaining the system, and so on **will cost the university**	“We should **stick to what already works** such as biometric scans and physical ID cards. This **gives us time to improve facial recognition technology**, especially its security”. “The **public opinion** towards FRT will matter **if**	“The **issue of consent** was always an issue of FRT due to **people worried about personal privacy**.” “Needs transparency with students to have their consent of what is being collected that they would **feel like their activities are being watched for other purposes**.”	“**This discussion helped me see how rapidly technology is developing**…**I also realized how important it is to teach people about the importance of their privacy,** even if they have nothing to hide.” “FRT is a prime example of how cons of improving technology may

		additional money.”	**people do not have a positive** experience with it.”		sometimes outweigh the pros. **I believe that at this moment, we should stick to alternative or already existing ways of identification**.”
3	FRT should not be used.	“It isn't **cost effective**; people can easily **bypass it by wearing a mask**.” “**Too costly** and comes with too many risks to be considered practical.” “**Amount of data…could lead to ransomware** or DDOSing or stuff of that sort.”	“**Even if the technology was used properly** and only alerted campus police when someone not registered comes on campus, then eventually the **security would stop paying attention to the FRT because it would be pinging them all day long**.”	“It **disproportionately affects people of color, and this disparity needs to be addressed**. I have also learned this technology is not ready for mass market adoption, and that **assurances are needed of a bias-free and secure** system.”	“**I went from staunchly opposed to mildly in favor, with some caveats**... When someone mentioned that this technology was not correctly recognizing people of color, **I suggested that implementing it on campus would give it a larger data set with which to become more accurate**.” “If I were to use our discussion today as the example, yes we talked about how it invades people's privacy but it would also make campus more secure (ideally) **we also talked about how much money would go into this technology and actually affect security**.”
4	FRT can be used but slowly phased in.	“We all agreed that it was **not an effective use of money** and just created more problems than it solved.” “I had many concerns…**a third party would be handling the system and database**.”	“FRT would make the university **vulnerable to even more cyber-attacks**…The group offered solutions such as **very heavily guarded and encrypted storage rooms** where physical local data of students and faculties information would be kept it.”	“I feel that **implied consent due to being affiliated is not good enough**.” “**As long as people know** that this technology is in use… that should be okay… **they have the option to go into these areas or not**.”	“After the discussion **I became aware of the legal issues that would come with the deploying of the technology**. There should be disclosure in certain areas and having more people overlook the storage and detection of people within this campus” “FRT and AI is only the beginning of this new age of surveillance and privacy. **I believe it is crucial for regulations and policies** to be implemented nationwide.”

5	FRT should be used.	“**How is stored data handled… with such a growing campus requires a lot of storage** and should be localized to secure the data won't be used by companies or be outsourced through some ulterior motives besides the school safety.”	“Because I believe that FRT is a **good technology to use but is it still not good enough**…still not the best tool to use… privacy concerns.”	“**It may flag people of color or even someone who is just wearing hats, or anything**, and that could create a problem, and get the innocent in trouble. Also, **if the system gets hacked into, the hacker can use other people's faces to commit other crimes**.”	“I **learned some smart and innovative ways to see just how accurate and efficient the FRT could be**. We discussed the use of the FRT in just a small section but still a good amount of traffic area on the campus to test and see how well the FRT works on its own. **If there is bias or inaccuracies, then either improve it or disregard the implementation** all together.” “**My perspective towards the system changed especially towards the safety of such a system and how stored data is handled**.”
6	FRT should not be used.	“**Sensitive information such as biometrics should not be lightly dealt with**…FRT will bring along a lot of violation to privacy laws and mistrust within the community.” “**Cost of implementation exceeds the benefit of the system**.”	“Though there are problems I believe that with the proper approach they can be fixed and properly applied. I see that **in the near future applications like this will be heavily utilized** on college campuses because of the potential and upside of this form of technology.”	“Even if FRT was more secure, that doesn't change the fact that **students will still be uncomfortable getting their faces scanned** every day. Our group and I agreed that **extensive surveillance** can make students feel like they are always being watched and would feel like they are not enjoying a full sense of **freedom**. FRT also brings forward privacy issues and **risk of discrimination**.”	“**I realized that…If FRT was implemented, then it would take large amounts of AI power, surveillance measures, and personnel to keep the FRT system secure**. This is costly. And the more AI that is incorporated into places, the more difficult privacy becomes, because going so far as to track someone's face can make people uncomfortable.” “**My personal viewpoint changed because my classmates proposed a new view to me about the detrimental effects of this type of technology**. I now hold the view that it is not wise to implement it, and also not fair to students that would not like to be

					recorded everywhere.”
7	FRT can be used but slowly phased in.	“It would also be good for us to begin with **physical security first**...do more to prevent issues such as robbery more than using AI and facial recognition.” “There are **potential data breach concerns** as well, since biometric data can be copied or stolen.” “**The cost of [FRT] would be better in the long run** compared to more police force.”	“**Technical issues regarding FRT that have not been solved** yet, such as spoofing and just the overall lack of accuracy in the algorithm.” “**Problems could be fixed in the long run as the technology getting better** since AI is constantly adapting and changing.”	“**There are many cases of bias and false positives in FRT that can lead to discriminatory situations** and legal troubles.” “It is prone to errors and bias. As someone who supports equality, **the implementation of racially biased technology…I cannot condone** the use of it on campus.”	“**After this case study, I see that there is a trade-off between privacy and cybersecurity and you can't have both**... this topic is a gray area in our field because even though we have good intention with the use of FRT, it also prone to bias and people using it with bad intention,.” “**My perspective did change a little because at first I was heavily against the use of AI or facial recognition in general on campus however, I was convinced that using it little by little and testing** it for any false positives, or perhaps creating our own AI that we can supply information to that is not racially biased, could be a better alternative.”

Overall, students were exposed to and able to develop a holistic understanding and mindset for responsible use taking into consideration the practical, plausible, and impact concerns related to FRT as depicted in the quotes (Table 2). In relation to *practice*, the following concerns were raised. First, the cost-effectiveness of using FRT was questioned by several groups. The technology is not cheap, and it requires constant updates. Students questioned if the trade-off between using FRT as opposed to increasing physical security on campus was worth the investment. Students also expressed practical concerns about data collection, maintenance, and handling. They were particularly worried about a third-party company handling personal and private data for university members. At least one team argued, though, that in the long run, investment in FRT will pay off.

In relation to *anticipation*, students focused on the potential security issues that will be created as increasing amounts of data are collected and stored. Ransomware and other cyber-attacks on the data were foreseeable problems. They also worried that in terms of the algorithms, FRT still had issues and was not a fully developed technology, especially given its use on a college campus with many students, faculty, and staff, and a possibly large number of guests. Some groups also argued that they anticipate the technology to get better and the availability of data from the campus might help improve the facial recognition algorithm.

Inclusion concerns were evident in students' discussion of the inherent bias of FRT, especially in relation to people of color and its ineffectiveness in case anyone was wearing a mask or a hat. They also brought up concerns about the lack of freedom for students and the extensive surveillance. False positive in recognition was another issue that was brought up. Overall, most groups concurred that using FRT did not create an inclusive environment.

Finally, *reflexivity* was reflected in student comments about changes in their perspective and in their thinking about the use of FRT. Students reported improved awareness of societal and ethical issues, the need for regulations, and the downsides of using FRT. Some students reported understanding that there is a trade-off involved and it is hard to balance security and privacy. They also reported that they think there is a need to educate everyone about privacy issues.

8 DISCUSSION AND IMPLICATIONS

In this paper, we present a study of how responsible use of technology can be taught to students using a role-play case study approach, as this method provided affordances for deliberate discussion of a topic. The PAIR Framework provided a lens to track student recognition and learning through the different phases of their engagement with subject matter.

The assignment of roles to students was critical in including different perspectives and leading to deliberate discussion focused on the pros and cons of using the technology and the foreseeable problems and improvements that can be achieved in the future. The discussion and subsequent assignments also provided students the affordance to reflexively analyze their own learnings. Overall, the study also points to the advantage of a loosely guided discussion that allows students to engage with a topic and express diverse viewpoints.

Interestingly, we found that although the groups discussed the same case and students played similar roles across the groups, the discussion varied, and the groups reached different final recommendations. The groups were rightfully cautious with employing a system that would likely change how different participants on the campus grounds interact, especially when the details of the change could not be easily anticipated. Ultimately, implementing a novel system in a new setting requires time and students highlighted their uncertainty through their discussion and decision.

This work has certain limitations. The data is from just one course. The role-play was not designed specifically to look at 'responsible use', although the case by default prompted that discussion given the need to analyze technology and make recommendations balancing societal issues. In the future, the PAIR framework can be used to design cases specifically for facilitating a responsible mindset.

ABSTRACT

The objective of this paper is to describe and analyse the backgrounds and attitudes of students participating in their first year of Bachelor's degree studies in engineering in the Finnish education system regarding the study of mathematics, as well as the students' basic mathematical skills in 2023. The data used in the study has been collected from two Finnish universities.

The data consists of Finnish and international students' answers to a mathematics basic skills test and their reactions to some statements about studying mathematics. International students' test scores were higher than Finnish students', especially in tasks related to differentiation and trigonometry. No significant difference was found between the answers of men and women.

Both Finnish and international students felt that mathematics will be important to them in their working life, but this feeling was much stronger among the international students. Women are more likely than men to agree on a statement of having worked hard in their previous studies to learn mathematics.

1 INTRODUCTION

1.1 Engineering students' mathematical skills

Students' mathematical skills and abilities have weakened in many European countries during the last couple of decades (European Commission 2024). The SEFI Mathematics Working Group has also noticed this trend in engineering education, which has led to them publishing a competence-based curriculum (SEFI Mathematics Working Group 2013). Understanding the level of students' mathematical knowledge and skills is essential for planning teaching methods and learning content. It cannot be assumed that students' skill level at the beginning of their studies remains independent of their starting year. Students are becoming a more heterogeneous group with different backgrounds, and there have also been changes in topics studied at previous education levels. In addition, the COVID-19 pandemic could have caused interruptions in mathematics studies.

One reason for the increase in heterogeneity is the internationalization of students, which leads to significant differences among students in the types of studies they have completed before university, particularly in natural sciences and mathematics. In Finland, the number of international students in engineering degree programmes has grown drastically. For example, at Lappeenranta-Lahti University of Technology LUT, there were only about 30 international students starting their studies in 2016, whereas in 2022 the corresponding number was more than 230 (Vipunen n.d.). Today, LUT University has a total of 7 international bachelor's programmes in technology.

Tampere University of Technology started analysing incoming engineering students' mathematical skills by the Mathematics Basic Skills Test (BST) in 2002 (Joutsenlahti, Ali-Löytty and Pohjolainen 2016). A modernized version of the test is still in use at Tampere University, the successor of Tampere University of Technology. All students on first year mathematics courses take BST at the beginning of their first semester. The test consists of 16 basic mathematical tasks that are considered essential to master at the start of the studies. Time limit for taking the test is 50 minutes. Students are instructed to take the test independently and not using a calculator, mathematical software, or other material. In recent years, students have taken BST in an unsupervised environment, so it cannot be verified if the students have followed this instruction.

BTS is implemented using STACK (System for Teaching and Assessment using a Computer Algebra Kernel) (Sangwin 2013) that provides automatic assessment of students' answers. If deficiencies are found in students' skills, they are guided to review material. The STACK version of BST was taken into use in 2018, but the mathematical tasks were quite similar already during the years 2002-2017. Results of BST have been analysed for the years 2006-2017 by Myllykoski et al. (2018), showing that students' results in BST deteriorated between 2013-2015. This was seen in, for example, weak skills in manipulating expressions and managing simple calculation rules. In 2006-2017, the weakest competence was found in test questions on trigonometry, differentiation, and logarithms.

1.2 Gender differences in mathematics

Finnish secondary schooling comes with several gender differences regarding mathematics. In grade nine, at the end of lower secondary school, girls' average performance in mathematics is better than boys', but girls are underrepresented among the top performers. Girls also have a lower mathematics self-efficacy and higher mathematics anxiety than boys. (Hiltunen at el. 2023.) At the end of the upper secondary school girls still have more negative feelings towards mathematics than boys at all performance levels. However, among the high achievers, girls seem to like mathematics more than boys. In this performance level there are also no gender differences in mathematics self-efficacy although in the lower performance levels it remains lower for girls than boys. (Metsämuuronen 2017.) In 2023 more girls took the upper secondary school matriculation exam in the advanced mathematics syllabus than boys, but boys performed better in the examination (Vipunen n.d.).

In upper secondary school, boys are more likely to choose advanced mathematics than basic mathematics, and vice versa for girls (Vipunen n.d.). There are no gender differences in the motives for choosing the advanced level mathematics, and the top motives for both girls and boys are the perceived usefulness of the curriculum, enjoyment and interest in mathematics, and self-efficacy, ability, and confidence in mathematics. However, the reasons for not choosing advanced level mathematics differ with girls justifying their decision with lack of enjoyment and interest, or self-efficacy, ability, and confidence statistically more often than boys. (Kaleva et al. 2019.).

According to Tossavainen et al. (2021), in the first year of engineering studies, women seem to have better performance in mathematics than men. No gender differences in mathematics self-efficacy were detected, but women appear to be more interested in mathematical thinking whereas men emphasise the utility value of mathematics more (Tossavainen et al. 2021). Yet, women show a stronger surface approach to learning mathematics than men (Rämö et al. 2023).

1.3 Research questions

The objective of this research was to better understand the mathematical starting level competence of the diverging engineering student body and explore the possible explanations behind the differences in skills. Studies on students' preliminary mathematical skills and perceptions on mathematics have been conducted earlier (e.g. Joutsenlahti, Ali-Löytty and Pohjolainen 2016, Charalambides et al. 2023, Francis and Jacobson 2022). Charalambides et al. (2023) studied students' prior beliefs and self-efficacy beliefs in relation to their initial mathematical skills, finding interrelations of the students' previous achievements and experiences with their beliefs and self-efficacy beliefs in mathematics. Francis and Jacobson (2022) observed that students' performance on a prerequisite test designed for Calculus I course was associated with their retention in the engineering programme. However, these studies did not specifically address genders or international and domestic degree programmes separately. Thus, the objective of this research was operationalised into the following two research questions:

RQ1: Are there differences in mathematics performance level or pre-university interests and attitudes towards mathematics between the i) women and men and ii) students in Finnish and international engineering degree programmes before the first engineering mathematics courses?

RQ2: Is the performance level or the differences in it connected to pre-university interests and attitudes towards mathematics?

2 METHODOLOGY

2.1 Participants

The participants of this study were first year engineering higher education students in two research-oriented universities in Finland, Tampere University (N=579) and Lappeenranta-Lahti University of Technology LUT (N=265). The total number of participants was N=844, of which 578 were men and 252 women. The average age was 21.63 (SD 2.63) years. 685 students studied in Finnish engineering programmes in one of the two participating universities, 159 in an international engineering programme, where the teaching language was English. The participants gave their consent to participate in this research and were informed that they could withdraw from the study at any point. Research permission was granted by both universities involved in this study. At LUT University, the data has been collected from students of the LUT School of Energy Systems faculty's departments of Energy Technology, Mechanical Engineering, Electrical Engineering and Sustainability Science. At Tampere University, the participating students came from all Bachelor of Science programmes in engineering. The data on international study programmes used in this article has been collected from three programmes of the LUT University: Energy Engineering, Electrical Engineering and Mechanical Engineering. These three Bachelor of Engineering degree programmes have been implemented in cooperation with Hebei University of Technology (HEBUT), China.

2.2 Procedure

In the beginning of their first mathematics course at the university level, the participants filled in a background questionnaire and completed the test in basic mathematics skills. Both the questionnaire and the test were online, and the students filled them outside of learning events. Their answers were collected, pseudonymized and combined for analysis. All statistical analyses were performed with Matlab. The original basic skills test had 16 tasks, but since there was a technical problem with one of the tasks in the online system, and one task had a translation difficulty, scores of 14 tasks were used in the analyses.

3 RESULTS

3.1 Basic mathematical skills

The basic mathematics skills test had 14 tasks, all worth one point. The students scored on average 10.42 points with standard deviation of 2.69 points. According to the two-sample t-test, $t(828)= .34$, $p= .73$, there was no significant difference in the basic skills test scores between men ($M=10.43$, $SD=2.71$) and women ($M=10.36$, $SD=2.69$). But, in the international programme the points ($M=11.54$, $SD=2.64$) were significantly higher than in the Finnish study programmes ($M=10.16$, $SD=2.64$), with $t(842)=5.92$ and $p< .001$. Histograms of the score distributions for the international study programme and the Finnish study programmes can be seen in Figure 1.

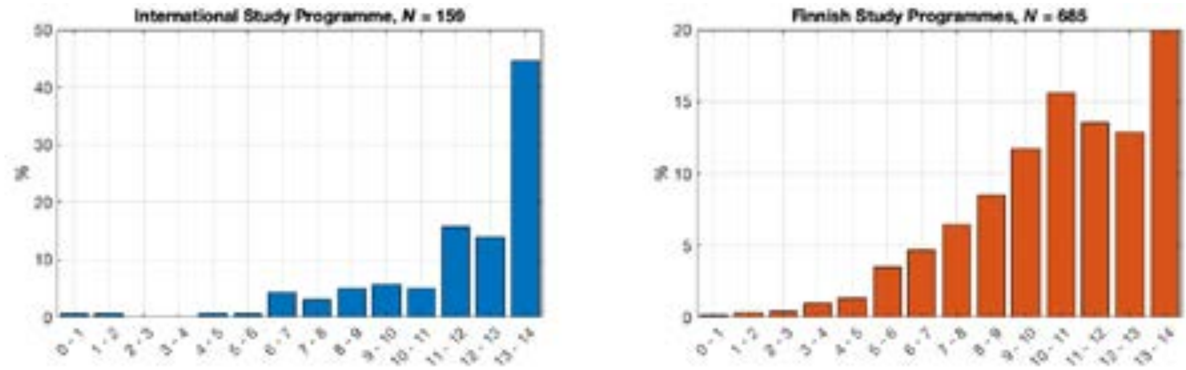

Fig. 1. Basic skills test score distributions for the international study programme (N=159) and the Finnish study programmes (N=685)

Figure 2 presents the differences for the international programme and the Finnish programmes in the means for each task with error bars. Positive difference means that the international programmes performed better. It can be observed that the biggest differences occur in tasks 10, 11 and 12. These tasks considered trigonometry (10 and 11) and the derivative of a fourth order polynomial (12).

Fig. 2. Differences between the means in BST tasks between the international study programme and the Finnish study programmes

3.2 The students' perceptions of mathematics studies

Students were asked to give their opinion on three statements about mathematics studies on a five-point Likert scale (1 = completely disagree, 5 = completely agree). The statements were

- L1. In my previous studies, mathematics was a pleasant subject for me.
- L2. In my previous studies I had to work hard to learn math.
- L3. I feel that mathematical skills will be important to me in the future in working life.

Students in general agreed with the first statement (M=4.04, SD=0.95), with no significant difference between men and women or between the international programme and the Finnish programmes, but for the second statement (M=3.60, SD=1.12) women reported having had to work harder (M=3.74, SD=1.08) than men (M=3.55, SD=1.12) by the two-sample t-test, t(828)=2.31, p=.02. No difference was observed between the international and the Finnish programmes. In L3, the students considered in general mathematics to be important for them in the future (M=4.23, SD=0.81), but by the two-sample t-test (t(842)=4.30, p<.001), the students in the international programme (M=4.41, SD=0.82) considered mathematics to be even more important than the students in the Finnish programmes (M=4.05, SD=0.83), with no difference between the genders.

We studied the correlation between the statements L1-L3 and the basic skills test result. Figure 3, produced with corrplot in Matlab, presents a grid of scatter plots between pairs of variables with a least-squares reference line with slope equal to a displayed correlation coefficient. Histograms of individual variables appear along the diagonal. The correlation coefficients are presented in red when p<.05.

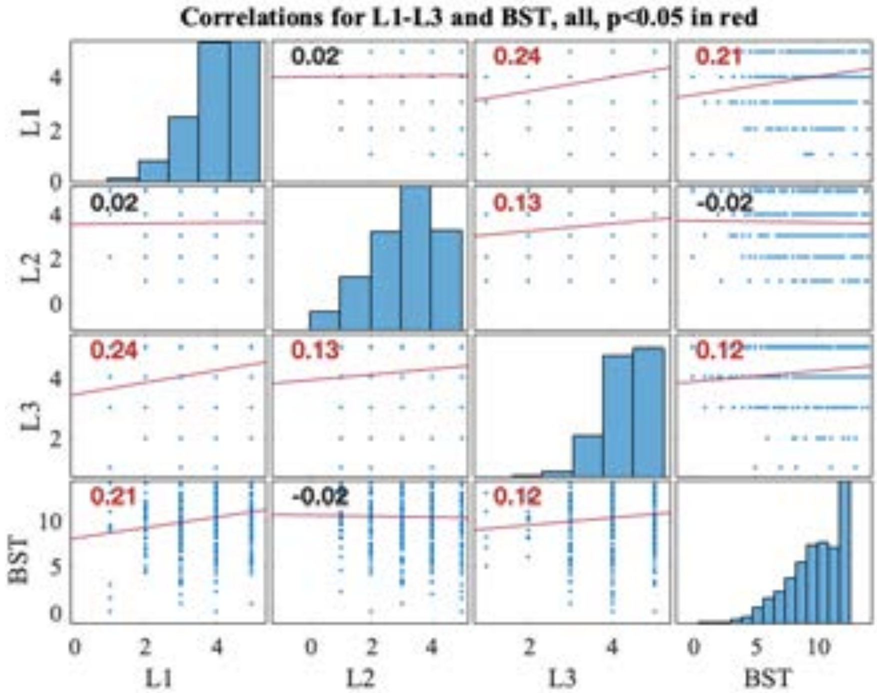

Fig. 3. Correlations between the statements L1-L3 and BST result

4 Discussion

In this study, more differences were observed between the students in the international study programme and the Finnish study programmes than between the genders. We observed that international students performed better on average in BST, and they valued mathematics utility higher. In many countries, students are accustomed to completing more homework and covering the entire textbook compared to Finnish students. Additionally, they might enrol in entry-test centres before securing a study place at Finnish universities. Due to certain scholarship requirements, international students might also be more motivated to study and get good grades. These aspects may explain their better performance in BST.

The biggest differences between the international programme students and Finnish programme students were found in two trigonometry tasks and a differentiation task. According to previous experiences, trigonometry is challenging for Finnish students (Myllykoski et al. 2018). Also, according to research, trigonometry is one area of mathematics that students find difficult and abstract compared to other mathematics subjects (Gur 2009). Previous research has also shown that first-year university students have challenges understanding angles in radians and using the unit circle

(Orhun 2010). The trigonometry tasks of BST are related to exactly these things. Perhaps the pre-university teaching approach (Ngu 2023) differs between the international programme students and Finnish programme students, which could explain the difference in trigonometry tasks.

BST did not show differences in mathematical skills between women and men. This was somewhat expected, because even though boys are overrepresented among the top performers in mathematics prior to university (Metsämuuronen 2017, Vipunen n.d.), the self-selection of girls to study engineering is much stronger than for boys, which is likely to make women a more homogeneous group in terms of mathematical abilities and even up the difference in performance level.

When it comes to pre-university experiences in mathematics, women reported having to study hard more often than men. By the end of upper secondary school, girls tend to harbour more negative feelings towards mathematics on all performance levels than the boys (Metsämuuronen 2017), and the experience of a heavy workload could contribute to more study stress associated with mathematics to women than men.

In general, the students' perceptions of having had to study hard in mathematics did not correlate with BST results. This might be due to students having varying interpretations of the respective statement. Some students find mathematics interesting and motivating, they aim high, and are prepared to work hard to learn. Some might struggle with mathematics and face difficulty in learning, and therefore feel that they have to work hard. Hence, in order to really understand the significance of working hard for mathematics performance, more detailed information is needed.

It should be noted that this study had certain limitations. One clear limitation of this study is the use of a non-supervised test, which may result in participants utilizing materials, calculators, software, or group work even though they were instructed not to do so. In the future, we aim to get back to pre-COVID-19 arrangements, where the test is taken under supervision. Additionally, two BST tasks had to be removed from analysis due to technical and/or language problems. Another limitation is the slightly different study programme profiles, as all Finnish programmes were grouped together, as well as all international programmes, potentially introducing variability in the results.

All in all, the student population has become significantly more international in recent years, and there are observable differences in skills and perspectives between students from different cultural backgrounds even more than between genders. Therefore, it is essential to know the students' skills in the beginning of engineering studies to be able to best facilitate learning. A test such as BST performed yearly can provide up-to-date information in the changing environment and thus assist teachers in planning learning materials and tutoring according to students' levels of knowledge in different areas of mathematics.

ABSTRACT

In order to achieve net-zero carbon emissions in the world by 2050, it is necessary to shape responsible and skilled individuals through Higher STEM Education. This paper focuses on assessing the perspective of STEM students regarding the incorporation of new curriculum activities and topics aligned with the evolving needs of today's society. Specifically, the study evaluates the inclusion of innovation, new technologies, and entrepreneurship in the curriculum, through a series of sessions, workshops, and discussions conducted in summer 2023. The paper highlights the significance of an innovative curriculum in STEM education and identifies the way essential skills and competencies of future engineers can be developed to face today's constantly changing world. This paper proposes applicable actions for institutions and associations involved in European Higher Education. By emphasising the importance of an adaptive curriculum, this research contributes to the ongoing dialogue on shaping STEM education to align with the demands of the

[1]Ljiljana Kherawi
ljiljana.kheirawi@best-eu.org

future, therefore fostering the development of individuals equipped to address the challenges posed by the rapidly evolving global landscape.

1 INTRODUCTION

1.1 General overview

This paper represents the perspectives of STEM students regarding the inclusion of a new and innovative study curriculum in STEM education. It is essential that engineers understand the challenges of the future of this planet and society, and realise the impact their solutions have (Bronstein and Lampe 2023). The challenges that engineers are expected to tackle in the future (Zhang and Morris 2020), can only be solved if the skills and knowledge related to them are integrated into Higher Education Institutions (HEI) policies and strategies (Hobusch and Froehlich 2021). Several technological sectors are increasingly in need of graduates who are aware, creative, able to keep up with constant innovation, and who do not hesitate to delve into challenges. In order to bridge the gap between science and engineering education and the skills needed for industries and communities of the 21st century, there has been a growing need from industry bodies to educate STEM students not just in innovation and new technologies, but also in entrepreneurship (Amalua and Shorta 2023, Lynch and Kamovich 2021, Hermann and Bossle 2020). Interestingly enough, the current integration of entrepreneurship, innovation, and new technologies in formal engineering education appears to be far from accomplished, although various studies agree on the importance of doing so (Bronstein and Lampe 2023, Marjoram 2015, Kaminsky 2017, Höller and Vorbach 2017). Hence, through an exploratory project, this paper aims to address the following research question: How should STEM studies be shaped according to the STEM students in order to provide them with the necessary tools to act responsibly?

1.2 Objectives of the research

<u>Objective 1:</u> Identify which skills are perceived as more crucial in the educational path of STEM students, by delving into the students' and young graduates' experiences within their educational path.

<u>Objective 2:</u> Define which parts of the mentioned topics should be most integrated into the curriculum.

<u>Objective 3:</u> Determine the activities through which the following topics can be integrated into the curriculum and ways in which they can influence students to achieve the necessary skills for the future.

2 METHODOLOGY

Data from November 2022 to August 2023 were analysed in two phases: primary research at the BEST Symposium on Education (BSE) and a secondary literature review. The BSE gathered opinions on STEM education from students at 16 universities across 10 European countries, with a focus on entrepreneurship, innovation, and technologies for sustainable development. This was complemented by a survey of 226 students from 63 universities, which examined the inclusion of sustainability in current studies, critical skills for the future to address global challenges, and activities to develop those skills. The survey data helped understand the usefulness of certain activities, the timing of student experiences with them during their studies, and the overall student engagement, ascertained through multiple-choice questions in a matrix format. Secondary research involved reviewing existing literature on the inclusion of innovation, new technologies, and entrepreneurship in STEM education curricula, as well as analysing data obtained from the primary research. Analysis methods included statistical quantification, pattern identification, idea generation, theoretical testing, and comparative evaluation. The Net Usefulness Score (NUS) and time variance were calculated to assess the impact of activities and the timing of student engagement.

$$NUS = \frac{(Number\ of\ students\ grading\ the\ activity\ with\ 4\ or\ 5) - (Number\ of\ students\ grading\ the\ activity\ with\ 1, 2\ or\ 3)}{Total\ number\ of\ people}$$

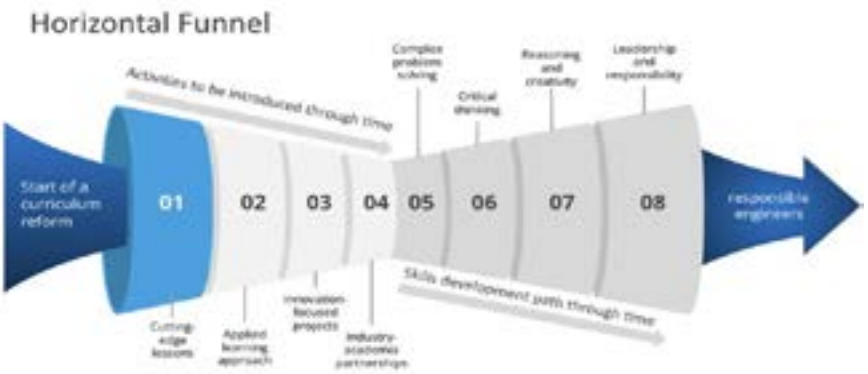
For assessing time variance, a normalised formula was applied by assigning numerical values to for each phase point of the studies (0 for Early studies, 1 for Middle of studies and 2 for End of studies). The number of students for each period was multiplied with the given value, and the resulting products were summed. The final sum was then divided by the total number of students who participated in the activity, with the result expressed as a percentage.

3 RESULTS

3.1. Skills development towards responsible engineering

3.1.1. Results

This section outlines proposed curriculum changes to foster responsible engineering. Key recommendations include integrating state-of-the-art technology lessons and practical work, with over 50% of respondents favouring hands-on experience over theoretical learning. Industry-academia partnerships and entrepreneurship skills are also highlighted as vital for adapting to rapid technological advancements. Figure 1 illustrates the proposed activities and their sequential introduction, alongside their role in enhancing soft skills like problem-solving, creativity, and leadership, ultimately shaping responsible engineers. Entrepreneurship skills are considered irreplaceable in the curriculum of engineering students to allow engineers to adapt to increasingly fast-changing scenarios and technologies (European Commission, 2018).



.

Figure 1. Horizontal funnel showing activities to be introduced in the curriculum (on the left, the order of activities is narrowing down towards right proportionally to introduction timing) and their impact on soft skills for responsible engineers (on the right, the order of activities is expanding towards right proportionally to development timing).

Through these activities, students recognise that first they would have the opportunity to develop complex problem solving skills. All students agreed that experiential learning will help them perceive the larger picture of the current sustainability challenges that the world is facing today, which in turn will have a positive influence on their creativity and promote critical ways of reasoning. Leadership and responsibility would be developed over time, resulting in responsible engineers post graduation.

3.1.2. Recommendations

To prepare engineers for the future, educational institutions must update curricula to reflect industry needs and societal expectations. This involves enriching programs with case studies, entrepreneurship courses, internships, and projects focused on innovation. Strengthening ties with industry is crucial for exposing students to real-world challenges and integrating innovation, entrepreneurship, and emerging teaching methods through collaboration. Incorporating state-of-the-art technologies and addressing global challenges within the curriculum are essential steps in shaping responsible engineers equipped for the 21st century.

3.2 Learning activities for enhancing skills of responsible engineer

3.2.1. Results

Five student focus groups evaluated activities for fostering sustainable development and responsible engineering education. Figure 2 illustrates these activities and their preferred implementation scales: individual, class-specific, cross-functional, and cross-organisational. The consensus was that sustainability, innovation, and problem-solving courses are most beneficial, suitable for various implementation levels. Activities like podcasts and industry partnerships were favoured for enhancing practical skills and soft skills development. The significance of leadership, communication, and creativity in achieving an entrepreneurial mindset is supported by Škare and Tejero (2022). Workshops, lectures, and internships with diverse stakeholders were also recommended for practical learning experiences.

Figure 2. Heat map showing correlation between specific activities to be introduced in the curriculum and frequency how often they were mentioned among the focus groups, categories by the scale of the implementation (from I - Individual approach to IV - cross-organisational approach).

3.2.2. Recommendations

To advance engineering education, students recommend a curriculum that emphasises practical application through hands-on projects and entrepreneurial activities. Collaboration across different majors should be encouraged to foster a diverse skill set, while soft skills development must be integrated via workshops and conferences. Additionally, innovative assessment methods need to be adopted to accurately track students' progress and ensure they are equipped for the challenges of responsible engineering.

3.3 Learning activities aimed at enhancing creativity and innovation

3.3.1. Results

Survey results, as illustrated in Figure 3, analyse student perspectives on the relevance and timing of activities that promote creativity and innovation within the curriculum. The Net Usefulness Score (NUS) ranges from -100% to +100%, reflecting when activities are experienced during studies: early (-100%), middle (0%), or late (+100%). The bubble size indicates the number of students who participated in each activity. Most activities are encountered mid-studies, with "Community or volunteer hands-on projects" and "Competitions, hackathons, innovation and entrepreneurship programs/challenges" often introduced earlier. Projects with real-life applications received the highest NUS of 67%, experienced by over 50% of students, mainly towards the end of their education (time variance of 27%). Community projects, engaged in early by more than 60% of students, also scored a high NUS of 56%. In contrast, "Simulation and future building scenarios" and "Projects linked to the UN SDGs" are highly valued (NUS of 39% and 52%, respectively) but less accessible, with fewer than half of the students having the opportunity to engage with them, typically in the latter half of their studies. Notably, activities with negative NUS, specifically "Experience working with digital twins" and "Project experience in the metaverse," had the least engagement and were introduced late in the curriculum, indicating a need for earlier exposure to these emerging technologies.

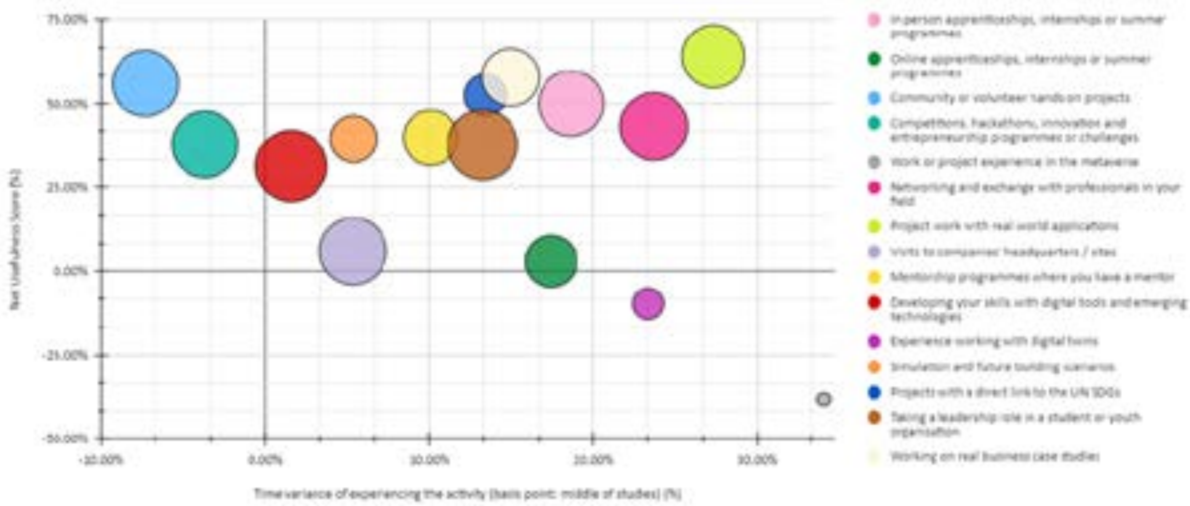


Figure 3. Bubble chart representing Student Activity Impact: Time variance vs. Net usefulness score vs. Student Engagement of specific activities

3.3.2. Recommendations

It is evident that the most useful and impactful opportunities for students are available to them only later in the studies. We suggest following the industry trends and making sure that the curriculum is up to date with all of the innovation and new skills that will be desirable for new engineers to have. Implementing “Simulation and future building scenarios” and “Projects with direct link to the UN SDGs” early in the engineering studies, would be the most impactful educational activity to be introduced in the curriculum of STEM students because they have a really high usefulness score compared to the number of students who had a chance to experience them (the smallest bubble). The second most impactful improvement would be reached by developing a system that allows any student to participate in those kinds of activities since not many students had a chance to experience them during their studies. Another important course of action is to implement additional courses on Project work with real world applications. In person apprenticeships, internships or summer programmes and Networking and exchange with professionals in your field both have a very high usefulness score, but face the barrier of having late time experience, thus earning a place in education only in very specific use cases and not as activities carried out across the board. We appeal to the inclusion of the mentioned activities earlier during stem studies.

4 EVOLUTION OF STUDENTS OPINIONS OVER THE YEARS

The paper submitted by BEST for the SEFI 2018 conference, titled "A Student's Perspective on Entrepreneurship and Innovation in European STEM Education," underscored the importance of entrepreneurial skills in engineering education. The paper analysed data from previous BEST Symposia on Education over the 13 years preceding the conference submission and related to four Events on Education (EoEs) (Porto 2017, Ankara 2015, Ljubljana 2010, and Zagreb 2009) organised by BEST, whose topics are directly or indirectly related to innovation and entrepreneurship. It advocated for competencies that enable students to be proactive and confident. The paper recommended practical, hands-on entrepreneurship education, facilitated through EoEs, to capture student opinions. It also highlighted students' desire for more practical projects and stronger university support for entrepreneurship, alongside a call for enhanced academia-industry collaboration to ensure curricula reflect real-world challenges.

In our current research paper, students advocate for a curriculum that embraces new technologies to keep pace with rapid technological advancements. The paper emphasises the importance of practical and experiential learning, urging educators to provide students with real-world examples and opportunities to tackle sustainability challenges directly. It stresses the need for skills like problem-solving, critical thinking, and active learning, while maintaining that entrepreneurship is essential for navigating fast-evolving scenarios. Additionally, it calls for the early introduction of topics such as sustainability, innovation, and problem-solving in educational programs to better prepare students for their future responsibilities. The evolution of student opinions from 2005 to the present shows a significant shift from a focus on entrepreneurship to a broader inclusion of innovation and new technologies, reflecting an expanded vision for STEM education. The latest paper emphasises the critical role of technology, advocating for its integration early in the curriculum to meet the changing demands of the job market and societal needs. While both papers underscore the importance of practical application, the current paper places substantial emphasis on sustainability, aligning with the global movement towards responsible engineering practices. In summary, over the years, students have maintained the importance of entrepreneurship but have expanded their focus to include innovation and new technologies. There is a clear trend towards integrating these topics earlier in the curriculum and aligning them with real-world challenges, particularly those related to sustainability. The evolution reflects a maturing perspective that recognises the multifaceted role of engineers in society.

5 SUMMARY AND ACKNOWLEDGEMENTS

To ensure constant adaptation and innovation in the curriculum of HEI in Europe, it is necessary to follow and understand the needs of today's students. This research pinpoints direction of those changes, placing the largest emphasis on the following:

1. Universities should focus more on practical and project work for students, throughout their whole studies;
2. Universities should strengthen the relationships with industry and other partners, in order to provide opportunities to students to learn on real-world problems;
3. Universities should expand existing curriculum with new teaching activities, such as soft skills training and workshops organised together with industry and other institutions. The topic of sustainability and entrepreneurship should also be included in formal course modules.
4. These activities have a high usefulness score but a small number of students had a chance to experience them during their studies. Therefore, HEI and other stakeholders (including industry) should focus on introducing them earlier in engineering curricula:
    - Simulation and future building scenarios;
    - Projects with direct links to UN SDGs;
    - Working on real business case studies.
5. Meanwhile we recommend to also keep the activities that already have a high usefulness score and a high participation such as:
    - Community and volunteer hands on projects
    - Project work with real world applications
    - In person apprenticeships, internships or summer programmes

To achieve future sustainability goals, we must educate engineers today. Effective education requires curriculum reforms, with investment from all stakeholders, to equip engineers with the necessary knowledge and skills to address forthcoming challenges. This paper invited professors and Universities to be the catalyst of this change.

ABSTRACT

This research explores the role of reflection-informed learning and instruction on students' learning in an introductory physics course. Participants of this quasi-experimental study were 199 engineering and science students (n=105 in the control group and n=94 in the intervention group). Students in the intervention group were instructed to reflect on their learning experiences after each lecture using the CourseMIRROR mobile application, while students in the control group did not. To answer our first research question (i.e., Did the students in the intervention group perform better than ones in the control condition?), we conducted Kruskal-Wallis tests, and results showed that the intervention group showed significantly better academic performance than the control group. To answer our second research question (i.e., Are the quantity and the quality of student reflection a significant predictor of academic performance?), multiple linear regressions were conducted, We found that the number of reflections was a significant factor in predicting a learner's academic performance, while specificity of reflections was not. Our study extends the existing literature on the impact of prompting student reflection in learning to a relatively underexplored context of large-size, lecture-oriented classrooms. Also, our study found that intervention in the form of encouraging students to reflect more often on their learning experiences can lead to improved academic performance. By evaluating reflection quantity and quality, our research contributes new insights into how these aspects influence academic performance. Lastly, our study adds to previous findings on utilizing mobile applications to support reflection activities in large classrooms by investigating their application in a traditional, lecture-based physics course.

1 INTRODUCTION

Reflection is a generic term for "human activities in which people recapture their experience, think about it, mull it over, and evaluate it" (Boud, Keogh, and Walker 1985, 19). Reflection can be classified into reflection-in-action and reflection-on-action (Schon 1983). Reflection-in-action is metacognitively reflecting on one's learning or behavior during learning, while reflection-on-action happens after learning or learning activities are completed (Schon 1983). In the context of undergraduate education, many science and engineering courses are taught in lecture-based format, especially in introductory courses where hundreds of students enroll (Owens et al. 2017). Reflection-in-action tends to be difficult to implement in this course as it may require significant changes in existing instructional methods. Reflection-on-action can be implemented individually outside the classroom after taking a lecture, so they seem easier to implement than reflection-in-action. Still, just with traditional instruction tools, promoting reflection-on-action in a large classroom can be challenging due to the logistics involved in collecting a large number of student reflections and assessing the relevance and quality of each reflection in a timely manner. By using digital technology accessible to individual students and instructors, such as a mobile application, individual reflection activities can be incorporated into a course more easily.

Reflection-informed learning and instruction (RILI) is a pedagogical model that encourages students to reflect on their learning in courses using technology and uses their reflection-on-action data to improve instructional strategies (Menekse 2020). The RILI model can be useful in undergraduate education from two perspectives: students and educators. Firstly, undergraduate students are given more autonomy in their learning, but such autonomy can lead to a lack of self-regulation of learning. Prompting students to reflect on their learning regularly can foster self-regulated learning (Zimmerman and Kitsantas 2005), thus preventing such situations. For example, students can review class materials that are particularly confusing or search for additional information regarding interesting concepts. Secondly, educators can leverage students' reflections as diagnostic tools to assess their understanding of new concepts and identify areas requiring further explanation (Menekse 2020). This facilitates the adaptation of instructional strategies and the modification of teaching materials to address students' needs or areas of interest. For example, after reviewing student reflection data, instructors may choose to post external online resources on a learning management system aimed at clarifying concepts that students found confusing. The advantages of the RILI model are particularly notable within the realm of engineering college education. This is attributed to the prevalent challenge faced in many college-level engineering courses, where instruction occurs within large class sizes, making it hard for instructors to monitor individual students' learning progress. Several previous works in engineering education employed the RILI model in various contexts. They investigated its impacts on problem-solving processes in a physics course (De Laet, Sijmkens, and De Cock 2021), improvement in the quality of reflection in an interdisciplinary engineering program (Wilhelm 2021), engineering teachers' instructional strategies (Eshuis, Mittendorff, and Daggenvoorde-Baarslag 2023), and academic performance in an industrial engineering course (Menekse 2020).

2 RELATED WORKS & RESEARCH QUESTIONS

The impact of reflection after learning on academic performance has been extensively studied, with research consistently highlighting its positive effects on students' academic performance. For example, a meta-analysis of 45 selected studies (Guo 2022) showed that the positive effect of metacognitive prompts on learning outcomes was consistent across undergraduate and K-12 students. Such studies were all experimental or quasi-experimental research but were limited to computer-based learning environments, excluding using digital tools in traditional classroom environments. Metacognitive prompts in this meta-analysis study include pre-learning (task perception, planning), during-learning (monitoring, control), and post-learning (evaluation, reflection). For example, Kauffman et al. (2008) showed that reflection prompts (i.e., questions designed to encourage students to reflect on how well they have solved problems and to evaluate and revise solutions when necessary) positively impacted problem-solving efficiency and writing quality. Another study by Wong et al. (2021) explored the impact of self-regulated learning (SRL) prompts, including reflection prompts, on students' engagement in SRL behavior and learning outcomes in Massive Open Online Courses. Results showed no significant impact on learning outcomes but a positive impact on SRL engagement.

Meanwhile, Menekse et al. (2022) compared the impact of generic and specific reflection prompts on engineering students' academic achievement in a course. Results showed that students who received the specific prompts performed significantly better on exams and projects than those who received the generic prompts. While numerous studies have explored the use of reflective prompts and digital tools in various educational settings, applying such methodologies to physics courses remains relatively novel. Regarding the impact of the number and quality of reflections, few studies have systematically tested these factors using robust models and indicators. Previous research (e.g., Menekse et al. (2022)) has examined the quality of reflections in general engineering contexts, but few studies applied multiple linear regression models to evaluate the predictive power of reflection quantity and quality, specifically in physics courses.

In higher education settings, technology-supported reflection on learning has gained significant attention as a means to enhance educational experiences. Various digital tools and platforms have been developed to facilitate reflection processes, enabling students to engage in metacognitive activities that deepen their understanding of course material and foster critical thinking skills. For instance, one design-based research by Leinonen et al. (2016) suggested two mobile apps for reflection (i.e., ReFlex and TeamUp). It showed their positive impacts on fostering K-12 students' classroom learning through reflective practices. They used the framework suggested by Fleck and Fitzpatrick (2010) to include various levels of reflection, from descriptive reflection (i.e., a mere description of events without further elaboration) to critical reflection (i.e., reflections with consideration of social/ethical issues). Another study by Knoth et al. (2020) explored how a mobile app named Reflect.UP promotes reflection at irregular intervals and its impact on students' learning experiences. This app was designed particularly to support student engagement during the introductory phase of a course by pushing reflective questions that refer to organizational knowledge (e.g., Where do I get a library card?), academic knowledge (e.g., How do I read a table?) and skills knowledge (e.g., Can I do what is required of me, and does what is required fulfill my expectations?). The empirical results showed what skills students wanted to improve eventually and how they were satisfied with the app usage. Still, the use of mobile applications to support reflection in traditional classroom environments, particularly in physics courses, is underexplored. Our study is among the first to investigate the impact of reflection prompts delivered via a mobile app in an introductory physics course.

This research aims to explore the role of reflection-informed learning and instruction in students' academic performance in an introductory physics course. We narrowly define student reflection as reflections on interesting and confusing concepts that students learned in each lecture. We set our first research question as follows: RQ1) Did the students in the intervention group perform better than ones in the control condition? The intervention for promoting reflection is using a mobile application that prompts students to leave reflections after each lecture. Also, to further explore why promoting reflection can be helpful for academic performance, we set our second research question as follows: RQ2) Are the quantity and the quality of student reflection a significant predictor of academic performance? The two research questions are answered by employing a quasi-experimental research method where we collected and analyzed student reflection data from an actual physics course.

3 METHOD

3.1 Participant

Participants of this study were 199 engineering and science students at a public university in the Northeastern region of the United States. They were enrolled in the introductory physics course for science and engineering. The Institutional Review Board (IRB) approved the recruitment of participants. Only students who consented to have their grade information were included in the data analysis. There were two sections of the same class. Students in one section were assigned as the control group (n = 105) as they were not asked to reflect on their learning. In contrast, the students in the other section were assigned as the intervention group (n = 94) as they were asked to reflect on their learning after each lecture during an academic semester. The same instructor taught both sections using the same learning materials and assessment items (e.g., homework, exams, etc.)

3.2 CourseMIRROR App

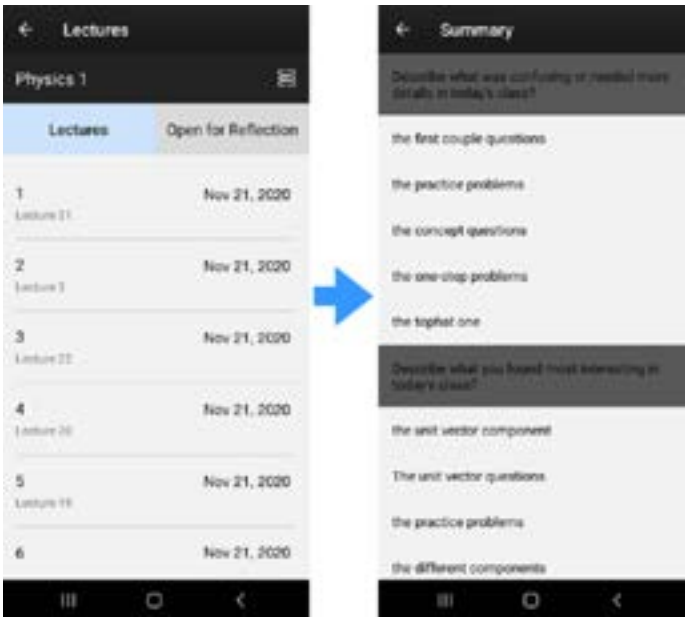

Figure 1. An example screenshot of the CourseMIRROR app.

CourseMIRROR (Mobile In-situ Reflections and Review with Optimized Rubrics) is a mobile application developed to prompt and collect students' self-reflection and in-situ feedback (Fan et al. 2015). This app collects data from student reflections to help instructors identify students' difficulties and provide additional feedback and support for student learning throughout the semester. Figure 1 shows an example of the app's user interface. On the left of this figure, students could choose one of the lectures of a course they are taking. After selecting one lecture, they were asked to answer two reflection questions, namely, 'Describe what was confusing or needed more details in today's class?' and 'Describe what you found most interesting in today's class?' Students were given a specified timeframe to submit their reflections on each lecture. Students and instructors could see the summarized list of responses for both questions, as seen on the right of Figure 1. Data collection through the app started after IRB approved the study. Students were encouraged to use the app, but it was not mandatory. Reflection data collected via this app was tracked only by the researchers, and we used anonymized IDs for each student who agreed to participate in the study. The instructor had access only to the summary of reflections that is automatically generated from the reflections.

3.3 Data Collection and Analysis

To answer RQ1, we compared the academic performances of the control and the experimental groups. The assumption tests (i.e., Shapiro test and Levene's test) revealed that both the normal distribution and the Homogeneity of variance assumptions were violated. Thus, we used the Kruskal-Wallis Rank-Sum test. The dependent variables were set as four measures of academic performance: the average of quiz scores, the average of homework scores, the average of exam scores, and the final score. The final score was calculated as a weighted average of the other variables based on the instructor's decision. The effect size and magnitude for each test were measured using eta-squared based on the H-statistic (Cohen 2013).To answer RQ2, we set predictors of academic performances as the number and the quality of student reflections. To calculate such predictors, we collected student reflection data from the CourseMIRROR server. The number of reflections for each student was calculated as the average of the total reflections written in the entire semester. The quality of the reflections was measured through two variables: the specificity score of reflections on interesting concepts and confusing concepts. The calculation of the specificity score was based on the coding schema developed by the authors' previous works (Butt 2023, Menekse 2020), where NLP (Natural Language Processing) algorithm was used to rate reflection specificity on a 4-point scale from 1 to 4. Scores 1, 2, 3, and 4 indicated shallow reflection without a statement of confusion or interest, vague reflection, general reflection, and specific reflection, respectively.

For both groups, only students who agreed to share their academic performance were included in the data analysis. The reflection data was collected from students in the intervention group who agreed to participate in this study. Nine students did not leave reflections, so we imputed their reflection count and specificity scores using a missing data imputation method called MICE (Multiple Imputation by Chained Equations) following the recommendation by Peugh and Craig (2004) and Cheema (2014).

4 RESULTS AND DISCUSSION

4.1 RQ1

Table 1. Kruskal-Wallis Rank-Sum test results to answer RQ1

DV	Condition	Mean	SD	χ^2	p-value	Effect size	Magnitude
Quizzes	Control	87.95	11.10	16.77	< 0.001***	0.08	Moderate
	Intervention	92.98	3.94				
Home-work	Control	92.81	13.36	6.45	< 0.05*	0.03	Small
	Intervention	95.22	10.63				
Exams	Control	62.67	20.69	57.89	< 0.001***	0.29	Large
	Intervention	83.11	8.79				
Final Score	Control	77.81	13.43	33.29	< 0.001***	0.16	Large
	Intervention	87.28	6.14				

**p*<0.05, ****p*<0.001

Table 1 shows the Kruskal-Wallis test results to compare the academic performances between the control group (n = 105) and the intervention group (n = 94). Reflections were collected from 27 lectures for the intervention group. The average set of reflections was 7.43 (SD = 5.80). As one set of reflections means two written reflections, one on confusing and the other one on interesting concepts, respectively, the average total number of reflections is 14.86 written by 94 students. The intervention group showed significantly better academic performance for all four dependent variables than the control group, with the significance level being 0.05.

These results align with the literature reviewed in Section 2 that proved the positive impacts of reflection intervention on academic achievement. Our results provide experimental evidence on the impacts of mobile-assisted learning, specifically within the relatively underexplored context of traditional STEM lecture-based courses, with even fewer focusing on physics education. Also, our results show that such impacts are effective not only in exam scores but also in ongoing academic performances, such as quiz and homework scores, despite the variation in the effect size.

In addition, the magnitude of effect size was large, particularly in exams, showing that reflecting on interesting and confusing concepts after each lecture positively impacted exam scores more than homework and quiz scores. Since homework and quizzes were conducted more frequently than mid-term and final exams, the positive impact of prompting student reflections might accumulate as students repetitively reflect, eventually becoming evident in exam scores. Future research may explore different measures of learning experiences other than academic performance.

4.2 RQ2

Table 2. Multiple linear regression results to answer RQ2

(a) Regression Statistics

$Multiple\ R^2$	0.06
$Adjusted\ R^2$	0.02
SE	6.07
F	1.75
$p\ value$	0.16

*(b) ANOVA statistics (*p<0.05)*

	df	SS	MS	F	$p\ value$
Number of reflections	1	180.6	180.65	4.91	0.03*
Specificity of reflections on interesting concepts	1	5.8	5.85	0.16	0.69
Specificity of reflections on confusing concepts	1	6.9	6.88	0.19	0.67
Residual	90	3314.6	36.83		

*(c) Coefficient of each predictor (*p<0.05, ***p<0.001)*

Predictors	Coefficient	SE	Standardized coefficient	SE	t	$p\ value$
Number of reflections	0.25	0.11	1.46	0.64	2.28	0.02*
Specificity of reflections on interesting concepts	-0.35	1.33	-0.17	0.66	-0.27	0.79
Specificity of reflections on confusing concepts	-0.45	1.04	-0.29	0.66	-0.43	0.67
(Intercept)	88.24	5.13	87.28	0.63	17.19	0.00***

Table 2 shows the result of multiple linear regression to explore which aspects of student reflections are significant predictors of academic performance. The estimated regression equation to predict one student's total score for the semester is as follows: (Total score) = 88.24 + 0.25 (Number of reflections) - 0.35 (Specificity of reflections on interesting concepts) - 0.45 (Specificity of reflections on confusing concepts). It turns out that the number of reflections was a meaningful variable to predict a learner's academic performance (F(1,180.6) = 4.91, p = 0.03*), despite the R^2 values being small. In contrast, the specificity of reflections was not. Such results were consistent for the other three dependent variables, i.e., quiz, homework, and exam scores.

Our analysis found that the more often students engaged in reflection after lectures, the more likely their academic performance would be high. This could indicate that even though students did not necessarily write high-quality reflections, the fact that they had time to reflect on their learning was sufficient for better academic performance. However, our result does not necessarily mean that the quality of reflections is less important than the number of reflections. Further research might investigate whether the specificity of reflections or another measure of the quality of reflections significantly impacts academic performances or may impact other parts of learning experiences.

5 SUMMARY

This quasi-experimental research explored the role of reflection-informed learning and instruction in students' academic performance in an introductory physics course. Regarding RQ1, results proved the positive impact of prompting reflections on all the measures of academic performance. Regarding RQ2, we conducted multiple linear regressions to examine whether the number and quality of student reflections are significant predictors of academic performance. It turns out that only the number of student reflections was a meaningful predictor. Despite our important findings, our study has a few limitations. First, as we decided to focus on academic performance only, we might have missed the positive impact of prompting student reflections on other aspects of learning experiences, such as motivation and engagement. Second, since we do not have any classroom observation data, there could be some factors that could have influenced students' reflection behaviors across two different sections. Third, as using the CourseMIRROR app was not mandatory, the average number of reflections was not high compared to the number of lectures.

Nevertheless, our study has a three-fold contribution to the engineering education community. First, our study extends the existing literature on the positive impact of prompting student reflection in learning to a relatively underexplored context of large-size, lecture-oriented classrooms commonly found in introductory engineering courses. Also, our study found that intervention in the form of encouraging students to reflect more often on their learning experiences can lead to improved academic performance. By evaluating both the quantity and quality of reflections, our research contributes new insights into how these aspects influence academic performance. Lastly, our study adds to previous findings on how a mobile application can be used to support reflection-on-action activities in a large-enrolment STEM course. While several studies explored the use of apps for reflection in various educational settings, we uniquely investigated their application within a traditional, lecture-based physics course.

ABSTRACT

Teaching Science-Technology-Society (STS) courses to engineering students can be challenging. Several studies have shown that engineering students fail to see the relevance of social and humanist science in engineering education, despite the importance of STS subjects in later professional life.

In this study, we have asked 1515 first-year engineering students about what non-scientific and non-technical topics they believe are important for engineers to be knowledgeable about. These data are analyzed, and the results are used to suggest a way of teaching these subjects in line with students' perceived relevance.

1 INTRODUCTION

Current discussions in engineering education highlight the need for educating engineers who take a broad perspective on their role in society (CDIO 2020). This is not a completely new development: For example, the American Society for Engineering Education has promoted education in ethics, sustainable development, diversity, and inclusiveness in engineering education for over two decades (ASEE 1999). It can however be argued that the pace of technological change and increased awareness of the complexity of technological challenges have amplified this need.

Engaging engineering students in non-STEM (science, technology, engineering, and mathematics) topics can however be challenging (Bombaerts et al. 2018; Skinner, MacGill, and Outhred 2007; Thorvaldsen and Henne 2017; Fjelland 2022). Students (and faculty members) seem skeptical towards the relevance of ethics, philosophy, and politics in a technological context, topics which at least in Norway have been termed somewhat derogatory as ‘soft subjects’.

This paper seeks to answer the questions of what topics outside science and technology 1st year engineering students perceive as relevant for engineers, and how this motivation can be employed to create engineers prepared to engage in society.

2 THEORY

Gaining knowledge into the pre-existing motivations of engineering students toward non-technical topics, may help in constructing an engineering education that points towards expanding the scope and system perspective of engineering education, while also being perceived as relevant by the majority of students.

To understand engineering student’s motivation for subjects outside of STEM, we will employ the concepts of intrinsic and extrinsic motivation. These concepts make out the basis for self-determination theory (SDT) developed by Ryan and Deci (Ryan and Deci 2017).

The distinction between intrinsic and extrinsic motivation is important for understanding the basis of SDT. Externally motivated learning activities, perceived as controlled by others, are often driven by punishment or external rewards. Intrinsically motivated learning activities driven by the student's own will, are found to be interesting, enjoyable, and appealing. There is a positive relationship between intrinsic motivation and persistence, effort, and engagement. Hence, SDT predicts that students will engage in learning activities they consider meaningful for later endeavors and in line with their interests. Achievements and effort will increase as students move from extrinsic regulation to intrinsic motivation of the learning activity (Ryan and Connell 1989).

The courses and subjects that make out an engineering program are only occasionally a matter of students’ choice. Hence, it would not be appropriate to interpret intrinsic/extrinsic motivation exclusively as a question of student control or choice. For this paper, it is more fruitful to interpret intrinsic/extrinsic motivation as a matter of students’ perceptions of relevance. Courses, subjects, or activities that align well with students’ perceptions of relevance are interpreted as being associated with high intrinsic motivation, and vice versa with extrinsic motivation (Johansen, Eliassen, and Jeno 2023). As mentioned above, ethics, politics, and philosophy seem to induce skepticism among students and faculty, at least partly due to a perceived lack of relevance in its educational context (e.g.Fjelland 2022). In this perspective, how can we motivate engineering students to engage with these topics, when they often seem removed from the primary technical-scientific interests of the students? Different approaches have been made to introduce STS-topics into engineering, with various results (see e.g. Axelsson 2009).

3 METHOD

In this paper, 1515 1st year bachelor engineering students from NTNU in Norway have been asked the question "Apart from learning what you need from science and technology to go into working life - what do you think is the most important thing for an engineer to know something about?" The students were all orally informed about the purpose of the survey, and that their participation would be anonymous. No personal data were gathered from the respondents.

The survey was conducted on students from a full range of engineering study programs, the four largest being mechanical, computer, electrical, construction, and renewable energy during the years 2019-2022, with 333 respondents in 2019 and 469,384 and 329 in 2020-2022, respectively. The survey was conducted during the first few weeks of the first term, as part of a compulsory first-year course called "Introduction to the Engineering Profession". It was conducted in a mix of physical and online lectures in 2019, and online lectures in 2020-22. The data were collected through online student response systems, using the system One2act from 2019-2021 and Mentimeter in 2022, with students responding with open-ended text responses. The responses vary from a single word to a few short sentences, with the majority being short lists of 1-4 topics.

These results were then put through a thematic analysis (Braun and Clarke 2006). Given the relatively clear and brief responses, subsequent clearly defined themes, and a large number of total respondents, the frequency of the different themes was then compared, and this is used to attempt to identify what the best starting points may be in engaging engineering students in non-technical and non-scientific topics.

4 RESULTS

To structure the presentation, we group the themes into four groups. These groups disclose the direction of the different themes' focus.

Group 1 has a *world perspective* focusing on the external consequences of the use of technology, and consists of the following themes:

- *Society:* references to society, but also history, politics, and consequences for the world (from the use of technology). In general, it is STS-oriented.

- *Ethics:* References to ethics, morality, knowing right from wrong, etc. General comments on consequences where it is not specified consequences for what (society/nature) is also coded here.

- *Environment:* References to the environment, climate change, sustainability, etc.

Group 2: has an *interpersonal perspective* focused on human interaction consisting of the following themes:

- *Collaboration*: References to collaboration, cooperation, and teamwork, but also to having ‘people skills’.

- *Communications*: References to communication, writing, and language skills

Group 3 has a *workplace perspective* consisting of the following themes:

- *Work:* General references to work life, but also safety, ESE, and other rules and regulations

- *Practical*: References to practical skills, the necessity of engineers to know the practical work workers do, connecting practice to theory, but also problem-solving of different kinds

- *Economy/management*: References to economy, money, management, and leadership of different kinds, including project management.

Group 4 has an *individual perspective*, looking at individual epistemic/cognitive skills, and consists of the following themes:
- *Method:* References to methodology on a more principled level, but also skills that hint at method, like critical thinking, creativity, logic, and variants of learning to learn.

- *Personal:* Personal qualities that do not fit into the method theme like openness, future orientation, order, grit, and some social skills.

In Table 1, we have sorted the different themes and groups of themes, including the frequency of the different themes.

Table 1: Frequencies of groups, and N and frequencies for individual themes.

Group total frequency	Group 1, *world* Total f =.40			Group 2, *interpersonal* Total f =.33		Group 3, *workplace* Total f =.30			Group 4, *individual* Total f =.20	
Theme	Society	Ethics	Environment	Collaboration	Communication	Work	Practical	Economy/ Management	Method	Personal
N	332	320	101	432	128	150	205	138	151	171
Frequency	.22	.21	.067	.29	.084	.099	.14	.091	.10	.11

In addition to the themes in Table 1, 5.1% of students responded with a technical or scientific subject despite this falling outside the scope of the question, 4.1 % answered with some sort of joke, and 3.6 % with an answer that did not fit any of the mentioned themes, often on a very general level of “seeing the big picture” or “having good general knowledge”.

The groups and themes are, however, not without connections. Group 1's focus is on the world outside engineering, society, and nature, and has connections to Group 3 as the focus is the effect engineers have on the external world through their job. Group 2 has a focus on relations to other humans: colleagues, clients, etc. It also touches on Group 3 as most examples of interaction are in a work-life setting. Group 3 is however focused on the work-life in a less human- and society-oriented sense but touches on Group 2 on some issues on management, and Group 4 where some descriptions of problem-solving are akin to the method theme. Group 4 has an inward focus, on individual skills, but also touches on group 2 in some personal qualities that speak toward social interaction.

Table 2: Relative frequencies of the total amount of students that are in both groups (columns vs rows), e.g. 40% have responses in Group 1, 7,4% have responses in both Group 1 and 2. N in parenthesis.

	Group 1, *world*	Group 2, *interpersonal*	Group 3, *workplace*	Group 4, *individual*
Group 1, *world*	.40 (608)			
Group 2, *interpersonal*	.074 (113)	.33 (501)		
Group 3, *workplace*	.067 (101)	.076 (115)	.30 (451)	
Group 4, *individual*	.047 (71)	.059 (89)	.050 (76)	.20 (302)

This thematic connection is partially reflected in the statistical connections in Table 2, where we can see the frequencies of interconnection between two different groups in students' replies. However, we also see other connections, e.g., students who have a world perspective, a workplace perspective, and an individual perspective tend to have the interpersonal perspective as the most common other group, even though the world perspective is the most common overall. For the interpersonal group, the world and workplace perspectives are positioned similarly.

5 DISCUSSION

The students' preexisting views on necessary knowledge for an engineer have different focus areas or clusters of motivation. They focus on the consequences (of engineering) on the outside world (Group 1), interaction with other individuals or groups of individuals (Group 2), the work as an engineer (Group 3), and individual skills (Group 4).

What we have listed are topics that students see as important in their future role as engineers. Topics that are perceived as relevant will generate a more autonomous form of motivation (Johansen, Eliassen, and Jeno 2023). Hence if a topic is perceived as relevant it will be associated with a more intrinsic motivation (Ryan et al. 2021).

To engage as many students as possible in engineering education creating responsible engineers, we should create cases and present problems that dip into as many as possible of these perspectives.

For example, real-world problems (Group 1) that engineers need to handle through their job (Group 3), involve the need to collaborate and communicate with people of different backgrounds (Group 2) which requires a set of personal skills (Group 4).

It is not hard to see how current problems can fit into such a discourse.

Climate change is an obvious example. It is a real-world problem. There are an increasing number of engineering jobs connected to the issue e.g. in renewable energy, but also still many in fossil fuels. Few, if any, sectors engineers work in are uncoupled from climate issues. Solving the problem requires not only skills in engineering and the natural sciences, but also an understanding of i.e. political processes and global power relations, and thus intimate cooperation between people from different fields.

A world in which war and conflict disrupt traditional flows of energy distribution and transportation of goods creates complex challenges. Designing projects where resources, infrastructure, and logistics are considered vulnerable would motivate the necessity of non-technical considerations. It also necessitates collaboration between engineers in different fields of energy and logistics together with representatives from the social sciences. This connects the world, interpersonal, and work perspectives, with personal skills entering through the openness needed to engage with peers and ideas from multiple fields.

As these surveys were conducted during the students' first term, we can to some extent infer that the students' responses are based on pre-existing perceptions of what is considered relevant for an engineer. If we are to appeal to these motivations, it would be wise to engage with them from the start of the students' education and not postpone engaging with STS-oriented topics until later in the study programs.

Student responses categorized as "world perspective" make out the largest cluster. A system-thinking approach (Axelsson 2009) to non-technical issues would be a fruitful way of combining this with the "work" perspective in framing STS topics for engineering students.

As the collaborative theme is the most common individual theme, the need for collaborating with people with different professional backgrounds to solve complex problems could be a particularly fruitful starting point. To have a basic understanding of other professions and their relationship to engineering is paramount for such a collaboration, and a strong incentive to integrate societal knowledge in engineering. Based on the statistical connections between the groups, the interpersonal perspective (Group 2) also seems to be well-positioned to bring the other perspectives together. This is the perspective that correlates the strongest with all the other groups.

Our suggestion when teaching non-technical topics to engineering students is to frame these topics in exactly the kinds of discourses described above, making them relevant to engineering and in line with students' preexisting perceptions of relevance. This is also in line with ideas in modern engineering education, like the CDIO standard on Integrated Curriculum (CDIO 2020).

5.1 Limitations

This survey has been taken from engineering students at one university in one country on questions that are probably not culturally independent. Furthermore, in

2019, the data were collected both during physical lectures and online lectures, creating a less homogenous data collection that year. In addition, the survey was taken within a course where the students had just had ethics and were moving on to the history of technology. Although no data collection is context-independent, the students' recent connection to some topics may thus skew the results compared to other contexts.

6 CONCLUSION

Despite suggestions from previous research, that bachelor engineering students have limited motivation to learn non-technical/non-scientific topics, we find several clusters of self-reported perceptions of relevance, which again might motivate learning these topics.

These motivations are however mainly dependent on the students' perceived use of these skills, knowledge, and competencies in their future role as engineers. We therefore suggest building educational tools for STS- and similar topics around these existing clusters of motivation. Notably, connecting a combined interpersonal, world- and work-perspective in STS learning contexts.

ABSTRACT

Prototypes serve multiple purposes in design such as communication, learning and decision-making. In fact, designers often perform multiple cycles of prototyping, testing and design refinement. Yet, design and prototyping processes are often taught in separate courses in the engineering curriculum, as a result of which students may not learn how to leverage the power of prototypes in thinking, learning and refining the design. This may limit their experience of design and negatively impact their self-efficacy for design. In this paper, we report on a field quasi-

[1]*A Kothiyal*
aditi.kothiyal@iitgn.ac.in

experiment comparing an integrated design and prototyping course with a separate design and prototyping course sequence in terms of students' engineering design and innovation self-efficacy at the end of the course/sequence, and gender differences in self-efficacy. We found that participants in the integrated course showed higher self-efficacy for design, and also that there were differences in self-efficacy between the genders with males reporting higher self-efficacy than females. We conclude by discussing implications of these findings for the engineering curriculum and the way design is taught.

1 INTRODUCTION AND RELATED WORK

Recognizing that engineering students are creators of the future world, engineering accreditation bodies include the ability *to design, implement and test innovative solutions* in the core outcomes required from engineering education (ABET 2023; CTI 2023). Responding to this call, engineering design has become an important focus area for engineering education practitioners and researchers (Froyd et al, 2012; Dym et al, 2005). Prototyping plays a vital role in design, because creating and interacting with prototypes supports thinking, learning and communicating during design (Bohmer et al, 2017; Lauff, 2018; Camburn et al, 2017; Aurigemma et al, 2013). Having prototyping skills allows students to transform their ideas into tangible artefacts that they can use to test, refine and iterate the features, and explore the design space (Newman et al, 2015; Yu et al, 2018). Traditionally, engineering curricula focused on manufacturing practices for prototyping, but the rise of accessible prototyping tools like 3D printers has shifted the emphasis towards rapid prototyping from an early stage (Blikstein, 2013). Design thinking, on the other hand, is a general approach which makes humans a focal point of design, ie, understanding the problem and the people that one is designing solutions for (Dam and Siang, 2021), and identifying users' needs. This methodology encourages designers to think critically, creatively, and deeply, and has therefore become of interest in engineering education (Coleman et al, 2019; Spee and Basaiawmoit, 2016; Acebo et al, 2018), and incorporated into engineering design education to make engineers more innovative (for instance, Zancul et al, 2017; Parmar, 2014). Design thinking also includes a phase of prototyping, as making and testing prototypes helps spark ideas and build a better understanding of the user and problem (Dam and Siang, 2021).

In our institution, the shifting landscape of engineering education led to a rethink of the approach to design and prototyping education. First, the emphasis on manufacturing practices was decreased and that on rapid prototyping was increased, giving students the skill to make things right from their first year. Secondly, a design thinking course was added to help develop students' skill in human-centered design and innovation. However, having students learn prototyping in isolation can result in tinkering, which can be unproductive for developing robust design solutions (Quan & Gupta, 2020). On the other hand, having students make 3d printed prototypes supports their learning of design thinking (Pearson & Dube, 2022). To address this challenge, we revamped our curriculum to integrate design thinking and prototyping skills into a single course. This integrated project-based course required students to work in teams on real-world problems, applying a systematic approach combining design thinking with prototyping skills. In this paper, we report on a field study comparing this integrated course with the previous sequence of separate courses in terms of students' self-efficacy for engineering design and innovation at the end of the course. We also if there are gender differences in self-efficacy after participation in each of the courses.

2 THEORETICAL FRAMEWORK

Self-efficacy is the "belief in one's own competences to perform an intended behavior in spite of barriers" (Lippke, 2020), and is a key construct that affects motivation and behaviour in engineering education, influencing the course of action students pursue, their effort, persistence and resilience, thought patterns, emotional reactions to situations and accomplishments (Ponton et al, 2001). In this work, we adopt Albert Bandura's theory of self-efficacy (Bandura, 1977) according to which self-efficacy is influenced by four primary sources: mastery experiences, vicarious experiences, social persuasion, and physiological and affective states. Scholars argue that it is important to create mastery experiences for engineering skills in the curriculum, as that will enhance students' self-efficacy for these skills (Ponton et al, 2001). By regularly and repeatedly engaging in design thinking and prototyping activities through courses, students practice these skills, confront challenges, and ultimately experience success, and this mastery could be a source of self-efficacy. Through working in teams and exposure to role models (teaching assistants and instructors), participants may enhance their self-efficacy through vicarious experiences. Social persuasion, in the form of constructive feedback, encouragement, and recognition from the teaching team and peers, may also affect self-efficacy beliefs. Together the emphasis on mastery experiences, vicarious experiences and social persuasion may contribute to students' self-efficacy in engineering design and innovation. In addition, we conjecture that the integrated experience of design and prototyping will provide more mastery experiences, along with the emotional arousal stemming from the failure-first, iterative design and prototyping process, together leading to a greater improvement in students self-efficacy than in the sequence of separate courses.

Literature documents the differences between males and females in their self-efficacy for engineering knowledge and skills (Milto et al, 2002; Litzler, 2014; Chachra & Kilgore, 2009; Whitcomb et al, 2020). Research further reports that while females sometimes make positive progress on self-efficacy during their engineering studies (Marra et al, 2009), they can sometimes also exhibit a decline in their confidence relative to males (Felder et al, 1995), suggesting that curricular experiences can impact the self-efficacy of males and females differentially. Therefore, we also investigate if the two courses have a differential impact on males and females.

3 BACKGROUND AND CONTEXT

The study was conducted in the Spring 2023 semester in the Indian Institute of Technology Gandhinagar where students are admitted based on their ranks on a national engineering entrance examination. All students across engineering disciplines take common courses during the first two years. In the first year, students used to take a course on prototyping trades, whose goal was to make students proficient enough in a range of traditional and newer prototyping trades to make artefacts in their course projects later in the curriculum, and second year students took a course on design thinking. During the COVID-19 period of online learning, students could not take the prototyping trades course in their first year because it is an entirely practical course, and so the course was split in two to manage the course load and offered during their second year across two semesters, Fall 2022 and Spring 2023. They formulated a project the first semester, in which they had to add value to an existing product and prototyped it in the second semester. In the Winter 2022 semester between these two semesters, students took the design thinking course to balance their load, in which they learned the design thinking process, making and testing low-fidelity prototypes. Thus, even though they learned design thinking and prototyping trades, these students experienced design and prototyping as distinct thinking and doing processes across one year (course DIS, Figure 1). With the importance of design thinking for innovation growing and change in industry prototyping practices, course planners decided to lower the emphasis on prototyping trades, and add practice in iterative design thinking and prototyping to develop innovative products.

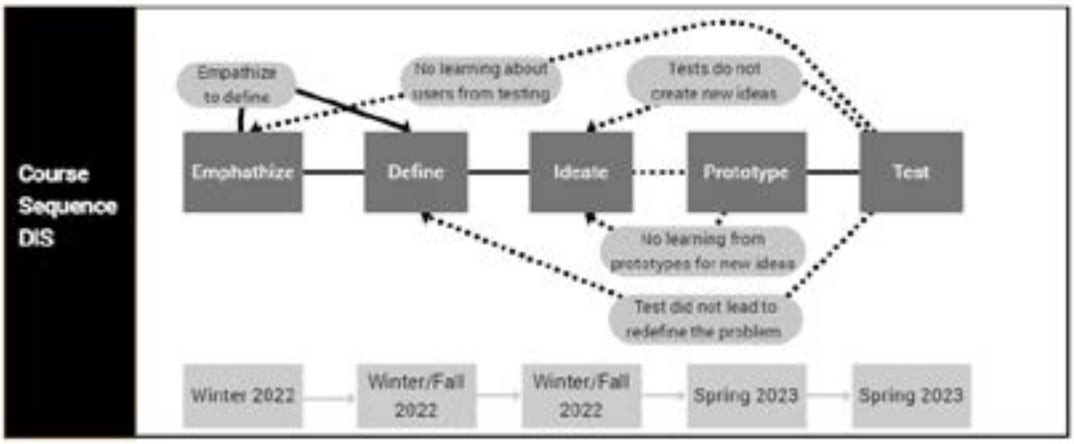

Fig. 1. Course structures of course sequence DIS

This revised emphasis manifested in a new design and prototyping course in Spring 2023 (course INT, Figure 2) for first-year students, wherein students apply the iterative design thinking process shown in Figure 2 to develop a product that solves a problem of their choice. The course includes lectures and activities on design thinking, and simultaneous practical training on a reduced set of prototyping trades. The students work on the project in teams from the start, gradually building up to prototyping, testing and revising once they acquire prototyping skills. They learn how to identify problems from the perspective of multiple stakeholders, and think creatively about the purpose of a product, materials and creating value, signalling a cultural shift towards design thinking, innovation and rapid prototyping practices. Design thinking was taught by the same instructor in both DIS and INT courses, while the prototyping trades were taught by different instructors. The revision, planning and implementation of both courses was done by prototyping instructor for the INT course.

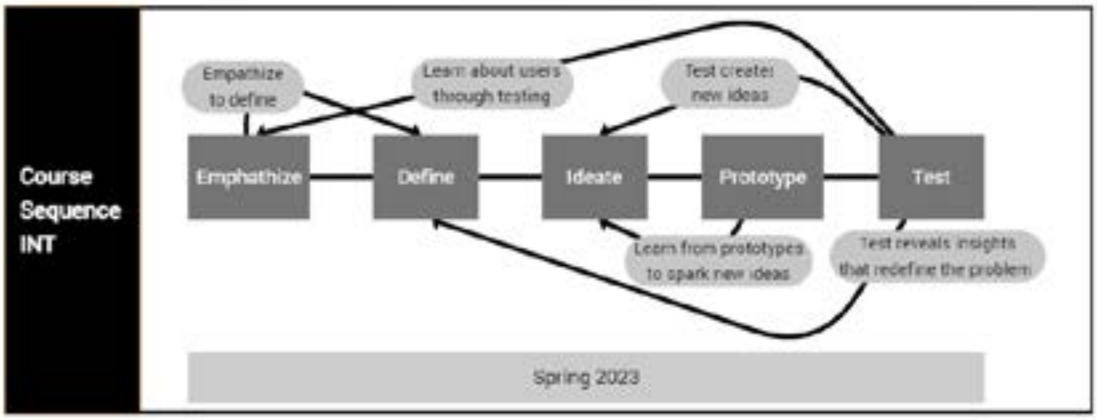

Fig. 2. Course structure of course INT

4 METHODOLOGY

4.1 Research Questions

We hypothesize that students who go through course INT will have higher engineering

design and innovation self-efficacy at the end of the course than students who go through the course sequence DIS. We also hypothesized that males would report higher self-efficacy levels than females in both groups. Our research questions are:

Primary RQ: Are there any differences in the engineering design and innovation self-efficacy between students who experienced the course sequence DIS and those who experienced the course INT?

Secondary RQ: Are there any gender differences in the self-efficacy after experiencing each of the courses?

4.2 Instruments used

We used reliable and validated surveys for assessing self-efficacy in engineering design and innovation, employing the Engineering Design Self-Efficacy Scale (EDSE) (Carberry et al, 2010) to measure engineering design self-efficacy and the innovation self-efficacy items from the Engineering Majors Survey (EMS) (Grau et al, 2016). The EDSE includes items to measure confidence, motivation, success expectancy and anxiety related to the engineering design and prototyping process. The EMS has items to measure confidence and interest in innovative thinking behaviors such as asking questions and generating ideas. In addition, our survey also had questions pertaining to participant demographics and the extent of their prototyping practices.

4.3 Research Design, Participants and Data Collection

We conducted a two-group field quasi-experiment, comparing the self-efficacy of two groups of students after they experienced either course sequence DIS (1 year) or course INT (1 semester). Since this is a field study, we could not randomize participant assignment to each group, nor ensure group equivalence. However, we argue that given that this was the first experience of design thinking and prototyping for both groups of students, and they were both drawn from the same larger population using the same common entrance test, the two groups were equivalent in terms of their engineering design and innovation self-efficacy at the start of the study. We measured their self-efficacy post course sequence DIS and course INT as the scores on the relevant items of the EDSE and EMS scales. We obtained ethical approval for our study from our Institute Ethics Committee and invited all students from both courses to participate. However only 125 students from the DIS course and 69 from the INT course and accepted our invitation, provided informed consent, and completed the self-efficacy survey administered using an online form.

4.4 Analysis Methods

To answer the primary RQ, we examined statistical differences in the self-efficacy scores between the groups using the Mann-Whitney U test. This non-parametric test was chosen because the data was not normally distributed. To answer the secondary RQ and examine statistical differences in the self-efficacy scores between the genders and groups we used the Kruskal-Wallis H test, followed by pairwise comparisons using the Dunn test and the Bonferroni correction.

5 RESULTS

To answer the primary RQ, the statistical analyses (Table 1) showed that participants in the INT group reported statistically significantly higher levels of confidence, motivation and success expectancy for engineering design ($p<0.05$). Interestingly, both groups reported similar levels of anxiety associated with engineering design. For innovation self-efficacy, again participants from the INT group reported statistically significantly higher levels of confidence for and interest in innovation ($p < 0.05$).

Table 1.Differences in self-efficacy between the INT and DIS Interventions

Indicator	Group DIS Mean (SD) (N = 125)	Group INT Mean (SD) (N = 69)	Mann-Whitney (Z)	Mann-Whitney (p)
EDSE Confidence	66.45 (20.8)	**71.79 (20.7)**	-2.342	**0.019**
EDSE Motivation	55.91 (27.9)	**74.52 (22.3)**	-4.727	**0.000**
EDSE Success Expectancy	60.60 (22.9)	**71.14 (20.1)**	-3.494	**0.000**
EDSE Anxiety	**53.40 (26.2)**	46.28 (29.3)	-1.856	0.064
EMS Innovation Confidence	3.24 (0.84)	**3.61 (0.81)**	-2.772	**0.006**
EMS Innovation Interest	3.41 (0.85)	**3.76 (0.85)**	-2.909	**0.004**

Table 2.Differences in self-efficacy between interventions and genders

Indicator	Group DIS Mean (SD) Male (N = 90)	Group DIS Mean (SD) Female (N = 35)	Group INT Mean (SD) Male (N =55)	Group INT Mean (SD) Female (N = 14)	Kruskal-Wallis (H)	Kruskal-Wallis (p)
EDSE Confidence	67.53 (25.9)	63.68 (21.2)	**74.26 (18.6)**	62.06 (26.1)	9.510	**0.023**
EDSE Motivation	55.28 (29.8)	57.52 (25)	**75.15 (20.2)**	72.06 (29.9)	22.383	**0.000**
EDSE Success Expectancy	61.23 (26.3)	58.98 (22.3)	**72.36 (18.4)**	66.35 (26.1)	13.219	**0.004**
EDSE Anxiety	**53.48 (18.4)**	53.21 (26.8)	51.07 (29.6)	27.46 (19.7)	11.689	**0.009**
EMS Innovation Confidence	3.31(1.1)	3.08 (0.99)	**3.62 (0.78)**	3.57 (0.95)	8.940	**0.030**
EMS Innovation Interest	3.42(1)	3.40 (0.79)	3.75 (0.89)	**3.80 (0.69)**	8.496	**0.037**

To answer the secondary RQ (Table 2), we found that male students, in general, rated their confidence higher than female students, and there is a statistically significant difference in confidence levels between interventions and genders. Pairwise comparisons suggest that the differences between the confidence of male students in the INT group is significantly higher than the confidence of female students in the DIS group. Next, male students in the INT group rated their motivation higher than female students, but the levels were almost similar for students from the DIS group and pairwise comparisons revealed that males from the INT group rated their confidence significantly higher than both males and females from the DIS group. Male students in both groups rated their success expectancy higher than female students and pairwise comparisons again show that males from the INT group rated their confidence higher than both males and females from the DIS group. Male and female students in the DIS group had similar anxiety levels, however interestingly, female students in the INT group reported lower anxiety compared to male students, with pairwise comparison tests suggesting that the reported anxiety of females in the INT group was significantly lower than the males in the INT group, and both males and females in the DIS group. In terms of innovation self-efficacy, while both male and female students in the INT groups reported similar levels of innovation self-efficacy, male students in the DIS group reported higher self-efficacy than females. Pairwise comparisons showed that males in the INT group reported significantly higher confidence than females in the DIS group. Regarding interest in innovation, males and females in both groups reported similar levels of interest and follow-up pairwise comparisons showed that there were no significant differences between any of the groups and genders.

6. DISCUSSION

Rapid prototyping tools have accelerated the iterations between ideation and implementation in design. The prototype is tested to refine the features and explore the design space (Yu et al, 2018) and this iterative process offers multiple opportunities to experience success through a gradually deepening engagement with the prototypes (Aurigemma et al, 2013; Newman et al, 2015). We conjectured that these successes offered by the INT course would serve as mastery experiences leading to higher self-efficacy at the end of the course, compared to students who go through the DIS course sequence, and in this work, we report on a field experiment studying this conjecture. We found that students who went through the INT course reported higher levels of confidence, motivation and success expectancy for engineering design, while reporting marginally lower levels of engineering design anxiety than participants who went through the DIS sequence. They also reported higher levels of confidence for and interest in innovation. These results suggest that though students practice the same set of skills, the experience of going through the design thinking and prototyping in an iterative manner in course INT better supported the development of self-efficacy than the DIS sequence. We argue that breaking the loop between prototyping and testing, and empathizing, defining and ideating (Figure 1) led to a situation where students were unable to use concepts of design thinking that they had learned in the previous semester, during prototyping, resulting in lower success and fewer mastery experiences. These findings agree with literature about the positive effects of rapid prototyping on students' design performance (for instance, Greenhalgh, 2016; Lantada et al, 2007) and relate to findings about students' perceptions regarding the usefulness of prototyping for design (Carfagni et al, 2020; Bohmer et al 2017; Fernandez & Jacobson, 2022). These results also agree with findings regarding the effect of design experiences on students' engineering design self-efficacy (Hulls & Rennick, 2020; Michael et al, 2012). Given that students had to develop a solution to a problem they identified, course INT is similar to students working in a makerspace, and so these findings also resonate with findings related to increases in self-efficacy with increased participation in makerspaces (Hilton et al, 2020; Morocz et al 2016; Andrews et al 2021; Carbonnell, 2019).

While it is interesting that the levels of anxiety were not significantly different between the two groups, participants from both groups in our study reported higher levels of anxiety compared to literature (Carberry et al, 2010). This suggests that, while there is an inverse correlation between confidence and anxiety, the strength of the relationship is different for our participants than previously researched populations. This phenomenon requires further exploration. We also found differences in self-efficacy based on gender, with males reporting higher levels of confidence, motivation and success expectancy than females, a finding which agrees with previous research (Milto et al, 2002; Litzler, 2014; Chachra & Kilgore, 2009; Whitcomb et al, 2020). However, given the small number of female participants in the INT group and high variance, we could not make conclusions regarding the statistical significance of these differences. Interestingly, females in the INT group reported statistically significantly lower levels of anxiety than all other groups, and in future work, we propose to explain this finding through qualitative data.

Through this work we contribute to engineering education the structure of a course which can enhance the engineering design and innovation self-efficacy of engineering undergraduates. We recommend that such a course be conducted in a project-based learning (de Los Rios et al, 2010) mode, where students start working on identifying problems and designing solutions right from the start of the course. Students are supported through lectures and activities about design thinking, and practical training in prototyping trades such as 3d printing, laser cutting, PCB milling, use of power tools, and joining and finishing. The goal is for them to be proficient in prototyping by the time they finish making their low-fidelity prototypes, so that they can do their high-fidelity prototyping and iteration phase during the last few weeks of the semester.

While our findings are promising, our study has limitations because it is a field quasi-experiment. Specifically, we could not randomize participant assignment and establish group equivalence because we chose participants and groups according to convenience: group INT consisting of first year students, and group DIS of second year students took the respective courses during the same academic year, with the DIS group following the old course structure and the INT group doing the revised course, and this experiment tested our conjecture regarding the effectiveness of the revised course. Students in the DIS course had not yet been exposed to engineering design or prototyping, and so for the purposes of our study of engineering design self-efficacy the two groups were equivalent. However, to eliminate possible confounds, generalize and better explain our findings, we propose to conduct further studies.

7. CONCLUSIONS

The role of prototyping in design has recently gained prominence because of the “democratization of invention” (Blikstein, 2013) brought on by economical and easy to use prototyping tools. In this work, we report on a study comparing an integrated design and prototyping course (INT) with a separate design and prototyping course sequence (DIS) with respect to students’ self-efficacy, and found that students in the INT course had higher self-efficacy after the course compared to students in the DIS course sequence. Additionally, we found differences between the self-efficacy of males and females, with males in the INT course reporting the highest self-efficacy. Notably, however, females in the integrated course reported lowest anxiety, a finding worthy of further exploration. These findings have implications for engineering education, suggesting that design and prototyping be taught in an integrated manner in a project-based course which offers numerous opportunities for mastery and vicarious experiences, social persuasion and emotional arousal which support the development of self-efficacy.

Keywords: *Engineering design, patenting, public speaking, innovation, self-efficacy*

ABSTRACT

The evolving role of the engineer necessitates the development of innovation skills among engineering undergraduates. Short term intensive projects are an effective way to supplement curricular design and innovation activities. In this paper, we present the findings of a study investigating the effects of a six-week invention program for engineering undergraduates. While the structure of the program is similar to a typical hackathon, the extended duration and an explicit emphasis on patenting differentiates this program from other hackathons. Focusing on self-efficacy as it is known to have a relationship with performance, we ask two research questions. Firstly, we ask if the program had effects on participants' engineering design, innovation, public speaking and patenting self-efficacy, and secondly, we investigate participant perceptions regarding the program features, and their learning during the program. Through a combined quantitative and qualitative approach, we found that participants' self-efficacy increased, and uncovered multiple positive outcomes resulting from the program, including skill development and transformative identity formation. Based on our findings, we offer guidelines for adoption by other engineering educators.

1 INTRODUCTION

The world's challenges necessitate engineers evolving into innovators. The initial phase of innovation involves sensing possibilities, envisioning realities, and proposing new outcomes through invention, which could manifest as a product, process, or patent (Denning and Dunham, 2006). This process aligns closely with design thinking and engineering design education (Coleman et al, 2019). Acknowledging this, engineering educators are integrating innovation-focused activities into curricula (for instance, Violante and Vezzetti, 2017; Barak and Usher, 2019; Liebenberg and Mathews, 2010) and promoting extracurricular events like hackathons, which are short-duration events where participants tackle problems and present solutions (Flus and Hurst, 2021). They offer practical experience and career opportunities for students (Garcia, 2022), while educators see benefits in skill development and industry-focused learning (Mehta et al, 2022). Hackathons are also linked to fostering innovative ideas (Heller et al, 2023), making them valuable for engineering undergraduates' innovation skill development. Although most hackathons prioritize pitching over patenting (Flus & Hurst, 2021), there is recognition within engineering education of the value of patent knowledge in enhancing design and innovation skills (Ozkul, 2008; Garris & Garris, 2017; Liebenberg and Mathews, 2010). Here we present a six-week extracurricular invention program called "Invention Factory" (IF) similar to a hackathon, but with a focus on provisional patent writing alongside identifying needs, designing solutions, prototyping, and pitching. The longer duration further differentiates this program from other hackathons, providing a platform for extended practice of design, prototyping, pitching, and patenting under the guidance of engineering instructors. In this work, we report on our study of the effect of this program on participants' self-efficacy for engineering design, innovation, public speaking, and patenting, and explore participants' perceptions of the program features and their own learning outcomes.

2 THEORETICAL FRAMEWORK

The "belief in one's own competences to perform an intended behaviour in spite of barriers" is referred to as self-efficacy (Lippke, 2020) and can affect motivation and performance during learning. Hence scholars argue for the examination and development of self-efficacy through appropriate curricular experiences as an important goal of engineering education (Ponton et al, 2001). Adopting Bandura's theory of self-efficacy (Bandura, 1977) in this work, we examine the impact of IF on participants' self-efficacy in engineering design, innovative thinking, public speaking, and patenting. Bandura suggests that self-efficacy depends on mastery experiences, vicarious experiences, social persuasion, and physiological and affective states. By engaging in the practical tasks of prototyping, pitching, and patenting, participants have the opportunity to acquire these skills, confront challenges, and ultimately experience success, which is a mastery experience. Teamwork, and exposure to peers and role models such as the facilitators and guest evaluators, may enhance participants' self-efficacy by witnessing the achievements of their peers. The program's emphasis on a supportive and affirming environment, with constructive feedback, encouragement, and recognition from facilitators and peers, aligns with the soc'al persuasion aspect of Bandura's theory. On the other hand, negative feedback and criticism can also lead to decreased self-efficacy. As participants engage in prototyping, pitching, and patenting activities, they may also encounter various physiological and affective states, such as excitement, anxiety, or satisfaction. Understanding and managing these emotions within the program context may contribute to the overall development of participants' confidence in their abilities. In summary, Bandura's social cognitive theory of self-efficacy offers a comprehensive framework to interpret the outcomes of IF.

3 CONTEXT AND INTERVENTION

IF is a six-week program wherein engineering undergraduates, in teams of two, prototype a potentially patentable product that addresses a real need, either consumer or societal or both. The main goal of the program is for engineers to recognize the opportunity to serve the world through engineering, and other goals include improving public speaking skills, acquiring the confidence to invent, developing awareness of how to protect intellectual property, project management skills, and learning how to work in teams. These learning goals are accomplished through participants 1) identifying a need and designing a solution that addresses the need, 2) demonstrating feasibility through a working prototype of the solution, 3) writing a provisional patent application for a utility patent that demonstrates the novelty and non-obviousness of the invention and 4) communicating the value of the product to various stakeholders.

IF is a project-based intervention which begins with facilitators establishing the norms of participation, such as working hours. Next, they form groups for a two-day ice breaking activity, which levels participants' prototyping skills and fosters connections among them, aiding in the identification of compatible partners. After the ice breaking, participants have five days to form teams, identify problems, brainstorm solutions, validate the novelty and prepare a six minute pitch. They delve into various facets of invention development, learning concepts about patents and patenting, ideation techniques, and prior art search. Facilitators offer guidance for ideation and pitching, addressing participants' concerns and anxieties regarding their initial pitches, while emphasizing effective communication strategies. Lectures on patenting along with interactive sessions to clarify any queries, help participants understand patent law and the process of drafting patent applications. At the end of week one, they present their pitches while facilitators give feedback on the problem and solution.

From the second week onwards, participants receive hands-on guidance from facilitators as they engage in the prototyping process. Collaborative efforts among teams facilitate the iterative refinement of prototypes, with participants offering feedback and assistance to one another. During this phase, participants pitch their inventions every week to guest evaluators from diverse backgrounds who provide critical feedback. These sessions are recorded and viewing the recordings with facilitators' who provide feedback on aspects such as script clarity, body language, and communication style, enable participants to refine their pitches further.

Starting from week three, structured tasks breaking down the patent application writing into parts guide participants through the drafting of patent applications, which they submit during week six. This structuring enhances participants' understanding of the patenting process, while also ensuring alignment in progress, enabling mutual support among peers and aiding in effective evaluation. Their understanding of patenting is tested by a mid-program assessment, and this also prepares them for the upcoming tasks. As the program draws to a close, teams prepare video pitches and live presentations for a panel of judges who award three prizes at each location to the best inventions. These final presentations require participants to distil the essence of their inventions into compelling narratives. The prospect of winning a prize motivates participants to deliver their best performances.

4 RESEARCH DESIGN AND METHODS

4.1 Research Questions

Based on the theoretical framework and existing literature about hackathons and short-term intensive projects, we hypothesized that self-efficacy for engineering design, innovation, public speaking and patenting would increase with participation in IF. Concretely, we ask two research questions about the effectiveness of IF:

1) What is the effect of IF on students' self-efficacy for engineering design, innovation, public speaking and patenting?
2) How do participants perceive IF?

4.2 Study Design

We employed a single group, repeated measures study to answer the first research question, conducting quantitative measurements of engineering design, innovation and public speaking self-efficacy at three points in time, namely, pre, mid, and post the program. As the participants took a patenting test at midpoint, to reduce the burden on them, the patenting self–efficacy measurement was done only pre and post program. We used a qualitative approach to answer the second research question conducting in-depth semi-structured interviews with participants at the end of the program. In addition, at one location of the program, researchers also observed the participants' daily activities during, and post working hours at the workspace, dorms, and cafeteria through participant observation to understand their perceptions as they develop throughout the program.

4.3 Participants

Engineering students of second year and above are invited to apply to IF and are selected on the basis of their motivation for innovation. Participants have diverse backgrounds, skill levels and a broad range of experiences, with approximately 45% from Mechanical Engineering and 15% from Electrical Engineering, and the rest from Civil Engineering, Chemical Engineering, Materials Science, Computer Science, Aerospace Engineering and Engineering Design. The program is conducted simultaneously at three locations and all 60 participants across all locations were invited to participate in this study. We had ethical approval for the study from our institutional ethics committee and participants provided informed consent. However not all participants completed all the questionnaires, and so the sample size for the quantitative study was 44.

4.4 Instruments Used

We used validated scales for innovation (Schar et al, 2017a), engineering design (Carberry et al, 2010) and public speaking self-efficacy (Morreale et al, 2007) for quantitative assessments. As no validated patenting self-efficacy scale was found, a specifically designed short survey consisting of five questions on a five-point Likert scale, was used to assess patenting self-efficacy. As an example, one of the questions was “I am confident in my ability to write a provisional patent.” The understandability of the questions in this survey were checked through pilot testing. A semi-structured interview guide was made for the participant interviews to capture perceptions about various aspects of the program and its effects.

4.5 Procedure for data collection and analysis

For the first RQ, we administered the self-efficacy questionnaires online; for three of the constructs (innovation, engineering design and public speaking) we did this at three time points, while for patenting self-efficacy we administered the questionnaire only pre and post program. 44 participants responded to the questionnaires at all time points, and we applied repeated measures ANOVA tests to examine differences in self-efficacy scores across the three time points. The self-efficacy score was calculated as the average of participants’ scores on all the items of the scale. For the second RQ, we conducted detailed semi-structured interviews with participants (N = 20, interviewed in teams), each ranging from a minimum of 45 to a maximum of 60 minutes, in addition to participant observations, to delve deeper into how they perceived specific program features and their own learning during the program. We analysed the transcribed interviews using thematic analysis to identify recurring themes and patterns within qualitative data. The data was first coded by one researcher (the second author of this paper) to identify the key themes through initial codes and categories related to the research question using Weft QDA software, and a code book was developed. Through a two-cycle coding process undergoing several iterations, the key themes were then refined through discussion between the two researchers until there was complete agreement regarding the themes, and we then together wrote the descriptions of the themes.

5 FINDINGS

5.1 The Effect of the ESP program on self-efficacy[2]

Our findings (Figures 1-4) show that there was a significant improvement in innovation self-efficacy, engineering design self-efficacy, public speaking self-efficacy and patenting self-efficacy scores across time ($p < 0.001$ for all four measures). Thus, participants self-efficacy on all four aspects of IF increased across the program.

5.2 Participants perceptions of the program and their learning

In terms of the program features, participants perceived that **icebreakers** were essential for fostering bonds, yet some participants found them inadequate, hindering peer interaction and partner selection, potentially affecting team dynamics as reported by Team 5, *“Because initially, in the dustbin task, we are divided into basically five groups. So, we are able to know only the five people of our group only and not the remaining 15 people.”* **Ideation was influenced by multiple factors** including facilitator feedback, personal experiences, socializing, and prior training, and participants perceived the need for extended ideation duration and facilitator diversity for better problem understanding as team 1 suggests *“if the program was for a longer time I would say a slower you know feedback would help maybe*

[2] ** denotes that $p < 0.05$, ** denotes $p < 0.01$ and *** denotes $p < 0.001$.*

because we'll get more time to think." Participants reported that **iterative processes and facilitator involvement were crucial for effective solution development,** emphasizing the critical role of timely and constructive feedback and support in refining ideas and prototypes, and contributing to project progress as Team 1 describes *"But yes their input at every step is required. I can't imagine them giving input once a week or twice a week. No I can't because I myself used to go to them and ask am I doing the right thing? What are the alternatives? What if I do this? It is very important that they come in."* They also appreciated the value of **diverse feedback from both facilitators and guest evaluators** as team 10 mentions, *"Yeah, so the feedback of guest evaluators was very important, because that was the thing that made us change the design system, [...] and those were real concerns, and they were people from different backgrounds, and they raised real concerns."* Participants reiterated that **refinement of pitches and communication expertise** were crucial for effective presentations, enhancing the overall program experience.

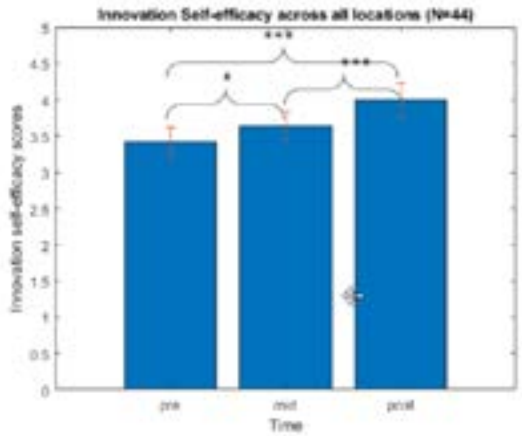

Fig. 1. Innovation self-efficacy

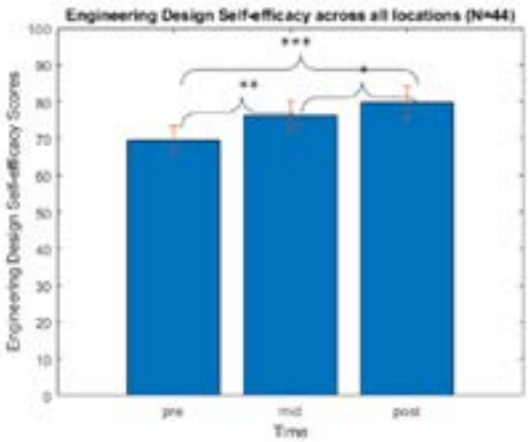

Fig. 2. Engineering Design self-efficacy

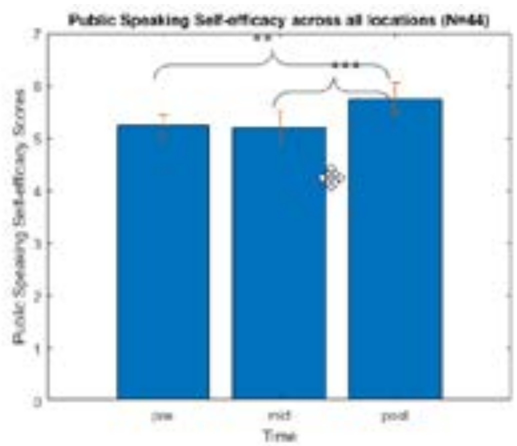

Fig. 3. Public Speaking self-efficacy

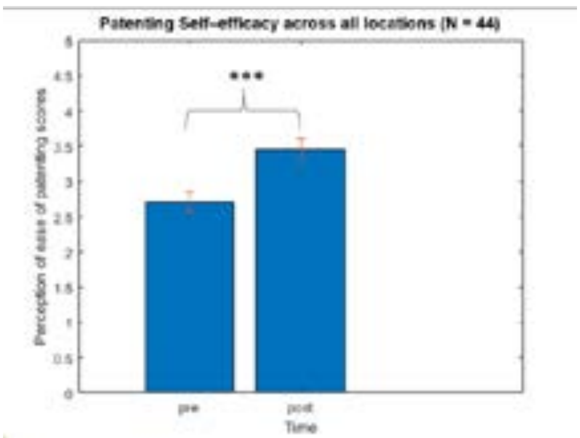

Fig. 4. Patenting self-efficacy

Regarding the culture of the program, participants acknowledged the **balance between competition and camaraderie**, highlighting the importance of fostering a collaborative learning environment as aptly described by team 10, *"we would not feel that kind of, you know, there is a negative feeling between teams, there was no such feeling in [location name], however everybody was working on the prototype, so that* *was the thing that you could be best friends even if you are competing, that was a great learning for me."* However, **cultural diversity posed challenges in communication** for some participants, necessitating inclusive strategies to address language barriers and foster participation as highlighted by team 8, *"Yeah, like, yeah, when there are group discussions, you know, we would sit together, and the initial phases, they would start speaking English, obviously, because we are there, so they consider us, but when the talking gets into deeper and deeper, there are jokes, they tell jokes and all, obviously, they will get into their mother tongue."* The **importance of prior relationships in team dynamics, collaboration, and supporting each other** was emphasized. Tolerance for different perspectives and going through an iterative process of discussing and refining ideas as a team was recognized as key to a successful collaboration as team 9 described, *"Like, as a partner, I like him pretty much. And, like, he supported my ideas. And also, he made my ideas into reality. Like, I was not that good with CAD modelling and everything. But, like, I had a good, like, tinkering mind. [...] So, I used to tell him and he used to make the things from my life. So, we both actually complemented each other in this journey."*

Commenting on their own evolution during the program, participants explained that engagement in IF **influenced their identity formation**, shaping their aspirations as impactful professionals, innovators, and entrepreneurs as succinctly put by Team 1 *"We can see invention in everything. If I don't do this I don't do that. Much better than the first week of inventions actually."* Participants acknowledged that **they were able to identify problems and gained a deeper understanding of them** only after engaging in IF as team 10 describes *"Throughout the program, so observing the problem was one more thing that I have learnt, so whenever, initially, before joining the program, when I walk through and I see a problem, then it was only a problem for me, [...] but now looking at the problem, I start thinking more, how can I solve it and how can I innovate it, even I see a solution to it, then I start thinking like, how can I improve it or things like that."* Participants recognized this as an **opportunity to apply their theoretical knowledge** as team 5 mentions, *"It helps us a lot in academics also. Basically, the concepts we learn during the classes. The program basically helps us to apply. Basically, in our project, we had gears. So, we have learned a lot about the gears also during the [program name] time,"* Next, they reported that they developed a range of skills from **CAD drawing to making observations, taking critical feedback, independence, professionalism and teamwork** as articulated by team 9, *"So, my first learning would be teamwork. Firstly, as an individual, you can't do everything alone. So, you need a team or a partner that could complement you and also how to do work and how to take work from them."* Importantly, participants spoke about **facing difficult situations and learning how to adapt** to them as team 8 elaborates, *"it was obviously one and a half months, and it was a journey of emotions, lots of emotions, frustration, anger, happiness, everything in between. [...] Yeah, definitely, to adapt to situations, adapt to scenarios as per his demands. [...] We had to face each and every emotion. We had to hold our horses, and then we had to strike hard against each and every time. We faced so many challenges, issues, failures.*"

6 DISCUSSION AND IMPLICATIONS

In this paper, we present a six-week extracurricular undergraduate engineering program focusing on identifying problems, prototyping, pitching and writing a provisional patent application for a solution. Our study found statistically significant increases in participants scores on engineering design, innovation, public speaking and patenting self-efficacy scales across the program, which indicates that participants self-efficacy for these aspects increased during the program. This agrees with research documenting the effects of participation in experiences such as design, making, entrepreneurship, innovation and leadership activities, which have been shown to result in an increase in students engineering design and innovation self-efficacy over time (Morocz et al, 2016; Andrews et al, 2021; Carbonell, 2019; Hilton et al, 2020; Hulls, 2020; Dungs et al, 2017; Schar et al, 2017b). Our qualitative findings suggest that students perceive the strength of the program lies in the environment which is conducive to immersing themselves in problem identification, solution development, pitching and patent writing across six weeks. They valued features such as guided ideation, an extended duration of prototyping with timely and constructive facilitator feedback, regular pitching with training for making presentations and critical guest evaluator feedback. They also appreciated the culture of the program, specifically the balance of camaraderie and competition, and collaborative aspects. We argue that together these features of the learning environment were sources of own and vicarious mastery, and verbal persuasion leading to the development of self-efficacy (Bandura, 1977). Further, participants reported developing an identity as an innovator, a deeper understanding of problems, and development of various skills including applying theoretical knowledge in practice. These findings resonate with previous findings which indicate that participating in hackathons positively impacts content learning (Pakpour et al, 2022), knowledge of socio-scientific issues (Pakpour et al, 2022; Medina Angarita and Nolte, 2020), knowledge of new technologies and industry relevant skills (Medina Angarita and Nolte, 2020), innovation self-efficacy (Gerber, 2012) and sense of being an engineer (Kusano and Johri, 2014). Finally, participants noted that the proverbial “rollercoaster” of six weeks, with emotional highs and lows, and the need to adapt to challenges was an important learning. This emotional arousal could have been another source of self-efficacy (Bandura, 1977).

Together our findings suggest that such a program can be an effective way to improve engineering students design and innovation self-efficacy. Therefore, we recommend such a program to engineering educators as a way to support the development of students engineering design and innovation self-efficacy. The program can be either within or outside the curriculum, and the guidelines below will help educators conduct such a program in their institution. Firstly, have sufficient time and focussed ice breaking activities to help participants get acquainted with each other and identify potential partners. Secondly, support ideation through design-thinking ideation techniques and provide constant feedback as students ideate. Thirdly, have facilitators with a wide range of experiences in innovation and train them to provide support and feedback to participants, giving specific examples of the kind of support to be provided in various situations, such as when to intervene and how, and when to step back. Next, provide participants with easy access to materials and prototyping tools so that they can iterate between designs and prototypes seamlessly. Fifth, have guest evaluators who come from diverse backgrounds (engineers, designers, homemakers, lawyers) and do not repeat evaluators in order to maximise diversity of feedback. Finally, have a communications expert who regularly provides feedback on participants' pitches and their communication skills.

While our study found statistical increases in self-efficacy, we are careful to generalize our findings because this was a pre-experimental field study of a specific program with the goal of studying if there was any effect of participation, and so we included all participants in our sample and did not have a control group. Further as our sample was not selected randomly but through volunteering, we could have self-selection bias resulting from only motivated participants volunteering. However, the detailed qualitative findings of participant perceptions regarding the program explain and triangulate the statistical findings. In future work, we plan to perform an experimental study to validate and generalize these preliminary findings.

ABSTRACT

Although there is a growing interest in understanding the emotions experienced by computer science students in educational settings, a significant gap persists in the current literature concerning the emotional dynamics and turbulences in long-term team projects. In this qualitative longitudinal study, we aimed to delve into the emotional experiences of 34 computer science students engaged in team projects. We used the experience sampling method and collected the data through online diaries after each team meeting. Through qualitative analysis of the diaries, we revealed the predominant emotions experienced by participants, the emotional turbulence encountered by team members, and the overall emotional trajectories of the teams. Our findings showed a dynamic emotional trajectory marked by turbulences in emotions such as excitement, frustration, stress, satisfaction, and pride: initial excitement often gave way to frustration and stress as teams navigated project complexities, yet this was mitigated by satisfaction and pride upon achieving milestones. Also, social emotions such as warmth, guilt, anger, and admiration emerged within the team dynamics. Our findings emphasize the significance of students' emotional experiences in team projects.

1. INTRODUCTION

In computer science education (CSE), students are frequently assigned team projects to address complicated issues and foster vital teamwork skills essential for their future careers. Teamwork, however, has many dimensions, including emotions. For example, according to Tuckman's stages of group development, emotions play a critical role in forming, storming, norming, performing, and adjourning stages of teamwork (Bonebright 2010). Indeed, research evidence shows that when students engage in team projects, they often encounter a spectrum of emotions (Atiq and Batra 2024) during the process, including academic emotions. Academic emotions encompass various psychological experiences that occur during the learning process and can be categorized into four groups: topic (subject-related), achievement (success-related), epistemic (knowledge-related), and social (social-related) emotions (Pekrun and Linnenbrink-Garcia 2012).

For instance, at the outset, students may experience topic emotions such as interest if they are drawn to the project subject, as well as achievement emotions such as hope or anxiety as they anticipate success or failure. Moreover, they may encounter epistemic emotions like surprise, curiosity, and boredom as they navigate new knowledge and understanding (Muis et al. 2015). Social emotions, such as warmth, trust, and anger, may also emerge based on interactions (Tormey 2021). It is important to note that these emotional categories are not rigidly separated, and emotions can overlap. For example, anger can be both an epistemic and social emotion. Also, one may experience more than one emotion at a given time: for example, excitement about a task, but also confusion. Additionally, emotions can be categorized as positive or negative based on their valence and activation (Scherer 2005).

Recent years have witnessed an increasing interest in understanding the role of emotions in engineering education (Lönngren et al. 2023, 2024), including CSE (Atiq and Barta 2024; Bosch et al. 2013; Girardi et al. 2021; Zhuang et al. 2022). Studies have shed light on the emotional aspect of learning programming, for example, revealing its profound influence on student performance (Bosch et al. 2013). Moreover, investigations into emotions such as confusion and frustration have sought to pinpoint instances where computer science (CS) students may require assistance during their learning journey (Zhuang et al. 2022). More recently, Atiq and Batra (2024) unveiled that positive and negative emotions experienced by the first-year students varied during programming tasks. However, there remains a gap in literature concerning the emotional dynamics of team projects, which are intrinsic to learning in CSE.

Since emotions are viewed as episodic events (Shuman and Scherer 2014), the timing of an emotional experience holds significance. This means widening the focus from specific emotions [normally understood as short-term episodes] to also include a focus on wider affective states. Indeed, while researchers often distinguish between emotions, moods, and affective states, this is something of an (artificially) imposed categorization since, in lived experience, many people often do not distinguish between them when asked about their feelings.

This affective aspect has been extensively explored in certain disciplines, notably mathematics (Muis et al. 2015), where learning activities like exercises and quizzes are typically completed individually within single class sessions lasting minutes or hours, rather than spanning days or weeks. Even when studies extend over longer durations, the brief period of each learning activity, often a single or double class session, remains central to the learning process in these fields. In contrast, project work in CS operates within a different temporal framework, extending over weeks or months instead of only minutes. Moreover, the social aspect is distinct, as interaction is integral to the learning process rather than an external or incidental component. Thus, there exists a gap in the current literature regarding an understanding of the emotional dynamics and turbulences inherent in team projects, which are characteristic of learning experiences in CS. The term ‘emotional turbulence’ means the different emotions experienced by students throughout their journey, reflecting changes in intensity and valence over time (Kellam et al. 2018). Despite the prevalence of emotional turbulence in team projects, existing literature also lacks long-term research design addressing this, particularly in CSE. This qualitative longitudinal study based on experience sampling aims to examine what emotions CS students experience in team projects and the complex interactions between emotions, particularly during emotional changes. The research question in this study was therefore as follows:

RQ: What emotions do computer science students experience during team projects and what are the underlying dynamics of academic emotions in this context?

2. METHOD

Since we were interested in what emotions were experienced by CS engineering students in team projects, qualitative methods were the most appropriate way to address our research question (Maxwell 2012). We used a qualitative longitudinal research (QLR) design. QLR is designed to capture significant moments, aspects of experiences, behaviors, actions, or transitions within a continuous, long-term framework (McLeod and Thomson 2012; Neale et al. 2012). By focusing on processes and the dynamic events that drive change, QLR allows researchers to understand how and why experiences occur and how and why they evolve (Lin 2023). We employed the experience sampling method, which is a structured diary technique utilized to appraise subjective experiences in daily life (Larson and Csikszentmihalyi 2014).

Experience sampling method enables participants to report on their thoughts, emotions, behaviors, and environment multiple times over a period (Van Berkel et al. 2017).

2.1. Data collection tool

We used an online short diary. Participants were asked to provide self-reports, answering questions such as “What were you feeling today in teamwork?” and “Why were you feeling those emotions?” Following each team meeting, participants received a link to an online, personalized diary and were requested to respond to the questions about the emotions they experienced during the day’s team meeting at last within 12 hours. Completing the diary took 5 to 10 minutes.

2.2. Participants and process

A total of 34 CS students from two technical universities in Switzerland participated in this study. Among them, 30 students belonged to one university, while the remaining four were from the other. The participants were in nine different teams. The researchers assembled seven teams from the first university, aiming for diversity within each team regarding culture, language, and gender. Teams consisted of a minimum of four and a maximum of five members. These teams were given a six-week project task by the researchers, unrelated to any coursework. The task assigned was to develop a language learning app. Participants had autonomy in choosing the languages to teach via the app, the development approach, and the programming languages to use. Weekly two-hour team meetings were held over the six weeks, with researchers solely observing. The task was not graded, however, participants had to present their app to the other teams in the sixth week of the project and the app had to function effectively. Students from the second university were in two teams and were fulfilling a course requirement and would be graded on their project by their instructors. The task was to develop software. Researchers were not involved in this team formation, project assignment, or evaluation. Initially, six students from these teams agreed to participate, but one member from each team withdrew during the process. They met every 15 days as part of their course requirements and collaborated on semester team projects.

Overall, of the 34 participants, there were 23 men and 11 women. Most participants, 23 out of 34, were bachelor’s students in their first or second year. The participants were from different countries including China, Switzerland, Morocco, Tunisia, Lebanon, Turkey, and France, among others. Language diversity was also evident, with participants speaking a range of mother tongues including, Chinese, German, Arabic, French, Turkish, and others. English emerged as the most widely spoken second language, with French being another prominent.

2.3. Data analysis procedures

The diaries of each participant were carefully analyzed by the first two authors and emotions were labeled independently to increase the reliability of the labeling (first step). After the labeling step, the self-reported reasons for why the participants experienced those emotions during that moment in the teamwork were considered to categorize them in terms of academic emotions (second step). After analyzing the participants’ emotional experiences week by week, we aimed to see the emotional change of each participant (third step) as well as the teams’ emotional trajectory (fourth step). For example, the emotions experienced by the members of Team-1 are presented in Table 1. The data analysis procedures, which include four steps (labeling, categorizing, week by week changes, and team's trajectory), were followed for each participant and team. In the following section, we present a general overview of findings derived from these procedures.

Table 1. Emotional turbulence of team members and emotional trajectory of Team 1

Teams	Participants (CODE)	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6
		Emotion (intensity) [a]: [Academic Emotions] [b]	**Emotion (intensity) [Academic Emotions]**	**Emotion (intensity) [Academic Emotions]**	**Emotion (intensity) [Academic Emotions]**	**Emotion (intensity) [Academic Emotions]**	**Emotion (intensity) [Academic Emotions]**
TEAM-1	**(P1T1M)**	Satisfied (3) [AE] Stressed (3) [TE, EE] Relieved (3) [SE] [Confidence][c] [TE]	Guilty (2) [AE, SE] Impatient (2) [EE] Satisfied (2) [EE, AE] Relaxed (2) [AE, EE]	Excited (3) [AE] Nervous (3) [EE, SE]	Excited (4) [AE] Happy (4) [AE, SE] Stressed (4) [EE, SE, TE]	Stressed (4) [SE, EE, AE] Relaxed (4) [AE, SE, EE] Satisfied (4) [AE, SE, EE] Fulfilled (4) [AE, SE, EE]	NA (No Answer)
	(P2T1W)	Dissatisfaction (2) [AE, SE, TE]	Satisfied (3) [AE, SE, EE]	Worried (4) [EE, SE]	Anxious (4) [EE, SE, AE]	Happy (4) [EE, SE, AE]]	NA
	(P3T1M)	Excited (3) [TE, AE] Frustrated (3) [TE, EE]	Confident (3) [AE, SE] Frustrated (3) [EE]	Happy (3) [EE, SE, AE]] Fatigue (3) [sleepiness]	Happy (3) [AE, EE] Frustrated (3) [EE]	Happy (4) [AE] Fulfilled (4) [AE] Proud (4) [AE, SE]	Proud (3) [AE] Sad (3) [SE] Satisfied (3) [AE] Happy (3) [AE] Nervous (3) [AE, SE]
	(P4T1M)	Good (3) [SE] Excited (3) [SE]	Sad (1) [No classification]	Neutral [No classification]	Fatigue (2) Unenthusiastic (2) [No classification	Good (3) [AE] Appreciated (3) [SE]	Interested (4) [TE, SE] Excited (4) [AE]

[a] Intensity (1-weak; 2-mild; 3- moderate; 4-strong; 5-intensive)

[b] Academic Emotions: [EE]= Epistemic Emotion; [SE]= Social Emotion, [TE]= Topic Emotion; [AE]= Achievement Emotion

[c] The participants did not explicitly mention this emotion in their responses to the first question of the diary. However, the authors labeled them interpreting the participants' responses to the other questions and placed them on the table. These emotions were indicated within square brackets without specifying their intensities.

3. RESULTS

In this study, we sought to investigate the emotions experienced by CS students during team projects, as well as to explore the underlying dynamics of academic emotions within this context. In this section thus we present the emotions mostly felt by the participants, the emotional turbulence experienced by team members, and the emotional journey of the teams.

3.1. The emotional experiences: Turbulences and trajectories

As seen in Table 2, the participants mostly experienced multiple emotions each week, both positive and negative.

In Week 1, for example, participants primarily experienced positive emotions such as excitement (27%), comfort, satisfaction, and happiness. However, some participants also had worries and stress, stemming from concerns about project expectations and deadlines. Additionally, fewer participants reported annoyance (4%). Overall, the first week was characterized by a mix of positive (65%) and negative (35%) emotions. In Week 2, satisfaction (17%) was the most prevalent. This was attributed to various factors such as achieving goals or completing tasks successfully. Additionally, comfort and excitement were common, since participants were settling into their roles and tasks. Happiness was also prominent, thanks to positive interactions within the team. However, some participants reported frustration (6%) and inadequacy, due to challenges or setbacks encountered during the week. Isolation (5%) was also present, due to lack of communication with team members. Overall, while positive (67%) emotions prevailed, there were also instances of negative (33%) emotions.

Table 2. The seven most felt emotions (f and %)[a] by the participants (n=34) week by week

Week 1 Total Entries (N=97)	**Week 2** Total Entries (N=78)	**Week 3** Total Entries (N=70)	**Week 4** Total Entries (N=87)	**Week 5** Total Entries (N=77)	**Week 6** Total Entries (N=90)
Excited (26, 27%)	Satisfied (13, 17%)	Happy (9, 13%)	Happy (26, 30%)	Happy (18, 23%)	Happy (24, 27%)
Comfortable (10, 10%)	Comfortable (11, 14%)	Satisfied (7, 10%)	Satisfied (13, 15%)	Satisfied (12, 16%)	Comfortable (12, 13%)
Satisfied (8, 8%)	Excited (9, 12%)	Frustrated (6, 9%)	Comfortable (8, 9%)	Stressed (9, 12%)	Proud (10, 11%)
Happy (7, 7%)	Happy (9, 12%)	Comfortable (5, 7%)	Excited (7, 8%)	Comfortable (7, 9%)	Satisfied (9, 10%)
Worried (6, 6%)	Frustrated (5, 6%)	Worried (5, 7%)	Motivated (7, 8%)	Excited (7, 9%)	Relaxed (8, 9%)
Stressed (6, 6%)	Inadequacy (5, 6%)	Excited (3, 4%)	Stressed (4, 5%)	Relaxed (3, 4%)	Excited (7, 8%)
Annoyed (4, 4%)	Isolated (4, 5%)	Disappointed (3, 4%)	Relaxed (3, 3%)	Worried (3, 4%)	Stressed (5, 6%)
Other (30, 31%)	Other (22, 28)	Other (30, 43)	Other (18, %21)	Other (17, %22)	Other (17, 19%)
In total 63 (65%) Positive and 34 (35%) Negative Emotions	In total 52 (67%) Positive and 26 (33%) Negative Emotions	In total 38 (54%) Negative and 30 (43%) Positive Emotions and 2 Neutral	In total 72 (83%) Positive and 14 (16%) Negative Emotions and 1 Neutral	In total 55 (71%) Positive and 21 (27%) Negative Emotions and 1 Neutral	In total 77 (86%) Positive and 13 (14%) Negative Emotions

[a] Frequency and percentages are based on the total entries.

In Week 3, participants experienced a range of emotions, with negative emotions (54%) being more prevalent than positive (43%) ones. Frustration (9%), worry, and disappointment were particularly notable, since participants encountered challenges during this period. Despite the presence of some positive emotions such as happiness (13%) and satisfaction (10%), they were outweighed by the negative ones. In Week 4, participants experienced predominantly positive emotions, with happiness (30%) being particularly prevalent. This indicates a shift from the previous weeks since the team overcame previous challenges and achieved significant progress in their project work. Excitement was also notable, reflecting a sense of accomplishment and engagement within the team. While there were fewer instances of negative emotions such as stress (5%), their presence suggests that the week was not entirely free from challenges or stressors. Overall, while positive (83%) emotions prevailed, there were also instances of negative (16%) emotions.

In Week 5, participants reported positive and negative emotions as they approached the final stages of their project. While happiness (23%) and satisfaction (16%) were prevalent, due to progress, stress (12%) and worry (4%) were also notable due to the impending presentation to other teams in the following week (Week 6). Overall, the combination of positive (71%) and negative (27%) emotions reflected the complexity of the team's experiences as they prepared to present their work to the other teams. In Week 6, happiness (27%) was prevalent, because of a sense of accomplishment with their progress. Additionally, pride (11%) emerged as a notable emotion in this week, indicating a sense of achievement and confidence in their work. Despite these positive emotions, some participants reported stress (6%), due to final presentations. The overall balance of positive (86%) emotions outweighed the negative (14%) ones. As seen in Figure 1, over the course of six weeks, 34 participants, in nine teams in the project reported a wide range of positive and negative emotions, and experienced emotional turbulences, reflecting the dynamic nature of teamwork.

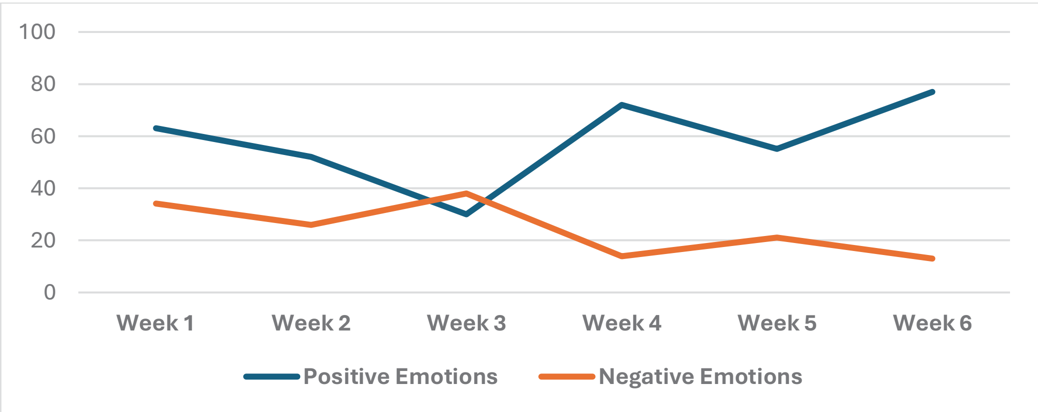

Fig. 1. Emotional journey of the teams

The journey began with positive emotions such as excitement and satisfaction, and negative emotions such as annoyance and stress. As the study progressed over subsequent weeks, notably from the second to the fourth, a mix of emotions emerged, reflecting periods of heightened turbulence characterized by frustration, stress, and worry. These emotional turbulences were influenced by a multitude of challenges encountered by participants. These challenges encompassed various aspects such as difficulties in effective team communication, obstacles in coding tasks, instances of team members' absenteeism, challenges in equitable workload distribution, the presence of unmotivated teammates, and the looming presence of impending deadlines. These antecedents were consistently reported by the participants, indicating the multifaceted nature of emotional experiences within the context of team projects among CS students. As the project concluded, positive emotions such as pride, accomplishment, and fulfillment prevailed, reflecting the participants' collective efforts and achievements.

3.2. The interplay between the academic emotions

The academic emotions experienced by the nine teams throughout their projects were influenced by a multitude of factors, spanning topic, achievement, epistemic, and social dimensions. Overall, the emotional journey of the teams reflected the emotions related to the task subject, the challenges related to coding, team dynamics, and collaboration challenges. Topic emotions, for example, mainly reported during the first week, varied among teams depending on their interest, familiarity, and experiences with the project task, that is, developing a language app. While many members of Team 5, for example, reported excitement in building a language app, many in Team 4, expressed stress, dislike, and nervousness related to the task's topic. The progress made on the projects, completion of coding tasks, and effective management of pressure and deadlines were significant antecedents shaping achievement emotions. For example, Team 4 reported the achievement emotions as they organized their coding tasks, and Team 9 reported hope and relief as they made progress in their coding work despite facing challenges.

Epistemic emotions were frequently reported in Weeks 2, 3, and 4. They were related to the coding process such as debugging and merging codes, or interfaces: frustration and surprise with debugging codes, and anxiety and boredom about the app requirements were reported. Team 2, for instance, reported frustration related to adapting the new coding interfaces and merging the different interfaces, while Team 6 experienced stress and anxiety due to barriers hindering their coding progress. Social emotions were shaped by factors, such as team dynamics, collaboration effectiveness, and support levels. Team 5, despite initial challenges, for example, reported warmth, trust, unity, and admiration within the team, fostering a positive atmosphere for collaboration, and overcoming challenges together. Team 6, in contrast, reported anger and stress due to various team dynamics such as taking the leadership, and collaboration styles, indicating the impact of team dynamics on social emotions.

4. SUMMARY AND ACKNOWLEDGEMENTS

In conclusion, the participants reported various emotions simultaneously throughout each week, illustrating the dynamic nature of team projects. Our findings align with existing studies on the emotions of CS students by Atiq and Batra (2024), Bosch et al. (2013), Girardi et al. (2021), and Zhuang et al. (2022). However, we offer unique insights by exploring the emotional dynamics in team projects over six weeks. Our study delves into the interplay between topic, achievement, social, and epistemic emotions within collaborative contexts, providing a comprehensive understanding of group dynamics. By capturing the participants' emotional journey that shows the evolution of emotions across weeks during the stages of group development (Bonebright 2010), we highlight both challenges and successes, offering valuable perspectives for supporting students' emotional experiences in team projects. For example, throughout the study, participants experienced a wide range of emotions, encompassing both positive and negative aspects. While confronting challenges, such as coding difficulties, they experienced negative emotions like anxiety and frustration, alongside positive emotions such as excitement, relief, and pride as they worked towards their project objectives. Additionally, our study indicates that participants' emotional responses to the same event varied, evidencing the subjective nature of emotional experiences (Scherer 2005).

In terms of academic emotions, the journey began with topic emotions, such as excitement and interest directly tied to the project task. Alongside these, participants experienced social emotions, including warmth and trust from positive team dynamics. Conversely, there were instances of annoyance and exclusion stemming from certain team interactions, highlighting the complexity of social dynamics within teams. As the project progressed, a dynamic interplay between social and epistemic emotions emerged. Participants grappled with feelings of isolation and inadequacy, reflecting social emotions, while also experiencing frustration due to encountering coding problems or merging issues, which are examples of epistemic emotions (Pekrun and Linnenbrink-Garcia 2012). Towards the finalization of the project, a mix of achievement and social emotions became prevalent. Participants felt a sense of accomplishment and happiness upon successful project completion, coupled with social emotion of pride in presenting their app to others. In short, this emotional turbulence underscores the significance of acknowledging and managing emotions in academic settings, especially within CSE. It highlights the importance of fostering supportive environments that cater to both academic, social, and emotional development (Tormey 2021).

Based on our findings, several didactic strategies can help manage the emotions that arise during team projects. Educators can address emotions in lectures by discussing emotional dynamics, focusing on worries that peak around week 3 and stress related to end-of-semester presentations. Introducing common emotional dynamics at the start of group work can better prepare students. By doing this, they can make students aware of emotional and group dynamics, helping them use this knowledge to improve their teamwork. For a more direct approach, a system could be developed to evaluate and summarize recorded emotions on a dashboard. This would allow lecturers to monitor the emotional state of their students and provide timely support when necessary.

4.1. Future steps

In this study, we have outlined the initial findings concerning the emotions experienced by computer science students in the team projects. Moving forward, our focus will shift toward understanding the social meanings attributed to these emotions within the teams. We aim to investigate how these social interpretations relate to team members' social identity, team learning, and overall satisfaction with the team project experience.

ACKNOWLEDGEMENTS

This study is a part of the research project, 'Effect of Emotions Experienced by Computer Science Students on Learning During Team Projects,' which has been funded by the BeLEARN Association.

Conference Key Areas*: Continuing education and life-long learning in engineering, Engineering skills, professional skills, and transversal skills*
Keywords*: High Impact Practice, Student Research Societies, Pandemic*
ABSTRACT

The form of talent development in higher education has existed for over seven decades and has consistently adapted to educational changes and met challenges. The Student Research Societies (SRS) were initiated by talented students who, with the help of their mentors, want to achieve more than what regular education could offer. The inception was followed by dynamic horizontal and vertical expansion. Nowadays, more than 10,000 students participate in the scientific student society movement in Hungary. A legally codified structure deeply embedded in higher education has emerged.

Students prepare scientific papers on topics of their choice with scholarly ambition, engage in research group activities, and present their findings at institutional SRS events. Based on recommendations from a professional jury, authors of worthy papers can participate in the biennial national conference. The National Conference of Student Research Societies (NCSRS) hosts competitions in 16 thematic sections accompanied by numerous community programs. Since 2023, the SRS has become an international event within the framework of the European Engineering Learning Innovation and Science Alliance program.

The SRS is a HIP that significantly enhances both students' learning experiences and outcomes, enriching many with the joy of research and scientific collaboration.

This paper examines the last decade of the Technological Sciences Section, analyzing the satisfaction surveys of the 2019, 2021, and 2023 NCSRS events. We compare the measurement results of the online event held during the pandemic in 2021 with those before and after COVID-19, examining how the pandemic has impacted scientific student association activities.

1 INTRODUCTION

Talent development in higher education can manifest in various forms. Specialized colleges within the public education system can be viewed as counterparts to those special collegiate groups whose material surpasses that of regular courses, deepening and broadening them. However, there are forms unique to higher education, such as specialized collegiate groups. Within these self-organized societies, students can delve into specific fields of study and, functioning as a professional community, engage with issues that interest them. In addition to contributing to the unfolding of talented students and facilitating their acquisition of valuable experiences beyond the compulsory curriculum, members of these specialized collegiate groups also engage in supportive activities. They organize consultations for their peers, participate in university programs promoting disciplines, and visit high schools for career orientation purposes, among other activities. Thus, they offer not only academic but also personal and professional development opportunities for students.

Another important pillar of university talent development is scientific student society activities. The Student Research Societies (SRS in Hungarian TDK) built upon university self-educational societies, have a history spanning more than seven decades. This activity, often referred to as a proper introduction to scientific research, is characterized by the relationship between the student and their mentor.

1.1 Brief history of the SRS movement

The Student Society movement in Hungary emerged in the early 1950s, spurred by teachers and students seeking greater academic freedom. Initially led by Natural and Technological Science Societies, it soon expanded to other fields, fostering research and creative endeavors despite bureaucratic constraints.

The movement gained momentum with the first National Conference of Student Research Societies (NCSRS) in 1955, bolstering student engagement in scientific research. Despite political pressures, it maintained its domestic character, contributing to the elevation of academic standards.

By the 1970s, the movement saw rapid growth, necessitating operational regulations and standardized rewards. The establishment of the National Conference of Student Research Societies (NCSRS) in 1973 further structured the movement's activities.

In subsequent decades, universities actively supported student scholarly pursuits, reflected in the expanding NCSRS (National Conference of Student Research Societies) participation. László Leindler's insights underscored the transformative journey of students towards becoming researchers, emphasizing the role of mentorship and language proficiency.

Structural changes in the 1980s, including the reorganization of NCSRS, marked a shift towards institutionalization and autonomy. The 1990s witnessed further evolution, with increased participation and diversification of sections (Anderle 2011).

Government support in 2013 formalized state backing for Student Societies, aligning with structural changes in higher education. The transition to a three-cycle system highlighted the need for early talent identification, addressed through initiatives like the National Excellence Program.

The New National Excellence Program and the Roska Tamás Scientific Lecture Institution provided additional support, fostering interdisciplinary collaboration and internationalization. By the third millennium, the movement stabilized, embracing online platforms for organization and outreach.

The expansion of NCSRS to Hungarian institutions outside of Hungary (i.e. neighboring nations) in 2013. Since 2023, NCSRS has also been organized for member universities of the European Engineering Learning Innovation and Science Alliance (EELISA). This has underscored the movement's global reach and commitment to innovation. Despite administrative challenges, the movement persevered, adapting to technological advancements and societal needs.

In conclusion, the Hungarian Student Society movement has evolved into a dynamic platform for academic growth and international collaboration, driven by a commitment to excellence and social responsibility.

1.2 National conference of student research societies 2013-2023

The NCSRS is an event of outstanding importance on a national level, combining multiple elements of talent nurturing and development. It is a conference where students can present their scientific achievements, which may have taken several years to accomplish. However, it is also a competitive event, as the awarding process follows strict rules. Also, it serves as a community-building occasion with numerous cultural and sports programs. And all of this is just the pinnacle of the complex talent nurturing process, which can begin when a high school student meets their mentor or when a university student selects an SRS topic of interest. (See Figure 1)

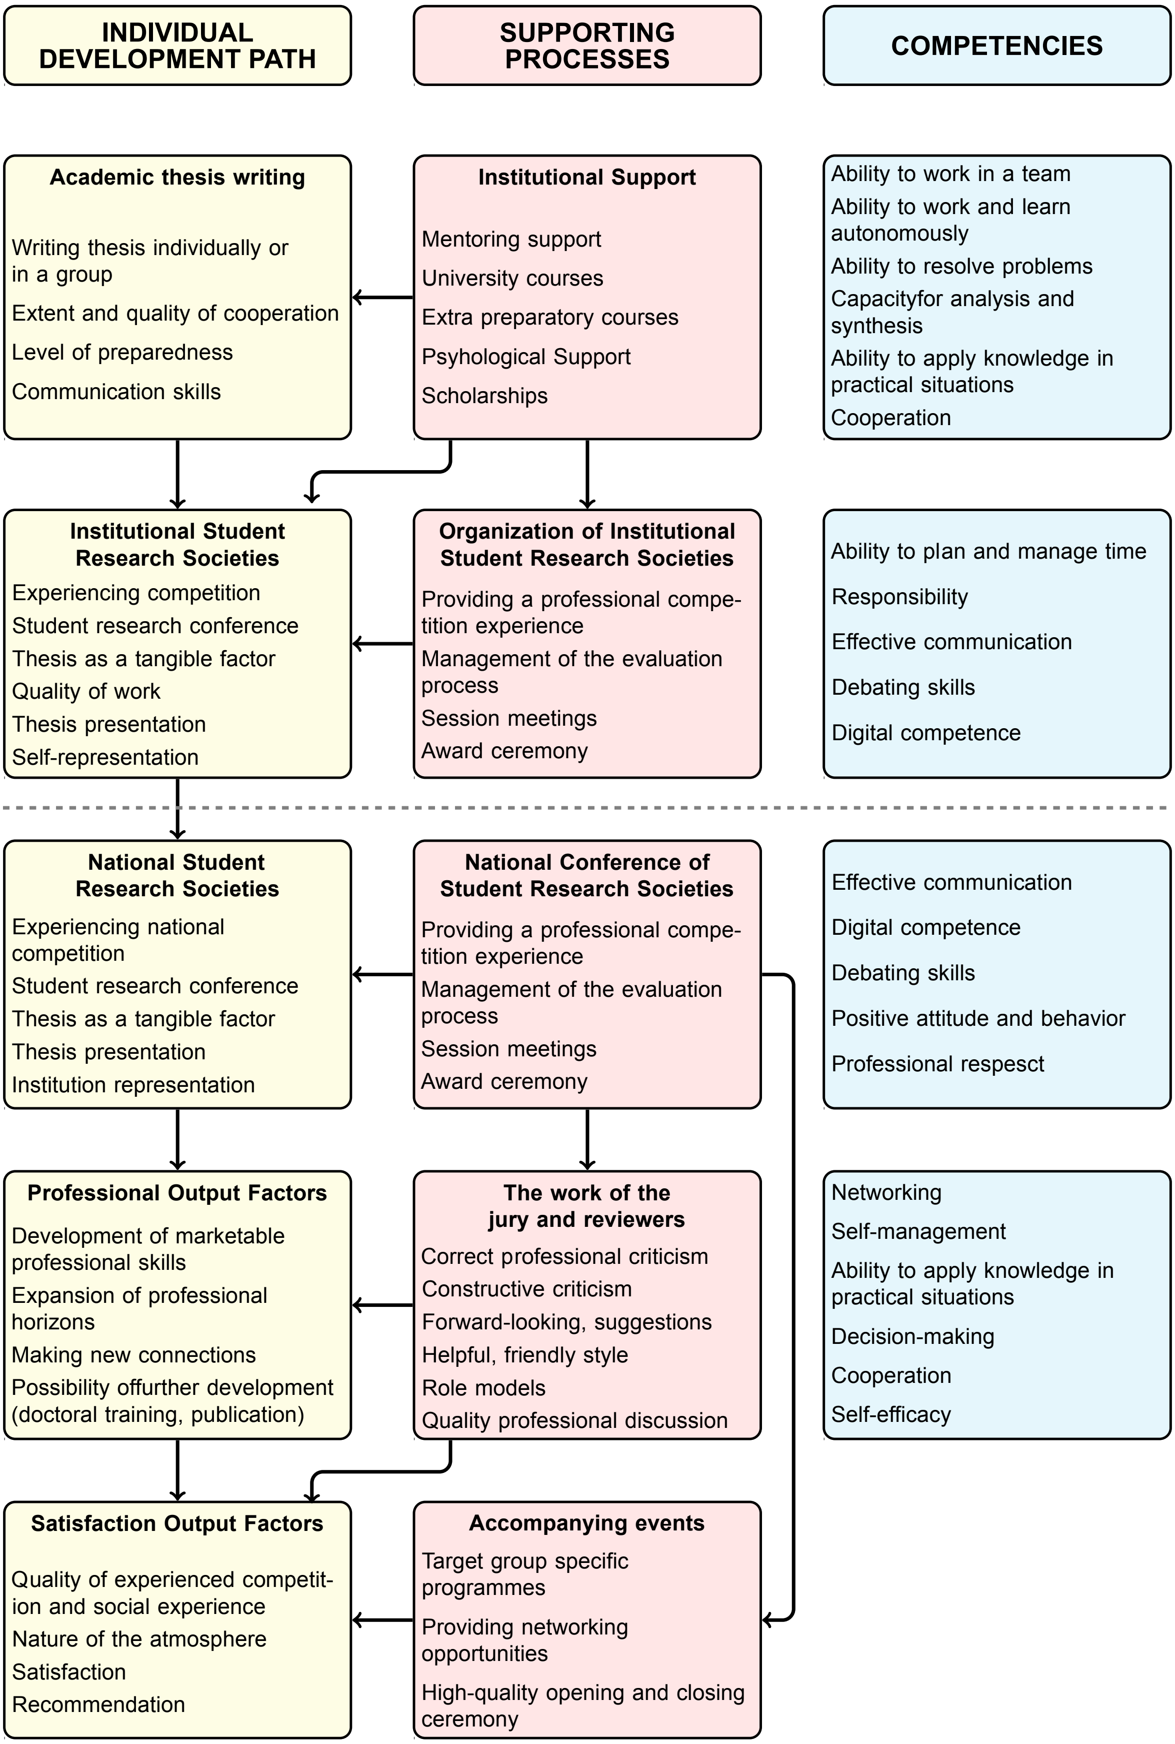

Figure 1: The multifaceted nature of SRS activities.(Koloszár et al. 2024)

In addition to competencies, it is worth discussing the rich array of abilities and skills that are developed through SRS activities. For our analysis, we will use the work of Kolchina and colleagues, who examined which skills are developed in the context of various activities of student societies (Kolchina et al. 2021). Study of the soft skills development in the framework of the activities of student communities. Propósitos y Representaciones, 9(2), 34. The preparation of scientific student papers and the presentation of results significantly contribute to the development of both hard and soft skill groups such as Professional skills (according to the specifics of the activity), Analytical/Research skills, Flexibility/Adaptability skills, and Leadership skills.

1.3 Competition and conference combined

Over the more than seventy years, a ritual has been established for how the biennial conferences, each lasting 3-4 days, unfold. Beyond the opening and closing events, there are many activities that enrich such an event. Personal encounters can facilitate the birth of new relationships and friendships, while cultural, sports, and other activities can alleviate the tension of competition and provide entertainment. The NCSRS differs from a large-scale conference series not only because of the competition but also because it offers a much wider range of optional programs. Besides the traditional city tours, it's common, for example, for choirs to form, performing at the closing event, and there are running races and communal folk-dance classes.

Just as scientific conferences are of fundamental importance to researchers, providing opportunities for meeting and networking with professionals working in similar fields, the same applies to students. NCSRSs foster scientific dialogue among students, where they can discuss their new ideas, theories, and research findings. Throughout the evaluation process and during the presentation of results, they can receive constructive feedback, contributing to the further development and refinement of research projects. Additionally, conferences offer opportunities to learn about new research directions and trends, as well as to expand professional networks and establish collaborations (Carter et al. 2019)(Kondratenko et al. 2022). Students can leverage the experiences gained here in the job market: they can work on real problems in their projects, learn to work in teams, and improve their presentation skills. Such supplementary events accompanying the competition also benefit supervisors, where they can share their experiences and challenges related to supervision. Such academic interactions are essential for the development of the scientific community and the dissemination of knowledge.

Daniel Lynch and his colleagues analyzed the impact of case study competitions on logistics and supply chain on the experiences of participating students, jury members, and alumni of the competitions. Using both quantitative and qualitative analyses, the study demonstrates how these competitions influence students' careers and educational experiences (Lynch et al. 2022). It is not uncommon for students to work independently or with peers on a research project and then present their findings. Many universities around the world organize conferences and competitions for this purpose. What makes the practice in Hungary unique is that these competitions culminate every two years in a single large event involving all higher education institutions in the country.

2 METHODOLOGY

2.1 The evaluation process

The organizers send the submitted entries to at least two reviewers, who evaluate them on the online platform. The presentations of the papers are organized into thematically optimal sections, each containing a minimum of 5 and a maximum of 15 papers. Sectional juries determine the ranking based on written evaluations and oral presentations. According to the rules of NCSRS, one-third of the presented papers in each section can receive first, second, or third place. Only one first place can be awarded in a section. Second and third places may be awarded multiple times, but the number of students ranked second or third may not exceed one third of the total number of entries in a section. Only first place winners in each section are eligible to compete for the most prestigious student awards, the Pro Scientia, Pro Arte, and Junior Pro Scientia Gold Medals. A total of ca. 50 of these are awarded biennially (Szendrő and Cziráki 2009).

The question arises: how does the regulation of the number of winners affect the students? Does it dampen the spirits of participants that even though they might have produced the best paper in their field, they did not receive the first prize? Mihaly Csikszentmihalyi analyses the utility of competition in the context of achieving the "flow" state in his book "Flow: The Psychology of Optimal Experience. (Csikszentmihalyi 1990). When a student is fully immersed in research activities, they can experience "flow." According to Csikszentmihalyi, competition is beneficial when it promotes this state, supporting individual challenges and skill development. However, if competition causes excessive stress or hinders individual development, it goes against the experience of "flow" and becomes detrimental.

3 RESULTS

3.1 Satisfaction measurements

By processing the results of satisfaction surveys, we examined the extent to which participants were satisfied with the professional implementation of the conference and how much their participation in the NSRS contributed to their professional development. The National Council of Student Research Societies deems it essential that the continuous improvement efforts receive feedback. Therefore, in 2019, 2021, and 2023, an online satisfaction survey was conducted. Below, we will analyze the results obtained in the three Technological Sciences Section of the NCSRS. We will specifically address how the pandemic has impacted the SRS activities within the Technological Sciences Section. Respondents were asked to rate the extent to which the statements applied to them and to answer questions. (In 2019 and 2023, a Likert scale ranging from 1 to 6 was used, and in 2021, a Likert scale ranging from 1 to 10 was employed in the measurements, which we considered in our calculations.)

The questions analyzed across all sections and years were as follows (See Table 1):

Q1: *I am satisfied with my own performance.*

Q2: *I had the opportunity to learn about research and research results of people my age.*

Q3: *By learning about others' research, I gained a lot of knowledge.*

Q4: *By learning about others' research, I got many new ideas for continuing my own research.*

Q5: *I felt the section I participated in was professionally coherent.*

Q6: *My own presentation fits professionally into the section.*

Q7: *I received useful feedback from the jury.*

Q8: *After my presentation, the jury asked questions.*

Q9: *During the section meeting, the jury treated me as a partner during my presentation and subsequent discussion.*

Q10: *The written critiques I received for my work were fair and helpful.*

Q11: *I can learn from the written critiques; they help me in my further work.*

Q12: *I gained useful professional connections.*

Table 1: The distribution of responses from the 2021 survey.

	1	2	3	4	5	6	7	8	9	10
Q1	0.66%	3.29%	2.63%	2.63%	3.29%	7.24%	9.87%	29.61%	13.82%	26.97%
Q2	0.66%	1.32%	3.95%	3.95%	5.26%	5.92%	7.24%	31.58%	9.21%	30.92%
Q3	2.63%	3.95%	7.24%	4.61%	11.84%	10.53%	17.76%	17.76%	10.53%	13.16%
Q4	11.84%	10.53%	15.79%	9.87%	9.87%	11.18%	11.18%	9.21%	3.95%	6.58%
Q5	4.61%	3.95%	11.18%	4.61%	10.53%	14.47%	11.84%	15.13%	9.21%	14.47%
Q6	4.61%	1.97%	11.18%	5.92%	3.95%	10.53%	7.24%	13.16%	13.16%	28.29%
Q7	7.24%	3.95%	6.58%	5.92%	3.95%	6.58%	9.87%	15.79%	9.21%	30.92%
Q8	3.95%	5.92%	5.26%	3.95%	2.63%	1.32%	4.61%	16.45%	7.89%	48.03%
Q9	2.63%	1.97%	3.29%	2.63%	1.32%	3.95%	5.26%	23.03%	13.16%	42.76%
Q10	1.97%	3.29%	3.95%	3.29%	4.61%	4.61%	8.55%	17.76%	15.13%	36.84%
Q11	3.29%	3.95%	7.89%	3.29%	6.58%	4.61%	5.92%	15.13%	12.50%	36.84%
Q12	21.05%	9.87%	11.18%	7.89%	10.53%	7.24%	7.24%	9.21%	6.58%	9.21%

We can conclude that the majority of students were very satisfied with the professional execution of the event. However, it should be noted that despite the organizers emphasizing the importance of students building valuable professional connections and being open to learning about their peers' work, 21.05% of respondents felt they did not gain useful professional experience (Q12), and 11.84% felt they did not receive new ideas for continuing their own work. In the second part of our analysis, we were curious to see if satisfaction changed due to the online nature of the conference during the pandemic, and how participants' opinions evolved when things returned to "norma". The distribution of responses to individual questions was not normal, so we used the Mann-Whitney U test to examine if there was a significant difference in responses to the questions in the various surveys. At a significance level of 0.05, the critical value is 1.96. The obtained Z values were always smaller than 1.96 in absolute value, indicating no significant difference between the responses to the examined questions in the two conferences compared.

The questions analyzed (see Table 2) across the Technological Sciences section in 2021 were the following:

S1: *The lockdowns have made it difficult to conduct scientific work at the appropriate level.*

S2: *I didn't have access to the necessary tools for my research.*

S3: *Maintaining communication with my supervisor has become more difficult.*

S4: *My supervisor had more time to assist with my research.*

S5: *I had more time for my SRS research.*

S6: *I gained better access to literature and databases.*

S7: *I wouldn't have even started my SRS if it weren't for the coronavirus and the resulting lockdowns.*

S8: *The institutional/departmental SRS conference was held online, and participating in it was a positive experience for me.*

Table 2: The distribution of responses from the 2021 survey about Covid-19 related questions in the Technological Sciences section

	1	2	3	4	5	6	7	8	9	10
S1	15.12%	12.79%	11.63%	5.81%	10.47%	16.28%	6.98%	13.95%	1.16%	5.81%
S2	25.58%	8.14%	12.79%	4.65%	3.49%	17.44%	5.81%	11.63%	1.16%	9.30%
S3	25.58%	11.63%	11.63%	8.14%	6.98%	12.79%	10.47%	9.30%	1.16%	2.33%
S4	25.58%	15.12%	18.60%	17.44%	11.63%	4.65%	1.16%	4.65%	1.16%	0.00%
S5	19.77%	19.77%	10.47%	6.98%	16.28%	11.63%	4.65%	6.98%	2.33%	1.16%
S6	52.33%	20.93%	9.30%	5.81%	4.65%	1.16%	2.33%	0.00%	2.33%	1.16%
S7	77.91%	6.98%	2.33%	2.33%	5.81%	0.00%	1.16%	2.33%	0.00%	1.16%
S8	11.63%	6.98%	3.49%	11.63%	10.47%	10.47%	6.98%	13.95%	10.47%	13.95%

It is evident that the audience's commitment to SRS is strong (S7) and that the pandemic did not significantly hinder student research work, although it did pose some challenges.

Figure 2: The most important numbers of the last six NCSRS conferences of the past decade

Figure 2 above where the x-axis represents the years, while the y-axis represents the number of submissions. Yellow represents the first, grey the second, brown the third, and mauve indicates the number of special prize winners. For first prizes, we also included the number of Pro Scientia, Pro Arte, and Junior Pro Scientia Gold medalists. It is worth noting that the Covid-19 pandemic did not deter the talents; the number of participants did not decrease. Detailed analyses revealed that while there was a decline in experimental fields due to closures, growth was observed in other scientific areas. This can also be explained by the fact that other activities, even entertainment opportunities, were restricted during online education, especially during quarantine, which created the opportunity for students to focus on preparing their submissions. For the Technological Sciences Section, we also marked the number of first, second, and third-place winners corresponding to the color codes used in the previous figure (see Figure 3).

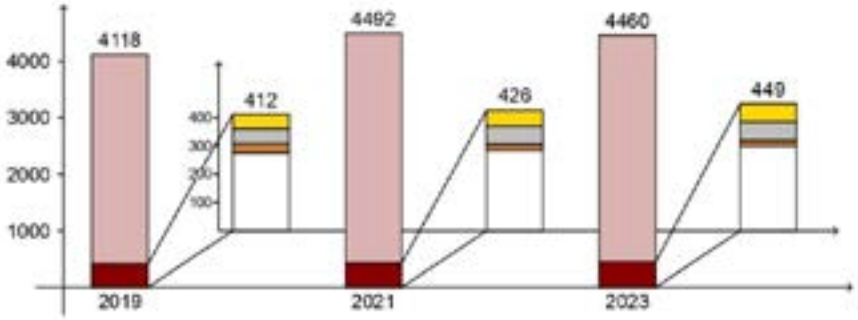

Figure 3: The number of participants in NCSRS (higher bars) and within that, the number of participants in the Technological Sciences Section across the years of satisfaction measurement

Engaging in scientific work as a student can significantly influence participation in doctoral programs. The research experiences gained through SRS activities enhance students' scientific skills and even increase their chances of enrolling in doctoral programs. As a result, students are better prepared for the challenges of doctoral studies and the world of scientific research.

4 SUMMARY

The SRS is a Higher Impact Practice (HIP) in pedagogy that significantly enhances both students' learning experiences and outcomes. From the perspective of modern engineering education, these conferences align with the trend of employing student-centered, project-based learning methodologies that focus on solving real, multifaceted engineering problems. The SRS movement supports the development of skills such as teamwork, communication, global awareness, professionalism, and social responsibility. Additionally, the conferences contribute to the internationalization of education and address future challenges in engineering training. SRS participants acquire individual and collaborative learning and research experiences that they can later leverage in academia and the job market. In the mentor-mentee relationship, the supervisor guides the student's progress, considering their individual abilities and needs.

All of this is practically implemented across virtually every higher education institution in Hungary, deeply embedded in academic activities. The SRS (Student Research Societies) is not only part of the research activities between student and mentor instructor but also deeply integrated into higher education. Participation in the SRS movement (as supervisors, organizers, reviewers) is a factor in academic advancement, and achievements in the NCSRS influence institutional accreditation. While science is important at the NCSRS, what is even more crucial is conveying to students the joy of understanding the world a little bit better and showing them how to stay engaged in this "flow" for as long as possible. This is also an educational task within higher education, setting an example, and perhaps, it's the most beautiful aspect of it all. In their work titled "The XXXIII National Conference of Student Research Societies: SRS Remains the Main Base for Scholar Training," Cziráki

Szabina, Szabó István, and Szendrő Péter conclude with the following thought (Cziráki, Szabó, and Szendrő 2019):

"The enduring success of SRS is built on a slow evolution while respecting traditions and addressing an existing demand for students' acquisition of additional knowledge. Of course, committed educators and researchers are needed who tirelessly strive to assist young talents. Thanks to them, students gain broader knowledge and skills, thus better positioning themselves for research careers or employment in other sectors upon completion of their higher education studies. Therefore, the saying 'SRS is eternal!' is not just a slogan but a fact."

ABSTRACT

This research project assessed a strategy training's efficacy in enhancing problem-solving skills among 59 mechanical engineering students at Ruhr West University of Applied Sciences in statics (TM1). Aimed at reducing high failure rates and subsequent student demotivation, the training employed structured tasks based on the problem-solving model in statics (cf. Müller-Slany 2018) and incorporated extensive collaborative reflection processes. It not only encouraged students to apply this process to new problems but also emphasized the importance of independent task completion. In addition to the deliberate execution of schema steps, the intensive reflection on results and problem-solving steps for each task is a key factor in improving problem-solving competence.

An experimental design has shown the intervention group's significant learning gains, with a 15.1% increase in knowledge and 14.8% in application. Correlation,

[1] *Kristina Lampe*
Kristina.lampe@hs-ruhrwest.de

variance and regression analyses showed that understanding the problem-solving scheme and the university entrance qualification grade were crucial for applying the scheme effectively, with math grade, prior knowledge, and the strategy training itself as the strongest predictors of scheme understanding, demonstrating the training's direct and indirect effects on problem-solving skills in statics.

Qualitative interviews highlighted the intervention group's deeper reflection on the problem-solving process, leading to a 19.3% higher solution rate in problem-solving in statics and a methodical application of the problem-solving scheme. These findings confirm the significance of structured strategy training in improving statics problem-solving skills. Future research should explore the training's long-term effects and its applicability across various academic and practical scenarios.

1 INTRODUCTION

This intervention study examines the effectiveness of a strategy training to promote problem-solving skills among 59 mechanical engineering students at the Ruhr West University of Applied Sciences in the subject of Technical Mechanics, aiming to counteract the high failure rates that lead to demotivation and dropout (Heublein et al. 2017). Students often lack the ability to transfer acquired knowledge to unknown problems (Bennett, 2005). The developed strategy training aims to bridge this gap.

1.1 Starting Position

The high dropout rate in engineering degree programs is particularly pronounced in mechanical engineering, where disproportionately high dropout rates are often attributed to performance issues and motivational deficits encountered during foundational courses, such as technical mechanics (Musekamp et al. 2014). These findings highlight the challenges in TM education and underscore the need for targeted learning methods to support students

1.2 Theoretical Background

In statics, problems can be successfully solved using a structured problem-solving scheme that always includes the same steps (Beer et al. 2013, Müller-Slany 2018, Gross et al. 2011). Statics tasks are solved through mathematical-mechanical modeling by creating and applying (conceptual) models. These models are solved using mathematical principles, such as formulating and solving equations, to achieve a task result and subsequently reflecting on it (Trump and Borowski 2015).

This process begins with a precise problem definition and the creation of free-body diagrams, which provide a visual basis for the formulation of mathematical equations. These equations enable the description and calculation of forces at rest or motion state.

The entire process involves transforming a real problem into a physical model, followed by mathematical model formation, and finally solving and reflecting to confirm the validity of the results in the context of the given problem. Model formation and the associated careful selection of assumptions are often not actively taught in TM1 education. The focus is on solving tasks in which the physical model is already given (Müller-Slany 2018, Gross et al. 2011, Kautz, Brose and Hoffmann 2018, Direnga 2021).

Research shows that mathematical abilities and subject-specific knowledge are key predictors of modeling competence in mechanics (Brandenburger 2016, Dammann and Lang, 2019, Müller et al. 2018, Fleischer et al. 2019). The university entrance qualification grade and the modeling ability have also been demonstrated to significantly influence performance in TM (Dammann and Lang, 2019). Müller et al. (2018) specifically investigated the role of physical-mathematical modeling on academic success in physics, finding that both mathematical and physical prior knowledge, as well as discipline-specific mathematical modeling, enhance academic success. Direnga (2021) further demonstrated that explicit practice with tasks aimed at training conceptual understanding in TM leads to better exam grades in TM1.

Therefore, teaching should be aimed at promoting these modeling and reflection competences by using an explicit strategy training. With this approach, the learners can not only improve their subject knowledge but also develop a deeper understanding of mechanics, which is essential for future engineering challenges (Musekamp et al. 2014).

1.3 Current state of research

Expertise research indicates that beyond inherent abilities, intensive training and high motivation are required for expertise in any domain, including TM (Gruber and Mandl 1992, Friege 2001). This suggests a necessity for educational interventions that go beyond traditional knowledge transmission, focusing on the application of knowledge through structured problem-solving processes (Wirtz and Strohmer 2013, Renkl, 2010).

The empirical evidence is scarce on long-term strategies that enhance learners' problem-solving abilities in TM1, often relying on conservative teaching formats that limit active engagement with the content (Kautz, Brose and Hoffmann 2018). Innovative teaching approaches that include reflection tasks, coaching by instructors, and active demonstration of heuristics are recommended to foster problem-solving skills in TM1 (Direnga 2021, Schmidt et al. 2020, Woitkowski 2020, Schukajlow et al. 2015).

2 METHODOLOGY

2.1 Research Questions and Hypotheses

This study assesses the effect of strategy training on problem-solving skills and aims to identify crucial factors that contribute to success in solving problems of statics. The following research questions are to be investigated:

- RQ1: How does strategic training influence mechanical engineering students' problem-solving skills in TM1?
- RQ2: What key factors contribute to successful problem-solving in statics?

The primary objective is to assess the strategic training's direct impact on enhancing problem-solving skills, with a focus on understanding the underlying schema and its application to statics problems. To answer these research questions the following assumptions can be formulated.

- H1: Strategic training significantly improves students' problem-solving skills in TM1 by enhancing both knowledge and application of the problem-solving schema.
- H2: Prior knowledge in mechanics, mathematics competence, the university entrance qualification grade and the knowledge about the problem-solving schema are significant predictors of success in problem-solving within statics.

These hypotheses are derived from existing research findings (Brandenburger 2016, Dammann et Lang 2019, Direnga 2021, Müller et al. 2018 and Schukajlow et al. 2015).

2.2 Research Design

This study takes place at the Ruhr West University of Applied Sciences. Using a 2x1 experimental control group design, the intervention's effectiveness is assessed by comparing the experimental group, experiencing the intervention, with a control group following the standard curriculum. By using pre-post design measurements, the initial level of students' problem-solving competence in TM1 can be captured as a control variable. Additional control variables are entrance grades, prior knowledge and schema knowledge. Using the analysis of descriptive data along with normalized learning gains and additional correlational, variance, and regression analyses, the hypotheses will then be investigated. Additionally, a qualitative approach is supplemented to reinforce the quantitative findings through structured interviews that include think-aloud protocols during the problem-solving process of a statics task.

2.3 Description and implementation of the intervention

The participants in the study were students of the Mechanical Engineering program at Ruhr West University of Applied Sciences, who were randomly assigned to groups to ensure the study's validity. The experimental group consists of 30 participants, while the control group includes 29 participants. The participants had an average age of 21.6 years with a male predominance. Data was anonymized, with informed consent obtained through Moodle and seminars. Participation and completion of the tests were mandatory components of the evaluation portfolio for passing the module. The developed intervention uses visual assistances as advance organizers and a structured and continuously repeated provision of exercises and solutions according to the specific problem-solving scheme in statics. By using the combination of structured worked examples, discussions, coaching, and independent completion of tasks through the students with pre-structured exercises, they are guided to reflect on and apply the problem-solving process to new problem situations (Bennett 2005).

The strategy training took place weekly in 95-minute sessions, with mandatory participation within the module framework. Required materials included weekly provided exercise tasks and prepared PowerPoint slides with processed solutions.

These were visually separated according to the schema steps, as well as the given pre-structured exercise tasks, consistently presented for each task and worked example. Initially, students received a brief review of the lecture content on the blackboard, followed by the presentation of the adapted problem-solving process for the weekly changing topic. This was succeeded by the joint discussion and reflection on an example task with a structured solution. After this introduction, students were shown the pre-structured task and began working independently while the instructor acted as a coach. The instructor encouraged peer discussions and observed the students' problem-solving process, always referring to the given schema and providing guidance. Once the majority of the students had solved the task, their solution, including all problem-solving steps, was compared with the prepared PowerPoint slide, and the solution was collectively reflected upon.

2.4 Description and test instruments

To evaluate the efficacy of strategy training two test instruments were developed and piloted. The Performance Test (LT) provides 17 items, each requiring processing through the application of individual problem-solving steps for solving statics tasks. These are open-ended but pre-structured tasks according to the schema steps from the four common topic areas of statics (force systems, bearings, internal forces and trusses). The items are presented in a Moodle test, with students being allotted 90 minutes to complete. The free body diagram is created via drag-and-drop elements, while other inputs for equations are entered directly into the system. Each item is processed step-by-step in the system, ensuring the entire problem-solving process per item is captured in Moodle, allowing overall problem-solving competence to be assessed based on the application of problem-solving steps cumulatively per task.

The Schema Recognition Test (SET) aims to measure the knowledge and understanding of the specific problem-solving schema in statics through 29 multiple-choice and 3 matching questions, implemented in a Moodle test, too. The items query the declarative knowledge about the schema by describing each of the problem-solving steps and their respective disciplinary relevance, as well as analysing (partially) computed tasks through the indication of the next required step or the matching of steps in a non-hierarchically organized solution template. A completion time of 90 minutes is also allocated for this test. The piloting phase yielded results for the LT and the SET. For the LT in the summer semester of 2023, an item reliability of 0.70 and a person reliability of 0.72 were reported with Rasch analysis, with four items of misfit and 63.8% missing responses, explaining 62.8% of the variance across 26 items. In the winter semester of 2023/2024, the LT has shown improved reliability scores (for items of 0.93 and for persons of 0.84) with two items of misfit, 39.5% missing responses and a 65.6% variance explanation across 17 items. The SET from semester 2023, which consists of 32 items, had an item reliability of 0.77 and a person reliability of 0.71. The SET inthe winter semester 2023/2024 demonstrated an item-reliability of 0.90 and a person-reliability of 0.72 across 32 items.

3 RESULTS

3.1 Results through analyses to research hypotheses

The strategy training exhibited a strong effect on the schema knowledge in TM1, with the intervention group showing a significant higher learning gain of 15.1% in schema knowledge, thereby, the intervention demonstrates a large effect size (Cohen's $d = -0.995$) through the group comparison of the sum scores in the SET, explaining 20.5% of the variance in the test. In terms of application, the strategy training also resulted in significant group differences, with a learning gain of 14.8%, a significant high effect size of Cohen's $d = -0.813$ and 14.6% variance explained in LT.

By comparing the sum scores of the groups off the pre- and post-performance tests, it can be seen that the strategy training group initially performed worse on average in the pre-test but achieved significantly higher average scores in the post-test (46.8| 28.3). The results are shown in table 1:

Table 1 Results on effects of intervention (RQ1)

Differences in	t-Test[2]	Normalized Gain	ANOVA
Schema knowledge	$t = -3.81$ $d = -0.995$	$\Delta g = 0.151$	$\eta^2 = 0.205$
Schema application	$t = -3.12$ $d = -0.813$	$\Delta g = 0.148$	$\eta^2 = 0.146$

The following diagram in fig.1 also shows the impact of strategy training on the problem-solving competence in statics (LT). It illustrates the group differences in the sum scores of the pre- and post-performance tests.

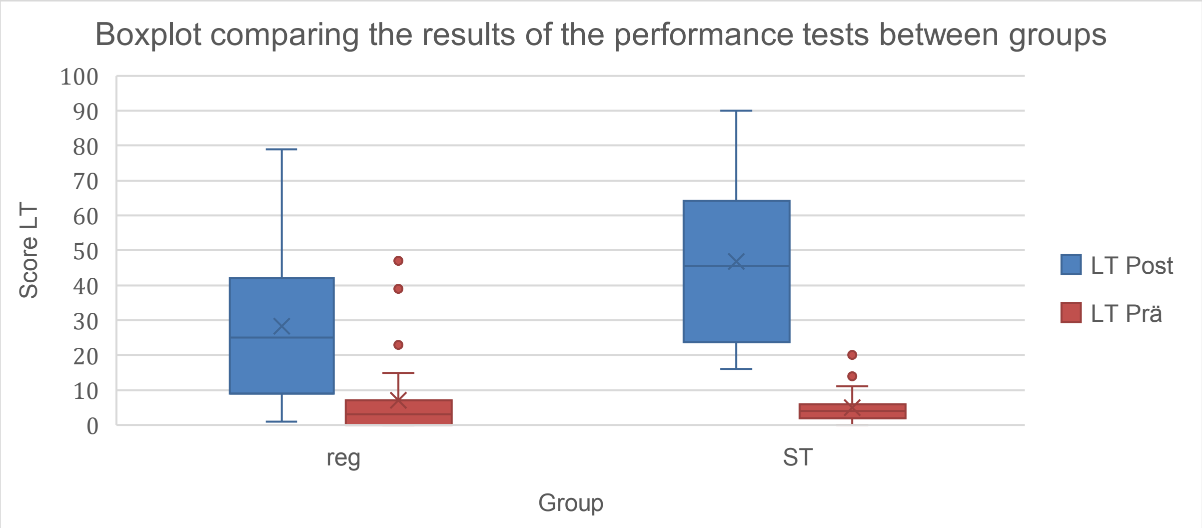

Fig. 1. Boxplots results on performance tests per group

The increased learning gain of the intervention group (ST) is also descriptively evident from the boxplots. The results from the interviews ($N = 10$) underline that the intervention group exhibits a deeper comprehension of the schema, which translates into more adept application in mechanical problem-solving tasks. This proficiency is due to their deliberate execution of the prescribed steps.

As a result of the schema's structure, there is a notably enhanced capacity for reflection — an integral, automatic component of the schema's final step. This is evidenced by a 19.3% improvement in the schema application success rate, assessed using a coding manual aligned with the schema steps, and a marked increase in reflective instances, with an average of 14 additional reflection moments at the given task. With these results hypothesis 1 can be confirmed completely.

To answer research question 2, the results of the final regression models and the relationship between schema knowledge and application are presented in figure 2.

[2] Here, the t-test is used to assess the difference in post-results of both tests between both groups.

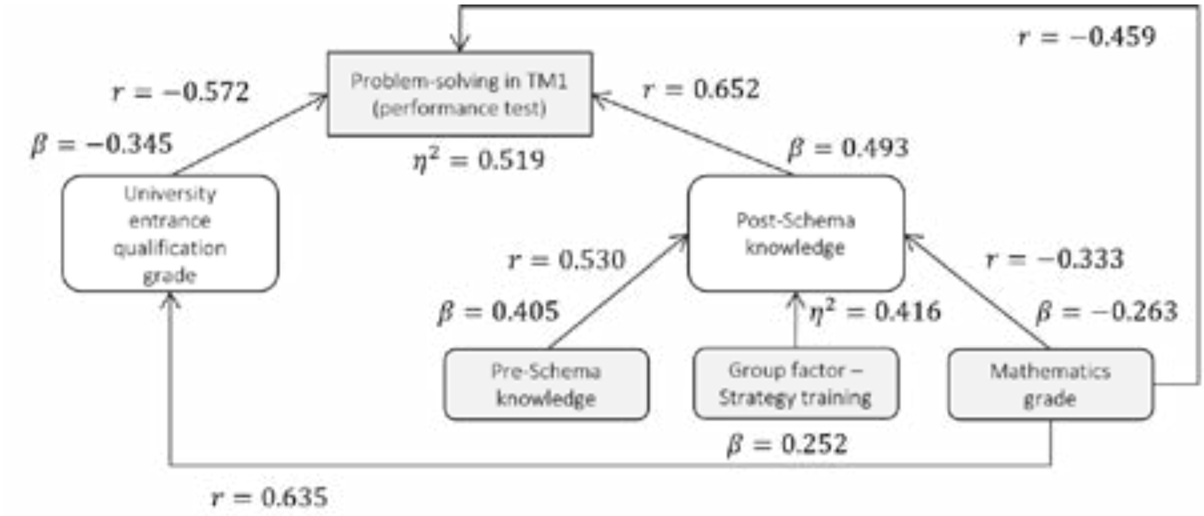

Fig. 2. Results on main predictors on problem-solving in statics (RQ2)

The final regression models for knowledge and performance tests connected through various control variables (prior knowledge TM1, school grades in mathematics, physics and university entrance qualification, schema knowledge and interest as well as self-concept) showcased the strength of post-schema knowledge (SET2) as the most influential factor ($\beta = 0.493$), with the highest correlation ($r = 0.652$) to the performance test. The other significant predictor is the university entrance qualification grade ($\beta = -0.345$ $r = -0.572$), both factors explain 51.9% of the variance in LT.

The other control variables do not represent significant predictors when these two dominant factors are included in the model. However, univariate ANOVAs have indicated that when considered individually, control variables such as prior knowledge, mathematics grade, the university entrance qualification grade, self-concept, the group (strategy training), and schema knowledge are significant influencers. Contrary to expectations, interest and physics grade show no significant nor weak influence on the performance test.

In the final regression model for the post-schema knowledge test, the math grade and pre-schema knowledge are significant predictors, with the group factor also exerting a notable influence. Specifically, post-schema knowledge, which is heavily affected by the group factor ($\beta = 0.252$), is a strong predictor of the performance test. This suggests that the group factor has a direct, significant effect on post-schema knowledge and an indirect effect on the performance test through schema knowledge, underlining the importance of targeted strategy training in improving problem-solving abilities. These results underscore the initial mentioned current state of research (Dammann et Lang 2019, Müller et al. 2018, Brandenburger 2016).

3.2 Discussion of results

In the discussion of results regarding the impact of strategy training on problem-solving competence in statics, it has been observed that strategy training positively influences the application of the problem-solving schema in TM1 (H1), revealing significant performance differences in the performance test between the two groups. The effect was mediated by the students' knowledge of the schema, which emerged as a stronger predictor. This indirect effect highlights the essential role of schema knowledge for effective problem-solving in TM1, thereby justifying the importance of strategy training that focuses on this schema. Students participating in strategy training showed enhanced abilities to reflect on their problem-solving process and outcomes. This suggests that strategy training fosters a deeper understanding. However, the anticipated influence of physics grades on problem-solving competence was not substantiated (H2), suggesting a disconnect between school-level physics and TM1's specific requirements. Conversely, mathematics competence proved to be a significant predictor (H2), emphasizing the foundational role of mathematical skills in engineering problem-solving. The study faced limitations, including a small sample size and the potential influence of the instructor on intervention outcomes. Additionally, the reliance on a single complex task for qualitative analysis might limit the generalizability of the qualitative findings.

4 SUMMARY AND ACKNOWLEDGEMENTS

An experimental control group design with a longitudinal approach implemented in a statics course of mechanical engineering ($N = 59$) showed, based on the results of the self-developed knowledge and performance tests, that the intervention group showed a significantly higher learning gain of 15.1% for the knowledge and 14.8% for the performance tests. The group comparison indicated a strong influence on the problem-solving competence of the students in the knowledge test (Cohen's $d = -0.995, \eta^2 = 0.205, p < 0.001$) and in the performance test (Cohen's $d = -0.813, \eta^2 = 0.146, p = 0.003$). The analysis identified understanding of the problem-solving scheme and the university entrance qualification grade as the main factors for the successful application of the scheme ($\eta^2 = 0.519, p < 0.001$). For scheme understanding, the math grade, prior knowledge, and the strategy training itself ($\eta^2 = 0.416, p < 0.001$) were the strongest predictors. These results demonstrate the direct influence of the intervention on knowledge and an indirect influence on the application of the scheme in problem-solving in TM1. Qualitative data from interviews emphasize that the intervention group reflected more intensively and profoundly on the results and the problem-solving process. The results show a 19.3% increased solution rate in problem-solving in TM1 for the intervention group, with an average increase of 14 units in the number of reflection moments. In addition to more intense reflection and the associated self-correction during the calculation process, a much stronger methodical application of the problem-solving scheme was evident. So, the study underscores the importance of structured strategy training for improving problem-solving skills in statics. Future research should focus on evaluating the long-term effects of the training and investigating the transferability of the approach to other academic and practical contexts. The findings suggest that deeper understanding and application of a problem-solving scheme through targeted educational interventions can be significantly improved, which has far-reaching implications for teaching methods in technical domains.

ABSTRACT

The field of Engineering Education Research (EER) in Europe has been steadily growing. Many publications have already focused on the growth of Engineering Education Research (EER) from different perspectives: journals published in, topics handled, methodologies applied, the globalisation of the field, etc. This paper presents an exploratory longitudinal bibliometric study of 54 European researchers in EER, focusing on three indicators: yearly publications, yearly citation, and current h-index. Based on a descriptive approach two conclusions are drawn. First, on average, EER researcher's average h-index is lower than that of researchers in other engineering disciplines. Second, researchers who begin their careers directly in EER demonstrate faster research output than those who start in other fields, while currently the latter group is still the largest. Future work will supplement this descriptive research with qualitative and quantitative investigations into factors influencing yearly research output, including group size, location, and historical context within the EER community.

1 CONTEXT

Throughout the last 30 years, the research focusing on Engineering Education is gradually growing in Europe (Bernhard 2018, Edström et al. 2018, Malmi et al. 2018, Lima and Mesquita 2018). The evolution of the European Journal of Engineering Education (EJEE) acts as a nice illustration. The journal, founded in 1976, originally focused on teachers sharing their experiences (de Graaff 2017). Thanks to the growth of the Engineering Education Research (EER) community, the number of research papers in EJEE has also systematically grown (Malmi et al. 2018). The success of EJEE was acknowledged by the impact factor it received in 2022.

In the US, the development of the EER field already started in the beginning of the 20th century (Williams et al. 2023). The Journal of Engineering Education (JEE), founded in 1893, culminated in a fully developed citation pattern in recent years (Wankat, Williams and Neto 2014). The tradition of EER in Australia is comparable to the one of Europe: it started around 1980, leading to the first publication in the Australasian Journal of Engineering Education in 1991 (Godfrey and Hadgraft 2009). In Africa few institutions recognise EER as valid research within engineering, but efforts are ongoing to strengthen the research field, including the creation of the Engineering Education Research Network in Africa in 2020 (Matemba et al. 2023).

Within Europe, Sorby et al. (2014) describe the history of EER in Portugal and Ireland. Wint et al. (2022) mapped the EER landscape in Ireland and the UK, and Wint & Nyamapfene (2023) focused more explicitly on the development of EER in UK. Edström et al. (2018) investigated the emergence of an EER-community in the Nordic countries. Very recently, Valentine and Williams (2024) compared the publishing behaviour in different countries in Europe in the time period 2019-2020, but without a longitudinal lens applied.

In this paper, instead of focusing on the EER-topics researched (Borrego 2007, Borrego and Bernhard 2011), the EER-methods used (Malmi et al. 2018), who's working in the field (Williams, Neto and Wankat 2014, Edström et al. 2018), the ratio of educational to non-educational publications (Valentine and Williams 2024), the evolution of the journals (Wankat, Williams and Neto 2014), or the globalisation of the field (Williams, Wankat and Neto 2018), we focus on **how European EER-researchers' output evolves over their career**. The long-term goal is to have a better insight (1) into the careers of EER researchers because this will enable researchers and evaluators to make better estimates of their own and others' careers, instead of just comparing with other engineering disciplines; and (2) into the dimensions that influence careers, so that targeted decisions can be made by researchers. We present and discuss here the results of a first exploratory study where we analysed EER researchers' profiles and their research output. Two research questions (RQ) are answered:

RQ1. What characterizes the European EER-researchers?
RQ2. How does the research output of an EER-researcher evolve in time?

2 METHODOLOGY

2.1 Methodologies used in similar research

Most research aiming to describe the characteristics of the field of research of EER in Europe uses quantitative research methodologies, such as bibliometric analyses based on citation analysis, reference discipline, author geographical location, author affiliation, and author disciplinary field data (Williams, Neto and Wankat 2014, Wankat, Williams and Neto 2014, Wankat, Williams and Neto 2014, Malmi et al. 2018, Williams, Wankat and Neto 2018, Lima and Mesquita 2018). Wint and Nyamapfene (2022) conducted qualitative research, more specifically semi structured interviews. Several authors used mixed methods, such as document analysis of publications supplemented with faculty interviews or narratives (Borrego 2007, Sorby et al. 2014, Edström et al. 2018, Wint et al. 2022). Longitudinal studies are however missing and are therefore the basis of our descriptive analysis implemented in this study.

2.2 Selection of European EER researchers

The goal was to compose a list of EER researchers who:

- published in EER journals (≥1 paper in an EER journal);
- are currently affiliated with a European higher education institute;
- are still active in EER (≥ 1 EER journal of conference publication after 2020).

EER researchers were selected by starting from a list of all members of the SEFI Special Interest Groups and the senior participants at the SEFI Doctoral Symposium (from 2018 to 2024), and then snowballing for additional names. The first criterion focuses on EER journals, which are aiming to improve engineering education through research methodologies. According to Malmi et al. (2018, 171) “EER can be characterized as a field which seeks to (1) build deep understanding of student learning in engineering sciences, (2) identify theoretical underpinnings for innovations in engineering education, and (3) evaluate these innovations to build empirical evidence and better understanding of their impact on students’ learning processes and learning outcomes.” The affiliation was checked through the institute's websites and the researcher's LinkedIn pages. The publications were searched through Scopus, as elaborated in the next section. 54 researchers were finally included in this study.

2.3 EER-researcher profiles and bibliometric research

This exploratory study is based on the EER-researcher profiles and a bibliometric study with Scopus as the research database. For each researcher the following indicators were retrieved:

(i1) country, defined as the country of the European higher education institute the researcher is affiliated to;
(i2) number of yearly citations at the beginning of the EER career and after every 5^{th} year after the start, until and including 2023;
(i3) number of yearly publications at the beginning of the EER career and after every 5^{th} year after the start, until and including 2023;
(i4) h-index on March 29^{th} 2024;

(i5) whether the researcher started their research career in EER (“no transition”) or in another research field (“transition”);

For (i2) and (i3) the beginning of the EER-career of the researcher was defined as the year of the first EER-publication (in a journal or in conference proceedings).

2.4 Analysis

To answer RQ1, descriptive statistics are provided regarding the countries in which EER researchers are active, the length of their EER-careers, their current h-indices, and most cited papers in EER and outside EER (for transition-researchers).

RQ2 is answered by tracking the number of yearly citations and publications of the EER-researchers throughout their EER-career. A linear regression is used to identify a trend for the number of citations and publications as a function of the number of active EER-years. The group of “non-transition” and “transition” EER-researchers is compared and a cross-sectional study of the h-indices is done.

3 RESULTS

The following two sections present the results related to the two research questions.

3.1 What characterizes the European EER-researchers? (RQ1)

The 54 researchers belong to 12 different countries within Europe (Fig. 1). The UK, The Netherlands, Sweden, and Denmark are the countries with the highest number of engineering education researchers associated to their national institutes. Two thirds of the researchers (N=37) have made a transition from another field of research to EER during their academic career, while the remaining one third started their research career directly in EER (N=17). In Sweden, UK, the Netherlands, Portugal, and Norway one can find the largest percentage of “transitioners” among the EER researchers. In Denmark and Switzerland, the opposite can be observed.

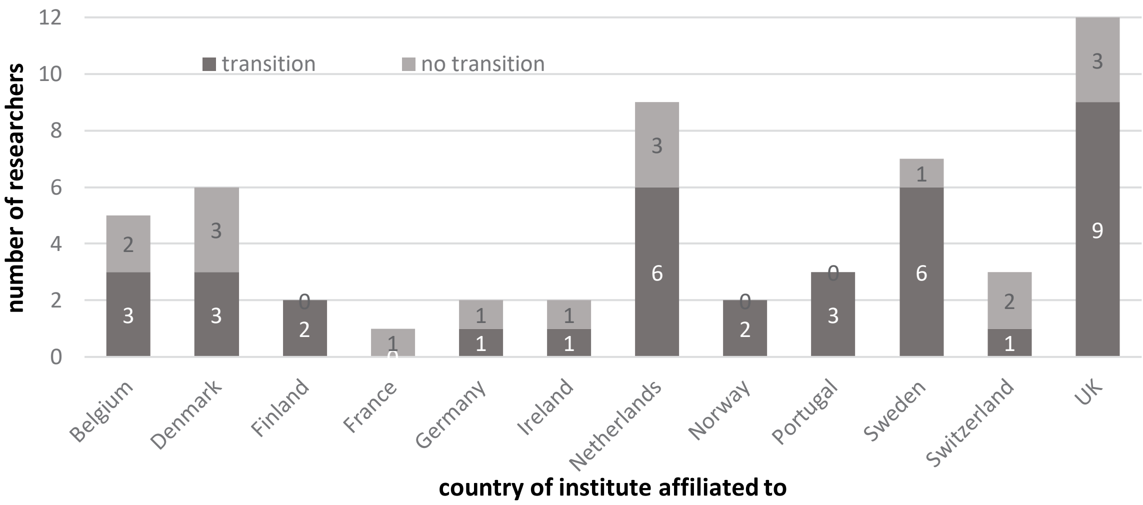

Fig. 1. Number of EER-researchers per country. The different shades indicate whether the number of EER-researchers started their career in another research area (dark: “transition”) or directly in EER (light: “no transition”).

Fig. 2 shows that most researchers have between 5 and 10 years of experience in EER. Among these researchers almost 60% are ‘non-transitioners’. In all the other categories the researcher who made the transition from another research area clearly outnumber the researchers that started their career in EER.

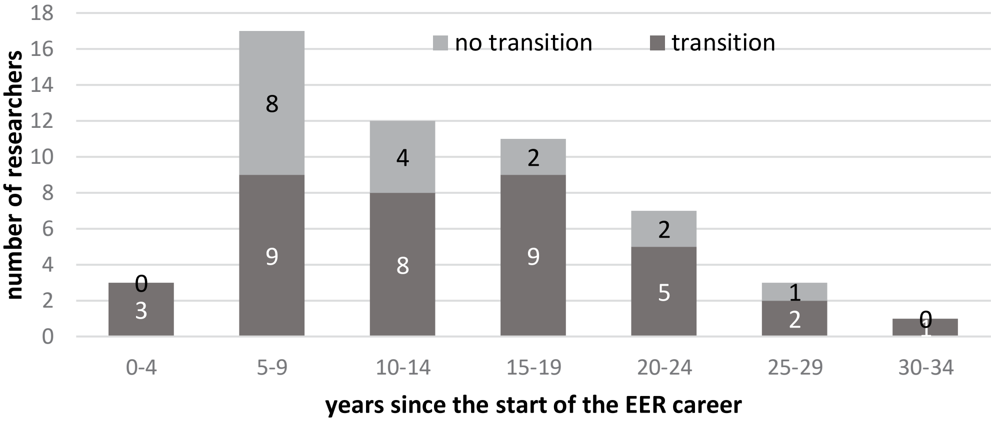

Fig. 2. Number of EER-researchers as a function of the current duration of their EER career*.* *The* different shades *indicate whether the number of EER-researchers started their career in another research area (*dark*: "transition") or directly in EER (*light*: "no transition").*

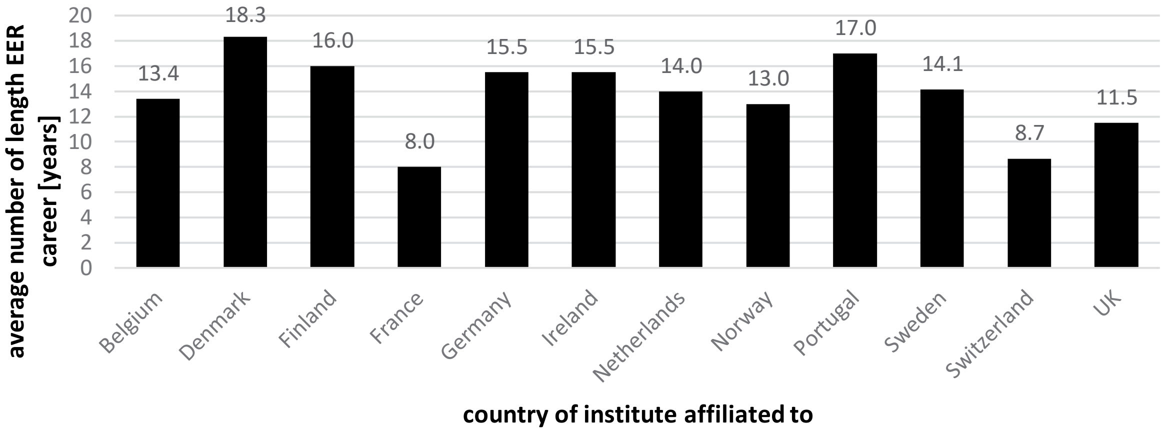

Fig. 3. Average number of years of length of EER career in years per country. Researchers are linked to the country of the institute they are affiliated to.

The EER researchers in Denmark and Portugal are on average the most experienced, as shown in Fig. 3.

The average h-index on March 29th 2024 of the 54 EER-researchers considered in this paper is 9.9. Researchers who started their scientific career in EER have on average lower average h-index ("no transition", average h-index of 8.2) compared to the researchers who started their research career in another research field ("transition", average h-index of 10.8).

The three highest cited EER-publications of the 54 authors respectively count 647, 629, and 295 citations and are about CDIO or/and PBL. For the authors who made the transition, the difference between their highest cited publication in EER and the highest cited publication outside EER can be computed and averaged across all researchers involved. The result is minus 87, indicating that researchers receive a higher number of citations for publications originating from their research career before entering EER.

3.2 How does the research output of an EER-researcher evolve over time? (RQ2)

To answer this research question, we counted the number of yearly publications and citations as researchers progressed throughout their EER career. Fig. 4 shows the number of researchers included in the analysis at the different time slots shown in Figures 5 and 6, associated with the different moments throughout their EER career.

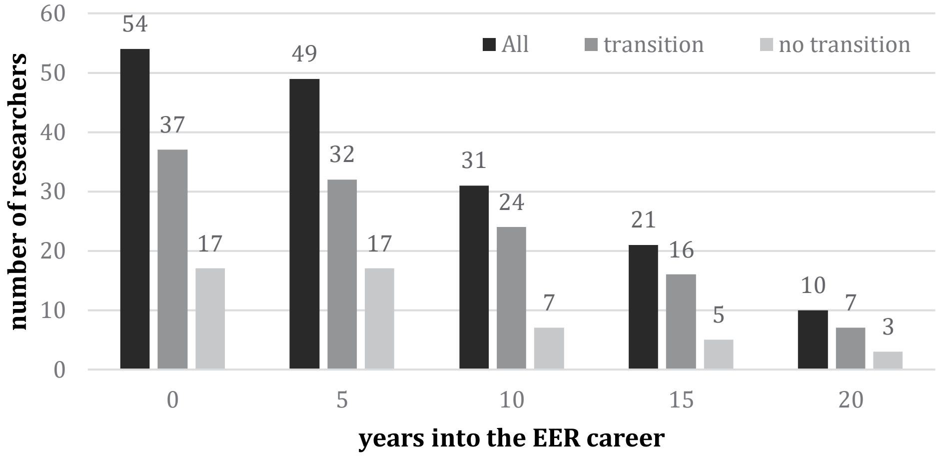

Fig. 4. Number of researchers included in this analysis, at different moments throughout their EER career.

Fig. 5 and Fig. 6 show the evolution of the research output over time using the number of yearly publications and citations, respectively. The time is defined as the number of years the researchers were into their EER career (for each researcher, year zero corresponds to the year of the publication of the first EER-paper). The research output, both in terms of number of papers and in number of citations, on average increases over time for the two types of researchers (transition and no transition). This is showcased in Table 1 by the positive slopes of the regression lines for the six graphs in Fig. 5 and Fig. 6.

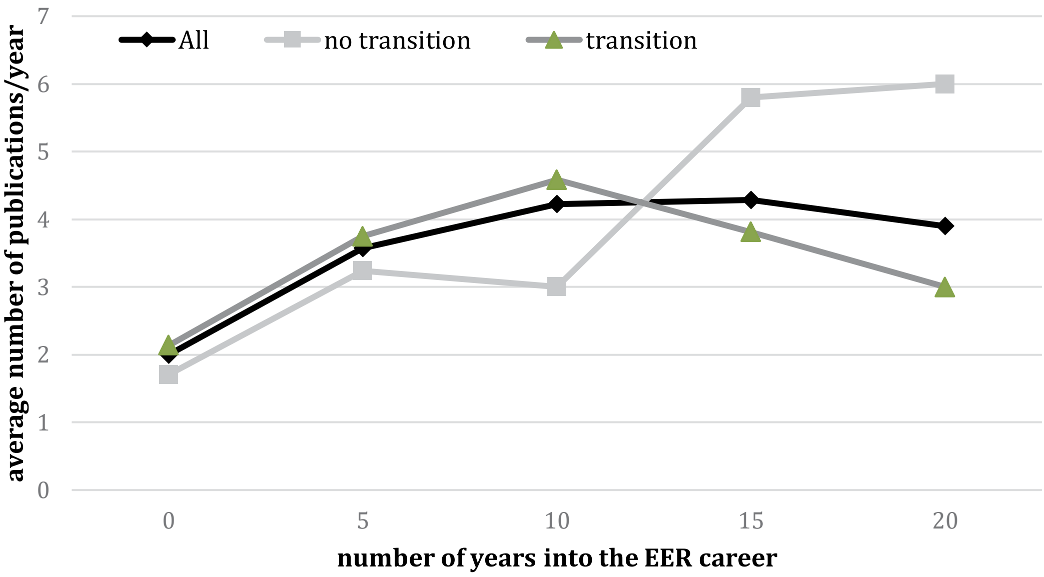

Fig. 5. Average number of publications/year as function of the number of years in the researcher's EER career.

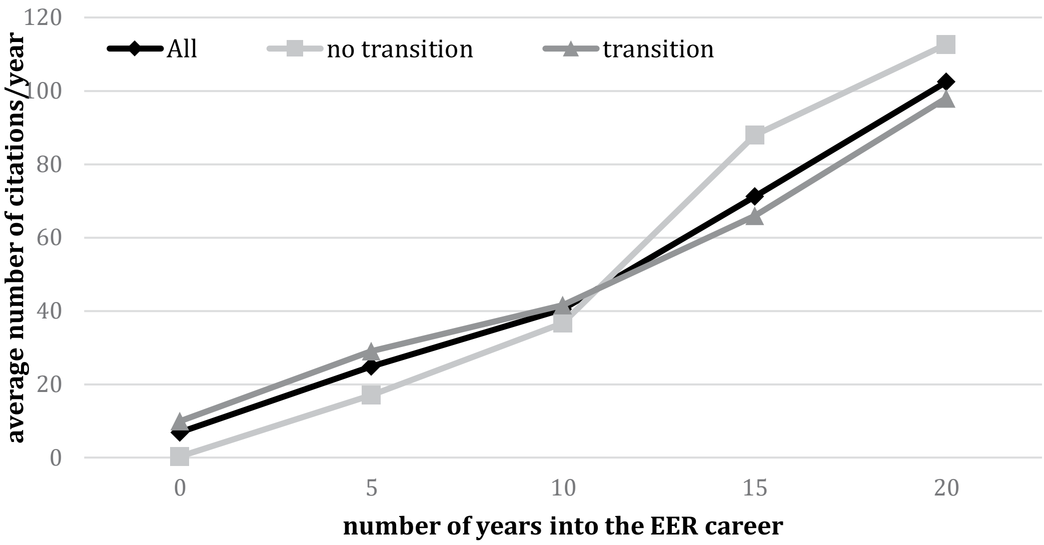

Fig. 6. Average number of citations/year as function of the number of years in the researcher's EER career.

As expected, the current h-index of researchers grows together with the duration of their EER career, as shown in Fig. 7.

Table 1: The slopes of the regression lines for the data in Fig. 5 and Fig. 6.

	all researchers (N=54)	researchers who started in EER (N=17)	researchers who made the transition (N=37)
number of publications/year	0.090	0.22	0.036
number of citations/year	4.7	5.9	4.3

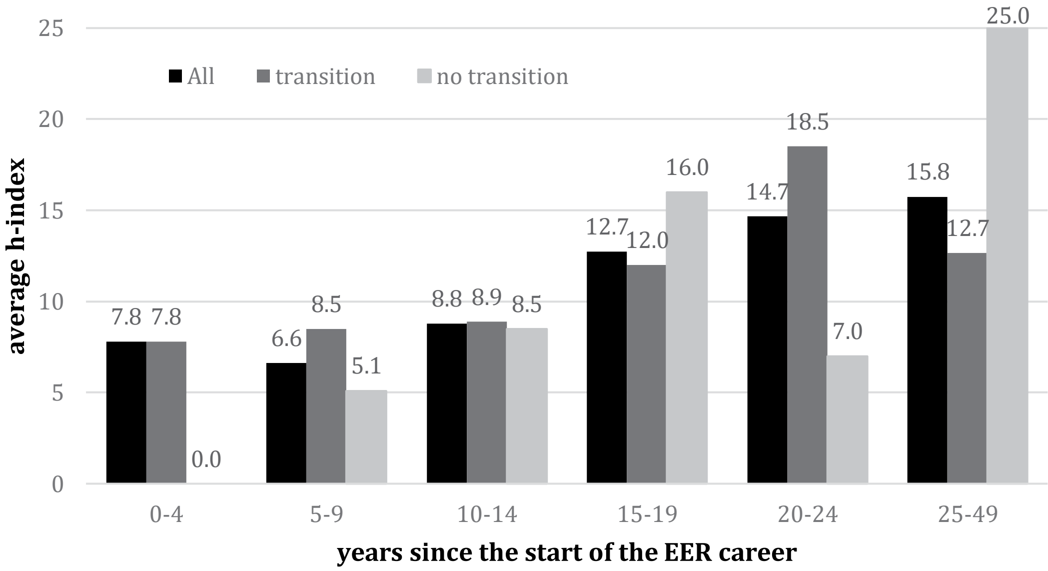

Fig. 7. Cross-sectional study of the average current h-index as a function of the length of the EER-career.

4 DISCUSSION

The 54 researchers included in this research are strictly selected from the SEFI community. As such, a well-defined and diverse subset of the larger EER-research community in Europe is obtained. The precise definition of an EER researcher remains an open topic, making it a valuable area for future investigation. In the paper of Wint and Nyamaphfene (2022), 122 UK EER-authors and 17 Ireland EER-researchers are identified. Edstrom et al. (2018) included in their study a pool of 223 EER-authors: 60 from Danish institutes, 88 from Finland, 7 from Norway, and 69 from Sweden. Valentine and Williams (2024) have 895 unique authors. This study uses a strict definition of EER researchers with close connection to SEFI, resulting in a smaller but more homogeneous research pool.

The 54 included researchers belong to countries where EER started to develop at different moments in different contexts, resulting in research groups of different sizes and with a mix of researchers directly starting their research career in EER or transitioning into EER from other research fields (Fig. 1) and length of their EER career (Fig. 3). Denmark for example counts relatively more experienced researchers and half of them started their career in EER. As can be seen in Table 1, researchers who start directly in EER on average proceed faster in their research output compared to researchers transitioning into EER from other research fields. This is a very promising conclusion for future researchers, and also confirmed by Gardner and Willey (2018) and Borrego (2007) who identified some hurdles experienced by non-EER-researchers who made the transition to EER. Dart, Trad and Blackmore (2021) confirm that many researchers transition to EER after completing technical engineering qualifications and they also identified some inhibitors in the transition.

The increase of the yearly publications and citations and the h-index over time (Fig. 7) is not surprising when considering active researchers (Lima and Mequita 2018, Györffy et al. 2022). Regarding the evolution of the number of publications over the career, Gingras et al. (2008) found a turning point at the age of 40 for the average annual number of papers in the top 10% cited journals. They attribute this decrease after 40 to the increase of the number of less experienced members in the research group. Most EER-research groups are however not yet large enough to see this effect. What we do see in the data, is the effect of previous research in another research field, apparent for instance in the regression model's non-zero yearly citation count in year zero (Fig. 6). Remark that the considerable higher yearly citation of transitioning EER researchers only remains present at the beginning of the EER-career (Fig. 6). A possible explanation is the field-specific publication and citation habits (Stapleton 2023). Humanities and social sciences have the least age-related growth of the independent yearly citation (Györffy et al. 2022).

The irregularities in Fig. 5 and Fig. 6 are caused by the relatively small sample and by consequence by the output of individual researchers. Williams et al. (2014) highlighted the potential of longitudinal research, but also mentioned the need of larger samples.

This descriptive research can be supplemented with qualitative and quantitative research in order to investigate the influence on the yearly research output of additional tasks and responsibilities within the institution; the institutional support for this type of research; the position of the researcher as an innovator or early adopter in the institution; the background of the researcher (discipline, PhD in EER, ...); etc.

ABSTRACT

Climate change is a complex and wicked problem, both its problem definition as its proposed solutions are controversial and relate to many different interlinked socio-political domains. However, this complexity should not lead to inertia, the crisis is urgent and we need to act. Educators are thus tasked with maintaining a challenging balance between teaching technical knowledge while also fostering a sense of ethical responsibility in students. They need to do this for a problem on which the ethical approaches are up for debate. This paper reflects critically on the notion of Phronesis (practical wisdom) as it is introduced as a pedagogical approach for ethics in higher education on the moral dilemmas of climate change. Phronesis is not in itself a theory on how to act, but rather it provides the domains necessary for moral development in students for the ethical reflection and practices regarding the complexities of the modern world. Education for responsible engineers should teach students to (1) recognize morally salient elements of the world; (2) recognize how these are integrated (3) integrate these in one's moral identity and lastly (4) be affectively invested in this moral identity. This paper argues that Phronesis can work as a didactical tool for systematically and purposefully engineering moral education, while also showing its limits compared to more classical approaches of rationalistic models of teaching ethics. In doing so, it tries to bridge a gap between the content and focus of moral education in climate change. (234 words)

Introduction

Climate change is a problem emblematic of wicked problems in the Anthropocene: greatly urgent, complex and unprecedented (Tromp, 2018; Incropera, 2016). This dire nature of climate change requires innovate ways of knowledge production and transfer. In other words, higher education institutes (universities and colleges) play a fundamentally important part in the way we think about, and act on, climate change. Mitigation of, and adaptation to, climate change requires highly specific technical knowledge, but, as is inherent to wicked problems, also a knowledge of society, humanity and ethics. The transfer of technical knowledge is a strong element in engineering education, but there is a division of labor where normative reflection on novel technologies is not traditionally a central part part of engineering curricula (i.e. Chech, 2013). However, the integration of the normative with the technical is fundamental for tacking climate change issues. As Reimers (2021) puts it:

The motivation to invent more sustainable ways of life requires more than an understanding of the science of climate change, the capacity to design technological innovations, or an ethical framework that help us aspire to live in more inclusive and sustainable communities, it requires an understanding of social systems and the development of ethical reasoning that can help us integrate critical thinking about the current impact of climate change, our moral imagination, the personal motivation to act and our competency to act in effective ways. (p. 4).

However, currently there is no clear framework for integrating ethics into climate change curricula. There is not a clear conceptual framework for distinguishing the technical and the normative, or even if a demarcation between technical science and values is even tangible (Douglas, 2009).

Furthermore, ethics in engineering education might be superfluous when it is only a form of abstract theory, as the point of ethical reasoning is to make more responsible decisions (act differently) in the world. As Midgley (2000) puts it: “gaining knowledge is not just collecting and storing facts, but becoming trained in handling them” (p.54). So, on the one hand there is the theoretical dimension of understanding the normative dilemmas of climate change, but on the other hand the university needs to provide students personal tools for the internalization of normative reasoning.

This approach is also framed as a requirement for a combination of academic (technical) knowledge with Phronesis (Tassone et. al., 2016). So, there is a conceptual ethical goal of mapping out the normative topoi in climate change on the one hand, and the effective didactical and pedagogical approaches of integrating ethics in higher engineering education on the other.

This article aims to provide a theoretical background for the development and feasibility of Phronesis in climate change education. It aims to map the normative dimensions of climate change as a reference point for the meaning of Phronesis in the age of the Anthropocene. Specific pedagogical practices may be drawn from that, but the translation of climate change normativity to specific educational practices is a different level of analysis. Thus the main research question of this article is: what should be the normative and pedagogical focus of higher education curricula regarding climate change? This article will start with a conceptual description of Phronesis, secondly it will integrate this concept in the normative problems of climate change. Lastly, this will culminate in normative pedagogical guidelines that may ground pedagogical strategies.

Education and Phronesis

The concept of Phronesis is rooted strongly in virtue-ethical theory. Rather than focusing on deductive ethics, starting from a general ethical rule and applying that rule to a specific situation, the concept signifies an inner mental state of virtue regarding a practical context. To be more specific, Phronesis refers to a form of practical knowledge (Kakkori & Huttunen, 2007, p. 20). For Aristotle, the cultivation of Phronesis is a necessary condition for an effective praxis of other virtues. In this regard, Phronesis is qualitatively different from the other virtues, as a person might be virtuous in one sphere of life, and not so much in others, but without an attitude of Phronesis a virtuous life is unreachable (Dunne, 2005, p. 52). The virtue-ethicist character of practical knowledge does not necessarily lead to a meta-ethical stance of moral particularism. Phronesis is categorized by Aristotle as a form of intelligence, but is eccentric as it is a prerequisite for ethical life (or conversely, living an ethical life is a signifier for the mastering of Phronesis) (ibid.). As a form of intelligence, certain ethical principles may guide ones' attitude in moral contemplation regarding a specific situation. However, the meaning and implementation of those principles is dependent on the particularities of that given situation.

In this sense, practical knowledge or virtues rationality is the anti-thesis to the instrumental rationality that is dominant in neo-liberal discourse. Its focus on the affective, narrative, and contextual nature of the human condition and its focus on practice, rather than providing some ultimate ontological conceptualization of 'the good', makes it a rather descriptive concept of the psychological attributes and competences of a virtues person, which has a plurality of normative dimensions as its starting point (Duvenage, 2015, p. 80). This 'mediating character' (between abstract meta-ethical principles and practical behavior) makes it applicable for educational purposes, as the basis for a pedagogical theory of moral development. Furthermore, it is specifically relevant for engineering education, as implementing abstract ethical principles in concrete, hands-on technology is one of the main challenges in engineering (Floridi, 2019).

The way in which Phronesis might have pedagogical usefulness is that it is a possible bridge between moral theory and moral practice. The simple fact that a person holds moral belief A, or is familiar with an ethical theory prescribing A, does not automatically mean that their actions will align with this belief. On the contrary, there is even some evidence that moral behavior is not that strongly related to moral believe at all (i.e. Haidt, 2001). Simply learning about moral theory, therefore, might not be a very effective way of educating ethics. Moral theory runs the risk of becoming a tool for moral confabulation or rationalization, rather than a tool for moral decision-making (Floridi, 2019). Action A is justified by Moral Theory A, retroactively in this model. This is opposite of the goal of moral education where Moral Theory A grounds the motivation behind Action A.

The great benefit of a moral pedagogy of Phronesis, therefore, is that it opens up pedagogical room for the cultivation of moral identity and emotion. This line of reasoning is well explained by Darnell et al. (2019) who build on the Aristotelian notion of Phronesis and sub-divide it into four different cognitive and affective functions, here summarized as:

Table 1: four dimensions of Phronesis

Constitutive Function	An ability to perceive the morally salient elements of a given situation and what is necessary to respond appropriately.
Integrative Function	Integrating different components of the good life to act wisely when ethically salient values are in conflict.
Blueprint	An integration of a conception of the good in one's moral identity.
Emotional Regulation	To be affectively invested in, and in line with, one's ethical convictions (not to be confused with 'limiting one's emotions)

Although Darnell et al. relate their psychological model of moral decision-making to moral pedagogy, it is not their main concern. However, it is indictive of how theoretical insight from moral psychology might inform effective moral education. This approach of Phronesis has a strong focus on moral affect, which is in contrast with the influential classical Kohlbergian model of moral development, which is focused more strongly on the cognitive understanding of moral principles. A discussion on the stages of moral development in the Kohlbergian paradigm is beyond the focus of this paper. The point is that this influential paradigm takes a classical rationalist approach to moral theorizing, which is criticized widely to fall short when it comes to moral practices (i.e. Carpendale, 2000). However, as Darnell et al. (2019) note, neo-Kohlbergians put more emphasis on the role of affect and moral identity in moral pedagogy. They conclude that the neo-Kohlbergian paradigm is not fundamentally incommensurable with their Aristotelian four-component operationalization of Phronesis.

So, the concept of Phronesis is useful when it comes to the translation of moral convictions into practice. Teaching ethics is not a merely cognitive endeavor, students have to be emotionally engaged with the material, and learn ethical principles not as external to themselves (for instance as part of a given ethical theory). Rather, teaching ethics is, at least partly, like teaching a competence that is more than the ability to regurgitate abstract ethical theory. However, Phronesis as practical wisdom has only been discussed on the conceptual level. Especially if we accept that moral competency involves one's attitudes and actions towards their surroundings, the concept of Phronesis should be applied to a real-life normative context. The next section will therefore discuss the normative dimensions of climate change. This will not only provide a context for a discussion on Phronesis, but also provide a framework for the content of climate change ethics education.

Ethics in Climate Change

There is no one ethics of climate change, as climate change is not one thing. It is a set of processes that are interlinked and over-determined. Climate Change has no one single moral object or subject. The moral complexity of climate change goes even deeper than a multitude of moral subjects with conflicting interests: there is strong disagreement on what even the moral subjects are. Often, normative discourse on climate change discusses future generations, but as future generations do not exist, per definition, it is not clear why we should have moral obligations towards them (Beyleveld, Düwell & Spahn, 2015). Climate Change drives horrendous extinction-rates, but species themselves are just biological categories, it is not clear why and if a collection of animals should be morally considered, especially when this conflicts with the interests of individual animals (Marris, 2020). All of this is not to say that future generations or species should not be morally considered, it is just to say that any discussion of climate change will sink into ethical and ontological quicksand when focused on one single aspect of its normative consequences.

Considering this complexity the discussion of the ethics of climate change will be extremely course-grained and, therefore, limited. It is not meant as an in-depth discussion of what humanities way forward in our geological predicament ought to be. The point of the discussion is to provide an overview of the basic moral approaches that arise in the face of the Anthropocene that can be the starting point of pedagogical approaches to climate change, especially when it comes to the cultivation of Phronesis as discussed above.

The starting point of the discussion is Miller and Eggleston's (2020) overview study *Moral Theory and Climate Change*. Instead of taking one aspect of climate change as a starting point, their study focuses on dominant ethical-theoretical frameworks and their applicability to climate change. This 'theory-first' approach fits the aim of this article well, as it provides a range of guiding principles, or normative foci, to consider the wide range of ethical dilemmas that arise on the warming planet. Studies that take a more 'bottom-up' approach are very suitable for fleshing out the moral conflicts within any given particular situation, but do not provide an overview of the different ethical principles that might guide our moral reasoning a-priori. Therefore, the top-down/theory-first approach fits better with the aim of providing the normative theoretical background in climate change ethics education.

The most salient distinction in the ethics of climate change on the theoretical level is the conceptual distinction between the personal and the systemic level. Almost all moral theories admit that the global and political/economic nature of climate change asks for a multi-leveled approach: combining both personal and political ethics. Following this multi-leveled approach, table 2 (appendix) will provide an overview of the different normative frameworks regarding climate change, this will be used to reflect on the meaning, feasibility and applicability of Phronesis in the teaching of climate change ethics.

Almost all scholars recognize the difficulty of applying ethics to a problem that has a) grave moral consequences and b) is outside the sphere of influence of any single actor. This does not mean that climate change is a classical collective action problem. I.e., climate change is different from providing a moral justification for paying for one's train ticket -even though deflecting from paying has no measurable effects on the world.

Gardinger (2006) explains well how climate change is different from a standard collective action problem. An extensive discussion on moral game theory is far beyond the scope of this paper, but the way in which climate change is a rather unique moral problem, or a "perfect moral storm" is in that is involves 1) a dispersion of causes and effects 2) a fragmentation of agency and 3) institutional inadequacy. In other words: to know what should be done, one should at least know what can be done, but the causal pathways driving climate change are very dispersed. Furthermore, as discussed, the moral scope is very opaque. And lastly, there are no institutional agents to restrict deflecting behavior adequately. This leaves a difficult moral-theoretical lacune, as focusing on one single aspect of climate change can actually be a way of deflecting, as it can be a way of avoiding the more costly necessities of mitigating climate change. Behaving ethically can be a way to behave unethically in climate change.

Being a Phronemos in the Anthropocene

Following the focus on policy-changes (rather than individual ethics) dominant in the (meta-) ethical paradigms, the conceptualization of phronesis as presented in the first part of this paper might not seem the right approach to moral education at first-glance. Or, it might have limited applicability, for instance in education for students in politics, but not as a more engineering-oriented approach to teaching climate-change ethics. Following table 2, most ethical theories leave little room for individual agency in the context of climate change, apart from -unsurprisingly- the virtue-ethicist approach. The great downside of the virtue-ethicist approach, however, is that it provides no framework on which virtues are central to the moral problem of climate change, or what it actually means in practice to live these virtues.

However, following Gardingers concerns of moral theorizing in climate change, Phronesis as a didactical approach might still be rather useful. The moral lacune of climate change asks for a re-orientation between the different moral schema's that philosophical theory has generated. This might be analogous to Kuhn's ideas of paradigm shifts. After a period of 'normal ethics' focused on puzzle-solving (how does theory x apply to moral problem z), we slowly get in a phase of 'crisis ethics' (with the anomaly of climate change). This means that in developing new technologies, we might have to think differently about their function. More fundamentally, engineering education is also about re-considering the role of oneself as an engineer. Moving beyond notions of instrumental rationality as explained in the theoretical framework, towards a reflective agent following virtues of environmental sustainability (Jordan & Kristjánsson, 2013)

Constitutive function

Different ethical theories may provide normative foci for interpreting the problem of climate change, in other words, have a constitutive function (as defined in table 1), rather than being treated as ethical-epistemic starting points that are incommensurable with each other. In more educational terms, this means that on a cognitive level, inquiry-based learning might appropriate when it comes to climate change ethics. Of course, recognizing salient values is extremely difficult and prone to biases. Here, ethical theory can, again, serve as a scaffolding-method of guiding the inquiry, rather than as a starting point of moral education. It is important to note that 'passive-learning', that is just learning the main concepts of a certain ethical theory has little effectiveness in higher education, especially engineering education (Newberry, 2004). A more pedagogically sound approach to teaching ethical theory is case-based learning. That is, teaching ethical theory in the way they are relevant in applied cases (Haws, 2013). However, as both these authors note, case-study based learning is not in itself sufficient for engineering education, as it does not necessarily foster sense of emotional engagement with the content. In other words, and to illuminate more the link with climate change: theory focused pedagogy is a necessary but insufficient method for cultivating sustainable virtues in engineering education students.

Integrative function

Regarding the problem of fragmentation of agency, educational practices can focus specifically on the level of analysis and, in effect, short-comings of any particular moral theory or normative focus. The rationalistic focus of Kantianism, for example, might be critiqued for being very anthropocentric[2] and individualistic. Pedagogically, methods like participatory simulations can be a way to get students familiar with the conflicts of values between different theories, and the levels of analysis that they play out on (Jacobson & Wilensky, 2006). To stay with the example of Kantian anthropocentrism and methodological individualism: a participatory simulation can involve an institutional actor, forcing students to re-think state-responsibility and animal representation while also getting familiar with Kantian theory cognitively. This is thus a different pedagogical method than case-based learning, as presented above. This approach fits more with the pedagogical goal of intellectual engagement than emotional engagement (Newberry, 2004). However, it is important pedagogically for engineering students to understand that ethics is more than the application of rules (as might be the risk with case-based learning only). Doing ethical heuristics, as is the case with participatory simulation, fosters a sense of understanding of the plurality of ethical approaches. However, as Haws (2013) notes, it might leave the impression that ethics is mainly about argument rather than acting. Further, some ethical theories might be easier to implement this way than others.

Blueprint

On the more affect-side of moral education, integrating values in one's moral identity is an important part in teaching ethics on a general level (see also Newberry, 2014). However, when it comes to climate change ethics, it is not clear what a moral identity might constitute in everyday life. Here, the virtue-ethics perspective of table 2 is obviously very relevant (a blueprint of the good life might entail a concern for all sentient beings, for instance), but again, there is no clear framework for which values are central in climate change ethics, especially in the very constructivist virtue-ethicist tradition. However, following the constitutive and integration functions that treats moral theory as foci, role-modeling can be a starting point for the development of moral identity in higher education.

Concretely this means that students may identify role models based on the value constitution and integration functionalities. Coming back to table 2., this means that positive role-models might serve as an exemplar for moral identity, giving blueprint a different meaning. There is some evidence that role-modeling has positive effects on the development of a moral identity in pedagogical practices (see Sanderse, 2013 for an overview). However, the concept of role-modeling presupposes a very prescriptive teacher-student dynamic as it treats explicitly the teacher herself as a role model. This might conflict with an ideal of neutrality that is still widely regarded in education, especially when it comes to higher education issues (Hess, 2002). Plenary class discussions, which are an important aspect in ethics education in general (ibid.) might not always be the right approach in fostering affective engagement through pedagogy. There is some evidence that students get defensive, rather than open-minded, when discussing topics that are affectively important for them (de Clerck & Rutten, 2014). Pedagogical tools that focus more on empathy than argument such as rhetorical listening might overcome such shortcomings. However, climate change is a

[2] Obviously, there are prominent exceptions like Regan (1983), if you like replace "Kantianism" with "traditional Kantian ethics".

difficult case as much of its effects regard people that are far away spatially or temporarily.

Emotional regulation

Moral education specifically centers around emotion. The links between moral belief and moral action are, at least partly, regulated by affect. The specific functions of affect in shaping moral behavior are touched upon in the first section of this article, but largely beyond the scope of this paper. When it comes to climate change ethics, emotions are integral as well. Especially salient for emotional regulation in the context of Phronesis is the role emotions play in changing attitudes and behavior towards climate change. Empirical research shows that learning about climate change has affectional effects, leaning towards negative emotions, often clustered under the term 'eco-anxiety'. However, this does not necessarily lead to a reduced sense of efficacy, it might even increase it (Maran & Begotti, 2021). The same study caveats that excessive exposure to information on climate change might also lead to 'eco-paralysis. This means that pedagogically, these emotions should be mitigated constructively. There is some qualitative evidence that collective action has a positive effect on mitigating eco-paralysis. In pedagogical terms, this urges teachers to focus on empowerment (see for instance Tassone, 2017 for empowerment pedagogy in higher education).

In this sense, Phronesis is both conceptually and practically a useful lens for moral education. On the other hand, Phronesis is centered strongly around individual moral development, as argued in the second section of this paper this is a too limited focus when it comes to climate change, both ethically and emotionally. The important paper by Newberry (2004) shows that pedagogy on emotional engagement is limited by what he calls the 'gravitational pull' of engineering curriculum. Students respond to what is being deemed important institutionally, and if practical ethics is a minor part of this, students respond accordingly affectively. In other research (Loonstra & Tassone, 2024) I have mapped the learning domains of a technical university as they are reflected in the intended curriculum. Indeed, affect-oriented learning goals are least dominant. A true change towards emotional engagement with ethics follows probably from an institutional change in the goals of the university, more even than specific pedagogical approaches..

Conclusion

Climate change is one of the most urgent problems of modernity. It touches upon virtually every sphere of life and is characterized by great wickedness. The anthropogenic nature of climate change and its dire effects make it a difficult normative problem. Technical knowledge and values are deeply intertwined, or at least extremely difficult to separate. Universities, as knowledge-producing institutions, have an important role to play in providing students with the right tools to understand climate change, and respond to it ethically. This practice-oriented goal of ethical competency asks for an integration of moral theory and affect in pedagogical practices.

This article has provided a conceptual analysis of Phronesis, an Aristotelian notion of the framework of education focused on moral pedagogy specifically. Phronesis is the counter-part of Kohlbergian approaches that were long paradigmatic in moral education, but are criticized for being too rationalistic. Phronesis can be understood as a form of practical wisdom, stemming from the cultivation of values in one's moral identity. Following Phronesis, moral education should focus on the cultivation of a 1) constitutive function 2) integrative function 3) moral blueprint and 4) emotional regulation. To analyze the ethical and practical feasibility of Phronesis in moral education it was juxta-positioned with the most prominent ethical schools of thought (utilitarianism, deontology and virtue-ethics) and their response to the climate crisis.

Phronesis has a strong focus on individual moral development, and might therefore, following the focus of the most dominant ethical approaches to climate change ethics, not be very well-suited for moral education on systemic issues. However, this article proposes that, as the most paradigmatic approaches to climate change ethics come with great intra theory-shortcomings as well (analogous to a Kuhnian crisis-science), the concept of Phronesis might be very useful as a method of a pedagogical re-orientation of ethics as well. On the constitutive dimension, ethical theory might serve as lens to distinguish between values. This follows a logic of inquiry-learning where students perform their own normative analysis with moral theory as a scaffolding tool. Case based learning is an important pedagogical strategy. On the integrative dimension, the problem of reconciling conflicting values can be important regarding the multi-leveled and multi-faceted dimensions of climate change. Mirroring complex-problem pedagogy, participatory simulation can provide a practice-like setting for weighing the strengths and short-comings of normative foci. The blue-print dimension is where Phronesis falls short as an approach to moral education in climate change, as it is too individualized and has limited practical applicability in the context of climate change ethics. Role-model approaches of moral education might be an approach to deal with these shortcomings, but come with other normative problems. Other pedagogical approaches such as rhetorical listening, do not suffer from these weaknesses, but are little concrete. Lastly, the emotional-regulation dimension is very salient when it comes to climate change ethics, but has to be embedded in a broader theory of empowerment and social change to be morally effective and affectionally appropriate. This translate to the university where institutional changes regarding the intended curriculum are important in fostering attitudes.

Appendix

Theory	Conception of ethics	Personal requirements in Climate Change	Systemic requirements in Climate Change
Act Utilitarianism	The ethical nature of an act is dependent on the maximalization of utility in its consequences.	The only real influence an individual can reasonably have on climate change is limiting procreation, as all other behaviors mitigating climate change are effectively meaningless compared to having fewer children.	Implement a temporal discount rate of 0 in financial models of mitigation efforts (as temporal closeness is morally irrelevant). Implement a supply-side Carbon Tax (as this is probably more effective than a Cap and Trade System). Finance adaption strategies for the least well-off by raising the highest marginal tax rates (following the principle of diminishing marginal returns).
Rule Utilitarian	The ethical nature of an act is dependent on its adherence to an ideal-theoretical moral rule.	All greenhouse gas (GHG) mitigating behaviors that do not reasonably conflict with other fundamental values, most prominently: limiting meat-consumption, fossil-fuel travel methods and	Implement a demand-side incentive system to promote alternatives to GHG-emitting activities via taxes. Implement a carbon-offsetting program (individual carbon-offsetting is logistically and societally too complex to be internalized as an ideal-theoretical rule).
Deontology	The ethical nature of an act is dependent on it being derived from that maxim through which you can at the same time will that it become a universal law. (conceptual principle of non-contradiction)	Problematic, as not-mitigating climate change is not conceptually contradictory. Possible solution: broader definition: do not act according to those maxims that are practically unsustainable.	Principle of right: Any action is right if it can coexist with everyone's freedom in accordance with a universal law, or if on its maxim the freedom of choice of each can coexist with everyone's freedom in accordance with a universal law. States ought to provide financial support for

		(prudence principle of non-contradiction) Duty to pressure government for systemic solutions.	mitigation and adaptation efforts to those countries that will be affected by climate change to the extent that the freedom of their citizens is severely limited. Or: implement an unconditional open-border policy rendering everyone free to escape the asymmetrical global effects of climate change.
Virtue ethics	The ethical nature of an act is necessarily dependent upon the virtuous nature of its actor.	Cultivate the right values for a virtues disposition towards nature (i.e. compassion for suffering, a will to justice for all parts of the environment, and a sense of reverence for and protectiveness towards the enchanted in nature) Or: Try to live *as if* in possession of those virtues, i.e. by mimicking a positive role-model (as climate change is a problem of great urgency, not well-suited for the time intensive practice of cultivating values).	The polis should be led responsibly: balancing the conflicting values.

ABSTRACT

The paper explores the potential of using narrative-centered pedagogies in Engineering Ethics Education (EEE), drawing insights from their successful application in nursing and business ethics education. While traditional methods in EEE focus on fostering moral reasoning through case-study analysis and teaching ethical theories, increasingly, there is a need for fostering soft ethical skills, such as moral sensitivity and creativity, which, in turn, demand new teaching approaches. Initially developed for nursing ethics, narrative pedagogy emphasises understanding experiences through storytelling and dialogue, contrasting with the decision-oriented focus of EEE. While narrative pedagogy allows for understanding stakeholders' motivations, there is a gap in translating this understanding into ethical decisions, which engineering students must make. Drawing from a literature survey of the existing research in ethics education, the paper describes three kinds of narrative pedagogy to be used for EEE. Despite its theoretical potential, narrative pedagogy has not been deployed in EEE due to a lack of systematic research on its effectiveness. The paper calls for more experimentation and documented case studies in teaching to explore the potential narrative pedagogy in EEE. Without such experiments, the theoretical potential of narrative pedagogy in EEE may remain unproven.

1 INTRODUCTION

1.1 Narrative ethics and narrative pedagogy in Engineering ethics education

Recently, there has been a growing interest in diversifying the methods used in teaching ethics in professional domains, such as engineering, design, nursing, business, law, etc. While standard teaching methods focused overwhelmingly on the fostering of rationality by promoting moral reasoning and moral deliberation as the main competencies that students were expected to acquire (Zhu and Clancy 2023), more recently, there has been a growing interest in developing methods for targeting skills and competencies that are more contextual and holistic, such as moral sensitivity, moral perception, moral imagination, moral creativity, empathy, etc. (Lönngren et al. 2023). While these latter competencies do not necessarily exclude rationality and reasoning, these are demonstrably focused on the a-rational part of ethics, namely what is left outside the mere rational exercise of reasoning about ethical issues as problem-solving attempts. For the purposes of this paper, I will designate these a-rational skills and competencies with the overarching term *soft ethical skills*.

While the need to foster soft ethical skills in engineering ethics education (EEE from now on), and in general in professional ethics education, is widely acknowledged, ethics instructors find that the methods for fostering these skills are rather unclear. For reasoning-focused skills, there is already a well-established pedagogy in EEE consisting of case-study analysis, discussions, and deliberations, paired with teaching ethical theories that are used to devise an acceptable solution (Jalali et al. 2022). However, such traditional methods cannot be used in the soft ethical skills pedagogy, which target another domain of thinking and feeling altogether (Tormey et al. 2022). Soft ethical skills demand new methods in teaching ethics, and ethics instructors will find themselves confronted with the need to think outside the box when devising methods for such elusive yet ambitious goals (Martin et al. 2021). It is clear that the same methods used for teaching moral deliberation and reasoning cannot work for moral sensitivity, imagination, and creativity. Still, there are already promising ideas and directions for pursuing a systematic approach to soft ethical skills pedagogy: arts-based methods, theatre, role-plays, stakeholder direct engagement, etc. (Frey 2015). These ideas either promote embodied pedagogy – i.e., using the body to express and enact ethical situations (van Grunsven et al. 2024) – or *narrative pedagogy*, which I will analyse next as a promising pedagogical approach that has been yet underexplored in EEE.

More than two decades years ago, Martha Nussbaum (1997) argued convincingly for the important role that reading fictional narratives plays in cultivating moral imagination through narrative imagination, i.e., the capacity to "put oneself in another person's shoes and to understand their emotions and desires" (Wright 2002). While Nussbaum argued that narrative imagination is necessary for everyone to become a world citizen (1997), we can extend this argument from citizens to any professional dealing with stakeholders, either directly or indirectly. Based on Nussbaum's ground-breaking work and on similar works (Newton 1995), the inquiry into the ethical and educational potential of literary narratives gained quite some momentum, branching out into *narrative ethics* (Netwon 1995; Adams 2008; Pehlan 2014), a distinctive field of research, at the intersection of philosophy and literary studies. Recognising the potential of narrative ethics, various educational researchers working on professional ethics education have coined different strands of narrative-centred pedagogy, most remarkably in nursing ethics. However, in EEE, narrative ethics and narrative pedagogy remained mostly explored. A brief literature search on EEE and narratives found 27 results out of which very few papers have engaged with the pedagogical potential of narratives for EEE. Several notable examples were (Miller and Bennett 2008; Hitt and Lennefors 2022; Halada and Khost 2017). What explains this hesitance to take up narrative-based ethics in the pedagogy of EEE? This paper explores the potential of narrative ethics and narrative-centred pedagogy for EEE, provides some explanations for past neglect of narrative-centred pedagogy in EEE thus far, and offers some concrete suggestions about the potential of narrative ethics for developing soft ethical skills in engineering ethics.

2. METHODOLOGY

In exploring the potential of fictional narratives and narrative-centred pedagogies for EEE, I am mainly drawing some insights from the previous usage of narrative pedagogy in nursing and business ethics. The first method is a literature review of the ways in which narrative pedagogy has been used in professional ethics education thus far, which resulted in a taxonomy of the types of narrative uses in ethics education. Using these insights, namely mapping what narratives can be used for which soft ethical skills, I then theorise possible narrative ethics uses for EEE as well as its limitations. I am mainly interested in exploring narratives' potential to achieve new pedagogical outcomes that traditional EEE methods do not usually deliver. For this second part of the paper, I use educational theory and philosophy as a ground for theory building: knowing the desired outcomes of EEE and the potential of narrative pedagogy, which learning outcomes are more likely to be achieved?

3. THE POTENTIAL OF NARRATIVE PEDAGOGY FOR ENGINEERING ETHICS EDUCATION

In a systematic review centred on the pedagogical interventions in EEE in the American context, Hess and Fore (2018) list the most common pedagogical activities as: "Codes of Ethics or Rules, Developing Code of Ethics, Ethical Tools, Processes, or Heuristics, Developing Heuristics, Philosophical Ethics, Case Studies, Developing a Case Study Micro-Insertion Real-World Exposure Community Engagement Discussion or Debate Presentation Peer Mentoring Individual Written Assignment(s) Team Project or Position Paper, Game" (Hess and Fore 2018, p. 562). Narratives can be found in both case studies – included in the reading material - and presumably can be embedded in individual written assignments. Yet narratives as a specific genre do not stand out in EEE pedagogy and are not considered a specific approach to teaching or developing assignments to deserve their own category.

In professional ethics education (such as engineers, designers, nurses, medical doctors, managers, or legal practitioners), the main aim is not in-depth theoretical understanding, rather, it is about developing the skills and competencies that will allow practitioners to act with integrity when a challenge arrives. This makes ethics education for professionals quite a unique discipline in educational sciences, with specific learning goals and instructional methods (Hess and Fore 2018). This uniqueness can be summarised as action-oriented, whereby theory is used only as an instrument that can help in fostering the competencies and the attitudes for ethical action (Clancy and Zhu 2023). In EEE, instructors are focused on the applicability of what they teach and on fostering lifelong competencies that can be drawn from by future professionals in various contexts. Because of this competency-first focus, with theoretical knowledge being a secondary concern, teaching methods that use extensive writing are usually discouraged. When EEE students are asked to write essays, the focus is on exploring an ethical issue and not so much on the quality of writing itself. This is why writing-focused pedagogies have been historically ignored in professional ethics pedagogy. Writing an argumentative essay is already difficult enough for engineering students who are not that familiar with writing long texts, and asking them to write fictional narratives seems even more demanding. What about case-study pedagogy? Could this be a way to introduce narrative pedagogy into EEE?

Traditional teaching methods used in EEE include case-centred approaches, the so-called microethics approach (Martin et al. 2021). In case-centred pedagogy, students discuss a fictional or historical case of a problematic issue in their profession and are asked to decide what needs to be done or who is blameworthy. The tools used to deliberate are ethical theories, which were then applied to find an acceptable solution to the case, to enhance the student's moral deliberation and reasoning capacities. Case-based pedagogy has its limitations which have been thoroughly discussed by Martin et al. (2021), who instead proposed also to consider macro-ethics alongside by discussing the wider societal, political and cultural context in which professional incidents occur. What interests us here is that case-based pedagogy is reasoning-based, whereas macro-ethics seems to target the soft ethical skills discussed above more. Macro ethics is about stepping outside the case and using a wider lens, while the targeted competencies are about moral perception and moral sensibility, hence more fitting for the development of soft ethical skills. However, there are no established methods for teaching macro-ethical approaches in EEE (Martin et al. 2021), neither narrative-based nor argumentative-focused. If narrative ethics is to enter EEE pedagogy more, macro-ethics seems to be a promising domain of application.

Narrative pedagogy has been used primarily in nursing ethics, the field where it was first conceptualised. Narrative pedagogy is a way of making sense of ones experiences by telling stories about them and enacting "crucial conversations" with others, usually colleagues in the same professional field. Narrative pedagogy was initially about making sense of an experience that already happened to a participant, and creating a shared common understanding through "an interpretive phenomenological approach" (Diekelmann and Diekelmann 2000, p. 226). This makes sense in nursing, where experiences of care are particular to each patient and care situation and where sense-making seems to be crucial. Understanding is built through dialogue and collective sense-making: "In this new pedagogy, ethics ceases to be answers, made within frameworks, or principles or rules applied universally to situations. These understandings are a part of the converging conversations" (Diekelmann and Diekelmann 2000, p. 229). We can see how different narrative pedagogy is from the traditional micro-ethical EEE approaches centred on reasoning, where the usual aim is arriving at the most acceptable solution for a given ethical case. Engineers do not strive for understanding of experiences or situations primarily, as their main concern is decision-making of how to design or implement a specific technology, hence the final aim of ethics is the right action (Zhu and Clancy 2023). This is not to say that understanding is not useful, but in engineering, this needs to be translated into a decision. Because of the decision-oriented focus on EEE, rather different from the focus on understanding in nursing ethics, it makes sense why narrative pedagogy has not been the first choice for EEE instructors. If narrative pedagogy allows for a deep understanding of the stakeholders and their motivations in engineering ethics, there seems to be one more step needed to arrive at a decision. Understanding alone is not enough to make an ethical decision. However, a too hasty understanding of the stakeholders also poses a danger. Engineering students may think that they understand all parties involved in a techno-social decision and rush to “solve” the problem with incomplete information. From this brief reflection, it should be clear that understanding alone is not enough to make narrative-centred pedagogy interesting for EEE pedagogy. We need to get something more out of narrative pedagogy since using narratives to make sense of morally loaded situations will not be enough for engineering students. The next section explores the multiple facets of narrative pedagogy for engineering ethics education.

4. TYPES OF NARRATIVE PEDAGOGY USED IN PROFESSIONAL ETHICS EDUCATION

The following table summarises the kinds of narrative pedagogy used thus far in professional ethics education and its targeted competencies. Each category will be explained below.

Table 1. Kinds of narrative pedagogy, teaching activities and targeted learning outcomes

Kinds of narrative pedagogy	***Teaching and studying activities***	***Targeted skills, competencies, and learning goals***
A. Discussing narratives created by others	• Film-based discussions • Collective discussions on a narrative text • Individual readings and reflections on a narrative (Text-based commentary)	• Moral sensitivity/ perception • Empathic perspective-taking (Narrative imagination) • Empathy and understanding • Stakeholder engagement (imaginary stakeholders)
B. Completing unfinished narratives	• Starting from a given scenario outlining an ethical situation, students imagine possible outcomes (in writing, discussions, or as a performance).	• Stakeholder engagement (imaginary stakeholders) • Empathic perspective-taking (Narrative imagination)

C. Creating narratives	• Writing a short story about a technology or an ethical issue with a technology • Sci-fi narrative writing with a focus on anticipation • Writing a poem, a short dialogue, a script for a performance • Performing as improvisation starting from a prompt	• Moral creativity • Moral imagination • Empathic perspective taking (Narrative imagination) • Responsible anticipation

4.1 Discussing narratives created by others

In this approach, the students read or watch the narratives created by others. The advantage here is that the creator of the narrative is usually an experienced writer/ artist, and the narrative has a certain quality about it, which makes empathic reactions more likely. The main goal here is that students make sense of the narrative, either individually or in groups, and expand their understanding of the ethical situation by imagining what it is like to be another person embedded in that situation (the fictional character or the testimony provider who narrates their experience), or by being confronted with the strangeness of the other perspective and having to make sense of the distance between oneself and the other. The learning outcomes of encountering narratives, already extensively explored in nursing and business ethics research, are: "thinking, empowerment, interconnectedness, learning as a process of making meaning, and ethical and moral judgment." (Brady and Asselin 2016, p. 2). It has been argued that, at least when compared with standard lectures, narrative pedagogy is more effective for increasing the moral sensitivity of students (Bagherian et al. 2023).

In EEE, experiments with encountering narratives have been done starting from film narratives (Hitt and Lennefors 2022) or reading fiction to make sense of the professional's ethically relevant experiences (Mawasi et al. 2022). In this case, students are exposed to the story, and then they create a common understanding of the story in the absence of the one who has lived the story. The fictional characters are not present to take part in the sense-making conversations, and students as spectators project themselves into the shoes of the fictional characters and think "as if" they were one. This has the potential of asking students to imagine being someone else, but it also poses a danger that, if the students' imagination capacities are limited, they will not be able to imagine what it is like to be another. On these limitations of imagination in the context of disability, see (van Grunsven et al. 2024).

4.2 Completing unfinished narratives

This is a somewhat more creative task. Students receive a narrative that has not been completed and are then asked to finish it by providing possible ends. This is different from the traditional case-based pedagogy, where students were asked to choose the most acceptable outcome using an ethical theory (Whitbeck 2011). Instead, students are asked to take into account the character's psychology and situatedness in a context, the available choices, and then choose the most likely scenario. This format can also be used to ask students to imagine the most appropriate ending but still keeping in mind the limitations of the main characters' psychology and perspectives. This relatively recent format has been employed in medical education with patient scenarios (Marei et al. 2018) and in business ethics (Kujala and Pietiläinen 2007). This format has not yet been explored in EEE; hence, further research is needed to map out its full potential, starting from its theoretical potential that has already been demonstrated in other branches of professional ethics.

4.3 Creating fictional narratives from scratch

Some pedagogies ask students to make up their own stories from scratch, such as improvisational pedagogies and narrative fiction-writing pedagogies. In improvisational pedagogies, students start a prompt, giving the outlines of a case and arrive at a story while performing it. Students do not know what the story will be at the end, they create it in the staged interaction with their colleagues. In fiction writing pedagogies, students write from scratch a story in which they make sense of an ethical case or explore the ethical implications of a technology. This approach has been less explored in EEE. One example is the work of Torras and Ludescher (2023) in the context of AI ethics. Another example is using the crafting of narratives in engineering education in general, without particular concern for ethics (Halada and Khost 2017).

The main difference between the three kinds of pedagogical approaches outlined above is the degree of creativity required from students, which ranges from creativity in making sense of other's stories to crafting their own stories. Standard narrative pedagogy, as used in nursing ethics and business ethics, is centred on using other's stories. Crafting one's stories seems to be an even more complicated task and not usually a method employed in ethics courses across all fields. Yet, in view of fostering moral creativity, it seems to be the most promising approach. However, narrative pedagogy is risky and has some pitfalls, making it a difficult endeavour for EEE.

4.4 An example of a practical application: writing a short Sci-Fi narrative

Using the narrative pedagogy approach of the third kind, creating fully a story from scratch, I designed an entire course centred around writing a Sci-Fi narrative as the main outcome of the course and piloted it in the academic year 2023/2024 at TU Delft (course code TPM042A). Students were asked to start with a specific technology and imagine a science fiction narrative of a maximum 1500 words centred around one ethical issue with that technology. The students received creative writing training in several workshops throughout the semester. The final sci-fi narrative was built in incremental steps (a pitch centred on the ethical question, an outline of the action, and a preliminary draft). Finally, students also wrote a reflective essay in which they commented on their own narrative and its ethical significance. The course was entirely elective, and it was taken only by students who were interested in story writing. I did not document the moral imagination before and after the course, as this was a pilot meant to test the pedagogical methods as such and the students' reactions to the narrative pedagogy approach. In the course feedback, all the students appreciated the class and were very engaged in its activities. I will offer the same course in the next academic year and document the moral imagination changes through elective student surveys before, during, and after the course completion. A lesson learned, and an immediate limitation is that narrative writing relies on skills that cannot be built entirely in one course, although all students did show a demonstrable improvement in their writing skills throughout this course. But because of this heavy reliance on writing skills, the courses centred on narrative pedagogy will need to be offered either only as electives or rely on narrative writing only as formative activity, with no influence on the final grade.

5. Discussion. Limitations of narrative pedagogy in EEE. Pitfalls and limitations

As mentioned, soft ethical skills require different approaches, more creativity, and less focus on providing reasons and exchanging arguments. While narrative-based pedagogy seems a promising direction to take for EEE, it is quite a rare occurrence in the current educational landscape. This is understandable, given the scant research that has been done on narrative ethics and its methods in EEE. Some instructors may be adventurous and inclined to try out new methods, but most prefer to stick by the already validated paths. The community of researchers working in EEE is constantly developing new methods involving arts and more playful approaches, but we lack a systematic way of testing just how effective these methods are. In the absence of these kinds of systematic studies on effectiveness and for collective educational experiments, we are left with anecdotal evidence and small experimental deployments in our own courses. This paper is also a call to explore more and try out the methods of narrative pedagogy in reproducible and documented case studies in EEE coursework. Without these experiments, we would not know if narrative pedagogy's theoretical potential in EEE can bear fruit.

The main limitation in implementing narrative ethics and narrative pedagogy in EEE stems from the lack of specific training for instructors. A narrative ethics instructor would need to provide guidelines to students on how to read a literary text, interpret it, perform it, and even write a fictional text. At some stages in these activities, professional writers or scholars from literary studies would need to be involved directly or indirectly. If ethics instructors want to experiment with narrative methods in their teaching, they will need to dedicate some time to learning these techniques and the scholarship grounding these methods, which means putting aside time in a time-scarce environment such as contemporary universities. A second limitation lies in assessing students' work. Similar to arts-based pedagogical activities, the criteria for evaluating narrative work are quite specific and revolve around aesthetic criteria as well as criteria for assessing the personal growth of students: how to evaluate the increased moral imagination or sensitivity remains an open question for EEE in general. How to evaluate a good story or a creative ending to a given narrative seems even more hazy. We do not have the assessment criteria in place to ensure that, as instructors, we can be fair to the student's work. For students, the main limitation of creative methods in ethics, such as narrative pedagogy, lies in the unequal distribution of skills: some students can feel more comfortable than others in writing fictional narratives or in interpreting texts, while others may feel paralysed. However, we should not assume that students will not enjoy some creative challenges, as seen in the pilot class on sci-fi narratives. Furthermore, everyone can experiment with artistic methods, and even if the outcome is not an artwork, the very process of thinking and reflecting about narratives and art is valuable in itself. We should not shy away from more experimental and arts-based methods simply because students may feel uncomfortable at the beginning.

However, ethics instructors may need to consider narrative pedagogy sooner than anticipated. With the rise of ChatGPT and other large language learning models, traditional written assignments in EEE are under threat as argumentative essays are written starting from a series of questions or prompts that can be generated automatically all too easily. In evaluating the correctness of the arguments, it becomes difficult to discern the student's work from an automated generated text. However, with narrative pedagogy, an important criterion is students' creativity and insight in interpreting a narrative or writing one themselves. Even if tools such as ChatGPT can write short stories or interpret or summarise existing ones, they cannot yet show the insight and unique style that a human interpretation can. Many have noticed that ChatGPT outputs sound and feel generic, cookie-cutter prose. While such generic prose would be acceptable for an argumentative essay, narrative pedagogy demands a personal point of view, a personal interpretation, insight, and creativity in one's understanding. Given that these raw qualities cannot be simulated by a large language model (yet), ethics instructors can turn to more creative assignments to avoid their students defaulting to the ChatGPT route. Narrative pedagogy and narrative ethics are roads not yet taken in engineering ethics education, but we may have to explore this path quite soon, given that other more standard paths are becoming unavailable.

ABSTRACT

This study proposes and evaluates a redesign with active learning activities of an interdisciplinary course on product manufacturing. Evaluation involved analysing past and current exam results to assess the impact of case-based learning on academic performance. Results show a positive correlation between joining more case studies and improved exam performance of second year Industrial Engineering and Management students. However, minimal to negligible improvements were observed among first year Industrial Design Engineering students. These findings

highlight the nuanced nature of the effectiveness of active learning, appearing to be influenced by various contextual factors.

1 INTRODUCTION

1.1 Research context

Over the last decades, active learning has gained significant popularity (Hartikainen et al. 2019) as an educational approach that emphasises engagement, cognitive development and problem solving (Gogus 2012). Active learning is defined as “anything course-related that all students in a class session are called upon to do other than simply watching, listening, and taking notes” (Felder and Brent 2009). It promotes deeper understanding and knowledge application (Edström, Soderholm, and Knutson Wedel 2007), and fosters higher order thinking skills (Bonwell and Eison 1991). For example, methods such as project-based and case-based learning are approaches to active learning (Biggs and Tang 2011).

The University of Twente (UT) integrates project-based learning as a fundamental element in its engineering programmes to motivate students and link theoretical concepts with practical applications (Dankers et al. 2013). Currently, several Bachelor of Science (BSc.) programmes are undergoing curriculum redesigns in response to trends, technological advances, and industry requirements. The changes involve introducing new courses as well as refining existing courses. This process involves an assessment and redesign of courses, content, and methodologies. Furthermore, the development of two learning factories — one focused on production and assembly, the other on additive manufacturing (Massa and Lutters 2024)— instigates course redesign. Learning factories serve as an educational concept that provides students with hands-on, real-world experiences in an environment that simulates industrial settings (Abele et al. 2024). The learning factories at the UT aim to blur the lines between education and research, working through a recursive master-apprentice model (Lutters et al. 2022; Damgrave, Massa, and Lutters 2023). To exploit the full potential of the learning factories as a valuable engineering learning workspace (Malmqvist, Edström, and Rosén 2020), new and existing courses are adapted to the learning factory environment and vice versa. Production 1, among the courses currently undergoing redesign, is an interdisciplinary course that examines the principles and processes of product manufacturing within both Industrial Design Engineering (IDE) and Industrial Engineering and Management (IEM) BSc. programs, with students from both disciplines simultaneously participating. The redesign aims to address student challenges, and includes practical learning components, potentially aligning with future learning factory education. An analysis using constructive alignment (Biggs and Tang 2011) identified possible improvements in current teaching strategies and showed potential for more integration of active learning.

1.2 Aim of this study

This paper aims to propose and evaluate active learning components to the Production 1 course. The study explores the use of case-based learning, involving the development and integration of case studies in the course. Evaluation includes analysing examination results to assess the effect of the redesigned course. In a general context, this study aims to enhance the understanding of how active learning, particularly case-based learning, influences academic performance in engineering education, also considering the influence of variables like study year and field of study. By exploring these factors, the research aims to address the impact of active learning approaches within interdisciplinary engineering courses.

2 BACKGROUND

2.1 Course information

Production 1 is a key course in IDE (first-year students) and IEM (second year students) programs, providing knowledge in product manufacturing. The course is a mandatory component of both study programmes, making all IEM and IDE students admissible. With an enrolment of approximately 250 students annually, it covers various production processes, emphasising theoretical understanding and practical applicability. The course is worth 2.5 European Credits (EC), equivalent to approximately 70 hours of work. Before the redesign of the course, 25% is allocated to lectures for all students, while the IDE students also devote 25% of the time to practical sessions. The remaining time is reserved for self-study. Completion of the course enables students to differentiate, describe, and justify manufacturing process selections. The course concludes with a written exam that assesses content understanding through twenty multiple choice questions and analytical application through four open-ended questions. The two-part exam ensures a holistic assessment, requiring students to pass thresholds in both parts.

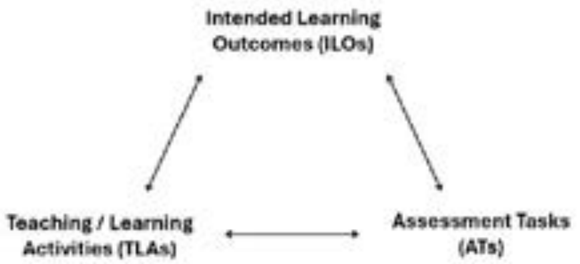

Fig. 1. Constructive Alignment (adapted from (Biggs and Tang 2011))

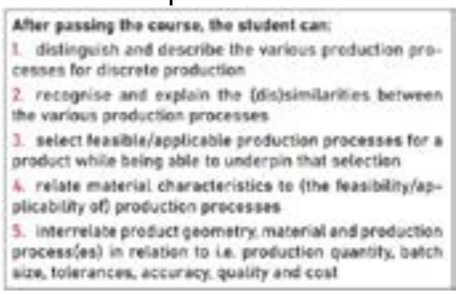

After passing the course, the student can:

1. distinguish and describe the various production processes for discrete production
2. recognise and explain the (dis)similarities between the various production processes
3. select feasible/applicable production processes for a product while being able to underpin that selection
4. relate material characteristics to (the feasibility/applicability of) production processes
5. interrelate product geometry, material and production process(es) in relation to i.e. production quantity, batch size, tolerances, accuracy, quality and cost

Fig. 2. ILOs Production 1

2.2 Constructive alignment analysis

Constructive alignment (Figure 1) (Biggs and Tang 2011) is used to identify improvement opportunities in the current course. Constructive alignment ensures alignment between intended learning outcomes (ILOs), teaching/learning activities (TLAs) and assessment tasks (ATs), fostering a learning experience that encourages the development of knowledge and skills (Anderson et al. 2001). Analysing each aspect and their relationships can identify potential misalignments within the course. Constructive alignment is also useful for its relevance to educational aspects of learning factories. It is essential in the design and operation of these environments, ensuring alignment between learning factories and the TLAs they support (Massa and Lutters 2024). Using constructive alignment is thus beneficial to the learning factories at the UT. In relation to the course, Bloom's Taxonomy (Anderson et al. 2001) reveals a focus on both lower- (ILO 1 and 2) and higher-order thinking skills (ILO 3-5) in the ILOs (Figure 2). However, lectures dominate the TLAs, limiting student participation and the application of knowledge, particularly for higher-order objectives. The ATs consist out of a final written exam covering all ILOs with multiple-choice questions targeting lower-order thinking skills, and open-ended questions assessing higher-order thinking skills. There is little formative assessment, consisting only out of a practice exam. In summary, this analysis highlights the potential for better alignment. While the ILOs and summative ATs are well-suited and well-aligned, some misalignment occurs due to the lecture-centric TLAs. This shows the opportunity to revise TLAs and integrate more formative assessment, while keeping the ILOs and summative ATs unchanged.

3 COURSE REDESIGN

3.1 Theoretical background for redesign

Active learning enhances students' abilities to apply knowledge and fosters higher-order thinking skills (Bonwell and Eison 1991), which aligns with the redesign objectives. Research confirms the efficacy of active learning on academic performance (Freeman et al. 2014; Aji and Khan 2019), particularly through group work (Prince 2004), while it fosters an inclusive environment (Ambrose et al. 2010). However, practical considerations like time limitations must be considered, for instance rendering approaches like game-based learning infeasible. The current course allocates a large amount of time for self-study: an effect of the reduction of lecture time (due to the pandemic, for example) in previous years. Therefore, adding active learning elements should not impose excessive time pressure on students. Given the emphasis on practical application in the higher order ILOs, methods that involve real-world scenarios, such as Case-Based Learning (CBL), are preferred. In CBL, students work to resolve real-world problems presented in case studies, transitioning from theoretical understanding to hands-on application (Srisawasdi 2012). It should be noted that this study focuses on case-based learning, not challenge-based learning. While sharing similarities (beside their acronyms), case-based learning offers a more direct application of learned concepts in real situations.

3.2 Case-Based Learning activities

In the design of the CBL activities, multiple factors such as motivation and feedback are considered. For instance, while active learning already fosters intrinsic motivation (Cavanagh et al. 2016), students will work in groups to stimulate social motivation. Moreover, participation in case studies is optional, aiming to call upon intrinsic motivation and to allow for analysis of the influence of participation on exam results. Sessions organised per study programme to address disparities in disciplines (Gijlers and Jong 2005). Groups work in four sessions of 1 hour and 45 minutes each, which are scheduled shortly after lectures that address case topics. Design problems, often used in engineering education (Lavi and Marti 2023), are used as cases. Cases are designed to be finished within this time, resulting in a maximum of around seven hours spend on case studies. Feedback is facilitated through self-assessment, peer-assessment, and teacher-assessment with both student assistants and the professor providing feedback to students during the cases. Sessions conclude with discussions/Q&A sessions focused on solution exploration, strengthening an interactive approach. The participants do not have to hand in any deliverables, as solutions are published online after one week for self-assessment.

Case study descriptions

The first case study revolves around an incomplete design plan for casting processes, where students have to develop a mould design and address specific questions on volumetric shrinkage and die clamping force. The second case study focuses on applying machining and separating process concepts to real-world production scenarios, requiring students to perform calculations and apply formulas to assess process feasibility, calculate cutting speeds and punching forces, and make informed decisions on tool selection and production quantities. The final two case studies focus on a more holistic perspective. Case study 3 involves analysing a physical product and CAD model of a prototype, prompting critical assessment, proposing materials, and finding alternative solutions that meet requirements. In case study 4 students give advice on production scenarios, showing understanding of factors like processes, materials, cost, and impact on efficiency and quality.

4 METHODOLOGY

4.1 Analytical approach and instrument design

Results of the Production 1 exam, which assesses the ILOs of the course, serves as an indicator of the impact of the CBL elements on academic performance. Quantitative data were gathered from the 2020-2021 (n=268) and 2023-2024 (n=231) exams, under old and new course structures. Student attendance during case studies in the new structure was recorded and discipline information per student was integrated to track disciplinary trends. The exams provide a basis for assessing the effectiveness of added TLAs across different student cohorts – provided that the exams and other conditions are comparable. The exams are conducted in controlled environments prohibiting e.g. cell phone use, and exams are written on paper and must be submitted in entirety, preventing access to past exams. This allows for selecting the multiple-choice questions from a repository – over more than 15 years this has not shown any trend in grades or ‘common memory’. For the new exam, the multiple-choice questions were identical to the 2020-2021 exam. As open-ended questions are easier to remember and are often discussed among students, they are different for every exam. Thus, new, yet similar, open questions were formulated to assess reasoning skills. Three experts declared the 2023-2024 and 2020-2021 exams equivalent in content, ILO match, and difficulty.

5 RESULTS

5.1 Participation in case studies

A total of 231 students, including 132 IDE students and 99 IEM students, participated in the redesigned course. Figure 3 highlights the participatory differences between IDE and IEM in case studies. IEM students have higher non-participation rates, but

Table. 1. Exam results and metrics across IDE, IEM, and the combined student cohort

		IDE			IEM			All		
Year	# of cases	n	avg	SD	n	avg	SD	n	avg	SD
2020-2021	X	166	5,60	1,39	102	5,79	1,60	268	5,69	1,49
2023-2024	≥0	132	5,64	1,25	99	5,99	1,49	231	5,80	1,37
2023-2024	≥1	103	5,62	1,27	51	6,22	1,48	154	5,84	1,38
2023-2024	≥2	81	5,63	1,28	39	6,61	1,48	120	5,98	1,41
2023-2024	≥3	64	5,57	1,17	28	6,69	1,44	92	5,95	1,35
2023-2024	4	28	5,87	1,18	16	6,89	1,54	44	6,25	1,37

Fig. 3. Distribution of cases attended by students and participation in individual case studies

those who are engaged are more likely to participate in all case studies. IDE students are more likely to participate, particularly in three case studies. Participation rates for individual case studies show similar levels of engagement between IDE and IEM. While the first case study attracted the highest participation rates, subsequent case studies showed a gradual decline. However, it must be noted that CS3 and CS4 were scheduled at less convenient time slots, while also facing severe weather conditions.

5.2 Exam results and impact of case studies

Table 1, Figure 4, and Figure 5 show the exam results for the IDE and IEM programmes and the overall results for the 2020-2021 and 2023-2024 academic years. For the academic year 2023-2024, the results are divided based on students' participation. Results are presented based on cumulative ranges for case study participation, as this allows a perspective on the influence of engaging in an increasing number of case studies. The standard deviations (SD) provide an overall impression of the consistency of the results. Notably, the SDs are relatively high, indicating that scores show variation. IDE provides a more consistent result, but in general, both still fall within normal SD ranges considering the grading scale. SDs in 2023-2024 suggest that exam scores are more consistent in the new course structure, however, the increasingly smaller sample sizes impede any definitive conclusions using the SD.

The combined results show an increase of 0.1 in the average grade (on a 0-10 scale) between the academic years 2020-2021 and 2023-2024. It shows a positive correlation between the number of case studies attended and exam grades, with students attending four case studies achieving an average grade almost 0.5 points higher than the overall average grade. However, the individual study fields reveal different trends. In the case of IDE, students who participated in all four case studies showed the largest improvement. Nevertheless, participation in fewer than four case studies yielded no improvement: even leading to examination grades below the average IDE grade. In addition, the average exam grade for IDE is only marginally

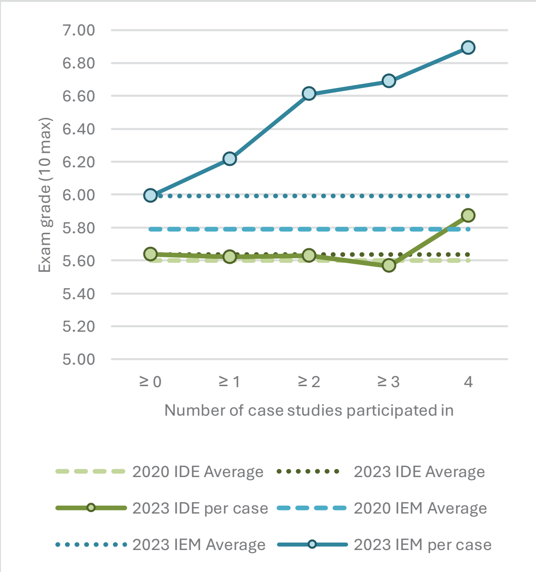

Fig. 4. Exam scores with case studies attended, alongside average exam grade

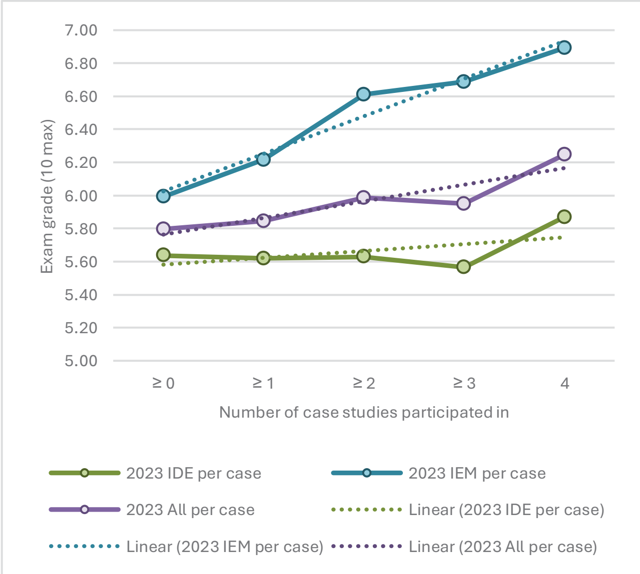

Fig. 5. Exam scores with case studies attended, linear

Fig. 6. Influence of participation in individual case studies on open questions

above that of the 2020-2021 comparative exam. Considering these results, the impact of case studies on enhancing academic performance in IDE is minimal, if not negligible. In contrast, the results for IEM show a convincing progression in exam grades with increased case study participation. Students who attend four case studies achieve an exam grade that is almost a full point higher than the average IEM grade. In addition, the average grade for IEM has increased by 0.2 compared to the 2020-2021 exam. These results clearly indicate a likely improvement in the achievement of learning objectives through the addition of case studies.

5.3 Open questions and impact of individual case studies

As one of the main objectives of the redesign was to incorporate active learning methods to enhance higher-order thinking skills, an analysis was conducted focusing specifically on the open-ended questions. The overview in Figure 6 shows the impact of participation in individual case studies (CS 1-4) on the results of specific open questions (Q 1-4), relative to the overall average score for that question. In the combined results, there is a slight positive impact across most questions, especially CS4 on Q3. In the IDE programme, contrasting patterns emerge, with certain cases even showing negative influences on the question results. For example, CS2 shows a negative impact on almost all open-ended questions in the exam. Furthermore, the highest positive impact is limited to only 8% for CS4 on Q3. These findings strengthen the consensus that case studies have minimal, and in some case even negative, impact for IDE in Production 1. In contrast, the IEM results shows only positive effects, with even the lowest positive effect in IEM corresponding to the highest positive effect in IDE. Both CS4, particularly on Q3, and CS2 illustrate the positive effects of case studies on performance in open-ended questions for IEM.

6 DISCUSSION

The results of this study provide interesting insights into the complex dynamics surrounding the integration of active learning methods, particularly case-based learning, into the Production 1 course. While second-year IEM students experienced significant improvements in exam performance with the addition of active learning elements, first-year IDE students showed little to negligible improvements. These findings highlight the nuanced nature of the effectiveness of active learning, appearing to be influenced by various contextual factors, including discipline and year of study. The improvements observed among second year IEM students are consistent with the existing literature, which highlights the positive impact of active learning strategies on academic achievement. However, the results observed among first-year IDE students challenge conventional assumptions about the universal effectiveness of active learning. Several factors may influence the observed differences. One explanation relates to the existing IDE curriculum being already saturated with active learning components – in comparison to the more ‘traditional’ IEM programme. Given that IDE students are already engaged in practical sessions in the course, the benefits of active learning elements may be diminished. The Binding Study Advice (BSA) for first year students introduces a further layer of complexity: a means of determining whether a student is suitable for a study, by posing a threshold of 45 EC (out of 60 EC) that students must pass. While the second year IEM students have already passed this threshold and will therefore not include 'unsuitable students', IDE students have not. An additional analysis was therefore conducted using interim BSA advices, using three categories (positive, neutral, negative advice). However, the sample size per group becomes too small to lead to reliable observations. Yet, in IDE the relation between a positive BSA advice and the grade for the exam remains marginal, indicating that the difference in exam result may be attributed to the study program. Moreover, despite the apparent positive impact of case studies on exam performance among IEM students, it is important to acknowledge the potential influence of self-selection bias. While there is a correlation between case study participation and improved academic performance, it is arguable that more motivated and academically inclined students may engage more in voluntary activities such as case studies, thus driving the positive correlation. However, the improvement in the average exam grade of the IEM students suggests that an external factor, the inclusion of case studies, is likely to play a predominant role in the improved performance.

7 CONCLUDING REMARKS

This study investigated the integration of active learning, specifically case-based learning, into the Production 1 course at the University of Twente, with the aim of improving student learning outcomes and addressing alignment challenges. The findings reveal the complex interrelations of factors that influence the effectiveness of active learning approaches in engineering education. The evaluation involved analysing past and current examination results to assess the impact of the redesign of Production 1, more specifically the impact of new elements within the redesigned course structure. The results showed that the incorporation of active learning elements, particularly case studies, significantly improved the examination performance of second-year IEM students, which is consistent with existing literature highlighting the positive impact of active learning on academic performance. However, first-year IDE students showed marginal to negligible improvements, challenging assumptions about the universal effectiveness of active learning. These findings highlight the need to tailor active learning implementations to different student populations, considering factors such as field of study and existing active learning elements. In the context of this research, the findings illustrate that IEM students benefit more from additional active learning elements, such as case studies, in Production 1. For IDE students, it is crucial to consider the current active learning load before introducing new elements such as learning factory activities in iterations of the redesign of Production 1. In general, it is important to subject active learning strategies to undergoing review to be able to ensure effective learning (Malmqvist, Edström, and Rosén 2020). In addition, future research should delve deeper into the complex dynamics of active learning, exploring how different factors influence its effectiveness while identifying optimal strategies for engineering education, including whether more active learning always leads to better outcomes.

ABSTRACT

Higher education must be prepared for the ever-changing needs of the world to ensure that future engineers receive extensive training and are equipped to provide significant contributions to both the workforce and society. It is important for higher education leaders to be aware of the need for regularly reviewing curriculum and take part in development to ensure quality improvement. Engineering education needs to be up to date and driven by the need to prepare graduates for the challenges posed by rapidly changing technology, industry, and society. This paper specifically aims to identify best practices for curriculum design in engineering education. Data was collected through the exchange of engineering and business curricula among members participating in the DECART project (DECART 2022). The shared curricula underwent critical examination based on key features related to curriculum components. The analysis included reflection and feedback from project partners. The findings hold significance for engineering educators in various contexts, offering insights into curriculum transformation, agility, and resilience amidst increasingly Volatile, Uncertain, Complex, and Ambiguous (VUCA) environments, which continue to influence engineering education and higher education.

1 INTRODUCTION

1.1 Curriculum Design

Curriculum design holds a pivotal role in shaping the educational journey, ensuring its alignment with industry requisites, fostering critical thinking, and endowing students with the competencies requisite for success in their careers. According to Kumar and Rewari (2022), an outcome-based approach to curriculum is imperative, with clearly delineated program and course outcomes, in line with the demands of accrediting bodies and global benchmarks.

An important consideration is that of graduate employability and ensuring that the curriculum is of relevance for the labour market (Davey et al. 2018). Curriculum review and revision must be done on a regular basis, in response to changing needs of industry and to ensure innovation (Dopson and Tas 2004). A recommendation from the research of Davey et al. (2018) indicates that it is critical to provide support for designing new curricula as well as re-designing current curricula. It has been argued that diverse stakeholders, such as students, graduates, facilitators, staff, industry, and business, and even parents, should be involved in co-designing and co-delivering curricula (Plewa, Galán-Muros and Davey 2015; Kumar and Rewari 2022). It is important that the curriculum is accessible and can be adaptive and responsive (Prideaux 2003).

In the evolving landscape of the 21st century, the engineering domain finds itself immersed in a milieu characterised by volatility, uncertainty, complexity, and ambiguity, often referred to as VUCA (Bennett and Lemoine 2014; Panthalookaran 2022). The unprecedented pace of technological advancements, globalisation, and dynamic market demands has birthed challenges necessitating engineers equipped with a distinct skill set.

To prepare future engineers for the demands of the VUCA environment, curricula must evolve. By furnishing students with essential skills and knowledge, curricula endeavour to promote sustainability and address intricate engineering challenges within a VUCA framework (Rouvrais et al. 2018). In the ever-evolving realm of engineering, the acronym VUCA serves as a guiding framework to comprehend and navigate the challenges emerging in today's swiftly changing environment (Panthalookaran 2022; Bennett and Lemoine 2014). Understanding VUCA in engineering transcends mere acknowledgment; it serves as a clarion call for both professionals and higher education practitioners.

Engineers must foster resilience, agility, and a mindset of continuous learning to thrive in future VUCA environments. Educational programs need to surpass the imparting of technical skills, integrating experiential learning, collaborative projects, and exposure to real-world scenarios (Rouvrais et al. 2023). Latha and Christopher (2020) anticipate in their paper that with training, VUCA and its associated challenges will metamorphose into opportunities, fostering a dynamic culture propelling Engineering Education towards progress and productivity. Niemczyk (2023) underscores the necessity of adopting a mindset shift to address the challenges of the 21st century within the prevailing VUCA environment. Integrating VUCA principles into engineering curriculum design signifies a departure from traditional, inflexible educational models. Program leaders must ensure that the curriculum is structured and implemented with the ability to navigate a context of uncertain changes (Ciolacu et al. 2023).

1.2 Theoretical Importance

The field of curriculum studies involves examining different approaches to designing, implementing, and evaluating educational programs. These perspectives may include curriculum as a product, process, praxis, or cultural context, among others.

Van den Akker's (2003) work focuses on providing educators and researchers with frameworks to understand and navigate the complexities of curriculum development. He presents the ten components metaphorically as the supporting strings in a spiderweb with the rationale for the learning at the web´s centre. Figure 1 explains Akker's components in a spiderweb.

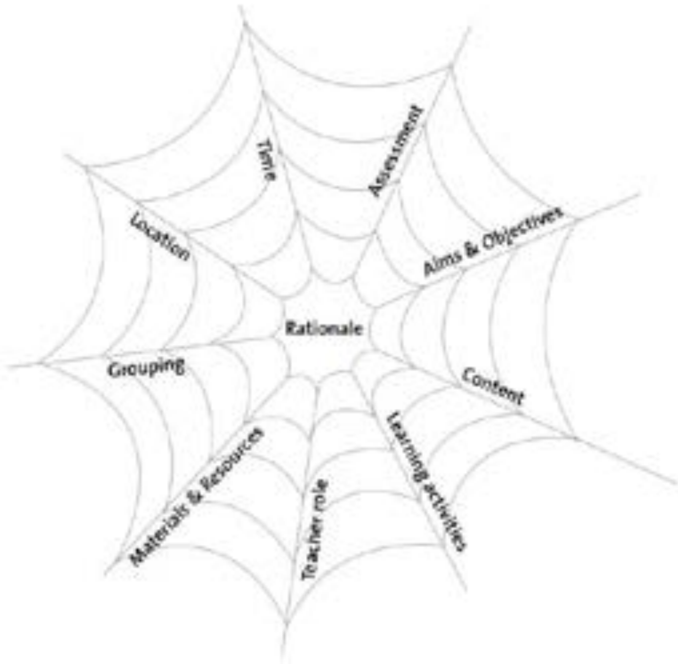

Fig. 1. Van den Akker's framework (Van den Akker, 2003:43)

Jonnaert et al. (2021) present a model that is valuable when transforming the curriculum and presents the curriculum as composed of three connected domains of educational policies of curriculum and of education practices. Figure 2 explains the components in Jonner's model.

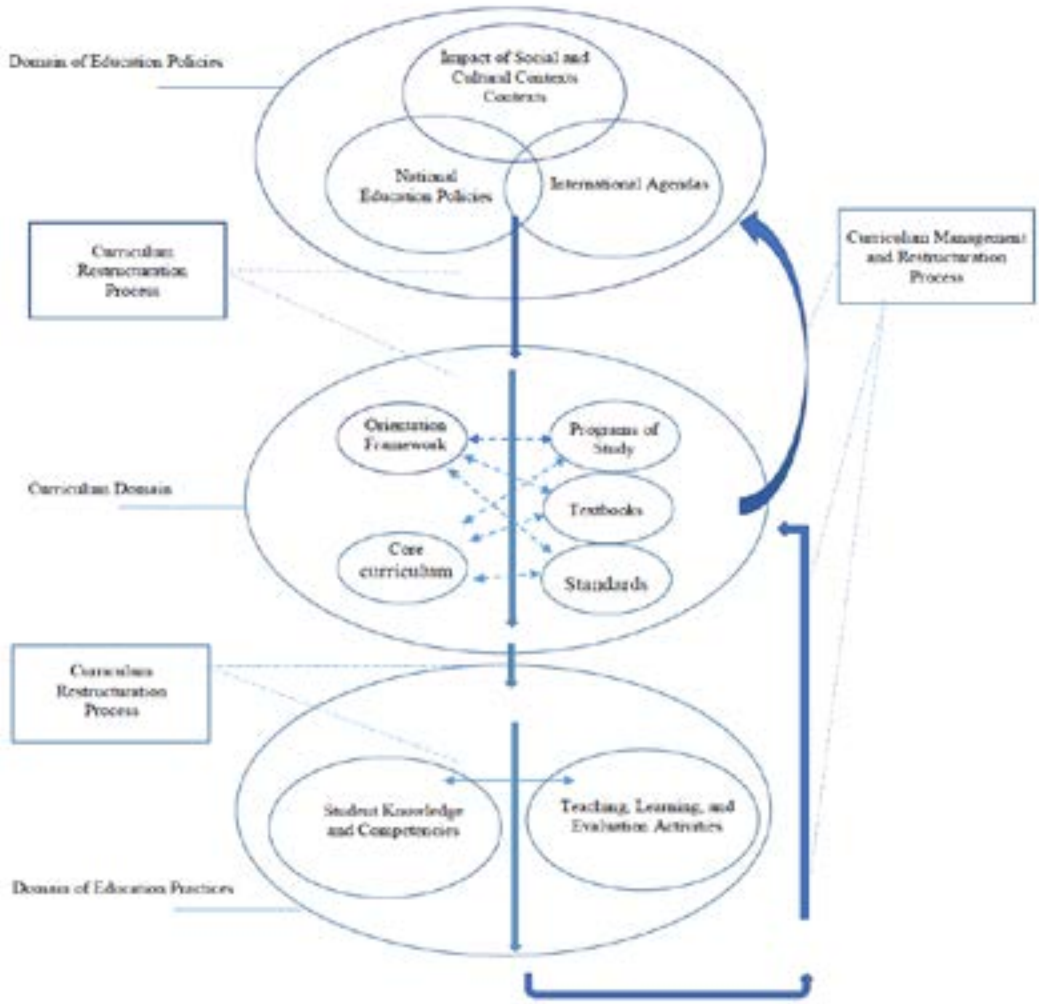

Fig. 2. The Jonnaert model (Jonnaert et al., 2021:11)

The CDIO (Conceiving, Designing, Implementing, Operating) model represents a framework for enhancing engineering education by focusing on a hands-on and project-based approach in an integrated manner with outcome-based education and a syllabus of learning outcomes (Crawley et al. 2014; Malmqvist et al. 2020). The twelve CDIO standards emphasise the integration of engineering fundamentals, personal and interpersonal skills, and real-world applications.

More recently, Brink et al. (2023) defined curriculum agility as an ability “to be responsive to changes in society’s, industry’s, and students’ characteristics and needs, by proactively and in a timely manner adapting the curriculum’s relevant organisational structures, learning outcomes, learning activities, and assessments” (27). In their perspective, ten principles of curriculum agility are defined, from educational vision to stakeholder involvement.

1.3 Question Addressed

The paper addresses the question of what best practices for curriculum design can be identified, based on actual and exemplary curricula in engineering education, reviewed by faculty from several countries and following the VUCA environment that we are navigating. Models from van den Akker (2003), Jonnaert (2021) and the CDIO standards (Crawley et al. 2014) formed the theoretical foundation in the analysis, which led to a specific new model with nine curriculum components (Audunsson et al. 2024). The results are from a study conducted in the DECART (Designing Higher Education Curricula for Agility, Resilience and Transformation) project (ERASMUS+ 2022-25). The project partners are from diverse higher educational institutions across three continents (Europe, Asia, and Africa), and are involved in Science, Technology, Engineering and Mathematics (STEM) and Management education.

1.4 Research Aim

The aim of this paper is to provide guidance to higher education leaders in STEM and Management education on curriculum design and sustainable resilient program transformation.

2 METHODOLOGY

The study primarily utilises reflective practices by faculty in Higher Education within the DECART project, specifically focusing on their roles as reflective educators. Consequently, the study aligns with the interpretivist paradigm. One of the DECART project's aims is to investigate curriculum design, which we approached through three phases of data collection and analysis.

In Phase 1, beginning in 2023, six project partners shared the curricula they were involved with, as well as other innovative and exemplary curricula they knew of. The shared curricula were mainly from Engineering and Management, reflecting the nature and objectives of the DECART project. Phase 2 involved a critical examination of these diverse curricula by the six project partners, focusing on key features related to the curriculum. The components identified in Phases 1 and 2 were discussed and analysed, resulting in the identification of nine components (see Results and discussion). The identified components may not be exhaustive and do not encompass all elements from the curriculum development literature. In Phase 3, all project partners (a total of 17 individuals related to the project) reflected on and engaged with the received feedback to identify best practices for curriculum design components. This analysis is presented below, in Results and discussion.

3 RESULTS AND DISCUSSION

The components that the partners identified are 1) learning outcomes, 2) entry requirements, 3) structure of program, 4) teaching methods, 5) location of teaching and learning, 6) teaching of interpersonal skills, 7) assessment methods, 8) language, and 9) ethno- and sociographic aspects. The following section thus presents the key points which were noted by project partners in terms of identifying best practices within the context of curriculum design.

3.1 Learning outcomes

It was indicated that learning outcomes or goals should promote co-building of knowledge, autonomy, communication, theoretical engagement, and intellectual independence. Also important is a good structure of the learning outcomes. The learning outcomes should have been explained in the module or course outline. Students should thus be aware of the goals or learning outcomes and should be able to know how to apply the knowledge that they gained to solve real world problems. It is also important that general and specific skills, knowledge, and attitudes are clearly outlined. The curriculum should also be practical, involving real-world implications and not just theory. It was considered important that the goals and learning outcomes have a direct impact in terms of leading to the training and education of graduates who can contribute to the development of society, enhance existing knowledge, address complex problems, and ultimately be responsible citizens.

Within the business context, it was noted that goals or learning outcomes should be more applied, and would typically be relevant for business stakeholders, which would include the students, who are often working. Goals and learning outcomes should thus be adapted to the context. It was also noted that goals or learning outcomes should incorporate national values.

3.2 Entry requirements

It was noted that entry requirements for students should be clearly outlined and should be detailed and understandable. There should be a link to national requirements, and these should be coherent with learning outcomes.

It was argued that entry requirements typically focused on the basic educational requirements, such as matric or similar, or a maths background for STEM subjects. Some degrees may also have specific requirements in terms of grades, language, and possibly practical work experience and a minimum age.

3.3 Structure of the program

The structure of the program should clearly indicate the academic timelines and schedules, and indicate the semesters, terms, and breaks. The duration of the programme and modules should be clear, with all compulsory and elective modules outlined. Learning pathways are explicit, as well as the hours, credits, format, location, and whether there are internships.

3.4 Teaching methods

It was noted that there should be diverse teaching methods. The learning methods typically include lectures, group work, projects, and case studies. There may also be guest lectures or presentations from industry professionals. The student experience is critical. Teaching methods should be coherent with entry requirements and learning goals. It was also noted that there is great value in incorporating a problem-based approach, flipped learning, and ensuring a student and faculty-friendly learning management system.

Key aspects to consider is to record the lectures, which became a critical practice during the Covid-19 pandemic. The level of the programme and the student must be considered. For example, Business School students are usually more mature, and often have a job. Adult learning principles and the integration of work and life experience of the student is thus incorporated.

3.5 Location of teaching and learning

The location of teaching and learning is important, especially in considering that there may be online teaching and learning. Students may also spend a semester abroad or be based in a company. It should be clearly outlined if the learning location may not only be confined to campus.

3.6 Teaching of interpersonal skills

The value of having diverse interpersonal skills was noted as critical for the development of students, especially to ensure that they were ready for the world of work, but also to empower them during their years of studying. The skills should be visible in the diverse modules. Various interactive and collaborative learning activities should be designed and integrated into the curriculum to enhance students' interpersonal skills.

The importance of developing soft skills for students was highlighted. These include teamwork, communication, leadership, decision-making, dialogue, conflict management, emotional intelligence, responsibility, time management, intercultural, and being able to work effectively individually as well as with others. Students should also be able to manage their own career development.

3.7 Assessment methods

It was noted that there should be diverse types of assessment. In certain instances, companies and/or other industry professionals may be involved. The value of continuous assessment was noted. Rubrics should be provided.

3.8 Language

It was highlighted that there is value in having instruction be provided in more than one language, especially where there are national languages. There is also value in having materials, module outlines, and assessments available in the relevant national languages. It is however important that necessary resources are provided, as this would have implications for various aspects related to teaching and learning.

3.9 Ethno- and sociographic aspects

Ethno-/sociographic components need to be well specified. It was noted that diversity is critical, especially with respect to the diverse backgrounds of students, as well as diverse educational backgrounds. It is also important to consider the culture and specific needs that international students may have. Related to this is the need to focus on communities, society, partnerships, collaboration, and values. Other important considerations include female representation and industry collaboration.

4 SUMMARY AND CONCLUSION

If we compare our 9 components to the models described in Section 1.3, we see that van den Akker’s framework (2003) provides a comprehensive view by integrating these components into a coherent system that emphasises the interrelationships between curriculum elements. It highlights the importance of considering the socio-cultural context, adaptability, and the alignment of learning activities and assessment methods with the intended learning outcomes. This alignment ensures a holistic and effective approach to curriculum design and implementation. The Jonnaert model (2021) integrates its components within a competency-based framework. Both our list and the CDIO standards (Malmqvist et al. 2020) emphasise crucial aspects of curriculum design. The CDIO standards provide a structured and integrated approach focused on producing graduates who can conceive, design, implement, and operate complex systems. They highlight the importance of active learning, integrated curriculum, and competency-based assessment, aligning closely with many components from our list, such as learning outcomes, teaching methods, and assessment methods. The CDIO framework, however, places a stronger emphasis on engineering-specific contexts and hands-on learning environments. Our framework highlights the importance of developing and accessing competencies in real-world contexts, promoting a more holistic and flexible approach to education that is responsive to the needs and backgrounds of all learners.

Although the structure from van den Akker (2003) and the above nine components appear comprehensive in describing a curriculum, it is important to ensure that the curriculum has the inherent property of flexibility to be able to readily respond to different VUCA situations. This was especially evident during the COVID-19 pandemic.

In summary, best practices in curriculum design for engineering education are multifaceted, encompassing industry relevance, active learning, interdisciplinary approaches, and a focus on soft skills development. A curriculum that adeptly integrates these elements not only equips students with technical knowledge but also cultivates the adaptability and versatility necessary for a successful engineering career. As technology advances and societal needs evolve, engineering education must remain at the vanguard of innovation to produce graduates capable of tackling future challenges.

We would like to conclude by underlining the importance of the findings and recommendations for a wide array of stakeholders, including educators, curriculum leaders, quality assurance and accreditation bodies, students, and industry players. These insights have the potential to drive curriculum transformation, agility, and resilience in the face of VUCA contexts. The paper accentuates the potential impact on curriculum and course development, engineering projects, student preparation, and engagement. The study findings hold valuable insights for engineering educators across various contexts, particularly as they were derived from real curricula and evaluated by faculty involved in curriculum design or reflective educators who grappled with swiftly responding to the challenges posed by VUCA conditions in Higher Education. The recommendations carry implications for curriculum development, enhancing student engagement and preparing engineering students for the future.

The study limitation, which is also its strength, is that it builds on the work of a small, closed group of DECART project partners. Nonetheless, all partners are experienced teachers who are deeply involved in curriculum design. The study limitations also include time constraints, and that the study drew on limited methods. This study is part of the DECART project, an EU funded Erasmus+, n 2022-1-FR01-KA220-HED-000087657 (DECART, 2022).

ABSTRACT

The growing emphasis on diversity, equity, and inclusion in engineering education shows the need for substantive changes within academic institutions and professional sectors. Despite numerous initiatives, traditional approaches often fail to

[1] *H. Murzi*
hmurzi@vt.edu

address systemic barriers hindering the full participation of historically marginalized groups. Moreover, the global context adds complexity to DEI efforts, necessitating a deeper understanding of how DEI initiatives align with theoretical frameworks. This paper explores the alignment between theoretical underpinnings and DEI statements in engineering education. The preliminary study aims to enhance the alignment of DEI commitments with theoretical foundations. The study utilizes results from a previous scoping review of literature which identified five emergent themes in the use of theories in engineering education DEI research: Institutional and Organizational Theory, Constructivist and Developmental Theory, Social Identity and Intersectionality Theory, Community and Cultural Theory, and Critical Theory. Three DEI statements from prominent engineering education organizations are analysed through these thematic lenses. The analysis reveals varying degrees of alignment between the DEI statements and theoretical frameworks, highlighting the importance of context in understanding and prioritizing DEI topics. While each statement demonstrates alignment with DEI theories, differences in focus and extent suggest opportunities for intentional writing of DEI statements. The paper provides an initial discussion on how to critically write DEI statements, underscoring the importance of theoretical foundations in guiding effective DEI initiatives. Further research could expand this analysis to other DEI policy documents to gain deeper insights into DEI efforts in engineering education globally.

1. INTRODUCTION

1.1 Background and Context

In recent years, there has continued to be an increase in the awareness and importance of diversity, equity, and inclusion (DEI) within engineering education (Direito et al. 2021). Work in this space has expanded across academic institutions, industry sectors, and societal discourse (Schindler 2022). There is a need to improve engineering programs in terms of access, inclusion, and providing spaces where all students and academics feel safe, included, and as they belong. However, despite multiple efforts in research, funding, and support programs, it has become increasingly evident that traditional approaches and surface-level initiatives are not providing the desired outcomes. Engineering programs are still not fully prepared to address the systemic barriers impeding the full participation of historically marginalized groups. Despite concerted efforts to recruit traditionally marginalized and underrepresented students, most of these efforts focus on increasing numbers and diversity. While important, it is also crucial to think about how to go beyond diversity to focus on inclusion and equity. Significant gaps persist between rhetoric and reality, hence, the critical need for a deeper examination of the efficacy and alignment of DEI strategies with theoretical frameworks in engineering education research.

In addition, engineering education as a global field faces issues with the lack of understanding of the importance of context in DEI work. DEI issues, initiatives, and conceptualizations might look very different and have different meanings across the globe. Similarly, there is a need to not only develop a better examination of the DEI space both from a practice and theoretical perspective but also to include global perspectives in these lenses. As part of this concern, we started to work in this space by engaging in conversations about DEI policies and practices with engineering educators from a wide variety of national and cultural contexts (Van Maele et al. 2023).

1.2 Purpose of the study

The purpose of this paper is to explore the intersection of how the theoretical underpinnings that have shaped DEI work in engineering education align (or not) with DEI statements in the field. By digging into the nuanced relationship between theory and practice, our goal with this preliminary work is to understand how engineering programs can better align their commitments to DEI with substantive theoretical foundations. This exploratory study is part of a larger research project that aims to understand (i) how DEI leaders in engineering education make decisions, including how theory informs those decisions, and (ii) how DEI issues are different depending on the context globally.

Central to our inquiry is the recognition that the mere existence of diversity statements within educational institutions and organizations is insufficient without a robust understanding of how these statements translate into tangible outcomes that dismantle systemic inequities and foster a culture of belonging for all.

We seek to unpack the complexities surrounding DEI initiatives in engineering education and to be able to provide a roadmap to make sure statements have a sufficient theoretical foundation. We argue that while DEI efforts have increased considerably in recent years, there remains a pressing need to interrogate the ways in which theory has been employed to inform and guide these initiatives. Moreover, we contend that a critical examination of different statements can provide valuable insights into the gaps between declared values and actual practices within engineering programs, thereby paving the way for more effective interventions and inclusive pedagogical, research, and mentoring approaches.

In light of these considerations, our goal is to contribute to the ongoing dialogue surrounding DEI in engineering education and catalyse efforts toward a more equitable and accessible future for all stakeholders in the field.

2. METHODOLOGY

Our initial approach in this study was to analyse three publicly available documents that relate to DEI in recognized organizations in engineering education. Results from a scoping review of the literature (Cao, Murzi, and Chowdhury 2023), were used to inform our analysis. The scoping review followed Siddaway et al. systematic review approach (Siddaway, Wood, and Hedges 2019). The search started with 422 articles that included diversity, equity, or inclusion in engineering education. After title refining and abstract screening, 252 articles were reviewed in full. The full-text sifting provided a total of 55 articles. The articles were analysed to understand what theories were used in DEI research in engineering education.

We used the 5 emergent themes from the scoping review to analyse these statements and identify examples of how the theoretical space was represented in the narrative of the statement. In the following sections, we provide more information on the preliminary results of the scoping review and the emergent themes used to analyse the three documents.

2.1 Scoping review emerging themes

As mentioned, our preliminary findings showed that work in this space falls under the following 5 emerging themes of theories:

2.1.1 Institutional and Organizational Theory (IOT)

This theme refers to theories and frameworks that emphasize different institutional practices and organizational structures that influence and promote Diversity, Equity, and Inclusion (DEI) in Engineering Education. The synthesis of these studies yields valuable insights showcasing various strategies that encompass faculty influence, program-level initiatives, and successful interventions aimed at enhancing inclusion in engineering. Some aspects of these frameworks include culture, climate and circumstance within an organization and its impact on different social groups. Similarly, some of this work focuses on pathways, support systems, transdisciplinary and sustainable approaches, and academic success (Pamulapati et al. 2021; Main et al. 2020; Gulbulak, Ertas, and Cordell 2020; Lee and Matusovich 2016; Fealing, Lai, and Myers Jr 2015; Hokanson, Phillips, and Mihelcic 2007; Leicht-Scholten, Weheliye, and Wolffram 2009; Taylor et al. 2017; Griffith, Hajiaghajani, and Griffith 2016; Sayles 2004).

2.1.2 Constructivist and Developmental Theory (CDT)

This theme highlights the different theories and frameworks developed from findings based on grounded theory or a mix of various theories that focus on creating supportive and inclusive learning environments, challenge dominant narratives, incorporate diversity and cultural awareness and promote authentic engagement and participation. These frameworks address various aspects, including understanding how to advance DEI based on the emergent knowledge of traditionally marginalized populations. This theme also includes aspects of emerging values, the influence of social, cultural, and political influences that impact students, conceptualizations of critical race, and experiences with the endemic nature of racism and its influence on engineering education (Simmons and Martin 2014; Sochacka et al. 2021; Corwin et al. 2020; McCall, McNair, and Simmons 2021; Dankert et al. 2019; Trytten et al. 2016).

2.1.3 Social Identity and Intersectionality Theory (SIIT)

In this section, theories and frameworks that view diversity as intersecting social categories like race, class, and gender were grouped. These categories shape people's behaviour, identities, and outcomes toward DEI in Engineering. Different theories or frameworks were used in the research included in this section, for example, professional identity development theory, social justice perspectives on diversity, equity, and inclusion, feelings of belonging, social cognitive theory and self, social identity theory. sense of community, expectancy-value theory, equity of parity model, model of motivation, and sustainable development framework (McCall et al. 2020; Cundiff and Murray 2020; Atadero et al. 2018; Casper et al. 2024; Lee et al. 2017; Park et al. 2020; Hernandez et al. 2017; Woodcock and Bairaktarova 2015; Scott and Martin 2014; Casper et al. 2024; R. M. Marra et al. 2010; Rose M. Marra et al. 2009; Whitcomb, Maries, and Singh 2021; Whitcomb et al. 2020; Lee et al. 2021; Artiles and Matusovich 2020; Roldan, Hui, and Gerber 2018; Godwin et al. 2016; Wint 2022; Corple et al. 2018; Pearson, Godwin, and Kirn 2018; Williams et al. 2016).

2.1.4 Community and Cultural Theory (CCT)

This theme highlights the different theories and frameworks that view DEI as prominent to cultural traits and social categories like race, class, gender, etc. These categories shape one's behaviour, identities, and outcomes towards DEI in Engineering. The theme provides the importance of understanding and leveraging cultural diversity, addressing inequities, promoting social networks and adopting culturally responsive approaches to enhance DEI in Engineering. These are frameworks that also focus on reducing stereotypes, supporting human-centred approaches, using social networks and capital-like Community Cultural Wealth (CCW), and emphasizing the significance of addressing historical and ongoing exclusionary practices and inequalities in engineering (Eastman, Miles, and Yerrick 2019; Tolbert Smith 2022; Wofford and Gutzwa 2022; Carrigan et al. 2019; Bowen et al. 2021; Martin, Simmons, and Yu 2013; Martin 2015; Perkins et al. 2018; Callens et al. 2019).

2.1.5 Critical Theory (CT)

This theme highlights the use of critical theories to address social justice issues in engineering, as critical theories aim to critique and challenge power structures and dismantle systematic oppression. The authors in this theme employ critical theories to advocate for transformative change in engineering education to promote DEI, including Afrocentric, indigenous, feminist, and intersectional approaches and ways of knowing and being. These frameworks also focus on the ongoing efforts to broaden academic discourses and promote forms of equity-oriented teaching in engineering education. Similarly, one of the goals is to promote agency and empowerment among marginalized groups by advocating for alternative perspectives and approaches that prioritize DEI and challenge oppressive systems (Blosser 2020; Secules et al. 2018; Roby et al. 2022; Blair et al. 2017; Foor, Walden, and Trytten 2007; Du and Kolmos 2009; Bowen et al. 2021; Bowen, Johnson, and Powell 2020).

2.2 Statements analysed

For this preliminary study, we decided to pilot our approach of coding some DEI statements using the 5 emerging themes as the lens for analysis. We selected statements focused on diversity, equity, and inclusion in two of the most recognized engineering education societies, i.e., the American Society for Engineering Education (ASEE) and the European Society for Engineering Education (SEFI). The statements we selected for our analysis were:

1. ASEE Statement on DEI https://diversity.asee.org/about/
2. SEFI Position Paper on Diversity, Equality, and Inclusiveness in Engineering Education: https://www.sefi.be/wp-content/uploads/2018/05/Diversity-2018-links.pdf
3. ASEE & SEFI DEI Joint statement: https://www.sefi.be/wp-content/uploads/2020/05/ASEE-SEFI-Diversity-Statement_updated.pdf

3. RESULTS

In this section, we summarize the result of our analysis of each of the emergent themes across the 3 statements and provide examples of how the theoretical theme has been presented in the statements (Table 1).

Table 1. Summary of the analysis of the three DEI statements

	DEI Statements		
Theories	ASEE	SEFI	ASEE & SEFI
IOT	Acknowledges the importance of inclusiveness and inclusion from an institutional perspective within the engineering education community and the engineering profession. It highlights the need for active engagement to promote the pursuit of engineering education and careers among historically under-represented individuals. Example: "In order for the engineering discipline to reach its full potential, however, the engineering education community and the engineering profession must better include all segments of our society."	Acknowledges the role of institutions and organizations, such as SEFI, in promoting diversity, equality, and inclusiveness within engineering education and the engineering profession. It suggests that creating inclusive environments involves structural changes within engineering education and professional settings. Example: "SEFI is committed to increasing the participation, inclusion, and empowerment of under-represented segments of society in all venues where engineering is taught, practiced, and supported."	Acknowledges the role of institutions and organizations in perpetuating discriminatory dynamics through preserving unexamined norms and values. It calls for action to transform institutional cultures and classrooms to create more inclusive environments. Example: "We must actively dissolve the systemic barriers that engineers have enacted against those who are implicitly and explicitly excluded from our engineering community."
CDT	Emphasizes the value of diversity in enriching educational experiences and driving innovation in addressing global challenges. It suggests that learning from experiences, beliefs, and perspectives different from our own fuels innovation and the development of creative solutions. Example: "We learn from experiences, beliefs, and perspectives that are different from our own. Diversity, both intellectually and socially, fuels innovation and the development of imaginative	Emphasizes the importance of diversity, equality, and inclusion in enriching educational experiences and driving innovation in addressing global challenges. It suggests that learning from diverse experiences, beliefs, and perspectives can strengthen the learning of all students. Example: "We learn from diverse experiences, beliefs, and perspectives. Diversity in all dimensions (individual, organizational, and societal) fuels innovation and the development of imaginative, holistic, and	Emphasizes the importance of examining and reshaping the focus, content, values, and norms of engineering and its educational environments. It advocates for creating collaborative and inclusive environments that value equity and celebrate diversity. Example: "We are therefore compelled by our professional and ethical commitments to exercise leadership to create and maintain collaborative and inclusive environments that value equity and celebrate diversity."

	and enduring solutions to global problems."	enduring solutions to global problems."	
SIIT	Recognizes various dimensions of diversity, including age, belief system, disability status, ethnicity, gender, gender identity, gender expression, national origin, race, sexual orientation, and socio-economic status. It advocates for equality of opportunity and the prevention of marginalization or non-inclusiveness based on visible or invisible differences. Example: "ASEE strongly believes that all must be provided with equality of opportunity to pursue and advance in engineering careers and that no individual should experience marginalization or non-inclusiveness of their contributions or talents because of visible or invisible differences."	Recognizes various dimensions of diversity, including physical ability, visible or invisible handicaps, race, ethnicity, sexual orientation, religion, gender, culture, geographical residence, and nationality. It advocates for providing equality of opportunity and preventing discrimination, marginalization, or exclusion based on conscious or unconscious biases. Example: "SEFI strongly believes that everybody must be provided with equality of opportunity, to pursue and advance their engineering careers, and that no individual should experience discrimination, marginalization or have their contributions or talents excluded because of conscious or unconscious biases."	Acknowledges the importance of considering intersecting identities and experiences, including race, ethnicity, gender, disability, socio-economic status, etc. It calls for promoting diversity and inclusion particularly among historically disadvantaged groups. Example: "We are committed to increasing the participation, inclusion, and empowerment of minoritized individuals who are commonly under-represented in all venues where engineering is taught, practiced, and supported.”
CCT	Promotes the creation of environments where every individual is respected and no one feels marginalized. It advocates for supporting the education, recruitment, retention, and advancement of historically under-represented groups in engineering education, engineering technology education, and the engineering profession. Example: "Our vision is to create and foster environments where every individual is respected and no one feels marginalized."	It emphasizes the importance of nurturing a culture of diversity in recruitment, retention, and advancement within engineering education and the engineering profession. Example: "Our goal is to create and foster environments where every individual is not only respected, but also feels safe and included."	Emphasizes the need for a culture of engineering that values different perspectives and serves the whole of society. It calls for creating environments that are welcoming, respectful, and valued for all members of society, regardless of their backgrounds and experiences. Example: "We envision a culture of engineering that values different perspectives, represents, celebrates, and serves the whole of society."
CT	Acknowledges the need for substantial progress to be made in achieving full empowerment for all segments of society,	Acknowledges the need for substantial progress to be made in promoting diversity, equality, and inclusiveness within	The text critically examines the historical lack of diversity in the engineering profession and its societal impacts.

	particularly those historically under-represented in engineering. It suggests that steady gains have been made in increasing diversity in engineering but that further progress is necessary to ensure full empowerment by all segments of society. Example: "While ASEE recognizes that steady gains have been made in the number of women, African-Americans, Hispanics, and Native Americans in engineering over the past several years, substantial progress must still be made to reach a state where engineering is fully empowered by all segments of our society."	engineering education and the engineering profession. It recognizes the potential negative aspects of teamwork for historically marginalized students and suggests interventions to address these challenges. Example: "Although teamwork plays an important role in the development of professional skills, it can also be a source of problems for under-represented students."	It advocates for challenging existing norms and values to address inequities and promote social change. Example: "A homogeneous engineering profession is absent the diversity of needs and experiences with engineered technologies, is unaware of barriers and problems that impact minoritized communities, and is insensitive of cultural values and perspectives — it is unable to fully accomplish its professional mandate to serve the whole of society."

4. SUMMARY AND ACKNOWLEDGEMENTS

Each of the three analysed texts demonstrates alignment with theories related to diversity, equity, and inclusion in engineering education and practice. This is perhaps not surprising in terms of the SEFI and ASEE statements given that some of the examples given in Table 1 show that these are very similarly phrased in places. However, they vary in the extent and focus of their alignment. which suggests the importance of context in the understanding and prioritization of DEI topics (Van Maele et al. 2023).

For example, the ASEE Statement on Diversity and Inclusiveness emphasizes the importance of inclusiveness in learning environments and the need for structural changes to promote diversity within engineering education and practice. The SEFI Position Paper on Diversity, Equality, and Inclusiveness in Engineering Education focuses on creating inclusive environments within engineering education and the engineering profession and on minimising bias. The ASEE & SEFI Joint Statement on Diversity, Equity, and Inclusion emphasizes the need for systemic change to promote diversity, equity, and inclusion within the engineering profession and education.

Our findings not surprisingly showed a lot of connection between the themes proposed and the statements revised. We consider the intentionality of these statements to play a role in this finding. Similarly, we could observe the varying degrees of alignment with the theoretical underpinnings of the statements. We consider this can open a conversation and suggest that engineering education institutions and organizations should critically review their DEI communication to ensure intentional alignment with theoretical frameworks. This does not mean to include language that recognizes all the themes, but we suggest including the majority of spaces. It is also important to recognize the context of DEI work, considering how statements and policies should be sensitive to local needs and consider global perspectives and diverse cultural contexts while also aiming for universal principles of equity and inclusion.

One limitation of our study is that given that the five theoretical lenses derive from a review of the existing DEI literature in engineering education when using these lenses, we can only refer to what extent policy statements adhere to the current practice in the field; this might change as our field evolves. Moreover, our review was limited to English language publications, it may have missed existing lenses from other linguistic regions in the world. Nevertheless, this paper provides a framework for writing DEI statements critically and intentionally. It would be interesting to expand this analysis to other DEI policy documents to see whether similar results would emerge.

Conference Key Areas: *Diversity, equity and inclusion in our universities and in our teaching, Building the capacity and strengthening the educational competences of engineering educators*
Keywords: *teacher tutoring, pastoral care, academic care work, equality*

ABSTRACT

Research and teaching constitute the primary components of academic work, yet academics also shoulder numerous other responsibilities, often categorised as internal and external service work. While some aspects of this work, such as administrative tasks, are acknowledged and compensated, many academics receive no compensation for delivering internal services, including student care.

Studies indicate that women faculty members often undertake more internal (invisible) service work than men, especially within STEM fields. Furthermore, disparities in service work allocation vary throughout academic careers. This study examines whether gender discrepancies exist in undertaking invisible work, particularly student care, among the engineering faculty at a Finnish university. We also compare the distribution of care duties between native and international faculty members. With a focus on teacher tutoring, we investigate how care duties are recognised, compensated, and rewarded.

Results indicate that caring duties appear to fall on Finnish faculty members and that women are overrepresented in teacher tutor roles. According to the responses, teacher tutoring, although crucial for student welfare and academic success, is often

[1]*J.K. Naukkarinen*
johanna.naukkarinen@lut.fi

undervalued and neglected in professional development discussions. Thus, the study underscores the importance of recognising academic caring duties as legitimate academic work and advocating for fair compensation and acknowledgement to foster equality and a supportive environment for all members of the academic community.

1 INTRODUCTION

Research and teaching are widely acknowledged as the main components of the academic work. Nevertheless, academics also hold many other duties. Much of this other work can be characterised as service work. Following Ward (2003), Guarino and Borden (2017) divide service work into internal and external services, with internal service consisting of activities related to tasks like faculty governance, faculty recruitment and promotion, student recruitment and admissions and program supervision, and external service including activities outside campus and directed to the profession and other communities outside academia.

Part of the service work, like defined administrative roles, is well recognised and compensated for, but many academics receive no compensation for service work, especially for delivering internal service, as this is expected of them as good members of the academic community (Guarino and Borden 2017). The University of Oregon Social Sciences Feminist Network Research Interest Group (SSFNRIG 2017) calls this kind of implicitly expected and uncompensated work invisible work and sees it as consisting of two types of tasks: 1) making the academy a better place for instance through diversity work (committees, task forces, mentoring, etc.) and 2) care work (mentoring, advising and helping students in general matters).

Several studies suggest that women faculty members perform more internal service work than men (Bengivenca & Drew 2021, Guarino and Borden 2017, Kinahan et al. 2021). According to (Misra et al. 2011), even when the overall task division is rather equal, women spend somewhat more time on mentoring and service. Furthermore, these gendered patterns of workload allocation are more pronounced among STEM faculties than others. Kinahan et al. (2021) recognised a similar perceived gender disparity in the allocation of service duties and student care responsibilities in one higher engineering education institution.

The gender disparities in service work appear not to be constant throughout the academic career. Misra et al. (2011) observed that especially among associate professors women engaged considerably more in mentoring and service than men with equal working hours. In another study, the gender difference in the service-related workload was greatest at the rank of assistant professor (SSFNRIG 2017). In addition to female faculty members, the invisible work seemed to be falling on the shoulders of marginalised groups, such as faculty of colour, queer faculty, and faculty from working-class backgrounds, who for example at the assistant rank spent approximately four times the mean for a non-marginalised professor on service (SSFNRIG 2017).

The invisible work including student care is not only uncompensated but often also undervalued in terms of promotion (Angervall and Beach 2020, Kinahan et al. 2021, O Connor 2021, SSFNRIG 2017). Hence, the uneven distribution of invisible work hinders the career progression of some more than others. O Connor (2021) argues that the stereotypical expectations of women being ‘naturally’ better at pastoral care lead to gendered differences in workload and further in climbing up the academic ladder. Angervall and Beach (2020) suggest that women feel more responsible for caring about others and thus accept low-promotability tasks more easily than men.

This study attempts to investigate whether similar gender differences in taking on the invisible work especially related to the pastoral care for students can be detected among the engineering faculty at a university in Finland. Pastoral care is understood here as supporting students' academic needs (guiding them on how and what to study), providing career counselling, being interested in students’ well-being, and directing students to specialised study counselling or health-care services if needed. In addition to gender differences, we also compare the distribution of care duties between the native and international faculty members. In addition to the responsibility allocation, we also want to enhance our understanding of how the student care duties are recognised, compensated for and rewarded as part of academic work.

2 METHODOLOGY

2.1 Data collection

For the first part of the research, we collected information about the ‘academic care providers’. We defined the most prominent care-related roles as 1) program heads, who for instance provide general advice and organise the orientation of new students; 2) teachers in the introductory courses, where new students are introduced to the degree and university, guided how to study, and provided information about their future career opportunities; 3) teachers in the thesis seminar courses, where students are educated about the basic skills and working methods in scientific research and 4) teacher tutors, who are defined as the liaisons between the degree program teaching staff and students, and who are expected to provide guidance in career planning and choosing subjects. Teacher tutors are part of LUT University’s study guidance and counselling services (eLUT, n.d.), but unlike other counsellors and advisors, they are not administrative personnel but academics, who carry out the duty alongside their research and teaching. This kind of role is also known as teacher-counsellor or pastoral care teacher.

The tasks of the teacher tutors vary slightly across the degree programs, but they usually include individual or small group discussions with students. Tutors can generally be regarded to have a more personal contact with students than course teachers. The emphasis of teacher tutoring is usually on the first year, but tutoring continues also after that.

The names of the informants were collected from the university intranet (program heads), the student information system and the curriculum database (course teachers), and the student intranet (teacher tutors). The Finnish respondents’ gender and ethnic background were deduced from the name and the non-Finnish respondents’ gender and ethnic background from the personal information and contacts of the first author. Most of the informants were known personally or by name by the authors, as the university is rather small. The stage of the career path was deduced from the person’s title. The classification of the career path stages follows the four-stage research career model used in Finland (Research.fi, n.d.). The data about the engineering faculty in its entirety with the information about gender distribution, ethnic background and working title were requested from the university human relations department.

For the second part of the research, we designed a survey that was administered to all teacher tutors of the engineering faculty. The survey consisted of two background questions (faculty and tutoring experience), ten statements about the resourcing and recognition of teacher tutoring, six statements about the support for teacher tutoring, a slider question about recommending the task/post of a teacher tutor, and two open questions (Why did you agree to act as a teacher tutor? What else would you like to say about teacher tutoring and its development?). The statements were rated with a 5-point Likert scale from fully disagree (1) to fully agree (5). The survey was administered to the teacher tutors by email from the survey tool with a personal link to the survey. The tutors who had not completed the survey within a week of its administration were reminded once about the survey.

The data collection followed the ethical principles of research with human participants of the Finnish National Board of Research Integrity TENK (TENK 2019) to which LUT University is committed. According to the principles, the informed consent of the adult informants was required, but there was no need for an ethical review. The survey was anonymous and voluntary, and the respondents were informed about the use of data for research.

2.2 Data analysis

The personnel data were analysed with descriptive statistics (frequencies, distributions), and the statistical significance of the differences of distributions between different groups was tested with the Chi^2 test. The survey data were compressed with the help of distributions and means, and the categorisation of open comments.

3 RESULTS

3.1 Division of care duties among faculty members

The data about the whole engineering faculty are presented in Fig. 1. The figure shows that there are more men than women in all stages of the career path. The first stage of the career consists of doctoral studies. Most of the people in the first stage leave the university after receiving their doctorate. The doctoral students' most important duty is research, and they are expected to complete their studies in four years. Therefore, they are generally exempt from other duties. Currently, international doctoral students significantly outnumber Finnish doctoral students, but in later career stages international faculty members constitute a clear minority. Considering that doctoral students are quite unlikely to be given care duties and that the ethnic division among doctoral students is opposite to that in later career stages, it was decided to include the faculty members only from career stages II–IV in the actual analysis.

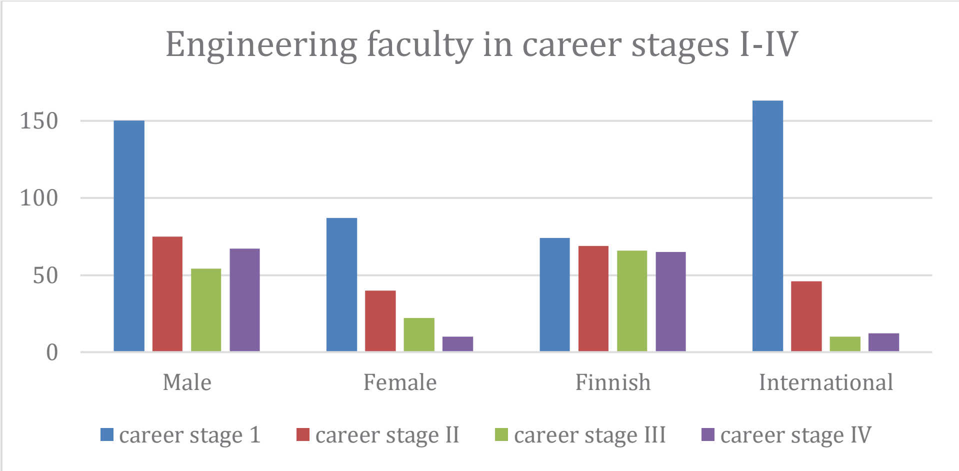

Fig. 1. Engineering faculty in career stages I-IV

In career stages II–IV the number of men is quite stable but the number of women decreases along the career path. The number of Finnish faculty members is also quite similar in all stages, but the number of international faculty members drops drastically after career stage I and then again after career stage II (non-tenure post-doctoral researchers and assistant professors in a tenure track).

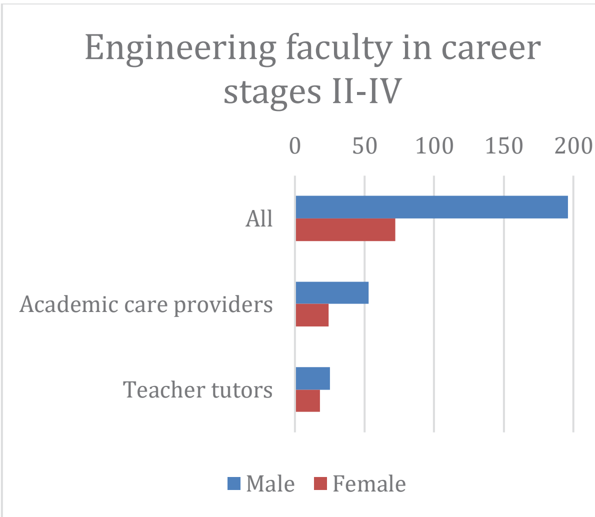

Fig. 2. Gender of engineering faculty in different roles

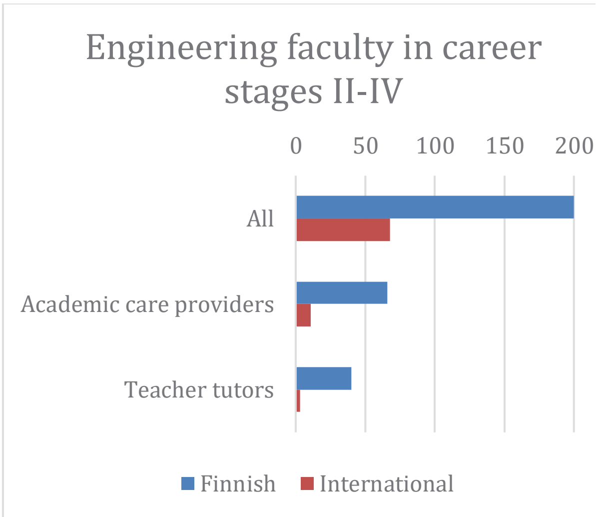

Fig. 3. Ethnic background of engineering faculty in different roles

Fig. 2 shows the numbers of men and women and Fig. 3 the numbers of Finnish and international faculty members in the whole faculty as well as among the academic care providers in general and teacher tutors in particular in career stages II–IV. The number of teacher tutors is included in the number of academic care providers. Based on the figures, it seems that compared with the composition of the whole engineering faculty, women may be overrepresented among the teacher tutors and the international faculty members underrepresented among the care workers. This was confirmed by a Chi^2 test with a 95% significance level, the results of which are presented in Table 1.

Table 1. The statistical significance of the differences of distributions between different groups

Compared groups (df=1)	Male vs. Female	Finnish vs. International

	Chi^2	p	Chi^2	p
All vs. Care workers	0.84	0.358	4.94	0.026*
All vs. Teacher tutors	4.87	0.027*	7.40	0.007*
Care workers vs. Teacher tutors	1.52	0.218	1.31	0.252

* Statistically significant difference at the 95% confidence level

A closer look at the composition of teacher tutors reveals that international staff are unlikely to become teacher tutors in all the stages of the career path. The numbers also suggest that women are proportionally more likely to become teacher tutors in career stages II and III, whereas all the teacher tutors in career stage IV were men. This is understandable provided that within the highest career stage of the whole engineering faculty, only 10/77 (13%) of the people were women and 7/67 (10%) males were teacher tutors.

Table 2. Teacher tutors' gender and ethnicity in different career stages (excluding the two teacher tutors who do not belong to academic staff)

Career stage	Male	Female	Finnish	Inter-national	Male	Female	Finnish	International
I	5	4	7	2	9 %	7 %	13 %	4 %
II	7	9	15	1	13 %	16 %	27 %	2 %
III	11	10	20	1	20 %	18 %	36 %	2 %
IV	7	0	6	1	13 %	0 %	11 %	2 %

3.2 (In)visibility of teacher tutoring

The survey on teacher tutoring was answered by 27/55 people, making the response rate 49%. The responses to the statements about the resourcing and recognition of teacher tutoring are presented in Fig. 4 and the responses to the statements about the support for teacher tutoring in Fig. 5.

The first five statements in Fig. 4 indicate that a fair number of people are able to reserve the necessary time for teacher tutoring activities. However, the tutoring duties are not well recognised as part of their academic work and are rarely addressed in the discussions on their professional development. The last five statements paint an even grimmer picture. None of the respondents report to have been specifically compensated monetarily for teacher tutoring, and only one out of 27 respondents agrees that teacher tutoring has been taken into account in the review of their work performance (either in the position requirement review or in the personal performance evaluation), which affects their salary. None of the respondents agrees either that being a teacher tutor has advanced their career or securing a work contract.

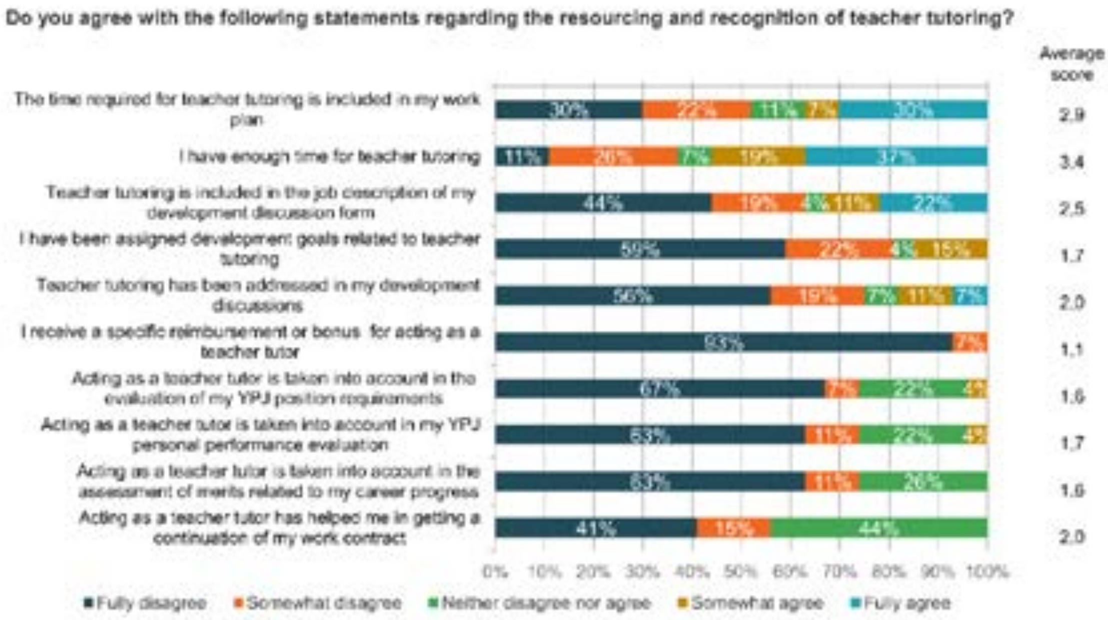

Fig. 4. Teacher tutors' views on resources and recognition of teacher tutoring

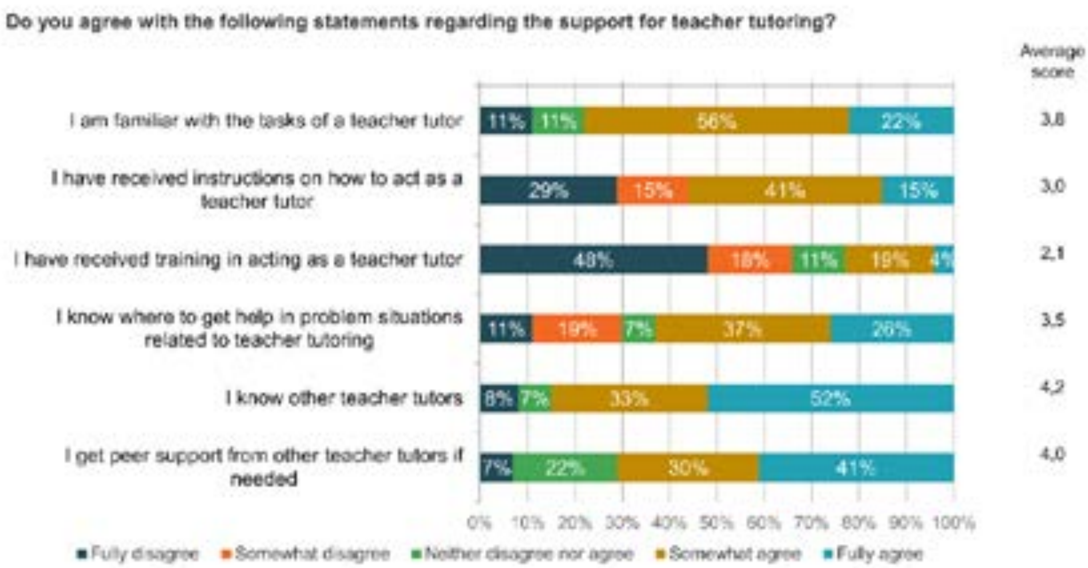

Fig. 5. Teacher tutors' views on support for teacher tutoring

Fig. 5 indicates that although it is relatively well acknowledged what it means to be a teacher tutor, almost half of them have received no instructions, and more than 60% of them have received no training in how to be a teacher tutor. Based on the survey results, peers provide most of the support for acting as a teacher tutor.

The open question about motivation indicates that most of the respondents (16/27) have been assigned as teacher tutors. Some of those ordered as teacher tutors did, however, see it fitting well with their other tasks:

It is a nice change and you get to talk to the students, which otherwise happens quite rarely. I am Finnish and there is a shortage of tutors, so in part I also have to [act as one] 😉 *[translated from Finnish]* whereas others see no connection with their other work:

That's a good question. Somehow I feel that's not my job. [translated from Finnish]

There were, however, also people who had a strong motivation for the task (9/27), although the source of that motivation varied:

I want to be easily approachable to students and help them in resolving their problems. [translated from Finnish]

I want to be a good example and help. [translated from Finnish]

Fifteen respondents also answered the last open question about any other things the respondents wished to say about teacher tutoring or its development. In their comments, the teacher tutors mainly called for better visibility of tutoring in the development and evaluation discussions, better definition of the tasks, more instructions and training, and better appreciation for the role.

4 SUMMARY

As already shown in previous research, women seem to bear more of the workload of the academic care work and be overrepresented especially in the role of teacher tutors. In the LUT context, the caring duties appear to concentrate more on the native Finnish faculty members than their international colleagues. The situation remains unbalanced even if the nationality of the student cohort is taken into account, as approximately one-third of the LUT engineering students but only 10% of the teacher tutors are international. Also expectedly, the work of the teacher tutors can be characterised as invisible work, which is not very well recognised in the processes of professional supervision and development or rewarding and promotion. All this leaves especially the Finnish-speaking women with the risk of being overloaded with low-promotability care work, which results in ‘the midcareer service gully’ (Misra et al. 2011).

Probably due to the uncompensated and low-promotability nature of teacher tutoring, the position of the teacher tutor is seldom a genuine choice of the individual but a task that is assigned to someone, whether they want it or not and whether it suits their work responsibilities as a whole. Yet the benefits of teacher tutoring and other care work for student welfare as well as for the speed and likeliness of their graduation are easy to envision. Better recognition of academic caring duties as rightful academic work in terms of both preparing and supporting people in their roles and compensating and rewarding people through pay and career progress is essential not only in making academia more equal for women but also in ensuring a better environment for all members of the academic community.

The results cannot be generalised to other universities with different kinds of student and personnel bodies and services for guidance and counselling. However, the statistically significant differences and the empirical support for the invisibility of the academic care responsibilities in the LUT University’s HR processes, which are well in line with earlier research on academic care, suggest that also other universities in and outside Finland might want to pay more attention to the distribution of the invisible care work within their organisation to ensure the fair treatment of the faculty.

ABSTRACT

Within the context of STEM education, students who enter university having studied mathematics in high school and men are considered the traditional population. From this perspective, students who do not correspond to such profile have more difficulties succeeding in their studies. Previous studies have shown that with some efforts, curricula can be made more inclusive. Therefore, this study investigated to what extent online forums help diverse students, as defined previously, succeed in the first year at university, a period where freshmen are most at risk to drop out and where we estimate that forums could support most. The study relied on quantitative methods to investigate the intended aim. More precisely, the research took on an explorative secondary data analysis in order to process data already available in Piazza Forums. Using a large sample (N=2337), our results revealed that indeed the use of forums in the first year at university is more beneficial for weaker students in terms of mathematics ability and for women

alexandra.niculescu@epfl.ch

1 Introduction

In the pursuit of fostering inclusive and diverse learning environments, higher education institutions worldwide are confronted with the imperative to embrace innovative strategies that go beyond traditional boundaries and foster equitable participation among all learners. Amidst this imperative, online forums emerge as a potential tool that could promote equity, and inclusiveness within higher education overall. Forums, are online platforms designed to facilitate asynchronous communication and collaboration. Furthermore, through annonymous features, they offer a safe space where individuals from diverse backgrounds can interact, collaborate, and co-create knowledge. Unlike traditional classroom settings, which may inadvertently privilege certain voices while marginalizing others, online forums provide opportunities for equitable participation and amplification of underrepresented perspectives, like having a weaker mathematical background, as well being a female. More nuanced, in first year at university, where the challenges to adjusting and succeeding still remain an issue, the potentials of forums to enhance student engagement, facilitate peer interaction and extend learning beyond traditional classroom settings – among more diverse populations - seem promising. Given the diversity of students' prior education when entering university and the challenges students face in the first year we estimate that forums could help diverse freshmen most.

1.1 Literature review

Poor student achievement, low study progress, and dropout have been increasingly recognized worldwide as issues of interest (OECD 2009; O' Neillet al. 2011). Especially in the first year of university study – a period of transition (Ruthig et al. 2008) – a high proportion of students who enrol in a study program leave the institution without completing the first year (Times Higher Education 2022). In particular, this seems to be a problem for non-traditional or diverse students, with a weaker mathematics background and women that seem to be most at risk as introductory courses can play a role in pressuring and discouraging them in continuing their studies. To cope with this unwanted situation problem, universities responded with a series of instructional redesign practices in the introductory courses. Therefore, finding the most suited instructional tools that could help this category of disadvantaged students succeed is key.

In higher education, forums have been advocated for the past twenty years. In their effectiveness, two mechanisms have been laid out to play a role: the enhancement of collaborative learning and the different feedback channels available and employed by the forum participants. In other words, forums use both mechanisms, which are also known for their strongest effects on student learning (Hattie and Timperley 2007; Wisniewski et al. 2020). Two lines of research are mainly streaming the effectiveness of online forums (Du et al. 2022): the first one focuses on the factors that affect student participation in the forums and the second one looks at whether this participation influences academic performance. Beyond the mechanisms that make forums efficient, the more interesting question is for whom are forums most useful?

Online forums have been advocated in STEM education for the past twenty years (Kortemeyer 2006). Their utilization resonates with constructivist and socio-cultural theories (Chen et al. 2018; Rovai 2004), which emphasize the importance of social interaction, collaborative inquiry, and knowledge construction in learning processes. Forums, by nature, embody the principles of social constructivism, as they provide a virtual space for students to actively participate in dialogues, share diverse perspectives, and co-construct meaning through collective discourse. Empirical investigations into the effectiveness of online forums have yielded insights into their impact on student learning outcomes and academic performance. In STEM domains, like introductory Physics course, for instance, evidence shows that online participation outside the classroom through homework activities is most useful for weaker students in terms of being at risk of failing the course (Kortemeyer 2009). Furthermore, the usually present gender gap, can be closed in a two-semester course, where the girls catch up with their male colleagues in terms of performance on final exams (Kashy et al. 2001). This could be partially explained by the fact

that forums promote deeper conceptual understanding (Roseli and Umar), foster higher levels of student engagement (Chen et al. 2018), and encourage peer participation among learners (Wallace 2003). At the same time, the gender gap has another alternative explanation, resting on the assumption that technology itself is a `gendered construct` (Sierpe 2000, p. 273), which is a neglected aspect when forums are used in STEM education.

One interesting aspect regarding the effectiveness of forums is how students' level of participation, in particular viewing and commenting are related to performance at the course level. On one hand, there are different levels of cognitive processing between just viewing and commenting on posts that may impact learning and overall performance (Chiu and Mok 2017). On the other hand, since the participation is voluntary and, most frequently, anonymous, students can participate in discussions where more diverse perspectives can be accommodated. As such, it was argued that the learning environment and the nature of the learners in MOOCs is different than the more closed online environments (Chiu and Hew 2018),.

There are many benefits available in online forums but as Kadagidze (2014) put it, they require their learners to participate; it allows them to take time to reflect and search for information before commenting or simply to observe the actions of their peers. In practical terms, the integration of forums into educational contexts requires careful consideration of instructional design, technological infrastructure, and pedagogical strategies. Educators must create structured forum activities that align with learning objectives, promote active participation, and cultivate a supportive online community. Furthermore, fostering a culture of respect, inclusivity, and academic integrity within forums is essential to ensuring productive and meaningful interactions among students.

1.2. Aim and research question

The aim of this research is to investigate to what extent online forums help diverse students, in terms of gender and mathematics ability, succeed in the first year at university, a period recognized as difficult for most freshmen.

We asked the following research question: Do forums help students with weaker mathematics ability succeed in their first year courses? The main hypothesis we will test is to predict the grade obtained in a given course with the participation indicators (views and contributions) as well as indicators for general mathematics ability (highschool education type and reference grade in first year algebra).

2 METHODOLOGY

2.1 Sample and Setting

Participants (N=2940) were students enrolled in courses (n=19) that make use of Piazza forums available in the first year of study at a Technology University in Central Europe, entering the program from 2017-2018 to 2020-2021. These programs deviate from mainstream, European university education in two ways: student-centred instruction known as project-based learning (PBL), and a strong international orientation: the programs attract a large proportion of international students. Among the 2940 freshmen in this study, about 30% of the students are female, 70% male. Most students enter the program directly after finishing high school where the typical age range is 18-20 years.

Prior education differs by nationality and mathematical track. The diversity of students' prior education and, hence, prior knowledge creates diversity in the challenges students face in the first year, a period where students are most at risk to drop out of studies and where we estimate that forums could help most.

2.2 Procedure for sampling

In this study the procedure for sampling employed k-anonymity at the student level and was approved by the Ethical Commission at our institution. Furthermore, we asked the unit in charge of academic data to enrich it with indicators of academic performance. Based on this, we arrived at a number of courses that could be further examined, without compromising the identity of the students.

2.3 Measures

Previous math education when enrolling at university. This variable contained the high school diploma that was followed by the student and contained the following categories: Swiss (Math and Physics or PAM, Biology and Chemistry, Other specialities), French and other diplomas.

Gender was the other indicator that accounted for demographic factors.

Grades in first year linear algebra (for control of general mathematical ability). The Linear Algebra grade served as a baseline for academic performance since the exam contains 80% of shared questions among the different sections of this course. This is operationalized as strength ability.

Study program, semester and course code.

Number of views (the student reads a discussion thread) as well as the *number of contributions* (the student posts a message) at the Forum level *as Student participation indicators*

Grades obtained in the course for which the forum was used in the first year of study.

2.4. Data analysis

A series of Chi-Square tests, mixed-effect regression model and an analysis of Deviance on the mixed effect model were performed to test the hypotheses proposed in our study. All analyses were performed using R Statistical Software (v4.1.2; R Core Team 2021) and the R package `lme4`.

3 RESULTS AND DISCUSSION

3.1 Preliminary analyses

While previously it was considered that the type of high-school diploma can be a reliable proxy for the mathematics level of students, we propose a different conceptualization: Strong vs Weak general mathematical ability, operationalized through a median cut of the first year Algebra grade. Figure 1 shows that there is a significant but small (Kramer's V=0.18) relationship (X2[4]= 91.93, p<.001) between the mathematical ability and highschool type. There are many strong students, with highschool types (Other, CH-Other, CH-BioChem) that are regarded as non-traditional or weaker and conversely, there are also many weaker students with highschool backgrounds (France, PAM) that correspond to the traditional STEM audience. We prefer using a general mathematical skill indicator rather than high school categories because it might reduce the risk for stigmatisation of a particular group of students, and offers a potentially more valid account of skills that predict success in the first year.

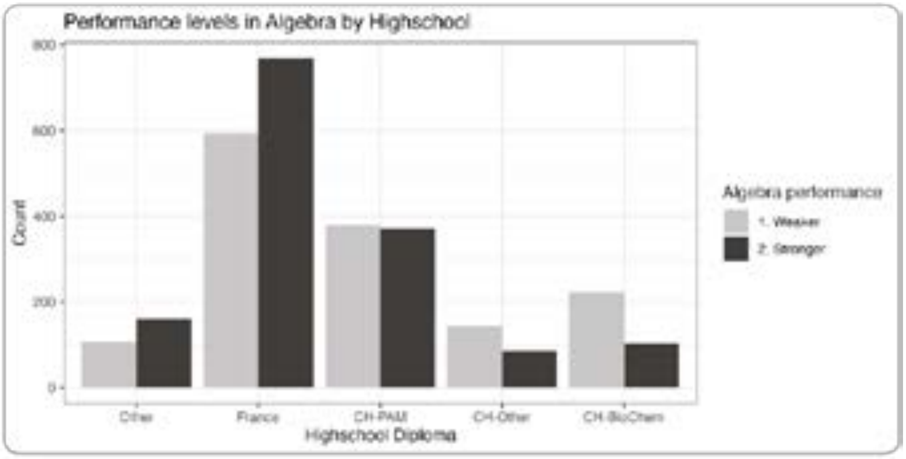

Figure 1. Algebra performance and high school type.

Another interesting feature of the algebra grade as a mathematical ability indicator is that it is only very weakly (Kramer's V=0.043) associated with gender (X2[1]=5.36, p=.02). We see in Figure 2 that there are almost as many men and women in the strong and weak categories and therefore decide to use the algebra performance as a gender-neutral baseline to observe gender biases in other disciplines.

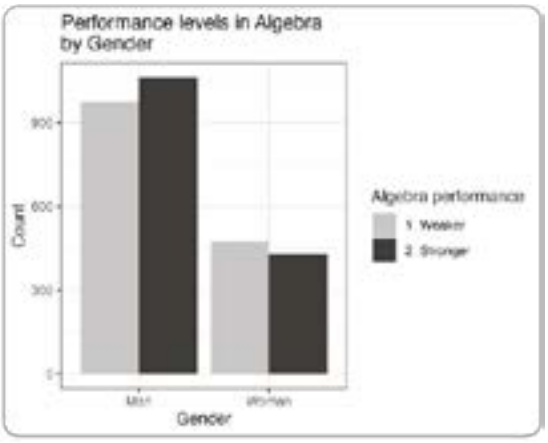

Figure 2. Algebra performance and gender.

3.2 Main analyses

To answer our research question, if forums help students with a weaker mathematics ability succeed in their courses, we assumed the grade obtained in a given course depends on the participation indicators (views and contributions) as well as an indicator for their mathematical ability (reference grade in first year algebra in terms of their strength) and gender. We build a mixed effects linear regression to predict the grade in 19 first year courses (n=4446 observations). Variations due to particular courses or students (intraclass correlations) are considered by including random effects in the model at two levels: student (some students participated in more than one course) and course (courses have different difficulties). The fixed effects are the forum use type (NONE, VIEW, CONTRIB), gender, and "mathematical strength" (or base level ability as weak vs strong).

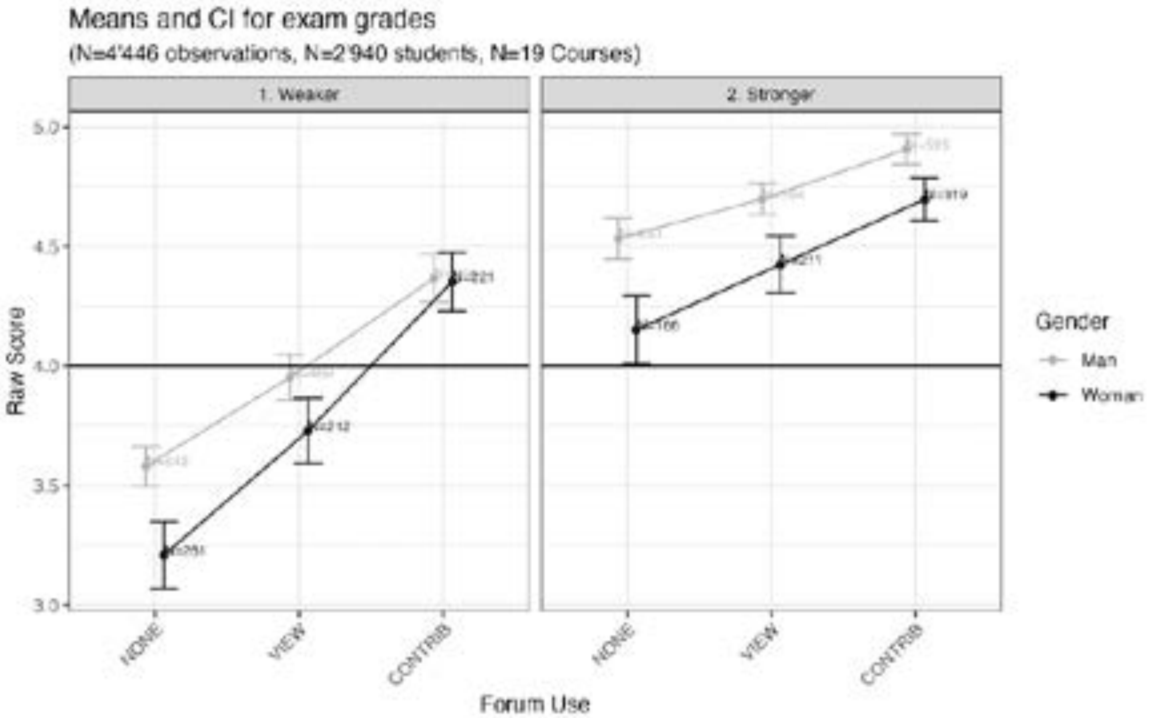

Figure 3. Forum use and exams grades by strength and gender

Figure 3 shows the course grades with a range from 0 to 6, where 4 stands as the passing grade. The model fit criteria (AIC = 11114.43, BIC = 11210.43), Pseudo-R^2 (fixed effects) = 0.18 and Pseudo-R^2 (total) = 0.58 demonstrate that our variables of interest contribute significantly to explaining variance in academic performance. Looking at the model fits in Table1, we can observe the following effects. The students that perform better are those with a stronger base level of mathematics ability (right panel of 3). Regarding forum participation, students who contribute then who view posts in the forum rather that those who do not participate perform better. Finally, Men perform better than Women overall. Furthermore, Intraclass correlations (ICC) are relatively low which indicates that 29% of the grade variation can be explained by the fact that the same student did the exams, and 19% of the grade variation can be explained by the course (ie. some courses are easier than others, such as all the grades obtained by students in a course are correlated). To interpret interactions, from the results reported in Table 1 we can say that participating in the forum (viewing or posting) benefits weaker students more than stronger students, conform to our conceptualization.

Table 1. Analysis of Deviance (Type II Wald chisquare tests) with grade as dependent variable

	Chisq	*Df*	*Pr(>Chisq)*
strength	648.3571	1	< 2.2e-16 ***
forum.use.type	143.0956	2	< 2.2e-16 ***
gender	17.1138	1	3.521e-05 ***
strength:forum.use.type	34.5135	2	3.203e-08 ***
strength:gender	1.9488	1	0.16272
forum.use.type:gender	6.2955	2	0.04295 *
strength:forum.use.type:gender	5.7539	2	0.05630

With respect to gender, the difference of grades between students who did not use the forum, viewed or contributed is larger for women than it is for men, which indicates that forum participation might be more beneficial for women. The triple interaction, although marginally non-significant (p=.05), hints towards the observation that forums are most beneficial for women with weaker math background. To conclude, it seems that the use of forums in the first year at university is more beneficial for weaker students in terms of mathematics ability and for females.

3.3 Discussion

To start with, the students that perform better are those with a stronger base level of mathematics ability. Regarding forum participation, students who contribute then who view posts in the forum rather that those who do not participate perform better. The benefits of forum use have already been establised (Kadagidze 2014) and in our study it is strongly related to success at the course level and that is even stronger for those with a weaker math background. This is in line with previous studies, such as Kortemeyer (2009) and important overall, as it allows students to pass the first year of studies. Finally, Men perform better than Women overall. However, the gender gap exists in the sense that the difference of grades between students who did not use the forum, viewed or contributed is larger for women than it is for men, which indicates that forum participation, as indicated by previous research (Kashy et al. 2001) might be more beneficial for women. In addition, the triple interaction (although marginally non-significant), points towards the observation that forums are most beneficial for women with weaker math background.

Overall, we can state that our institution is probably not different than other higher education environments in STEM domains but the direction of our findings indicates that encouraging forum use has the potential to improve student performance and passing rates in the first year.

3.4 Limitations

First, the k-anonymization process we have outlined might have introduced a bias in the selection of courses, since we only retained those with many overall students, and for which all possible types of participation (contribute, view, no participation) could not identify the participants. Second, in terms of study design, we did not use an experimental approach therefore our conclusions are of correlational nature and do not imply causality.

3.5 Scientific relevance

This research could enhance the educational processes at universities as well as help better explain how diverse students engage with/in several courses and how this affects their overall performance for various achievement outcomes in the first year. It could further help the education at such institutions by providing recommendations for practice that could be relevant for different stakeholders: it could feed into the first-year commissions with potential for improved feedback practices. It might also be relevant for centres for pedagogical resources, in terms of training of teaching staff that is active in this transition period.

ABSTRACT

Competition can be a powerful tool for boosting student motivation, often leading to at least good short-term results and aiding in achieving learning goals. We investigated this by implementing EduML, a novel learning analytics system integrated into the university's learning management system. EduML offered students a leaderboard to track progress, while course personnel could view statistics more in detail. To assess the effectiveness of EduML, we analysed learning outcomes and feedback of students in compliance with the improvement of design-based research. Our investigation unveiled a favourable reception: students embraced EduML as a benchmarking tool, with the leaderboard feature notably amplifying their motivation. However, the range setting after a critical mass of submissions received less favourable feedback.

1 INTRODUCTION

Algorithms can come to the rescue when hardware and brute force approaches fall short, offering necessary finesse. Driven by the ever-increasing competition within the industrial sector, algorithms are constantly evolving to optimize efficiency. Efficiency is integral to sustainability. This focus on efficiency is not just limited to industry; it should also be a core principle emphasized in higher education. This saving mindset is precisely what Tampere University's Data Structures and Algorithms (DSA) course aims to instill. By imposing constraints on command counts in student solutions, DSA goes beyond simply teaching syntax. It forces students to consider the performance implications of their code, prompting them to optimize and find creative solutions. This focus on efficiency permeates the entire course. It prompts students to contemplate performance and optimization concerns. Consequently, the final assignment evaluation relies on command counts and optimization metrics.

The course leverages a custom tool called EduML to enhance learning analytics and provide tailored visualizations. To further motivate students and highlight the impact of design choices on code efficiency, the EduML provides performance histograms and a Top-5 leaderboard. This low-stakes competition allows students to compare their solutions and gain awareness of achievable performances. This approach, combining pedagogy, EduML, and a focus on performance optimization, places the impact of code design choices at the forefront of student learning. Thus, this study asks:

1. What were the most significant effects of EduML on the course practice?
2. How did students perceive the competitive setup?
3. Which were the identified benefits and challenges associated with learning out-comes?

2 RELATED WORK

Traditionally, schools have relied on extrinsic motivators like gold stars, best student awards, honor rolls, and even pizza parties to boost student engagement. These reward-based systems are often referred to as "external regulation". Research by Deci and Ryan suggests that external regulation can actually undermine intrinsic motivation, the natural desire to learn and achieve (Deci, Koestner, and Ryan 2001).

This happens because external rewards can shift the focus from the enjoyment of learning itself to the pursuit of the reward. Instead of using external regulation, education should strive intrinsic motivation, where students develop a genuine interest in the subject matter. According to self-determination theory (SDT), intrinsic motivation stems from fundamental psychological needs such as autonomy, relatedness, and competence (Ryan and Deci 1985; Deci and Ryan 2012).

Autonomy involves the desire to endorse one's actions and behaviours willingly, without feeling coerced, bribed or pressured. It plays a crucial role in guiding individuals even in activities that may not inherently seem enjoyable or stimulating, such as work or life responsibilities. When individuals feel autonomous in these activities, they are more fulfilled and engaged. Relatedness cultivates happiness and fortifies social cohesion. By contributing their expertise and aid within their social circles, individuals not only enhance their competence but also earn respect from others, which adds to their felt competence. Competence refers to the need to feel effective in one's interactions with the environment, to feel capable and proficient in mastering challenges, and to experience a sense of accomplishment. Competence is achieved through accomplishing personal goals, that are self-determined (Ryan and Deci 2000).

Under the umbrella of SDT, there are multiple mini theories, such as goal content theory (GCT) that focuses on the types of goals individuals pursue and how they relate to their basic psychological needs (Ryan and Deci 2019). Within the realm of competition, when students establish goals that resonate with their individual passions and principles—such as acquiring new skills or challenging their own boundaries—it cultivates intrinsic motivation.

2.1 Competition

The SDT addresses the complex relationship between competition and the influence in a student motivation both via intrinsic and extrinsic motivation mechanisms. Competition may reflect a “controlled” orientation indicative of extrinsic motivation, if it stems from external incentives such as points, grades, recognition, or the avoidance of punishment. Thus, competition is often perceived as a questionable method of motivating students due to the varying responses it elicits. Not all competition is detrimental though. Some students thrive in competitive environments, viewing them as opportunities to test and improve their skills. This aligns with an autonomous orientation, where students are internally motivated to learn and excel. Research by Mekler et al. suggests that healthy competition can foster engagement, goal setting, and a short-term boost in intrinsic motivation (Mekler et al. 2013). Competition and gamification can also make serious, useful but uninspiring routine tasks more interesting; the “games with a purpose” capitalize on the motivational power of competition while still focusing on achieving meaningful learning outcomes (Medlar and Głowacka 2022).

Leaderboards foster competition. They can be a powerful tool for boosting (short-term) extrinsic motivation by appealing to human being's inherent desire for social comparison and competition (Kim 2015). Goal discrepancy also matters. Nebel et al. found learners in lower ranks exerted more effort climbing the leaderboard, therefore learned better, likely due to the larger gap between their current position and desired goal (Nebel et al. 2016). Our own research (Niemelä et al. 2023b; Niemelä et al.

2023a) adds a layer of nuance, showing students near the top, but not quite at the top, were most likely to push themselves further.

It is imperative to consider the potential impact of competition on all students. Unhealthy competition fosters a win-lose mindset and can isolate students, undermining their sense of connection and potentially leading to decreased motivation and well-being. Moreover, competition often exacerbates feelings of discouragement and disillusionment among struggling students (Vansteenkiste and Deci 2003). Social comparison, especially when faced with low scores, can thus be detrimental.

3 METHODOLOGY

The recently implemented enhancement aims to improve learning outcomes by further developing the Plussa learning management system (LMS). Our specific focus is on the course area related to data structures and algorithms, along with integrating a new module called EduML. This integration utilizes the Learning Technology Interoperability (LTI) protocol, specifically developed for LMSs to facilitate the integration of remote tools. The primary goal of our development effort is to create a more comprehensive learning experience for students by incorporating gamification elements to enhance motivation. Instructors are provided by better facilities to observe and analyse the progress of the participants.

The course development will employ design-based research (DBR). DBR is a methodology particularly suited for educational settings, where interventions (like the LMS and course area) are designed, implemented, and evaluated to refine the design and contribute to knowledge about effective learning environments (Anderson and Shattuck 2012; Fishman et al. 2013). Iterative approach embedded in yearly course fosters on-going innovation. Large enrollment (650+ in 2022, 700+ in 2023) necessitates robust systems for smooth execution with limited personnel.

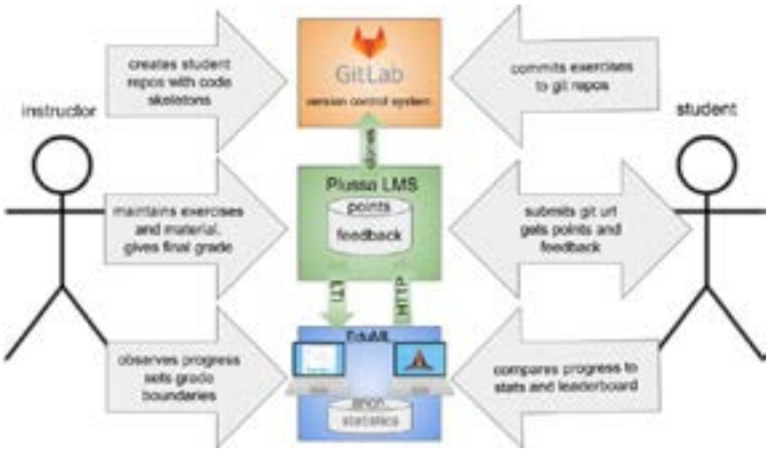

Fig. 1. EduML integrated to Plussa LMS via LTI

In addition to our team's self-reflection, feedback and developmental ideas were gathered from students both before and after the implementation of the EduML module. Quantitative results were enriched with Likert-scale responses, while qualitative data were analysed using content analysis methods, with main categories agreed upon and analysis conducted independently by two reviewers. By incorporating both qualitative and quantitative inquiries, this study employs a mixed methods approach.

3.1 Research context

Fig. 1 illustrates how Plussa LMS was augmented with new services via the Learning Tools Interoperability (LTI) protocol. Building upon our existing infrastructure, we have already incorporated a peer-review platform and Repolainen into our Plussa ecosystem. Repolainen creates git repositories for courses, ensuring consistency in visibility and access rights for both students and course personnel. The latest addition is EduML, currently in an experimental phase and will undergo further development throughout successive DBR cycles, ultimately being refined into a fully productized learning analytics solution for other courses as well.

The most essential grading criteria of the final assignments was the performance. The lower the performance estimate (hereafter perfestimate), the better the student's result. The perfestimate is based on command counters, also known as instruction counter or program counter, which utilizes a specialized register in the CPU that holds the memory address of a current instruction. Fewer executed commands for the same end result indicate a more efficient implementation. In Plussa grading, the perfestimate is a single number created as a weighted average of the command counters of the required functions; the weight indicates the prominence of each function. The perfestimate grader gave a detailed, per function formula. The result of the formula (perfestimate) was delivered to the EduML comparative view.

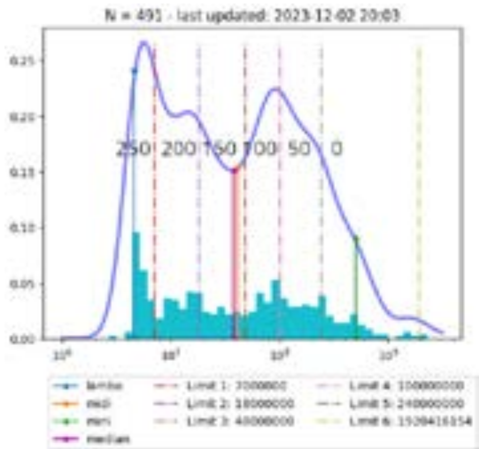

Fig. 2. Instructor view, points from 250 to 50 added for clarity to the figure.

Fig. 3. EduML students' view: statistics and top-5 leaderboard shown for top-50 performers.

4 RESULTS

4.1 EduML instructor view

Fig. 2 presents instructors' view on students' collective performance, focusing on performance ranges (areas between limits). Each of the six ranges (except the rightmost) grants an additional 50 points, with a maximum of 250 points. The total course points amount to 5000 and the course grade is on a scale of 1 to 5, with each grade separated by 1000 points. Students' perfestimates are shown with a cyan histogram and a smoothed kernel density estimate (KDE, the blue line), where the y-axis shows the percentage, and the x-axis shows the perfestimates.

EduML has a user interface allowing instructors to set and change the ranges. The ranges can be validated using instructors' view. Ranges were set at approximately equal intervals on a logarithmic scale after reviewing around 70 student submissions. Additionally, three perfestimates from course personnel's model solutions (mini, lambo, and midi) aided in setting the limits. Mini represents the worst result (thus the highest perfestimate) that still passes but receives no additional points; lambo represents an estimate of the best scores (250 p.); midi presents an average solution (150 p.).

Student results shown via EduML provide better insight for setting ranges than limited staff reference implementations. The distribution of perfestimates turned out to be non-Gaussian (flatness and bimodality). In addition, the wide range of perfestimates necessitated the use of a logarithmic scale.

4.2 EduML student view

Fig. 3 illustrates the students' view of EduML, offering a detailed portrayal of statistics and a leaderboard. This visual component forms a core element of the EduML system. Central to this design is the representation of individual student progress in an engaging manner, fostering both intrinsic and extrinsic motivation gracefully received by, e.g., this student: "*The automatic grading was beneficial as it allowed for immediate results, enhancing my reflection on progress. However, self-assessment was less useful, while comparing my performance with peers was notably stimulating.*"

The EduML system's visual design choices, as indicated in Fig. 3, coalesce around the emblematic representation of the highest level of achievement, the transparent display of significant metrics such as "Best Score," "Level," and "Reward Points," as well as a bar chart depicting the distribution of students across various levels. These elements are deliberately crafted to provide immediate feedback and a sense of achievement, resonating with the students' psychological need for competence.

The histogram was offered as a competitive landscape for all students. This design was underpinned by the notion of balancing healthy competition with the risks of fostering undue stress. The leaderboard was offered as further incentive among the top performers of the course. Unknown to the students, only the top-50 performers were shown the leaderboard, a move that aimed at reducing possible negative effects of competitive elements among less able students. It aimed to motivate students through a display of their standings relative to their peers, for example, "*Trying to win with optimizing skills in Anonymous Leaderboard is definitely a great motivator.*"

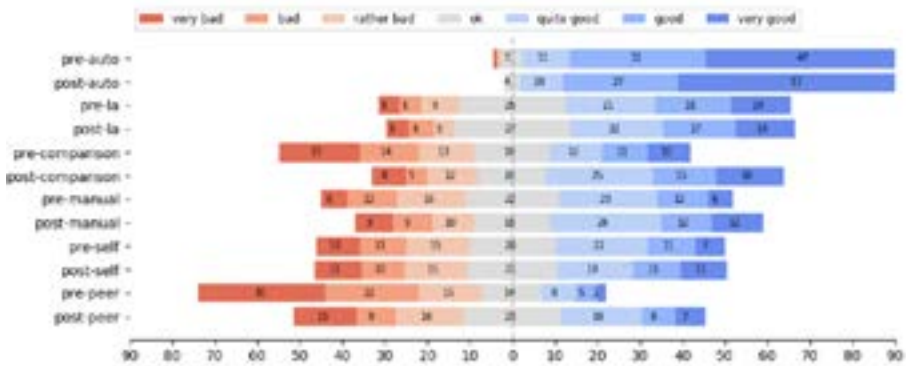

Fig. 4. Students' preferred grading methods, pre(N=393) vs. post (N=224).

4.3 Students' views on EduML and other grading methods

Fig. 4 shows auto-graders as the most favoured grading style, having 47% of students expressing a preference for it. Interestingly, the popularity increased further to 57% after students gained experience with it in Fall 2023. Conversely, Fall 2022 data revealed a different dynamic. While initial enthusiasm mirrored that of Fall 2023 (47%), it subsequently declined across all categories, reaching 40% by semester's end (Niemelä et al. 2023b). The observed disparity between cohorts highlights the potential influence of ongoing development efforts. Since initial implementation, significant progress has been made in both speed and robustness of the auto-grading system, which may explain the improved student experience in Fall 2023.

EduML (LA & comparison) adds to the student satisfaction. EduML covers learning analytics aspects, such as more statistics, and EduML's leaderboard and histogram give students insights of others' performance, for instance: "*comparisons with other students' performances were stimulating"* and "*I completely changed my mind after the first part of the project, with perfestimate. I found it very interesting to see where on the curve I was in each optimization phase."* Learning analytics tracks student progress over time and identifies areas where additional effort may be required. By monitoring their growth and achievements, students develop a sense of competence. EduML, by comparing student performance with their peers, offers stimulating insights into relative strengths and weaknesses, which helps students identify areas for improvement and ultimately fosters a sense of competence.
While manual grading enjoys continued advocacy from students who value its personalized and context-specific feedback, it has been critiqued for subjectivity and a lack of transparency. Furthermore, its scalability is limited, often resulting in generic feedback in large courses like DSA. Additionally, the time intensiveness of manual grading can lead instructors to prioritize essential tasks over routine assessments. Finally, manual grading may not effectively address concerns regarding coding style, an area well-suited to automated linting tools. Peer-review, the least favoured method, suffered from reputation and perceived lack of fairness/expertise. However, by providing full code for review and focusing on efficiency tips (not impacting reviewee grades), the course fostered curiosity and a notable average increase.

4.4 Learning outcomes, cumulation of perfestimates

Fig. 5 tracks the longitudinal evolution of performance estimates during the grading period. The y-axis uses a logarithmic scale to handle the range of values. The green line represents the mean, while the magenta line indicates the median. The shaded dark green area illustrates the standard error of the mean (SEM), reflecting variability in perfestimates, shrinking as more submissions arrive, which is also evident in the median. The dark rising curve shows cumulative number of students, using a linear vertical axis on the right.for clarity. A momentary downward spike in the median, immediately after the reveal of the ranges suggests possible sandbagging (strategic underperformance to benefit from looser grading). Starting around Nov

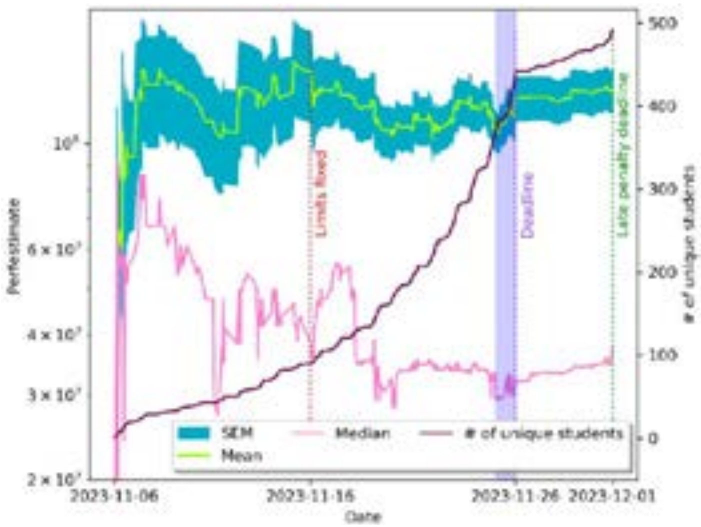

Fig. 5. The cumulated perfestimates

17th, the median decreases again, indicating overall improvement in perfestimates, with another downward spike (blue bar) just before the deadline, likely due to high-performing late submissions. Between the deadline and the late-penalty deadline, a few poorer submissions cause the median to rise slightly.

5 CONCLUSIONS

RQ1. Effects of EduML: Instructors: improved control and accuracy of grading. **Students:** enhanced visibility of overall performance, insights into achievable goals, heightened motivation from competition, alongside occasional frustration.
RQ2. Student perception of competitive setup: Generally positive reception with significant levels of interest and inspiration. **Minor negative responses**, primarily self-disappointment and concerns about ”gaussiatization”, forcing the bell curve.
RQ3. Identified effects on learning outcomes: Pros: cultivation of a growth mind-set and improved retention rates when the feedback of auto-graders and EduML were combined. **Cons:** allegations of range manipulation through sandbagging. While statistically detectable instances have not been alarmingly prominent so far, the potential exists, speaking for pre-fixed (but less accurate) ranges based on staff submissions.

ABSTRACT

The meteoric rise of GenAI has caused many educators to be consternated by its potential to undermine assessment. However, there is a more optimistic view to instead focus on the pedagogical affordances that GenAI can bring, for example, in tailoring personalised learning experiences for students. In this pilot study, we investigate ChatGPT-4's potential to act as a one-on-one tutor for engineering and mathematical concepts. We use three research-informed prompt strategies and simulate interactions with high-, mid-, and low-performing students. We find that the learning experience is best tailored to high-performing students. However, to gain comfort in using it, the experience must be error-free. We discovered performance varied by topic, but there indeed are topics that ChatGPT-4 can engage with error-free or with a slight chance of errors.

1 INTRODUCTION

Generative artificial intelligence (GenAI) through ChatGPT-3.5 became a mainstream topic of interest in higher education in early 2023 due to its ability to achieve passing grades in many different assessment tasks (Nikolic et al. 2023). This heightened concerns regarding cheating, plagiarism and academic dishonesty (Mai, Da, and Hanh 2024). Other negative connotations associated with GenAI include bias, lack of transparency, factual incorrectness, and privacy concerns (Ivanov 2023).

While much focus has been placed on the risks, there have been several studies looking at the benefits. A key benefit in higher education is the ability of GenAI to provide personalised learning experiences, with targeted learning content customised for the student, accompanied by practice questions and step-by-step solutions (Menekse 2023). A systematic review by Crompton and Burke (2024) discovered various beneficial use cases for students, including 24/7 support, explaining difficult concepts, conversational partners, personalised feedback and materials, writing support, self-assessment, facilitating engagement, and self-determination. Collectively, the benefits resemble the capability of a student having a personalised tutor by their side, available at their beck and call, and for a fraction of the price. For years, academics have explored technology in education (Gregory et al. 2015), this study examines GenAI's tutoring potential. In recent months, some tutoring implementations have appeared in the literature but are mainly focused on being used to provide hints, feedback or integrated into another system (Phung et al. 2024; Pardos and Bhandari 2024; Frankford et al. 2024), while this study explores a self-contained private tutor experience. However, there are a number of GPTs (plugins) like 'Tutor Me' by Khan Academy available, but the prompting is not open source, and no empirical studies within the context of this study could be found.

The reported risk when using GenAI is its tendency to hallucinate, especially when it comes to referencing (Buchanan, Hill, and Shapoval 2023). While more recent GenAI models such as ChatGPT-4 improved accuracy substantially, accuracy remains dependent on the selected GenAI platform (Nikolic et al. 2024) and prompt engineering (Hebenstreit et al. 2023). Furthermore, the constant updates to AI models and the flawed benchmarking standards currently used by AI companies, such as MATH (Hendrycks et al. 2021), complicate the assessment of these models' risks for educational use (Zhang et al. 2024). Therefore, without selecting the correct GenAI platform and appropriate testing, such an application risks teaching students incorrectly, which could hinder learning, necessitating the pilot study.

In this pilot study, we explore three different prompts designed to provide students with a computer-based tutor experience powered by generative artificial intelligence. The purpose is that a student would be able to copy/paste the prompt and then experience a highly engaging and accurate one-on-one tutor experience provided by GenAI. The pilot is tested within the fields of engineering and engineering mathematics. The content is taken from core courses within the engineering program. Preliminary work exploring the reliability of various GenAI platforms within these fields concluded that ChatGPT-4 was the most suitable (Nikolic et al. 2024). Research assistants are used to simulate the experience to determine its reliability and usefulness before transitioning into a larger study. Therefore, this study aims to answer the research question, "*Using a pre-drafted prompt, can ChatGPT-4 provide a reliable and useful tutor experience for undergraduate engineering students?*"

2 METHODOLOGY

2.1 Preparation

The idea of using a computer to tutor a student instead of a human is not new. Thirty years ago, Merrill et al. (1992) explored the differences between human and computer-based tutoring. The study found that human tutors provide students with key services: scaffolding knowledge, being interactive and providing feedback, monitoring problem-solving, intervening when they get way off track, and helping them detect, locate, and repair errors. These principles have been used to help devise a rubric to test the suitability of ChatGPT-4 and the chosen prompts. The rubric is comprised of seven criteria, each scored on a 4-point scale.

- relevance to the topic area,
- reliability and accuracy,
- pedagogical effectiveness (clear explanations, examples, scaffolding, and assessment techniques),
- interactive engagement,
- progression to more difficult concepts,
- contextual understanding (address the underlying question, learner needs, and anticipate follow-up queries), and
- use of examples and illustrations.

As mentioned in the introduction, ChatGPT-4 was selected due to preliminary work that found it suitable for engineering and mathematics and superior to ChatGPT3.5, Gemini, and Copilot (Nikolic et al. 2024). However, it was found not to be 100% accurate, hence the need for this simulation exercise. While creating a specific GPT environment (formerly known as plugins) for the task is possible, e.g., Assistants API, the intention was to test for the simplest implementation that could be universally adopted by any student across the world with access to ChatGPT-4. No GPTs were used. The prompt developed by Mollick and Mollick (2024) was used for the simulation as a starting point (full prompt available from the reference). This was classified as Prompt 1. Before data collection commenced, the research team ran through multiple simulation exercises to learn and understand how the prompt controlled the behaviour of the output. From this, slight tweaks to the prompt were introduced to alter the experience. Prompt 2 was altered to be more aware of the specific context and focus more on reassuring learning through questioning. Prompt 3 (see Appendix A) was targeted at better pinpointing what the student did or did not know and making the responses succinct, as ChatGPT-4 could over-explain at times. To start the tutorial process, the prompt would be copied into ChatGPT-4, and the user was asked for the content area they would like to learn about, and some positioning questions were asked. A unique tutorial experience commenced from this initiation sequence.

2.2 The Experiment

For the pilot study, two engineering mathematics and two engineering subjects were selected, representing core courses from the engineering program. They were selected as they represent the backbone of future year content. One topic from each mathematics subject was tested, and two topics from each engineering subject. In mathematics, the content areas consisted of *integration* and *multivariable chain rule*.

From engineering, the content areas consisted of *fluid pressure on circles*, *squares*, *triangles, Bernoulli's principle*, the *Rankin power cycle*, and *psychrometry charts*. This gave a total of six topics tested.

In our interactions with the ChatGPT 'tutor', we role played interacting with the tutor as a high-, mid-, or low-performing student. That is, we tested three different use cases

for each prompt:

Case A: This simulates a high-performance student who knows everything and always provides the correct answers when prompted.

Case B: This simulates a student in the middle of the academic bell curve. A correct answer is provided for 50% of the responses, and a wrong answer for the other 50%.

Case C: This simulates a student who constantly fails. When prompted, a wrong answer is always provided.

Each interaction for each case lasted at least 20 minutes. Many interactions, examples and questions occurred, and scoring was based on this collective experience. Interactions were scored against the 7-criteria rubric outlined in section 2.1, with qualitative notes recorded to document interactions. Examples of interest were also recorded and discussed regularly across the research team, helping to create uniformity.

2.3 Limitations

Only six content areas have been analysed, two for engineering mathematics and four for engineering. Being a pilot study, these topics were selected randomly to discover a broad understanding of capability and cover only a fraction of possible content areas. Therefore, the results only indicate what to expect across these content areas.
