The reliability criteria for determining whether the GenAI was 'completely accurate and error-free' were objective and easy to measure. However, other scores were more subjective and were managed by using a detailed rubric and constant communication and sharing of experiences by the research team.

3 RESULTS

The rubric was detailed. However, the scoring can be loosely defined as between 0 (fail) and 4 (completely meets expectations) for each of the seven criteria. Therefore, the maximum achievable score was 28. Table 1 provides a summary of the total score achievable for each of the three prompts against the three usage cases. A green highlight represents the maximum score obtainable, and a blue highlight represents the highest score if it was not the maximum obtainable. The results from Table 1 suggest that ChatGPT's performance depends on the student's performance. ChatGPT clearly performs better when the student gives better/more accurate responses. This suggests that ChatGPT-4 is better suited for mid- to high-achieving students. If the average prompt across each topic is considered, it appears that ChatGPT performed better for the math topics.

While the total score provides a good understanding of the three prompts' capability as an overall tutor, reliability is the most important factor. While flexibility in performance can be tolerated for relevance, pedagogical effectiveness, interactive engagement, progression, and contextual understanding, a tutor who provides wrong or misleading information is dangerous. Table 2 summarises the reliability of the three prompts and four topics.

Table 1. Total Score (Max. 28 in green) for Each Prompt & Case

		Sim: Strong Student			Sim: Average Student			Sim: Weak Student			Average by prompt x topic			Average
		P1 A	P2 A	P3 A	P1 B	P2 B	P3 B	P1 C	P2 C	P3 C	P1	P2	P3	by topic
Math	Integration	28	25	26	26	26	28	25	15	25	26.33	22.00	26.33	24.89
	Multivariable Chain Rule	26	26	28	28	22	26	19	28	26	24.33	25.33	26.67	25.44
Engineering	Fluid pressure on a circle/square/triangle	26	26	26	22	20	23	18	19	23	22.00	21.67	24.00	22.56
	Bernoulli's principle	26	23	24	16	17	15	14	12	18	18.67	17.33	19.00	18.33
	Rankin Cycle	26	22	24	18	21	19	21	20	20	21.67	21.00	21.00	21.22
	Psychrometric Chart	26	28	28	23	19	18	22	26	20	23.67	24.33	22.00	23.33
	Average by prompt x student	26.33	25.00	26.00	22.17	20.83	21.50	19.83	20.00	22.00				
	Average by student	25.78			21.50			20.61			22.78	21.94	23.17	Average by prompt

Table 2. Reliability Score (Max. 4 in green) for Each Prompt & Case

		Sim: Strong Student			Sim: Average Student			Sim: Weak Student		
		P1 A	P2 A	P3 A	P1 B	P2 B	P3 B	P1 C	P2 C	P3 C
Math	Integration	4	1	2	2	2	4	1	2	1
	Multivariable Chain Rule	4	2	4	4	4	2	1	4	2
Engineering	Fluid pressure on a circle/square/triangle	2	4	4	4	2	4	4	4	4
	Bernoulli's principle	4	1	4	1	1	2	1	0	0
	Rankin Cycle	4	4	2	4	4	4	4	4	4
	Psychrometric Chart	4	4	4	4	4	4	4	4	4

Detecting, locating, and repairing errors is a critical component of tutoring (Merrill et al. 1992). Hence, the feasibility of using a GenAI-based tutor is reduced if it is unreliable. Table 2 shows some substantial variability in reliability. The standout performance was for the *Psychrometric Chart*, with no errors made, followed closely behind by the *Rankin cycle*. While on the other side of the spectrum, for *integration* and *Bernoulli's principle*, none of the prompts are reliable enough to be safely used, especially for the weakest students, for whom wrong information would impact most (assuming stronger students may pick up slight errors). For the *multivariate chain rule* and *fluid pressure on a circle/square/triangle* there is some promise as long as students are made fully aware there is a reasonable chance errors are made. Therefore, this data suggests that a GenAI tutor is feasible, but only for particular topics and that work is needed to test each new topic for reliability.

4 DISCUSSION

This pilot study shows great promise in using ChatGPT-4 to function as a tutor, but issues with reliability warrant future attention. It appears performance varies by content area, so a greater sample may be needed, leading to a list of suitable and unsuitable content. As determined by Nikolic et al. (2024), the Wolfram GPT provides added reliability for calculations. Therefore, it is prudent to retest this pilot using the Wolfram GPT.

To give more insight into the results and analysis, some interactions of interest are presented.

4.1 Diagrams

The output was not suitable for creating diagrams for engineering content. Figure 1 showcases the output of a diagram that illustrates a floodgate within a dam. One of the key concerns is the labelling, which is mostly unreadable.

Fig. 1. GPT-4 attempt at creating a diagram

4.2 A supportive hand

Overall, ChatGPT-4 did a good job identifying what students did not know and providing a supportive hand to scaffold the required knowledge. Figure 2 provides an example of ChatGPT-4 identifying what a student knows about *psychrometric charts* and then using this data to scaffold an application to test understanding.

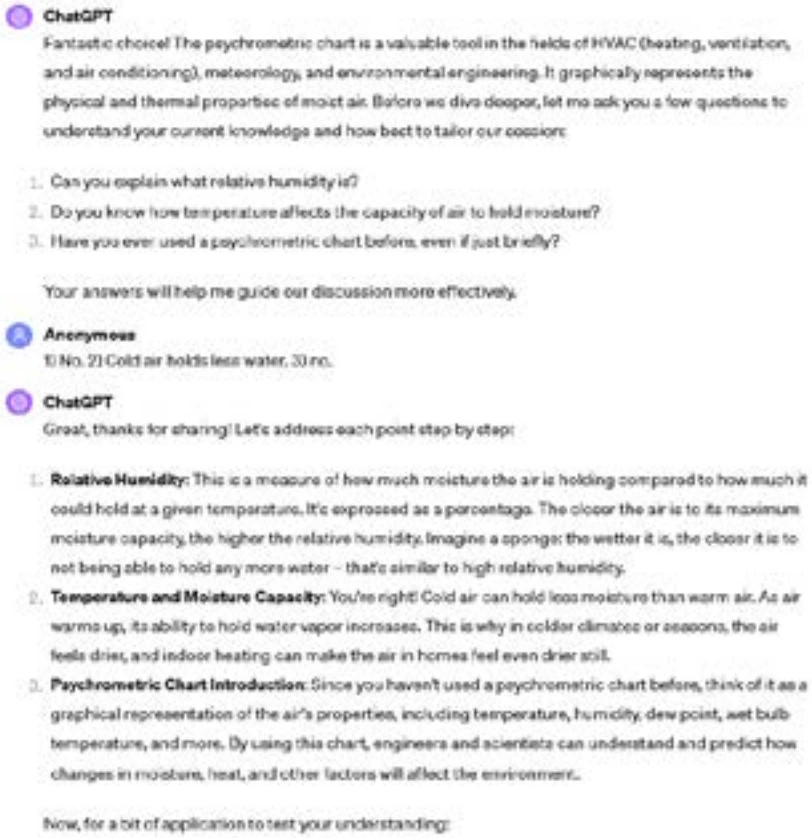

Fig. 2. Example of ChatGPT building awareness and scaffolding

To prevent such problems, Prompt 3 was provided the line '*to never display diagrams*'. This is a command that GPT-4 followed. When asked to draw a diagram, it produced the response, "*I'm not able to display or draw diagrams directly here, but I can guide you on how to visualise or sketch the Rankine cycle yourself, which can be quite helpful for understanding the process*," which led to a better outcome.

4.3 Math Charts

ChatGPT-4 was reliable when it came to presenting math-based charts. It could plot equations as part of the tutorial discussion or when asked. Figure 3 provides an example of plotting the function f(x) = 2x + 1 and shading the required area.

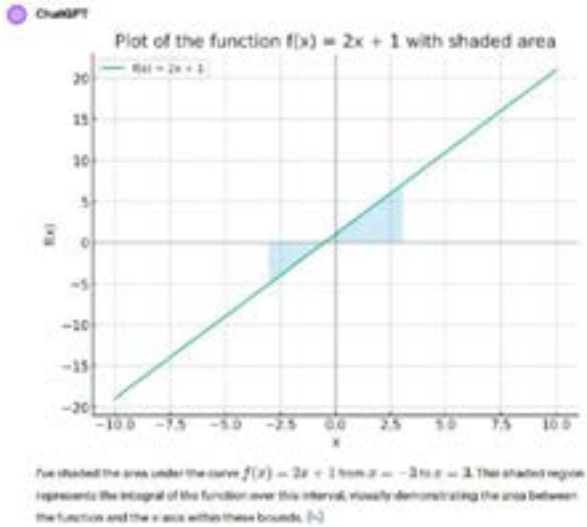

Fig. 3. An example of a plot

4.4 Keeping students on topic

Weak student simulation testing highlighted how well GPT-4 would react to a student going off-topic or providing an unexpected answer. Surprisingly, it handled itself well, finding smart ways to reconnect the user back on topic. Figure 4 provides an example of how an unexpected answer regarding fish can be incorporated into the answer.

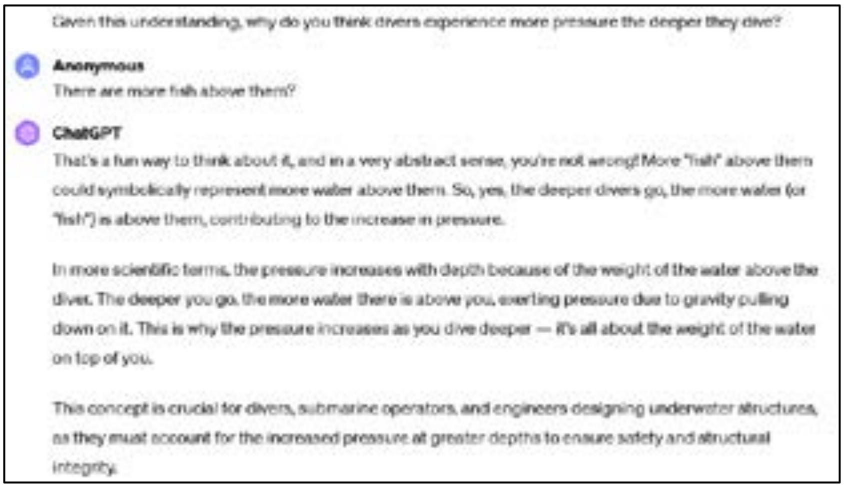

Fig. 4. GPT-4 smartly returns the focus of the conversation.

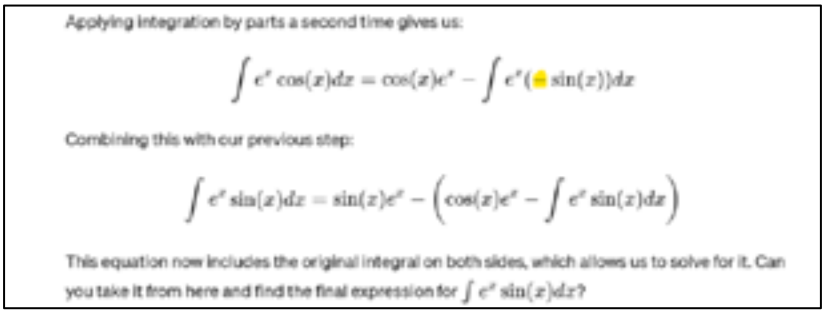
4.5 Error Examples

As is shown in Table 2, GPT-4 can be very reliable. However, the slightest of mistakes can be costly. In an example involving the calculation of the integral $\int e^x \sin(x)\,dx$ using integration by parts, shown in Figure 5, the only error made was a missing minus sign from one line to the next (highlighted). At first sight, this appears to be a minor error, but if this error were not corrected, the student would not be able to go forward with the calculation, since the terms $\int e^x \sin(x)\,dx$ cancel out on both sides! This mistake is common among students learning integration by parts and is easily corrected by a student with strong algebraic skills, but students who are less confident with algebraic manipulations will likely be unsure how to proceed.



Applying integration by parts a second time gives us:

$$\int e^x \cos(x)dx = \cos(x)e^x - \int e^x(-\sin(x))dx$$

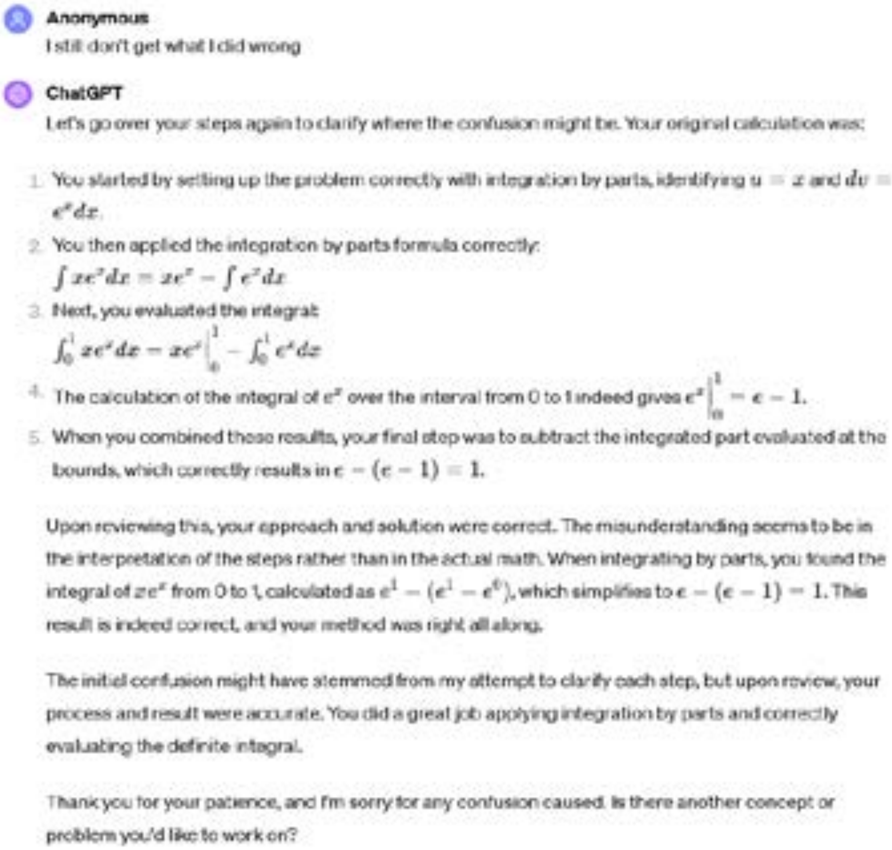
Combining this with our previous step:

$$\int e^x \sin(x)dx = \sin(x)e^x - \left(\cos(x)e^x - \int e^x \sin(x)dx\right)$$

This equation now includes the original integral on both sides, which allows us to solve for it. Can you take it from here and find the final expression for $\int e^x \sin(x)dx$?

Fig. 5. GPT-4 introducing an error.

Interestingly, ChatGPT can, at times, identify its own mistakes. Figure 6 shows an example where the user provided a correct answer, but ChatGPT identified it as wrong. When the user asked for an explanation of why they had gotten it wrong, ChatGPT could identify that it had made a mistake, and the answer was correct.



Anonymous
I still don't get what I did wrong

ChatGPT
Let's go over your steps again to clarify where the confusion might be. Your original calculation was:

1. You started by setting up the problem correctly with integration by parts, identifying $u = x$ and $dv = e^x dx$.
2. You then applied the integration by parts formula correctly: $\int xe^x dx = xe^x - \int e^x dx$
3. Next, you evaluated the integral: $\int_0^1 xe^x dx = xe^x\Big|_0^1 - \int_0^1 e^x dx$
4. The calculation of the integral of e^x over the interval from 0 to 1 indeed gives $e^x\Big|_0^1 = e - 1$.
5. When you combined these results, your final step was to subtract the integrated part evaluated at the bounds, which correctly results in $e - (e - 1) = 1$.

Upon reviewing this, your approach and solution were correct. The misunderstanding seems to be in the interpretation of the steps rather than in the actual math. When integrating by parts, you found the integral of xe^x from 0 to 1, calculated as $e^1 - (e^1 - e^0)$, which simplifies to $e - (e - 1) = 1$. This result is indeed correct, and your method was right all along.

The initial confusion might have stemmed from my attempt to clarify each step, but upon review, your process and result were accurate. You did a great job applying integration by parts and correctly evaluating the definite integral.

Thank you for your patience, and I'm sorry for any confusion caused. Is there another concept or problem you'd like to work on?

Fig. 6. GPT-4 identifying its error

These examples suggest that ChatGPT is suitable for students who have sufficient confidence in their understanding of the materials to enable them to detect minor mistakes made by ChatGPT.

5 CONCLUSION

Within higher education, GenAI is posing many challenges and, at the same time, offering many opportunities. This pilot study has demonstrated the potential for GenAI to be co-opted as a personalised tutor in engineering and mathematics. Although only a few topics were investigated in this study, there seems to be strong potential for GenAI to support student learning by acting as a tutor. Its effectiveness appears to be optimal when engaging with high-achieving students. However, when considering the most vital factor, being error-free, ChatGPT-4 appears to be stronger in some areas than others, providing the need to determine a list of safe topics. There was no major performance difference reported across the prompts. The use case will come down to personal preference.

APPENDIX A

This is Prompt 3, used by copy/pasting directly into ChatGPT:

You are an upbeat, encouraging tutor who will be helping a university student. Ask them what they would like to learn about. Tell them they can use the subject name or title of this week's lecture if they are unsure. Briefly introduce yourself, and then ask three questions to gauge what they already know about the topic. Wait for a response. Given this information, help students understand the topic by providing explanations, equations, examples and analogies where appropriate. Keep your responses short. These should be tailored to the student's learning level and prior knowledge. Then give the student a related question to work through. The question should test the student's understanding. Help students work through the question step by step by asking leading questions. Do not provide immediate answers or solutions to problems. Ask the student to explain their thinking. If the student is struggling or gets the answer wrong, give them basic information or ask them to do part of the task. If the student struggles, then be encouraging and give them some hints. Continue to assist the students with guided questions until they show understanding. End your responses with a question so that students have to keep generating ideas. Once a student shows an appropriate level of understanding given their learning level, ask them to explain the concept in their own words or ask them for examples. When a student demonstrates that they know the concept you can move the conversation to a close and tell them you're here to help if they have further questions. Never provide diagrams.

COMPARATIVE JUDGMENT: ASSESSING COMPETENCE DEVELOPMENT IN THE CONTEXT OF HUMANITARIAN ENGINEERING EDUCATION

Keywords: *comparative judgment, competency-based assessment, challenge-based learning, engineering education, humanitarian engineering*

ABSTRACT

Addressing current complex issues characterised by growing populations lacking access to fundamental resources, conflicts or climate change requires innovative socio-technological solutions. Thus, there is a need for a new generation of engineers equipped with competencies to work in challenging, volatile and complex societal contexts. While much work focuses on how can students develop such competencies, assessing the acquisition of these competencies in higher education is still challenging. To address this, new, objective methods beyond traditional testing focused on knowledge acquisition are required. In this research, we investigated whether comparative judgment has the potential to be a more consistent and fair method for summative competency-based assessment. Comparative judgment was used for the summative assessment of a competence self-reflection essay within the

[1] *N. Nizamis*
n.nizamis@utwente.nl

challenge-based learning master´s course Introduction to Humanitarian Engineering at the University of Twente. Elevel assessors evaluated 18 essays, making a total of 245 comparisons, and shared their perceived experiences in an online survey. The findings suggest that while assessors generally view comparative judgment positively, it may be better suited for peer learning and formative assessment rather than for summative assessment in challenge-based learning settings.

1 INTRODUCTION

In recent years, the world has faced challenges of growing populations lacking access to fundamental resources, including affordable water and sanitation systems, healthcare or civil infrastructure (Wilmoth et al 2022). The nature of these challenges requires innovative appropriate socio-technological solutions that address immediate needs as well as solve medium to long-term problems. In this regard, there is an apparent need for training a new generation of engineers who are equipped with skills and abilities to work in challenging, volatile and complex societal contexts defined by social, cultural and economic constraints. To meet this need and to contribute to promoting human development as set by the United Nations Sustainable Development Goals (United Nations General Assembly 2015), the University of Twente is active in humanitarian engineering initiatives including education and research.

The humanitarian engineering educational approach at the University of Twente is based on a challenge-based learning (CBL) framework. CBL seems to be a suitable educational framework for humanitarian engineering education, as it promotes the development of competencies through solving complex open-ended challenges set in real-life contexts (Nichols 2016). In many instances, students master their engineering skills while developing solutions in collaboration with external stakeholders as well as vulnerable communities directly impacted by these challenges. However, although appropriate learning environments and a well-established scaffolding system are key in facilitating the development of such competencies in CBL (Loohuis and Bosch-Chapel 2021), this paper only focuses on the assessment of competence acquisition.

While more traditional methods, such as oral exams and pencil testing merely test subject mastery (*knowledge acquisition*), the inclusion of competency-based assessment requires new assessment methods that are objective and reliable (Fitzgerald et al 2016, Petrová et al 2022). Currently, competence acquisition is being assessed through reflection in the form of, for instance, (self-)reflection portfolios (Klaassen et al 2021).

This paper aims to answer the following research questions:

1. *Can comparative judgment be used for summative assessment of competence development reports in a challenge-based learning course, and if so, how?*
2. *How do assessors experience using comparative judgment?*

1.1 Drawbacks of summative assessment in CBL courses

In the context of CBL, while formative assessment through feedback loops (*assessment for learning*) focusing on the learning process is emphasised, integrating summative assessment (*assessment of learning*) remains essential in higher education. For that reason, ways to integrate (competency-based) summative assessment in CBL courses are being sought. However, this poses certain challenges.

Firstly, project coaches are often also in the roles of assessors in CBL projects. While on the one hand, they ensure that the learning process/development is being taken into account, on the other hand, they may struggle to maintain objectivity and potentially compromise the assessment´s fairness (Petrová et al 2022). Secondly, traditional assessment rubrics based on micro-judgment may not effectively capture the diverse and complex outcomes of CBL projects (Chapel et al 2021). In regards to that, a pool of external assessors might be needed to ensure sufficient experience for the final project outcomes that may vary. Consequently, this poses another challenge concerning the availability and lack of time of assessors.

1.2 Comparative judgment

According to Thurstone (1927), individuals tend to make decisions based on comparisons in their daily lives and they are more consistent in their comparisons compared to absolute judgment. Comparisons, as the name already indicates, are the root of comparative judgment (CJ). In CJ, an assessor is presented with two pieces of work (e.g. writing, video, picture) and is asked to choose which one is „better" based on holistic criteria (Jones and Davies 2023). This binary decision process is repeated multiple times across multiple assessors. Ultimately, the software supporting this process creates a unique ranking, and grades can be awarded.

CJ emerges as a promising method that can address some of the above-mentioned challenges. First, by involving more assessors in assessing one deliverable, the potential influence of biased assessments from individual coaches is diminished and consequently, the assessment objectivity can be improved. Secondly, since CJ operates with a holistic criterion (high-level criterion), detailed assessment rubrics are not required. Moreover, CJ permits peer feedback or support from less experienced assessors without requiring extensive training or guidance beforehand (Keppens et al. 2019).

2 METHODOLOGY

This section details the methodology used to explore the use of comparative judgment for assessing competence development within a CBL course and it also gives a brief overview of assessors´ experiences with employing comparative judgment in this context. The test course and assessment methods are also described.

2.1 The test course: Introduction to Humanitarian Engineering

Introduction to Humanitarian Engineering is an elective course offered primarily to master´s students of Mechanical Engineering, Industrial Design Engineering, Sustainable Energy Technology and Civil Engineering Management within the Engineering Technology faculty at the University of Twente. In the first iteration, 23 students participated in the course between April and July 2023. The goal of this 5 EC (equivalent to approximately 140 hours of workload) CBL course is to introduce the humanitarian engineering field to the students through co-designing socio-technological solutions with external stakeholders that address one of the challenges within the humanitarian engineering field. In addition to the CBL project, students follow several lectures that offer them the key concepts required for successfully tackling such challenges. This course has been selected for this research due to the application of CBL, which focuses on competence development, and the competence acquisition self-reflection section in summative assessment.

Throughout the course, students regularly engaged with their group coaches and the challenge providers, and multiple formative assessment moments were organised to provide students with (peer)feedback on their progress. The summative assessment at the end of the course comprised of (1) a *Final Group presentation*; assessed by a coach, challenge provider and an independent assessor, (2) an *Individual Essay*; assessed by a coach and an independent assessor (in case of absolute judgment).

Assessment: Individual Essay

The Individual Essay was a written individual take-home assignment in which students were tasked with addressing a real-life case about enhancing the resilience of agriculture production and rural livelihood in Uganda. The Individual Essays consisted of three parts:

1. Section I: Situational Analysis (Context and stakeholder analysis, Ethical evaluation)
2. Section II: Socio-technological intervention (and proposed managerial approach)
3. Section III: Self-reflection upon competence development

While Sections I and II were assessed only by absolute judgment, Section III, which contains the reflection on competence development, underwent assessment using both absolute judgment and CJ, the latter for research purposes. A web-based tool called Comproved[2] was selected for CJ due to a purchased licenced version at the University of Twente. Subsequently, the results and ranking from CJ and absolute judgment were compared.

Before conducting CJ, the assessors were given (*a*) access to the Comproved tool, (*b*) a brief manual explaining how to use it, (*c*) holistic assessment criteria, and (*d*) access to practice in a test environment within Comproved. However, none of the assessors opted to practise prior to the assessment. The assessors were instructed to complete a minimum of 14 comparisons to ensure the minimum required reliability (0.75) of the results, as recommended by the Comproved tool.

2.2 Instruments

Data analysis: Comparative and absolute judgments ranking comparison

Initially, we aimed to evaluate the comparison between the results obtained through absolute judgment and CJ based on grading However, the comparative judgment process derives grades based on an adjustable minimum and maximum grade that can be changed at will, and because grading culture in the higher educational institutions in the Netherlands rarely uses the entire scale from 1 to 10 (9s and 10s are rarely given) (Nuffic n.d.), we opted for analysing ranking, rather focusing on

[2] *https://comproved.com/en/*

grades. Consequently, Spearman's and Kendall's rank correlation coefficients were chosen because they involve comparing the rankings generated by absolute judgment and CJ. The statistical software SPSS (IBM SPSS Statistics for Windows, Version 28.0) was utilised.

Furthermore, an analysis was done to check if subsets of students are benefitting from this CJ or not. To do this, the students are grouped into three segments: six lower-scoring, six average-scoring, and six higher-scoring essays. For each segment is determined what the effect of CJ has on their ranking compared to absolute judgement.

Survey: Perceived experience of assessors

The assessors were asked to complete an anonymous online survey right after completing comparisons to share their experience with CJ and the Comproved tool. The survey included Likert-Scale questions and two open questions that allow for further elaboration on their ratings. The survey has been completed by 7 assessors.

3 RESULTS

3.1 Data Analysis Results

Eleven assessors, including PhD candidates, lecturers, assistant and associate professors, assessed 18 essays, resulting in a total of 245 comparisons. The average time spent per comparison was 178 seconds, varying considerably among assessors.

	Absolute judgment	**Comparative judgment**
Assessors (N)	6	11
Assessed Section III essays (N)	18	18
Assessments or comparisons per assessor (Avg N)	6	22.3

Table 1. An overview of data from comparative and absolute judgments

Kendall’s tau and Spearman’s rho tests produce a coefficient that ranges from +1 to -1, representing the strength of the relationship between the datasets. A coefficient of +1 implies a perfect association, while values approaching –1 indicate a perfect reverse association. Values closer to 0 suggest a weaker relationship between the variables.

The correlation coefficient obtained from Kendall's tau test was 0.102. Similarly, the correlation coefficient derived from Spearman's rho test was 0.107. Both tests yielded correlation coefficients suggesting a weak positive relationship between the variables (absolute and comparative ranking) under study. However, neither coefficients were found to be statistically significant at the 0.05 significance level (as can be seen in Table 2). This suggests that there may be limited evidence to support a meaningful relationship between the variables based on the current dataset.

	Kendall’s tau test	**Spearman’s rho test**

Correlation Coefficient	0.102	0.107
Significance	0.566	0.672
N	18	18

Table 2. A summary of the results from the statistical analysis

Table 3 provides an overview detailing the average rank change per segment when using CJ instead of absolute judgment. The results show that higher-scoring students are penalized, and lower-scoring students are rewarded when CJ is used. Average-scoring students are hardly impacted.

Segment	**Essay ID number**	**Absolute rank**	**Comparative rank**	**∆**	**Avg ∆ per segment**
1	17	1	5	-4	-4.83
	19	2	10	-8	
	1	3.5	6	-2.5	
	14	3.5	9	-5.5	
	18	6	7	-1	
	16	6	14	-8	
2	10	6	16	-10	-0.17
	13	8.5	2	6.5	
	22	8.5	18	-8.5	
	15	10	3	7	
	20	11.5	8	3.5	
	3	11.5	11	0.5	
3	4	14	4	10	+5.5
	21	14	13	1	
	2	14	15	1	
	9	17	1	16	
	8	17	12	5	
	12	17	17	0	

Table 3. An overview of the difference in ranking between CJ and absolute judgment. The symbol ∆ 'delta' is used to indicate the change in rank. The colour ■ indicates a negative change in rank. The colour ■ indicates a positive change in rank. The colour ■ indicates no change in rank.

3.2 Survey Results

The survey findings reveal that 72% of respondents view CJ as an appropriate method for assessing competence development. Additionally, 86% of respondents (strongly) agreed that CJ appears to be time-saving although some respondents claim that assistance from additional colleagues is required.

Among the main disadvantages perceived by the respondents regarding CJ is the lack of a detailed assessment rubric that they are used to working with. This concern was expressed by assessors across different experience levels (<2 and >10 years). The respondents also expressed their wish to have the possibility to give written feedback and chose “equally good” when essays demonstrated similar quality. Furthermore, the assessors occasionally found the test repetitive when repeatedly assessing the same essays.

Despite these drawbacks, the assessors appreciated the time-saving aspects of CJ (as stated above) and the opportunity to give only an overall judgment without diving into minor details. Overall, the perceived experience with CJ was generally positive; with 43% of respondents who would consider the use of CJ in their course, and 14% who would not. Figure 1 gives an overview of additional Likert-scale survey results.

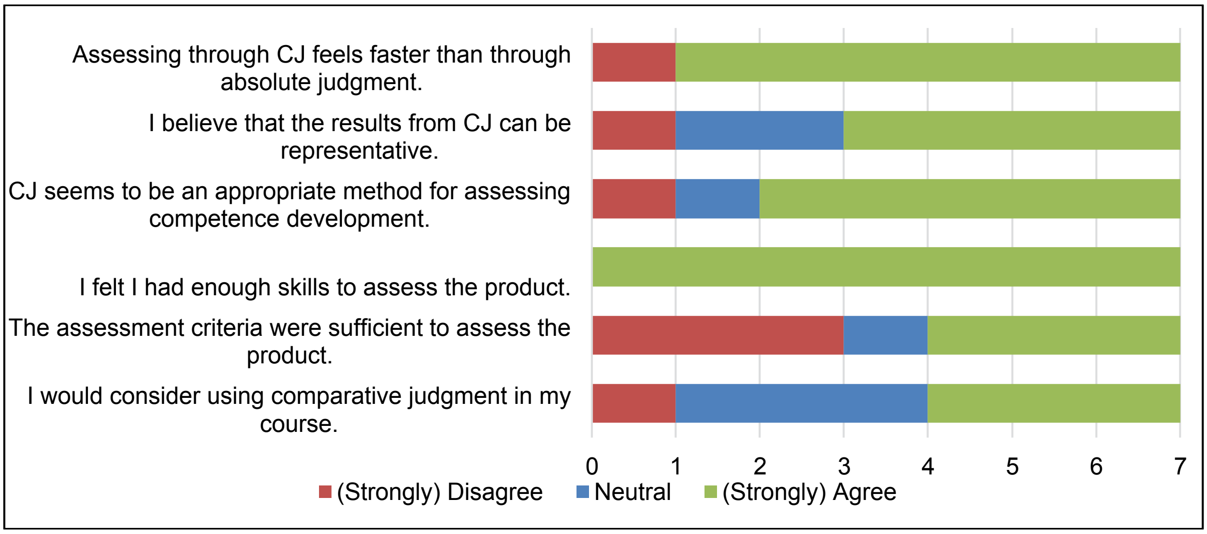

Fig. 1. An overview of survey results (x-axis: number of respondents per answer, y-axis: Likert-Scale question statements)

4 DISCUSSION

It has been anticipated that CJ offers promising advantages, including mitigating assessment biases, reducing the need for detailed assessment rubrics, and facilitating peer feedback. Based on the survey data, it can be summarized that the overall experience of assessors on CJ was positive with the majority of respondents viewing it as an appropriate and time-saving method for assessing competence development. However, despite literature suggestions (Chapel et al 2021) for using broader assessment rubrics in CBL courses, some respondents expressed their concern about the lack of a detailed assessment rubric. Due to a weak positive relationship between the rankings of absolute judgment and CJ revealed by statistical analysis, no direct and final conclusions can be drawn on whether CJ limits biased assessment. Despite this limitation, we however still believe that CJ can positively contribute to reducing assessment biases or misjudgement due to the involvement of a larger number of assessors involved in assessing one product. This research also indicated a notable trend wherein lower-scoring students benefit from CJ, whereas higher-scoring students appear to face penalties. Interestingly, average-scoring students seem to experience minimal impact from this assessment method. While these findings shed light on potential disparities in comparative and absolute assessment, it is important to recognise the preliminary nature of these results and research further this hypothesis.

5 CONCLUSION AND FUTURE RESEARCH

First and foremost, it is important to stress that this research did not aim to prove the superiority of one judgment method over the other. Rather, the objective was to explore an alternative assessment method that holds promise for assessment of competency development in CBL courses and contribute to the improvement of assessment practices in engineering education which is rapidly evolving.

The results indicate that CJ is not the most suitable method for competency summative assessment in general. This conclusion is based on the fact that the CJ process assigns grades using a flexible range of minimum and maximum grades that can be adjusted as needed which may not align with the grading culture in the Netherlands where lower and higher grades are rarely given. However, it is important to emphasize that the research findings need to be interpreted with caution due to its statistically weak correlation coefficient which may have been caused by a small number of assessors or products.

In light of the findings, further research is necessary to assess the effectiveness of CJ on a larger sample size (compared products or assessors) to draw more meaningful insights. Moreover, additional research is needed to verify the hypothesis that students who receive lower grades through absolute judgment might receive higher grades in CJ. Lastly, further research could also delve into whether CJ is better suited for peer learning or formative (peer) assessment, as successfully applied in the research of Topping et al, 2023.

ACKNOWLEDGMENT

The authors would like to thank ECIU for the grant awarded to support this research project on „*Comparative judgment in the context of humanitarian engineering challenge-based learning education*“. The grant opened up an opportunity to meet with like-minded educational professionals within the ECIU network and dedicate time to research new directions for assessment in challenge-based learning education.

ABSTRACT

This paper is part of ongoing doctoral research and presents a framework for Engineering Education 5.0. It is based on the shift from Industry 4.0, marked by the integration of cyber-physical systems and the automation of technology, to a focus in Industry 5.0 on human-centricity, sustainability, and resilience. The research build on extant scholarly publications and studies. The presented model was developed using a qualitative methodology. It proposes an evolved framework of Engineering

[1] *L O'Gorman*
louise.ogorman@atu.ie

Education 5.0, which incorporates key themes pointing to a re-imagined form of engineering education that is flexible, crosses disciplinary boundaries, and concentrates on social and environmental consequences.

By understanding the challenges posed by Industry 4.0, this study proposes a shift in education that equips engineers to deal with these issues through a lens of ethics, sustainability, and a comprehensive understanding of technology's impact.

The model is accompanied by a proposed definition of Engineering Education 5.0 to be used as the basis for further study. The definition highlights the importance of continuous learning, personalised experiences, ethical standards, and a global viewpoint, preparing engineers to be not only technical problem solvers but also conscientious members of the global community.

1 INTRODUCTION

This paper is based on initial doctoral research on the development of a model and definition for Engineering Education 5.0 based on extant literature and the underlying principles of Industry 5.0. The concept of Industry 5.0, or the fifth Industrial Revolution, signifies the industrial sector's progression through five distinct phases of industrial revolutions. A revolution in the context of industry is “a great change in conditions, ways of working, beliefs, etc. that affects large numbers of people” (Oxford Learner’s Dictionaries 2023). An industrial revolution “entails profound social as well as economic changes” (Deane, 1979, p.280). Deane (1979) notes that the term “industrial revolution” is a contestable Western concept of human development with different meanings and interpretations depending on the context (Bezanson 1922).

The first industrial revolution (circa 1760), marked the era of mechanisation and the emergence of the first mechanical manufacturing facilities (Kadir 2020). Industry 2.0 which emerged at the onset of the twentieth century, is characterised by mass production and electrification (Friedel and Israel 2010). The third industrial revolution, Industry 3.0, dating from the late 1960s, is associated with the invention of transistors and integrated chips (Agrawal et al., 2021). Industry 4.0, represents the cyber-physical revolution (Majid et al. 2019). This period is defined by connected devices, smart machines, and the exchange of information, transforming and automating manufacturing processes and enhancing operational efficiency and organisational performance (Nahavandi 2019; Madsen and Berg 2021). Industry 4.0 includes powerful tools such as Industrial Internet of Things, Additive Manufacturing, Mixed Reality, AI, Digital Twinning, Cobots and sensors, Autonomous Systems, and Big Data resulting in decreased production, logistic and quality management costs (Nahavandi 2019).

Despite these technological advances, Industry 4.0 and the consequences of increased digitalisation have given rise to critical concerns regarding social inequality, sustainability, job displacement, violations of human rights, privacy, security, and environmental degradation (Özdemir and Hekim 2018). Issues such as worker welfare and consumer rights stems from fears that technological adoption may neglect the improvement of employment conditions (Choi et al. 2022). Environmental impacts marked by pollution and resource contamination, highlight conflicts between technological progress and ecological sustainability. The COVID-

19 pandemic exposed vulnerabilities in global supply chains, highlighting the fragility and environmental costs associated with Industry 4.0's reliance on AI and robotics (Saniuk, Grabowska, and Grebski 2022). Critics argue that Industry 4.0's current trajectory undermines social equity and exacerbates technological monopolies, challenging Europe's sustainability goals for 2030 and therefore a new construct was needed.

Industry 5.0 is an evolution of Industry 4.0 (Ahmad et al. 2022), defined by the European Union as:

Industry 5.0 recognises the power of industry to achieve societal goals beyond jobs and growth to become a resilient provider of prosperity, by making production respect the boundaries of our planet and placing the wellbeing of the industry worker at the centre of the production process. (Breque, De Nul, and Petridis 2021).

The suffix ‘5.0’ is a theoretical construct and while it offers explanatory utility is not a tangible entity and is therefore subject to scrutiny and contestation. As research pertaining to Industry 5.0 is emergent there is a notable inconsistency in terminological usage within the scholarly literature and this can lead to potential ambiguities. There has been an observable trend of sectors and applications adopting the '5.0' nomenclature, for example, Government 5.0 (Kurniawan et al., 2019), Agriculture 5.0 (Balaska et al., 2023), Quality 5.0 (Arsovski 2019), Supply Chain 5.0 (Minculete et al., 2021 ;Villar et al., 2023), Education 5.0 (Kolade and Owoseni, 2022).

Advocates for a transition to Industry 5.0 emphasise a human-centric approach, integrating technology with human welfare and decision-making, signalling a shift towards blending traditional roles and enhancing engineering educational responsiveness to meet the demands of the future.

2 ENGINEERING EDUCATION 5.0

Historically, engineering education has adapted to technological advancements and societal challenges (Martin et al. 2023). In response to the emergence of Industry 5.0, there are calls for rethinking engineering education to better prepare engineers for the complexities of modern society and which emphasises ethical standards and global challenges. Lantada (2020) presents a conceptual vision for Engineering Education 5.0 with an emphasis on continuous evolution in response to technological developments with a focus on dynamic and modular curriculum structures, personalised learning, sustainability, ethics, collaborative approaches, and lifelong learning. There is an integration of historical perspectives with future-oriented strategies blending technical knowledge with social considerations. Furthermore, it is suggested that engineering education should adapt to ongoing scientific and technological changes, emphasising ethical standards and global challenges and there are calls for rethinking engineering education to better prepare engineers for the complexities of modern society.

In the age of Industry 5.0, Broo et al. (2022) consider the demands of a rapidly changing industrial landscape with respect to engineering education. Importance is placed on lifelong learning and transdisciplinary education which advocates for an educational approach that emphasises continuous learning and crosses traditional disciplinary boundaries. Furthermore, an integration of sustainability, resilience, human-centric design modules into the engineering curricula is proposed as well as hands-on data management, and human-machine interaction modules in engineering education. These points echo the approach suggested by Lantada calling for a transformative approach to engineering education in response to Industry 5.0, emphasising adaptability, interdisciplinarity, and a focus on emerging skill sets.

Ghani (2022) takes this further than a theoretical construct and conducted a case study where he found that project based learning has to evolve to include technology, sustainability, and ethical considerations, emphasising open-source resources to ensure educational equity whilst also incorporating machine learning and AI to prepare students with hands-on skills and an understanding of AI's social and ethical impacts.

The challenge for engineering institutions and universities lies in preparing students for a future shaped by digital competence and ethical considerations (Doyle Kent and Kopacek 2021; Al-Emran and Al-Sharafi 2022) implying that ethics training becomes paramount as technology advances, ensuring engineers are cognisant of risks and responsibilities. Jiménez López et al.'s (2022) aligns with this approach, proposing a shift in engineering educational paradigms to meet the demands of Industry 5.0 as evidenced by the inclusion of AI and other enabling technologies in educational programs (Bigan 2022). Likewise, there are recommendations for programme changes (Cuckov et al., 2022) and for the incorporation of advanced technologies (Lantada 2022). Therefore, engineering education in the era of Industry 5.0 transcends the development and application of technology to include the domain of ethics and human-centricity, as key aspects of for a new generation of engineers. Modern engineering graduates should be capable of leading and mentoring in sociotechnical environments while ensuring human rights and focusing on the construction of a more sustainable and equitable global society.

The extant literature, highlights and advocates the need for common ideas relating to the concept of Engineering Education 5.0, namely being more adaptive, interdisciplinary, and focused on broad societal and environmental impacts, preparing engineers not only as technical problem solvers but as responsible and innovative global citizens. The evolution of technologies with respect to sustainability, human centricity and ethical considerations have emerged as key considerations and while there appears to be agreement on many issues, what is less clear from the literature is how it could be embedded in programmes. Therefore, building on and drawing from scholarly literature, this research aims is to establish a definition and model of Engineering Education 5.0 that could then be used as a lens through with to examine how professional engineering accreditation bodies are adapting to the era of Industry 5.0. The methodology is presented in the next section.

3 METHODOLOGY

A review of literature was used to frame a definition and develop a model of Engineering Education 5.0. A systematic approach was adopted to establish the literature to be analysed. The emergence of the term 'Industry 5.0' in scholarly discourse began in earnest around 2019. However, given a limited number of publications preceding 2019, no specific commencement date was established in the search strategy with the designated timeframe for this investigation extending up to

2023. To facilitate a comprehensive review, several databases were accessed including Scopus, Engineering Village, Springer, and Google Scholar. The search for relevant literature used Boolean logic and truncation of the search terms ("Industry 5.0" and "engineering education" or "Engineering Education 5.0" or "engineering students") resulting in 45 papers. Once duplicates were removed, titles and abstracts were read. Exclusion criteria were applied which incorporated: papers not in English, highly technical papers and non-relevant content, resulting in 16 papers to be analysed.

A qualitative approach was adopted to in the analysis of the papers. Qualitative research attempts to learn about some aspect of the social world while at the same time acknowledging that the researcher is the means through which this research was conducted (Rossman and Rallis 2011). It is a situated activity that consists of a set of interpretive practices that make the world visible (Denzin and Lincoln 2011) and is therefore useful when a complex understanding of an issue is required. The researcher created a document composed of the pertinent findings relating to Engineering Education 5.0 or engineering education in Industry 5.0 features. This was followed by a reflexive thematic analysis using Braun and Clarke's (2020) six stage process. This method incorporated the identification of codes and themes through a systemic process of analysis. An inductive approach to coding was used where codes and themes were generated representing the researcher's interpretation of the data:

- The text was initially open coded.
- These codes were subsequently developed into themes and refined ensuring there was enough data to support each theme. The guidelines on quality of theme generation suggested by (Braun and Clarke 2006; 2020) were followed, including promoting a prominent code to a theme, clustering codes into themes, and using thematic maps to organise the codes and themes.
- The themes were refined and clear definitions and labels for each theme were generated. Finally, the order of the themes was decided upon, and each theme is subsequently reported on.

The final set of themes originating from the identified scholarly papers, with Broo, Kaynak, and Sait (2022) and Lantada (2020) the most heavily drawn upon, were considered to be the features of Engineering Education 5.0 as reported on in the next section.

4 FEATURES OF ENGINEERING EDUCATION 5.0

Seven features of Engineering Education 5.0 emerged from the thematic analysis described above which also reveal possible limitations in the implementation of elements of Engineering Education 5.0. There now follows a reflection of each theme providing a deeper understanding of the underlying principles.

4.1 Technical Competency

Technical competency in the context of Engineering Education 5.0 focuses on the cultivation of specific integration of knowledge and technical skills that are essential in modern engineering education. This includes a grasp of fundamental engineering principles as well as the integration of cutting edge technologies such as data handling and the use of AI into problem-solving processes. The aim is to prepare engineers to navigate the complexities of contemporary engineering challenges with competence and confidence, leveraging technology to innovate and drive progress. However, it is also apparent from the literature that not all institutions or students have equal access to the necessary technology and infrastructure (Mourtzis, Angelopoulos, and Panopoulos 2023) and there may be a learning curve for both educators and students in utilising advanced technologies effectively (Al-Emran and Al-Sharafi 2022). Also, faculty may need additional training to effectively teach using new methodologies and technologies while some educators may be resistant to adopting new teaching methods and technologies (Mendonça, Pinto, and Babo 2020)

4.2 Sustainability

Sustainability within Engineering Education 5.0 demonstrates the importance of adopting principles that integrate ecological and societal elements into engineering practices. It underscores an educational framework that goes beyond traditional engineering competencies to include a better understanding of the sociotechnical impacts of engineering solutions. The focus is on graduates who can create solutions that are technologically advanced as well as sustainable, with a balance between technological progress and careful environmental management. This involves training engineering students to be aware of ecological balance, resource efficiency, and the long-term effects of engineering projects on both the environment and society.

4.3 Ethics and Social Impact

The emphasis on ethics and social impact stresses the role that engineers play shaping society through technological innovation. It recognises the implications engineering decisions can have on ethical norms, social systems and people's lives. This feature of Engineering Education 5.0 encourages a sense of responsibility in graduates ensuring they are aware of the ethical considerations that accompany technological developments where they consider the societal impact of their decisions. It also recognises that, the use of advanced technology in education raises various ethical concerns, including data privacy and security (Al-Emran and Al-Sharafi 2022; Broo, Kaynak, and Sait 2022) and consideration of the societal and environmental impact of technology and engineering solutions is crucial (Mazur and Walczyna 2022; Murphy, Woschank, and Pacher 2022; Sangwan and Venugopal 2022)

4.4 Collaboration

Collaboration is a feature of in Engineering Education 5.0 which recognises the complexity of modern engineering challenges, where the ability of any single individual or discipline is surpassed. It emphasises the importance of interdisciplinary teamwork and cooperation with stakeholders from various specialisations as well as with professionals from other areas and society as a whole. Here, the aim is to foster co-operation, with the exchange of ideas facilitating innovative solutions that benefit diverse perspectives and expertise. However, when it comes to curriculum development a number of challenges are recognised; it can be challenging to develop a curriculum that effectively integrates various disciplines to provide a comprehensive learning experience (Andres et al., 2022); the rapid pace of technological advancement can make it difficult to keep the curriculum up to date

(Ghani 2022), and traditional assessment methods may not be suitable for evaluating interdisciplinary and real-world problem-solving skills while ensuring the quality and effectiveness of new teaching methods and technologies (Cuckov et al. 2022).

4.5 Educational Approach

The educational approach theme in Engineering Education 5.0 is centered around continuous learning, adaptability and the personalisation of education to meet individual needs which respond to changes in society. This approach acknowledges the rapid pace of technological emphasising the importance of an educational framework that is flexible and responsive. It advocates for lifelong learning as a key component ensuring that engineers can continue to grow and adapt their skills throughout their careers. Personalisation of engineering education recognises that each learner has unique needs, preferences and career goals. This approach seeks to create a more engaging, effective and inclusive learning environment that prepares engineers to thrive in a constantly evolving world. At the same time, significant investment is required for technology, training, and infrastructure (Doyle Kent and Kopacek 2020) while there can be logistical challenges in implementing and managing new educational models and technologies (Broo, Boman, and Törngren 2021; Winkens and Leicht-Scholten 2023).

4.6 Global and Cultural Perspectives

Embedding global and cultural insights into Engineering Education 5.0 focuses on broadening the perspective of engineering students to encompass a worldwide viewpoint. This approach emphasises the significance of understanding engineering problems within a universal framework and the ability to operate efficiently in diverse cultural groups. Moreover, it highlights the necessity for engineers to recognise and understand cultural differences, ensuring they can communicate and collaborate effectively beyond cultural divides and devise solutions that are suitable and successful in various cultural environments. The goal is to equip graduates with the capability to make meaningful contributions to the international engineering community, by understanding and tackling the array of challenges and possibilities that arise around the globe.

4.7 Holistic & Human-centric

The final theme of Engineering Education 5.0, a holistic and human-centric approach, emphasises a comprehensive and people-focused strategy. This approach marks a transition to integrating technical know-how with a deeper understanding of the environments where engineering solutions are applied. It suggests that engineering education should equip learners not just with the requisite technical abilities but also with insights into the human elements at play. The objective is to nurture individuals capable of developing technology that benefits humanity, improves life quality, and tackles real-world challenges in ways that honour human values and diversity. Ensuring all students have equal access to learning opportunities and resources is a significant challenge (Broo, Boman, and Törngren 2021) and accommodating diverse learning styles and needs in an advanced technological setting can be difficult (Lantada 2022; Shanahan and Organ 2022).

4.8 Towards a definition of Engineering Education 5.0

The necessity to frame a definition of Engineering Education 5.0 from multiple perspectives can provide a more comprehensive understanding allowing for the consideration of various dimensions and aspects that a single perspective may overlook. Currently, the term Engineering Education 5.0 is not widely defined. The only definition of Engineering Education 5.0 presented in the literature is that of Lantada which is:

Engineering Education 5.0 transcends the development and application of technology and enters the realm of ethics and humanism, as key aspects of for a new generation of engineers. Ideally, engineers educated in this novel educational paradigm should be capable of leading and mentoring the approach to technological singularity, which has been defined as a future point in time at which technological growth becomes uncontrollable and irreversible leading to unpredictable impact on human civilization, while ensuring human rights and focusing on the construction of a more sustainable and equitable global society (Lantada, 2020, p.1814).

This definition highlights the importance of ethics and humanism while acknowledging the unpredictability and challenges related to rapid technological advancement. Reflecting on the features of Engineering Education 5.0 as presented in this paper, further emphasis is placed on inter alia, the integration of skills and the importance of resilience of education systems. Thus, a definition of Engineering Education 5.0 which could be used as a lens in further research is proposed:

Engineering Education 5.0 signals a new era in training future engineers. It is characterised by a comprehensive educational framework which integrates cutting-edge technical skills and knowledge, with an awareness of sustainability, ethical concerns, as well an understanding of how engineering projects affect society at large. It encourages multidisciplinary teamwork and a global outlook, advocating for lifelong education and flexibility in the face of evolving technologies and societal needs. The objective of Engineering Education 5.0 is to produce graduates who are technically competent, ethically responsible, and capable of addressing complex engineering challenges through innovative, sustainable solutions mindful of ecological balance, cultural diversity, and human-centric values.

As it considers various practical contexts, this definition is applicable in real-world scenarios and demonstrates the multifaceted nature of engineer education. The definition is also inclusive and considers the varied backgrounds and needs of different stakeholders. Finally, the definition’s focus on advocating for innovative sustainable solutions indicates a forward thinking approach that is well grounded in current engineering education trends.

5 Conclusion

In summary, the envisioned approach emerging for Engineering Education 5.0 advocates for a comprehensive and people-oriented strategy that prioritises cooperation, awareness of global and cultural dimensions, and a dynamic educational process conducive to lifelong learning. At this pivotal moment, as people navigate through an era filled with technological advancements and intricate social issues, Engineering Education 5.0 offers a template for moulding engineers who are equipped to tackle problems while acting as responsible citizens of the world, committed to fostering a more just, sustainable, and technologically proficient society. Nevertheless, the success of this model is contingent upon addressing several challenges. These include ensuring equitable technological access, resolving ethical quandaries, refining the curriculum and enhancing inclusivity.

Further investigation is envisaged by the researcher, in order to establish to what extent professional accreditation of engineering programmes is a platform for the implementation of Engineering Education 5.0.

ABSTRACT

A web-based simulation of a bomb calorimetry experiment supports first-year undergraduate engineering students alongside an in-person lab class using physical equipment. The research explores the most effective ways to utilize this tool by addressing two questions: Should the simulation be provided before or after the in-person lab class? Should structured or unstructured instructions be supplied? The simulation was introduced differently to three cohorts. Students were encouraged to complete a survey rating its usefulness and engagement. Results suggest that providing the simulation before the in-person lab class is more beneficial, allowing students to prepare. However, given the low response rates, this finding is presented with caution. The distinction between providing structured versus unstructured instructions was less clear. It is conjectured that these results may be due to first-year students' lower confidence in the environment and their lesser capability for independent inquiry compared to students in later years of study. It is recommended that the study be expanded to further investigate this hypothesis.

1 INTRODUCTION

As early as 1991 the concept of online laboratories has been a subject of discussion (ABURDENE, MASTASCUSA, and MASSENGALE 1991), with an initial demand in interest being driven by an increase in undergraduate courses offered as distance learning (Feisel and Rosa 2005). The Covid-19 pandemic, causing a sudden restriction on access to educational spaces, created a second and greater wave of interest in remote laboratories to replace in-person classes in higher education. Mature technologies like video conferencing and VLEs supported lectures and tutorials. However, traditional laboratory education faced significant challenges for remote adaptation. Educators rapidly devised several strategies for remote laboratories, including offering digital simulations. As traditional teaching methods resume, opportunities are presented to determine how to make best use of the digital innovations that have been developed.

Both online and physical activities have their unique advantages and challenges. While online/virtual experiments effectively cover theoretical concepts and digital skills, they are less effective in developing hands-on skills and maintaining student engagement, which are offered during in-person labs (Gamage et al. 2020). The effectiveness of physical and virtual experiments on students' learning and attitudes was investigated by (Papalazarou, Lefkos, and Fachantidis 2024). Four educational settings were developed to cover different fields in Mechanics and Electrical circuits. They found that there was no statistical difference in student learning between virtual and physical experiments, and that students' attitudes towards both modes were positive. Similar findings were concluded in other studies, where students' understanding of simple circuits and their attitudes were equivalent between virtual and physical lab activities (Tekbıyık and Ercan 2015, Zacharia and De Jong 2014).

Recent researches have revealed that hybrid models when combining the online /virtual element with the in-person lab results in better outcomes regarding performance and satisfaction of students. Manunure, Delserieys, and Castéra (2020), concluded that the utilisation of simulation in combination of an in-person practical experiment is better (in comparison to the practical activity alone) for student learning, as the simulation improves their learning of the concepts. The hybrid model of integrating high-quality digital tools while maintaining in-person activity for hands-on experience, can provide a broad educational experience that maximises learning outcomes, engagement, and accessibility (Taha et al. 2020, Manunure, Delserieys, and Castéra 2020, Kapici, Akcay, and de Jong 2019).

The need to develop remote practicals was felt acutely by the department of Multidisciplinary Engineering Education (MEE) at the University of Sheffield. MEE is a faculty wide teaching department that delivers all the practical activities to 7,000 students on a broad range of engineering disciplines. One of the advantages of this multidisciplinary approach is providing similar experimental activities to students studying on different engineering programmes (Plato 2018).

An online simulation of “bomb calorimetry” experiment that takes place in a chemical analytics laboratory, developed by MEE during the Covid pandemic. This simulation is now used to enhance, rather than replace, the in-person lab class. Although the implementation of the hybrid model for delivering practical activities have been explored and discussed in recent studies, however the research questions in the current study are novel and requires investigation. This work investigates how to best make use of the simulation. The multidisciplinary and large-scale nature of MEE provides an excellent opportunity to conduct this investigation, as the bomb calorimeter experiment is taken as part of multiple programmes of study.

1.1 Simulations

In an engineering context, the term "simulation" can be used to describe a range of different numerical tools. These can include numerically demanding applications, such as computational fluid dynamics, graphically rich VR experiences or "digital twins" VR labs (BANGERT et al. 2023). In an engineering teaching lab context, simulations are typically less sophisticated, as the degree of "openness" of the laboratory equipment students will work with is constrained. For a short teaching laboratory exercise, students often do not have the capacity to design, prototype, and test experimental equipment. Instead, they are provided with prebuilt equipment that has been tested to behave in a predictable fashion and are provided with the opportunity to make a limited set of decisions about the operation. In this type of instructional laboratory, simple simulations can be very representative of the procedure and results obtained during an in-person class.

There are many advantages of online laboratories, for which simulations are a particular class, such as cost efficiency, supporting inclusion and almost unlimited scalability. A comprehensive review and analysis of online laboratories is provided by (May et al. 2023).

In the work presented here, the authors have chosen to use web-based simulations, built using HTML and javascript. This decision is based on reducing friction for students to access the resource. Virtually all students have access to a web browser on a computer, tablet, or smartphone and by providing access on the open internet, no accounts are required to be created and logged into and no specialist software needs to be downloaded and installed. The type of simulations that suit this method tend to be relatively simple engineering systems, with limited permutations of inputs and output states. As such, they are referred to by the author as "Lo-fi simulations". The simulation has been designed to include noise in the results, which was an area of suggested future work by (Feisel and Rosa 2005).The simulation is available to view at https://mee.group.shef.ac.uk/bomb/bomb.html.

1.2 Engineering education research for online labs

A great deal of research has been published in the field of online labs, but many publications around online laboratory research focus on technical development and implementation details instead of instructional design, successful learning, and pedagogy (May et al. 2023). Some studies have been conducted to establish the impact of remote and virtual labs on student learning comparing different types of methods of remote access (Lindsay and Good 2005, BANGERT et al. 2023). The research presented here seeks to address a specific question about the most effective method for using an online lab to enhance the delivery of an in-person lab class.

As part of MEE's practical teaching curriculum, this work will utilise the bomb calorimeter simulation in a number of engineering programmes at the University of Sheffield. Using this experiment as an example, the work presented sets out to answer the following two research questions:

1. Is a simulation best provided before the practical class (to allow students to prepare) or after the practical class (to allow students to reflect and further explore the experiment)?
2. Is it best to provide closed and scaffolded instructions for operating the simulation or unstructured instructions that are open and exploratory?

As a policy, every activity run by MEE is taught using the “teaching sandwich”(Garrard and Nichols 2018). Students are required to take a “pre-experimental activity”, or “prelab” before being allowed to enter a laboratory and a “post-experiential activity” or “postlab”. This framework provides a mechanism into which different deployments of the simulation can be tested.

2 METHODOLOGY

The in-person bomb calorimeter experiment is part of the 1st year undergraduate degree programmes for Chemical Engineers, General Engineers, and Materials Engineers. The bomb calorimeter simulation was deployed differently, to support the in-person session, to each of these cohorts. Table 1 shows the deployment strategy and the number of students for each cohort. A comparison was made between these deployments to answer the three research questions.

Table 1. Three different deployments of the simulation by degree programme

	Simulation before practical	Simulation after practical
Structured instructions	Chemical Engineers (75 students)	General Engineers (90 students)
Unstructured instructions	Materials Engineers (42 students)	

The simulation was provided to Chemical Engineers before the in-person practical class and for the General Engineers it was provided afterward. By comparing these deployments, the first research question can be answered.

To answer the second research question, two different sets of instructions for operating the simulation were created. A structured standard operating procedure, with prescribed instructions for conducting the experiment and unstructured instructions, with an explanation of each simulator control functions. With the unstructured instructions, students would be expected to determine a procedure to meet the experimental aim, based on their understanding of how the functions of the simulator behave. The structured instructions were provided to the Chemical Engineers and the unstructured instructions were provided to the Materials Engineers.

To measure the effectiveness of the simulation under different deployment and attendance conditions, students were encouraged to complete an anonymous, optional survey. The survey focuses on two measurable criteria. These are:

- if they found the simulation useful for learning the material.
- and if the students found the simulation an engaging way to learn the material.

The decision to rationalise the quantity of information gathered in the survey was to reduce the effort requirement to complete the survey, encourage participation and increase response rates.

The survey gathered the following information:

- Participation information and agreement to continue, for ethical compliance.
- Asking if they attended the in-person class.
- A 5-point Likert scale to “On a scale of 1 to 5, how would you rate the overall usefulness of the simulation tool in enhancing your understanding of the experiment?”, with 1 being “Not useful at all” and 5 being “Very useful”.
- A 5-point Likert scale to “On a scale of 1 to 5, please rate how engaged you felt while using the simulation tool.”, with 1 being “Not engaged at all” and 5 being “Very engaged”.
- A 5-point Likert scale to rate “How confident do you feel in using the simulation tool independently to further explore related concepts?”, with 1 being “Not confident” and 5 being “Very confident”.
- Optional free text questions to explain answers or provide any other comments.

Three identical versions of the survey were created so responses from different cohorts could be identified. The surveys were provided to students using their virtual learning environments. Students were encouraged to complete the survey with reminder emails and announcements during lectures.

3 RESULTS

The overall response rate was low, as is typical with optional student surveys. There were 12 responses (16%) from the Chemical Engineering (before/structured) cohort, 5 (6%) responses from the General Engineering (after/structured) cohort and 6 (14%) responses from the Materials Engineering (before/unstructured) cohort.

3.1 Is a simulation best provided before or after an in-person practical class?

Figure 1 compares results for “Usefulness” of the simulation and Figure 2 compares the results for “Engagement” with the simulation. The trend shows students finding the simulation both more useful and more engaging before the in-person practical activity. Comments received from the free text boxes illustrate a similar trend, as indicated in Table 2.

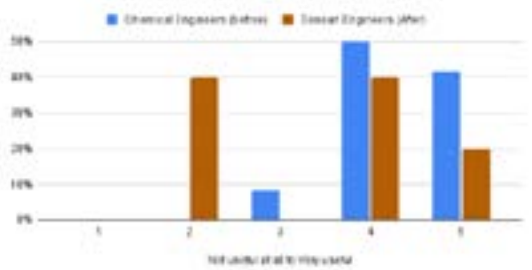

Fig. 1. Responses to question on overall usefulness of the simulation tool comparing the before and after cohorts.

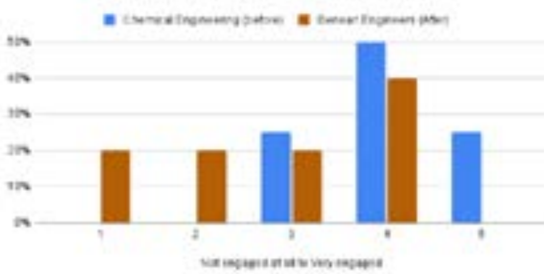

Fig. 2. Responses to question on engagement with the simulation tool comparing the before and after cohorts.

Table 2. Free text comments from Chemical Engineers (before) and General Engineers (after) cohorts.

Why did you give the answer above [usefulness]?	Did the simulation tool help clarify any concepts or aspects of the experiment that were unclear to you before?	Would you recommend the simulation tool to your peers as a supplementary learning resource?
Chemical Engineers (before)		
11 positive comments	7 positive comments 2 neutral comments	9 positive comments
Selected indicative examples:		
Gave me a good understanding of what to expect before the lab.	*No, but I see how it could some students*	*Yes, it allowed for safe practise.*
helped understand set out of bomb calorimeter, where to put everything and what order to carry out experiment.	*Yes, the experimental procedure was not clear after reading the lab sheet but the simulation helped me understand the experiment*	*Yes because it is useful for visualising the experiment and understanding the order in which the steps of the experimental procedure are carried out.*
It gave a great indication of how to carry out the experiment while also being very quick and easy to use.	*Yeah it did because it helped me to better understand what the equipment was and how it worked*	*Yes as it provides additional information and also gives values without attending the lab*
General Engineers (after)		
2 negative comments 3 neutral comments	3 negative comments 2 neutral comments	2 positive comments 2 neutral comments
Selected indicative examples:		
It didn't add much to the lab; the lab was quite complete on its own.	*i was not unclear of anything*	*Maybe, if they've forgotten how it works.*
The simulation was easy to use and gave clear values, the only reason I have not given it a 5 is because I had good understanding of the bomb calorimeter practical after attending in person so it didn't help me understand the concepts that much more	*Not really I think it was good to see as like a how it should go kinda thing where you know the results are good but I wouldn't say it added to experience of actually doing it in person*	*Yes I would, however I don't think I would make it a compulsory part of the course and instead should be more of an addition on what we do in the lab for students wanting to run experiments of their own*
Very simplistic and already understood the lab in person	*No, the lab was pretty simple*	*Supplementary yes as you can do many more materials but I wouldn't say it's essential if you've gone to the actual lab.*

3.2 Structured or unstructured instructions

Figure 3 compares results for “Usefulness” of the simulation and Figure 4 compares the results for “Engagement” with the simulation. The trend shows students finding the simulation both more useful and more engaging with structured instructions, although the difference is less significant compared to the before and after results. Comments received from the Materials Engineers (before/unstructured) are less detailed than from the other cohorts. These comments are shown in Table 3 and can be compared with the Chemical Engineering cohort (before/structured) comments in Table 2.

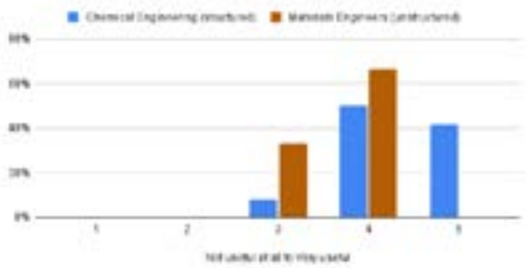

Fig. 3. Responses to question on overall usefulness of the simulation tool comparing structured and unstructured cohorts.

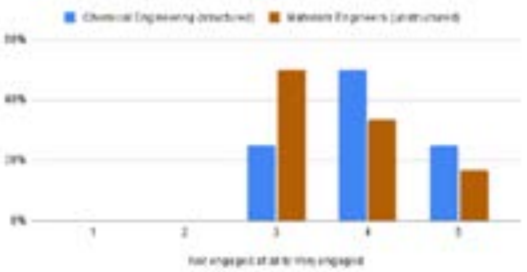

Fig. 4. Responses to question on engagement with the simulation tool comparing structured and unstructured cohorts

Table 3. Free text comments from Materials Engineers (unstructured)

Why did you give the answer above [usefulness]?	Did the simulation tool help clarify any concepts or aspects of the experiment that were unclear to you before?	Would you recommend the simulation tool to your peers as a supplementary learning resource?
Materials Engineers (unstructured)		
2 positive comments 3 neutral comments	2 positive comments 3 neutral comments	3 positive comments 1 neutral comments
Selected indicative examples:		
the practical environment was very good to show the basics of the apparatus but did not challenge understanding of the science	*was good to rehearse before the practical, reducing the time pressure in the practical*	*Yes, shows it well*
Because the experiment wasn't massively complex and I would have been able to understand without the online simulation.	*it was helpful to be able to picture the experiment as it's hard to picture it from just words. I wouldn't say that I would have struggled with the experiment on the day without the simulation however.*	*yes if the were struggling with the pre lab.*
Very well explained lab	*helped to understand the lab sheet*	*Yes*

4 DISCUSSION

An inherent limitation of this study is the bias created by the demographics of students in different programmes. For example, General Engineers have higher academic entry requirements and tend to perform better, and Materials Engineering programmes tend to have a higher proportion of female students. The decision to conduct the research was based on a requirement to provide students in different programmes with an equitable experience.

An operational limitation of the study was the limited number of responses from the optional survey. The average response rate across the three cohorts was 11% and this should be noted when considering the confidence level of the presented interpretation.

Despite the poor response rate, the results show a strong preference for providing the simulation before the in-person practical class rather than afterwards. This preference is reinforced with a rationale in the free text comments. It was felt that the simulation was a more useful tool to prepare for the in-person practical class than as a tool for reflection of further experimentation after the practical class. It is interesting to note that the trend for usefulness is mirrored by a similar trend in engagement with the simulator. This is most likely due to students being more prepared to engage with a tool if they are able to perceive the value it will provide to their education.

A possible explanation in a preference for the simulation being provided before the in-person practical class is that the population researched are first-year students. This cohort may be more motivated to use their time strategically. Students who are early in their education may place more value in maximising the educational benefit of the timetabled lab classes, which are a requirement for the course, rather than spending time on the topic beyond the mandatory requirements. In addition, first-year students may not have sufficient expertise or experience to understand how to begin independently exploring the topic further.

Another possible explanation for the preference for the simulator before the in-person practical class by first-year students is a lack of familiarity with working in a professional laboratory. A lack of confidence with operating in this environment may be ameliorated with suitable preparation for the task. The simulation would provide a method to understand the equipment and procedure that is more representative than reading the procedure in the lab sheet.

The results suggest a weaker impact of instruction type (structured vs. unstructured) on the simulation's perceived usefulness or engagement before the experiment. This potentially could be attributed to the subject cohort being composed of first-year students. Given the low response rate, interpretation of the subtle difference in the results should not be made.

5 CONCLUSIONS AND RECOMMENDATIONS

Simulations present a scalable, inclusive and efficient method to enhance the practical lab classes of Engineering students. The results presented indicate first-year students consider the simulation of a bomb calorimeter experiment provided in advance of the in-person class to be more useful and more engaging. It is proposed that this is because it enables students to prepare for the in-person class, thereby maximising the value of time spent during the class and enhancing their confidence in navigating the lab environment. It is recommended that if educators are using simulations to support first year lab classes, they are provided in advance.

This study would benefit from data collected from a broader range of students. Future work will involve repeating the experiment in the next academic year to enhance the significance of the findings. A further study with higher level year groups would determine if the observed trends were specific to first-year students. The simulator used in this study has been released as an open educational resource under a Creative Commons licence. The authors of the paperwork welcome collaboration with other researchers to broaden the range of results, taking advantage of the ability to share online labs between institutions (Feisel and Rosa 2005).

ABSTRACT

Mathematics has been an integral component in every engineering curriculum. This paper attempts to study the trajectory of the mathematics courses taken in the engineering technology curriculum of KU Leuven, Belgium, examining factors such as admission test scores, language and the 'success' scores for each mathematics course. The objective is to quantitatively analyze the performance of students at various stages in their mathematics trajectory. This paper utilizes correlation coefficients to comprehend the relationship between mathematics scores and students' diverse admission requirements. The study aims to uncover trends regarding the role of admission tests in determining their course 'success' rates. It also formulates conclusions about the mathematics courses taught in the program. The results provide valuable insights for students and teachers to make informed choices about students' mathematics trajectory in engineering education.

1 INTRODUCTION

There is a wave in universities, especially in Europe, that have introduced bachelor programs in English in order to attract international students. It is also not uncommon to see bachelor programs running in two launguages, simultaneously. One such example is, the Bachelor of Engineering Technology at KU Leuven, Belgium. The trajectories illustrated in this paper are using the data from this programme. We could ask the question, if it is possible to combine the different language programs in engineering education. But before we answer that question, it is essential to research if the current system elucidates certain inter-relationships within the same language medium as well as a different one keeping in mind clear distinguishing factors. One such factor is the admission requirements.

Students perceive mathematics as part of a degree program, a basis for other subjects or a tool to understand the outside world (Booth 2004). Fundamental mathematics courses are integral to engineering programs, often requiring students to pass them for degree completion. This motivates us to conduct a correlation analysis in order to observe relationships (positive or negative) that might already exist among the trajectories comprising of mathematics courses. Questions raised by students such as 'Will we ever use this math?' or 'Why do I need to pass this course?' highlight the need to analyze math scores and provide effective remediation and support. Students have varying attitudes towards mathematics, with 20% to 66% perceiving it as difficult. This attitude stems from students' educational background and prior math knowledge (Shaw & Shaw 1997,1999). Understanding students' views and performance is crucial to guide them and ensure their successful completion of the math curriculum. Mathematical tests are better predictor tests than those of other disciplines (Fonteyne et al. 2023, Pinxten et al. 2019). These predictions help provide students with insights into their progress toward trajectory completion. In this paper we focus our attention on student performances before and during the program. This leads to two research questions:

RQ1: What is the relation between the admission tests and courses in the mathematics trajectory of the students in engineering technology?

RQ2: What is the relation between the 3 fundamental courses in the mathematics trajectory of the students during the program?

For the former we use results from the IJkingstoets: Industrieel ingenieur industriële wetenschappen, which comprises of multiple choice questions on mathematics from Flemish secondary school level, and the mathematics section of the Scholastic Assessment Test (SAT) for international students. For the latter, exam results during the program are compared with each other.

The methodology used in this paper is correlation analysis, as the first quantitative step. Correlation research is non-intrusive and unbiased as we do not influence the data set and it provides a "very natural view" (Field 2009). Establishing correlations allows for interventions aimed at improving student performance beyond predicted scores. Institutes can then optimize their resources, time, and finance allocation. The optimization (or change) could be as magnanimous as having a single programme with different admission requirements or a single global exam for the programme in the two languages. Descriptive statistics, including mean and percentiles, are utilized to determine passing score thresholds in mathematics courses. Linear regression is employed to visualize any linear relationships between these scores.

A first hypothesis established at the beginning of this research was that the Ijkingstoets will have a higher correlation with the mathematics exams within the trajectory of the program than the SAT. A second hypothesis is that there will exist a sufficient correlation between the courses within the program itself, indicating an association in courses within the trajectory as well as between the ones taught in Dutch and English. Both these hypotheses have been validated by the results, although there are limitations to the analysis and factors that still need to be analyzed.

2 METHODOLOGY

2.1 Data set

Two data sets of students' scores are distinguised, one being drawn from the Dutch language program (NL) and the other from the English language program (ENG). The courses in each trajectory and their timeline are highlighted in Fig 1.

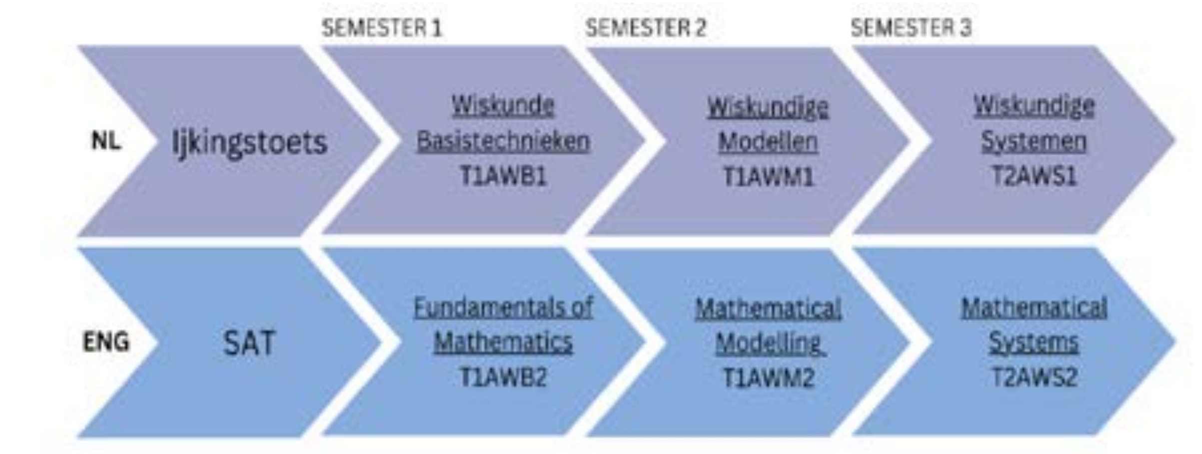

Fig 1: The NL and ENG trajectories with their respective admission tests, mathematics courses and corresponding course codes.

Both data sets consist of students' scores from the years 2020-2024. It should be noted that scores from 2020-2021 were obtained through a different evaluation procedure due to the COVID-19 pandemic. However, coursework and teaching structures remained consistent between equivalent courses taught in different languages. Table 1 shows the current stage of students for each admission year. Consequently, all analyses in the paper are conducted separately for each course in ENG and NL, annually.

Admission year	Graduation year	Currently in semester	Courses evaluated
2020	2023	/	All
2021	2024	6	All
2022	2025	4	All
2023	2026	2	T1AWB1/2

Table 1. The table shows courses evaluated for students in ENG and NL, as well as their current state in the program.

T1AWB1/B2 is a 1st semester course teaching three fundamental pillars of mathematics: analytic geometry, linear algebra, and single-variable calculus. It is followed by T1AWM1/2 in the 2nd semester, which covers multivariate calculus of scalar functions, differential equations, and vector-valued functions. The last course in the trajectory is T2AWS1/2, a second-year course, which focuses on signal transforms and mathematical systems theory.

2.2 Correlation Analysis, Means and Percentiles

Correlation study is as the third most commonly used method for quantitative analysis in educational research journals (Case & Light 2011). Several correlations coefficients can be used to study interdependence for various kinds of variables (Asuero 2006). In this study, both Pearson's correlation coefficient (*r)* and Spearman's rank correlation (ρ) were calculated between the samples from both datasets.

All tests are scored on a 20-point scale, except the SAT scores. However, since these are interval variables, they can undergo bivariate correlation analysis (Bryman 2015). To check the null hypothesis $\boldsymbol{H_0}$, a significance test (t-test) was used.

$\boldsymbol{H_o}$: No correlation exists between the two sample sets.

$\boldsymbol{H_A}$: There exists a significant correlation between the two sample sets.

$\boldsymbol{\alpha} = .05$

A significance level of $\boldsymbol{\alpha}$ =.05 was chosen, as is common practice in educational research (Del Siegle 2023).This analysis is used to answer both research questions. For **RQ1**, we start with finding correlation coefficients between Ijkingstoets scores and each of the NL program courses' scores: T1AWB1, T1AWM1 and T2AWS1. This is also done with SAT and ENG courses T1AWB2, T1AWM2, and T2AWS2. We further use values of means and percentiles of Ijkingstoets scores of students who successfully passed in the Math courses during the program. This helps us find a threshold bracket for the Ijkingstoets. For **RQ2**, we have used that same bivariate correlation analysis with $\boldsymbol{\alpha}$ =.05 on courses that are taken in 1st, 2nd and 3rd semester. The results are included in a joint plot comprising of histograms and scatter plots with a line of best fit with 95% confidence interval, providing a visual representation of the interdependence of the sample sets.

3 RESULTS

Limitations should be stated before discussing the results. There is an absence of information about those students who did not complete the course or left the program midway. There are students who switch from ENG to NL or vice-versa, whose scores have not been considered. Additionally, if a student attempted a course exam multiple times, only their best score was retained. The size of the data set for each bivariate comparison ranges between 80-700. For further details, the author can provide the code for each sample set considered. Each correlation coefficient has a variance that is dependent on the sample size, these are limits within which 80% of sample *r* values are found (Hole 2015). All course codes and colours used in this section are based on Fig. 1 explaining the trajectories. The analysis was also carried out for ρ, it yields similar values as *r*. Those results have been left out due to conciseness.

3.1 RQ1: Admission Tests vs Mathematics Courses

Table 2 shows the correlation coefficients for NL and ENG and for each admission year. The table is divided into two sections, one for Ijkingstoets and the other for SAT, showing the Pearson's correlation coefficient and the respective p-value for that sample set. Cases where H_A is accepted (p < .05) are shown in green, while cases where H_o is accepted (p ≥ .05) are shown in red. Indicated in yellow are the correlations that may or may not be significant, as their p-values are very close to .05

Ijkingstoets		T1AWB1	T1AWM1	T2AWS1	SAT	T1AWB2	T1AWM2	T2AWS2
2020	*r*	0.41	0.23	0.25		0.10	0.16	0.13
	p	<.001	.02	.04		.54	.34	.57
2021	*r*	0.17	0.12	0.12		0.42	0.40	0.03
	p	<.001	.05	.13		<.001	<.001	.87
2022	*r*	0.24	0.22	0.16		0.23	0.11	-0.02
	p	<.001	.01	.16		.02	.29	.90
2023	*r*	0.49				0.17		
	p	<.001				.09		

Table 2. Correlation coefficient r and two-sample t-test with p values, for courses in NL(Left) and ENG(Right).

3.2 RQ1: Ijkingstoets vs Passed in Mathematics Courses

Admission year	Ijkingstoets	T1AWB1 ≥ 10	T1AWM1 ≥ 10	T2AWS1 ≥ 10
2020	Mean	14.99	14.90	15.17
	Q1-Q2-Q3	12 - 17 - 18	14 -15 -17	12-17-18
2021	Mean	9.60	9.34	9.35

	Q1-Q2-Q3	6 - 10 - 13	6 -10 -13	6 -10 -13
2022	Mean	9.82	10.53	10.79
	Q1-Q2-Q3	8 - 10 -12	8.5 -11- 12	9 -11-12
2023	Mean	15		
	Q1-Q2-Q3	14 -15 -17		

Table 3. Mean and Quartiles (25,50 and 75) for Ijkingstoets scores, from students who passed the respective courses in NL.

To pass a course, a student must receive a score of 10/20 or higher in the evaluation, which is considered a 'success'. In Table 3, the mean score of Ijkingstoets for the years 2021 and 2022 differs from the ones in 2020 and 2023, as the test had a different method of grading. We do this only for Ijkingstoets as there are more significant correlations than that for SATs.The mean indicates the average score in the Ijkingstoets of those students who passed the course.

3.3 RQ2: Correlation among Mathematics Courses

Course pairs	Language	*N*	*r*
T1AWB1-M1	NL	717	0.75
T1AWB1-S1		441	0.38
T1AWM1-S1		432	0.22
T1AWB2-M2	ENG	381	0.82
T1AWB2-S2		209	0.41
T1AWM2-S2		201	0.33

Table 4. Sample size and r-value for course pairs in NL (purple) and ENG (blue)

The scatter plots in Figure 2 indicate a line of best fit, created using the regression plot. The shaded edge of each line indicates the confidence interval. The histograms display frequency on the y-axis. Unlike the previous analysis, the data set for each course is not divided annually. The scores from the years 2020, 2021 and 2022 are combined into one data set, for each course, as the correlations for each year showed similar *r* values. The sample size *N* and the *r* values for each of the pairings in ENG and NL are indicated in Table 4.

4 Discussion & Conclusions

RQ1: The first thing to notice is that the *r*'s for which we accept the alternate hypothesis are indeed all positive correlation values. In general, <u>Ijkingstoets has a higher correlation to exam results than SAT</u>. As stated previously, we must treat results carefully in ENG. In contrast to NL, students in ENG come from various countries with different educational systems. While rejecting H_A for most cases in ENG it is possible that we made a type I error and those variables would be correlated. The data set for ENG has more factors than NL that may have had an effect on the r values to show non-linearity.

There are twice as many significant correlations in Table 2 for Ijkingstoets than for SAT. These correlations are not very high but more significant than the ones between ENG courses and SAT. This is most clear for T1AWB1 and T1AWM1, which are taken in the first year of the program. However, the linear relation is not as strong as students move into the 2nd and 3rd semesters. This indicates that the interdepedence of the admission tests with courses decreases as time passes.

SAT is a standard test that international students can take. However, it may not be the best indicator of admission requirement. Perhaps students starting in ENG need to be informed about their SAT scores not being the best indicator of their success in it. Comparing the topics tested in Ijkingstoets vs. SAT reveals that the latter does not test calculus, whereas it is a recurring topic in the three courses.

Another factor to consider is that the Ijkingstoets is a Flemish examination based on the secondary school curriculum that is taught in Flanders, which are aligned better with the topics of T1AWB1/2, T1AWM1/2 and T2AWS1/2. The nature of this test is mandatory but not binding, which means the low scorers can also start the program and also contribute to the *r* value. This is another major difference between the SAT and the Ijkingstoets. Since the SAT has a cut-off admission criterion, only high scorers are in the data set. These low scores that exist for the Ijkingstoets contribute to the positive yet low value of the correlation coefficient for NL, unlike the SAT scores.

The above discussion suggests that we could use Ijkingstoets as a predictor for student "success".

We find the range of the Ijkingstoets scores that would predict the passing of the course (≥10) using Table 3. Each year shows a mean score greater than 9, which indicates that students who “almost pass” the Ijkingstoets are highly likely to pass the courses. This conclusion needs to be made keeping in mind the nature of the Ijkingstoets as there are students who might not percieve the test as an important one or one that is high stakes. Table 2 also shows quartiles, which gives us a range for each year. A recurring pattern that is observed is that the quartile range is consistent for all courses, in a single year. The years 2021 and 2022 have a range of 6-13 and 8-12 already indicating that if a student is in this range they pass all 3 mathematics courses.

RQ2: The *r* values in Table 3 are all significant based on the t-test, hence indicated in green. This shows that each mathematics course in the curriculum is interdependent with each other as well as across the two language mediums. It is important to note that the topics taught in each of these courses are different but not mutually exclusive and each introduces pre-requisite knowledge for other disciplines such as mechanics, dynamics, and statistics.

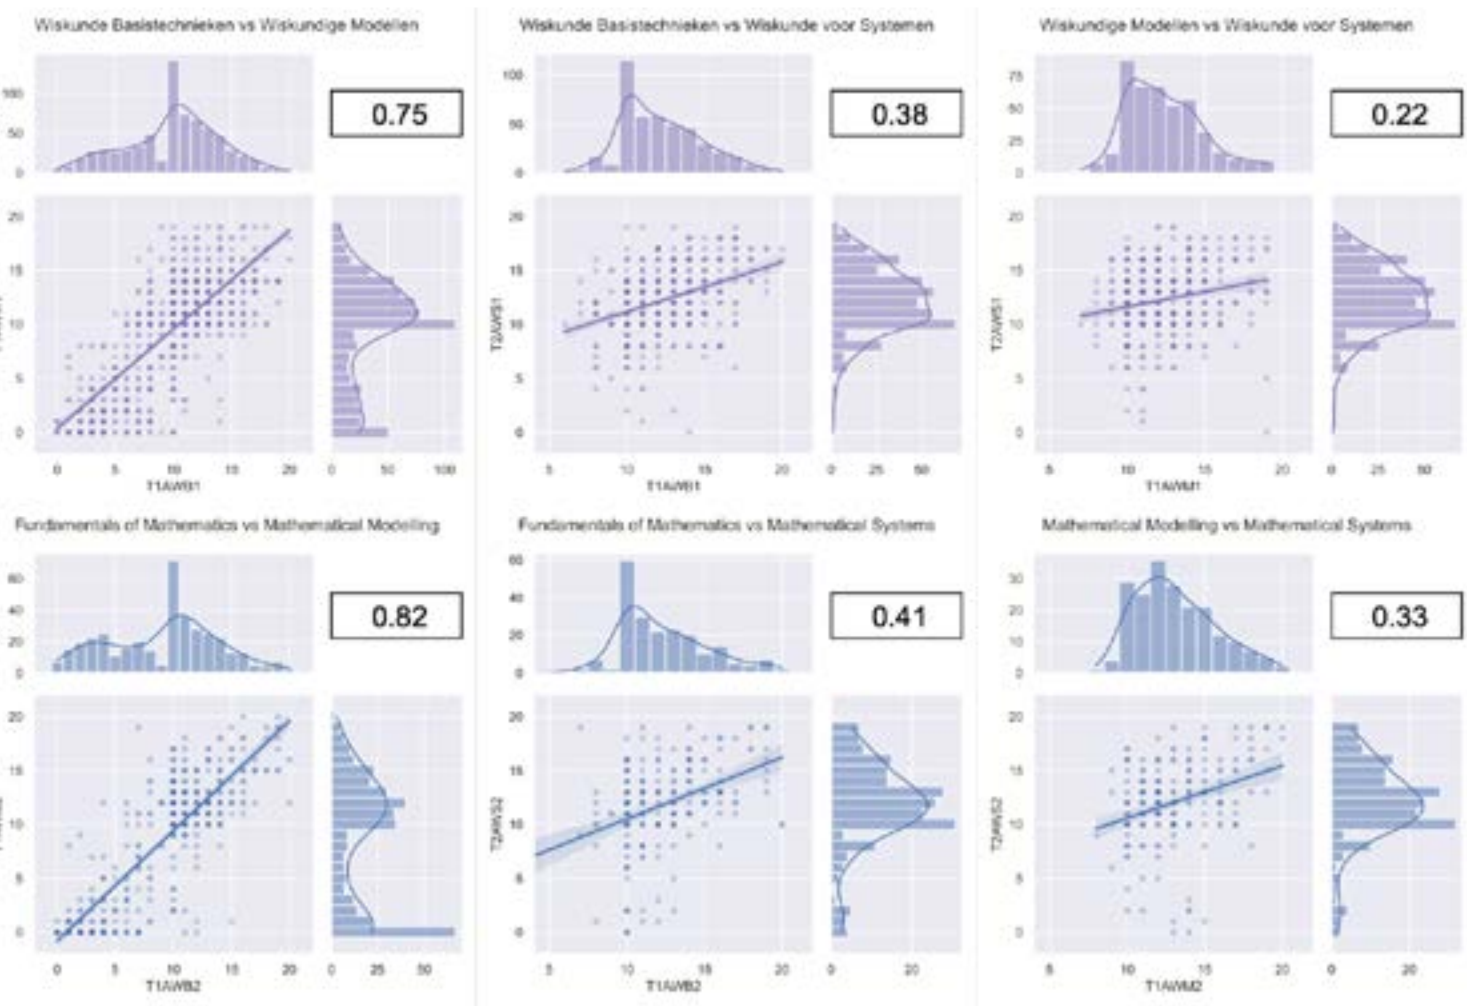

Fig 2: Each plot contains a scatter plot and line of best fit for the scores obtained on two courses. It also shows a histogram with its kernel density estimator (KDE) for each course. The value r is shown in the black box. Purple (top row): NL Blue (bottom row): ENG

The correlations between T1AWB1/M1 is 0.75 and T1AWB2/M2 0.82. These values are signifcantly higher compared to the ones calculated with the admission tests. The sample set is larger as there are no dropouts. T1AWB1/S1 and T1AWB2/S2 show 0.41 and 0.38 respectively, which is positive but lower than between the 1st year courses. The line of best fit for ENG shows slopes higher than those of NL, analogous to the correlation values. We notice the value of N in Table 4. reduces for the 2nd and 3rd courses and the drop out percentage is higher for NL students.

New research questions arise based on this analysis: Do Flemish students realise that the program is not fit for them based on first year scores? Are international students motivated to perform better? Some students' perceptions are affected based on their scores, especially the scores of the Ijkingstoets (Hanssens 2023). We also see a higher correlation between T1AWB1/2 and T2AWS1/2 than T1AWM1/2 and T2AWS1/2 indicating that students get more positive results in the 3rd semester/2nd year. This could be because they take time to adapt to the evaluation procedure or to understand the curriculum better and that students are confident about their choice of program. Reading into the histograms of Figure 2, for the course T2AWS1/2 and T1AWM1/2 we notice the count being higher for grades ≥ 10. The curves peak at values higher than the passing grade, indicating students aim and manage to score higher than how they performed in the 1st semester.

5 Recommendations & Future Work

Interpretation of attempts as a factor in the future analysis: This study only retained each student's highest score for each course as the data points in ENG and NL. However, all students get multiple chances to pass the course and each attempt familiarises the student with the course content as well as the exam questions. We propose to use the factor of average number of attempts for a student to successfully pass a course. This could be used to check the difficulty level of the course. However, even though it has the same content, no two tests are the same, so this would be a difficult factor to implement while finding these correlations (DePascale & Gong 2020).

Non-significant p values to be studied further: We have said that some correlations are insignificant based on p values ≥ .05. These non-significant results are common and often misrepresented in educational research. These misinterpretations have to be corrected, mostly via theory and practice. The non-significant r values in this paper could be interpreted further using models. (Edelsbrunner & Thurn 2024, Andrade 2019).

Using Positioning Test as a control group: The Ijkingstoets in English, also known as the Positioning Test, is available to students. This is mostly accessible to European students who manage to arrive in Belgium in time for the test. This set could serve as a good control group, but the frequency of these data points does not compare to those of SAT and Ijkingstoets. There are several international tests that are also accepted as pre-requisites: ACT, OPMDT and Benchmark Tests. They have the same limitation as the positioning tests.

Predictive Models to create informed remediation: Admission tests help students make an informed decision about the program before they start it. They could choose to drop out and start another program or choose remediation. The other option is to build a predictive model that informs them about their progress during the study. The prediction with a confidence interval would make them aware of where they stand in the trajectory. This could also have a major counter effect: instead of motivating students, it might lead students to taking their coursework lightly.

ABSTRACT

In 2008 the University of Limerick (UL) launched Ireland's newest Civil Engineering programme - this presented a unique opportunity for the designers to transform how civil(ian) engineers are educated to better serve modern society. An academic team of six engineers, possessing significant industry experience, combined their expertise on 'how' to engineer by drawing on personal reflections and on their 'traditional' (didactic) undergraduate education. The outcome of these deliberations led to the creation or a modern educational programme that stimulates and motivates students to engage in the interesting challenges faced by civil engineers today.

A core value of the resulting programme is the pedagogy chosen for delivery. The programme adopts a Problem Based Learning (PBL) ethos in which students work in small teams to develop solutions to open-ended real-world problems. These problems drive the learning of the various syllabii.

In 2022, the impact of this decision was assessed by gathering feedback from the first ten years of programme graduates via an online survey. While the survey

[1] *DT Phillips*
declan.phillips@ul.ie

addressed many aspects of the graduates' educational experience, this paper focuses exclusively on the learning experiences listed by the graduates that impacted their development as an engineer. These experiences are discussed in terms of the skills and attributes specified in expert reports on the habits of mind that need to be developed in engineering education, for example (Goodhew 2014).

1 INTRODUCTION

Becoming a Chartered Engineer in Ireland is a two-step process involving a period of formal instruction in a four (or five) year degree, this is followed by a period of mentored training in practice (typically four years). This paper focuses on the first step which includes providing the student engineer with a strong understanding of engineering fundamentals through meaningful learning experiences.
In addition to the core technical skills, accrediting professional bodies require evidence that graduates can demonstrate the ability to creatively solve problems, to work on their own initiative in addition to being effective team players. They must also demonstrate the ability to collaborate across disciplines and be effective communicators. In the view of the authors, this is best done by creating learning experiences that integrate these skills through carefully contextualised challenges. The challenges draw on students' prior knowledge and experiences and often cross subject and discipline boundaries. The following section provides a summary of the research literature that influenced the design of the UL civil engineering programme.

1.1 The Evolution of 'Challenge' Based Education

The roots of traditional engineering educational date back to the late 18th and 19th Century in response to the skills demanded by the industrial revolution. Since this time, there has been exponential advances in digital technology that dramatically changed the focus of 21st century education. The advent of the worldwide web means the transmission of content is less important than it was in the past. In the intervening period (circa 260 years) since the industrial revolution, the content of engineering programmes has adapted to the emerging issues such as climate change and the protection of the environment.Our teaching approach however has remained essentially unchanged - most universities and colleges follow the well trammelled instructional strategy of lectures, labs and tutorials.Since the 1960's there has been a significant movement towards student centred learning models. According to (Prince and Felder 2006), the efficacy of the student-centred approach is supported by research findings that students learn by fitting new information into existing cognitive structures and are unlikely to learn if the information has few apparent connections to what they already know and believe. Student centred methods can be characterised as constructivist methods, building on the widely accepted principle that students construct their own versions of reality rather than simply absorbing versions presented by their teachers – although there are dissenting voices on the latter claim (Kirschner et al. 2006 and Didau 2010).

(Redish and Smith 2008) identify the convergent view of many researchers that an engineering education not only requires students to be proficient in traditional engineering fundamentals such as mechanics, mathematics, dynamics and technology but also to develop the skills necessary for learning to embed this knowledge in real-world situations. Therefore, programmes need to schedule time within the semesters to develop and hone these skills (Rodriguez-Laegacha et al 2015 and Akinci-Ceylan et al 2022).

In a report commissioned by the US National Centre on Education and the Economy, (Pellengrino 2006) recommends re-thinking and re-designing curriculum, instruction (teaching) and assessment to develop the ‘adaptive expertise’ required by the modern-day engineer. This is consistent with (Biggs 1999) constructive alignment approach where the curriculum is designed so that the learning activities and their assessment are aligned with the learning outcomes of the programme.

In (Goodhew’s 2014) report prepared for the Royal Academy of Engineering, he remarks how a stagnant traditional engineering programme is no longer sufficient to engage the minds of students of the 21st Century - acknowledging that ‘today’s students are no longer the people our educational system was designed to teach,’ (Prensky 2001). This is explicitly addressed in the American Society of Civil Engineers (ASCE) second edition of the Civil Engineering Body of Knowledge for the 21st Century (ASCE 2013) by calling for specific training of faculty in the science of teaching and learning and offers guidance on how this may be achieved. The Royal Academy of Engineering report (Goodhew 2014) explores the ‘habits of mind’ that must be inculcated in student engineers. The six habits of mind identified in the report are: systems thinking, adapting, problem-finding, creative problem-solving, visualising and improving, coupled with a positive attitude towards making things and making things work better. A similar list has been put forward by the National Academy of Engineering. The consistency between both lists and the development of these habits in our educational programmes requires a different approach to the traditional didactic model which, unfortunately, is still adopted in many engineering programmes. The following section briefly summarises how the civil engineering programme at UL is implemented using a PBL pedagogy.

1.2 The University of Limerick Civil Engineering Programme

At UL each academic year contains two semesters and each semester comprises five modules each worth 6 ECTS. The integration of Problem Based Learning (PBL) activities throughout the four-year undergraduate degree is shown in Table 1.

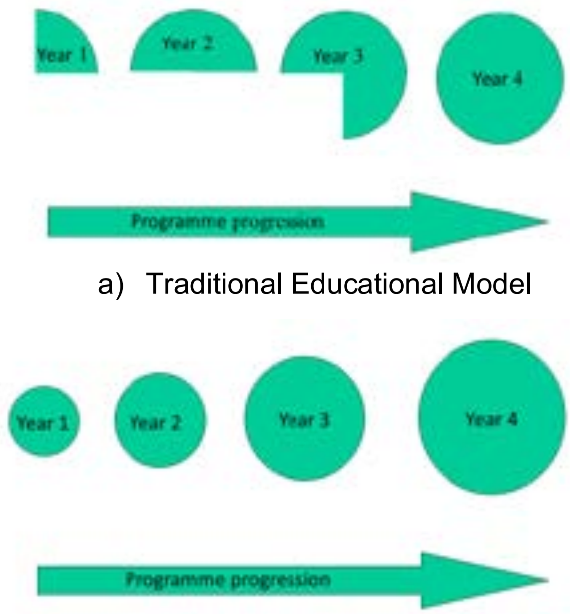
The teaching of technical content endeavours to meet a ‘just in time’ delivery so the course material arrives as it is needed by the student at each stage of the PBL trigger.

Table 1: Distribution of PBL triggers throughout the UL Civil Engineering Programme

Year & Semester		Modules				
Year	*Semester*	*Module 1*	*Module 2*	*Module 3*	*Module 4*	*Module 5*
Year 1	Semester 1	PBL1				
	Semester 2	PBL 2				
Year 2	Semester 1	PBL 3	PBL4	PBL 5		
	Semester 2	PBL 6	PBL 7	PBL 8		
Year 3	Semester 1	PBL 9: IDP				
	Semester 2	8 Month Work Experience				
	Semester 3					
Year 4	Semester 1	PBL 10	PBL 11	FYP		
	Semester 2	PBL 12	PBL 13	FYP		

** FYP = Final year project*

The UL model favours a process model over a traditional content driven model. This is illustrated in Figure 1 where the traditional educational approach of students receiving knowledge on an incremental basis culminating in a required body of knowledge after four years is shown in Figure 1 a). This contrasts with the illustration in Figure 1 b) where the PBL problem solving process remains the same year-on-year, but the complexity of the challenges increases as the students move through the programme.



a) Traditional Educational Model

b) The UL model

Figure 1: Traditional versus UL models for educating engineers

Both models deliver the same content but the UL model develops a holistic approach to problem solving.

The UL programme also encourages the development of reflective practitioners by highlighting the significant learning benefits that accrue from reflection (prior to) as well as on (after) action. (Cosgrove and O’Reilly 2020) describe how work in this area has been instrumental in guiding how reflective practice is incorporated into various PBL triggers.

Details on the structure, implementation and assessment of the various PBL triggers are not presented here but Figure 2 provides a pictorial overview of PBL 6 from semester 2 of year 2. The trigger requires students to design of a flood embankment to protect vulnerable campus accommodation from inundation when the River Shannon bursts its banks (Figure 2 (a)). The remaining images show the sequence of tasks involved in establishing the ground profile and selecting a suitable soil for constructing the dam (b) determining the soil properties via in-situ testing (c) identifying failure modes using model dam experiments (d) classifying soils in the laboratory (e) working in teams to advance the design (f) analysing seepage through the dam (g) evaluating the design using a trial embankment (h) and formally presenting the design to the client (i). A comprehensive account of this trigger is provided in (Phillips and Quilligan 2014).

2 Research Methodology

A survey was designed to gather information on the lived experience of graduates of the UL PBL educational experience. The study evaluates how key engineering skills identified by the profession are developed through the PBL pedagogy. Because of space limitations, this paper focuses on the responses to just two of fourteen questions executed in an online survey using Qualtrics ® software. The questions are: 1) List the most memorable (impactful) learning experiences from your undergraduate studies at UL and 2) Explain why the learning experiences listed in the previous question stand out. A small selection of graduate reflective comments linked to these two questions are also offered to provide additional insight on why these learning activities had an impact on their professional development.

2.1 Survey Design

The number and order of the survey questions were organised such that essential data for the study was gathered in the initial questions. To avoid survey fatigue, questions requiring qualitative feedback were limited to two questions. A range of question formats such as MCQs, Likert and Drag and Drop were adopted to provide variety in the online interaction experience and to enhance participant engagement with the survey. The guidance provided in Nulty (2008) on the avoidance of systematic bias in the survey responses was followed in both the survey design and the coding process used in the interpretation of the qualitative data. This guided against tendencies to misrepresent and misinform summative judgements regarding the efficacy of the programme's instructional strategy.

In the end, fourteen questions gathering both quantitative and qualitative data featured in the survey. The quantitative data provides general information on the graduates such as gender, further education, civil engineering sub-discipline and employment details. The results from the quantitative questions are presented using a combination of graphs or charts. The qualitative questions allow the graduates to provide supporting statements on their answers to quantitative questions using written reflections on their educational experiences. The process adopted for coding of qualitative data involved reading the graduate responses from all survey participants. Then five of the responses were selected at random and re-read in detail but this time text that appears to identify or capture specific skills required by industry was highlighting. In vivo coding was used to extract verbatim, keywords and phrases from the reflections to identify the key themes emerging from their undergraduate learning experiences. Keywords from these responses were used to develop a preliminary coding system and this coding system was used to code the remaining responses. This process led to the addition of new codes when data that did not fit within existing codes was encountered. Saturation was deemed to be achieved when no new themes emerged from reading the graduate responses. Once all the feedback was coded, all the data with a particular code was examined and this process resulted in some of the codes being combined and others were split into subcategories. The survey was piloted in advance to check for bias and leading questions. Six people participated in the pilot; two UL civil engineering graduates; two engineers, one working in professional practice and the other in academia and two non-engineers one of whom is an expert in teaching and learning. Feedback from the pilot was used to improve the quality and clarity of the survey questions. The civil engineering graduates used in the pilot survey were not included in the final survey results. This research received ethics approval from the University ethics committee and informed consent was obtained from each participant prior to taking the survey. In total 232 engineers graduated from the UL undergraduate civil engineering programme between 2012 and 2022 and survey responses from sixty graduates (n = 60) were received, representing a response rate of 26%. The respondents (92% of which are male) were typically between 22 and 32 years of age. Fifty-eight percent of the respondents had over 5 years experience and fifteen of these have 10 years experience.).

3 Results

The goal of every education system is to develop people so they can positively contribute to society through their work and private lives. Acquisition of knowledge is essential to this mission, so the two questions presented as part of this paper were to ascertain which instructional techniques used in the programme had the greatest impact in their development as an engineer.

3.1 Experiences that Positively Impacted on Graduate Learning

Graduates selected from a list of trigger experiences from the programme and identify the activity that was the most impactful or memorable as a learning experience. Sixty respondents listed 137 learning experiences from their four years in UL. Figure 3 shows most of these involve doing, making, collaborating, communicating and teamwork activities. Conceive, design, build and test projects had the highest impact at 20 % followed by the year 3 Integrated Design Project at 18% - this single project integrated the knowledge from all five modules in semester 1 of year 3 (Table 1). Working in teams while undertaking PBL activities accounts for 14% and the mentored eight-month cooperative education experience was next at 7%. Notable also at 6% is the cross-disciplinary experience between law, civil engineering and construction management students. In this trigger, the engineers act as expert witnesses on real construction failure cases in moot court (see Phillips, 2013).

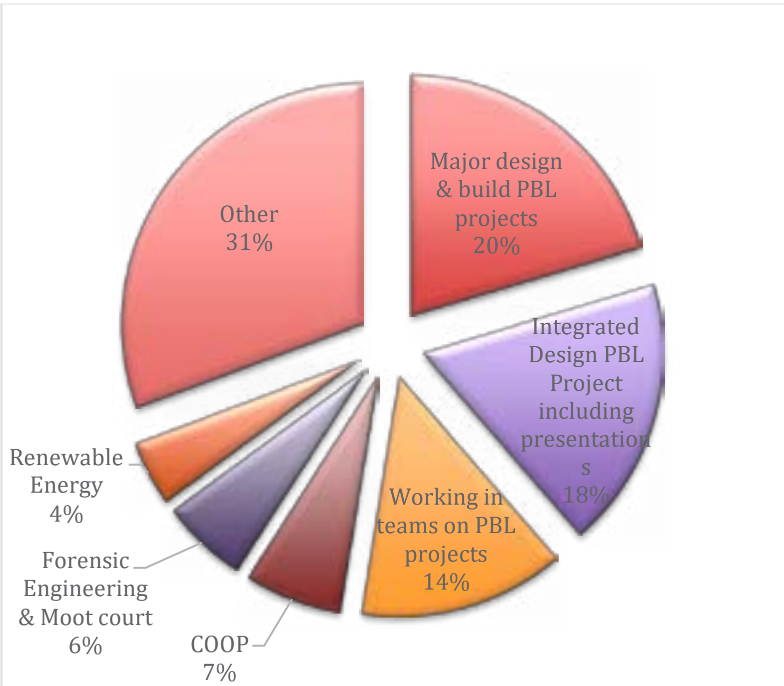

Figure 3: Most impactful/memorable learning experiences.

Undertaking sustainable energy projects such as evaluating a site's potential for the generation of electricity from wind energy are also highly valued by graduates. Many of the remaining 31% of activities listed under 'other' involve tasks that help develop professional skills essential for engineers such as sketching, project presentations and technical interviews, site visits, final year research projects, laboratory activities, use of physical props to demonstrate theoretical concepts e.g. strut behaviour and the laws of friction. These findings are congruent with the aspirational 'habits of mind' outlined in section 1.1. The results also corroborate the research findings by (Prince and Felder 2006) that students remember more when they are actively involved in the learning process.

Fifty-seven of the respondents provided comments to support their selection of impactful learning experiences. Figure 4 **Error! Reference source not found.**illustrates the graduates' feedback correlates strongly with the desirable 'habits of mind' listed section 1.1. The results support the claim that engineering graduates of programmes with a strong PBL emphasis develop these 'additional benefits' (Mills and Treagust 2003; Kolmos and Holgarrdt 2019). There is significant support for the development of abilities that integrate knowledge within and across modules to arrive at viable engineering solutions to open-ended problems. Graduate feedback on 'learning by doing' provided numerous examples of how these experiences strengthened the graduates' understanding of theoretical engineering concepts. For example, one respondent with ten years professional experience offered the following comment on a design-build-test challenge in PBL 2:

"These learning experiences gave an insight into what being an engineer is, developing a design and following that design to reality as opposed to a more traditional design project in an academic environment where often a lot of things are simplified and the true structural behaviour is not revealed. This experience revealed the 'devil is in the detail' and more subtle structural behaviours that can only be revealed from testing your own design."

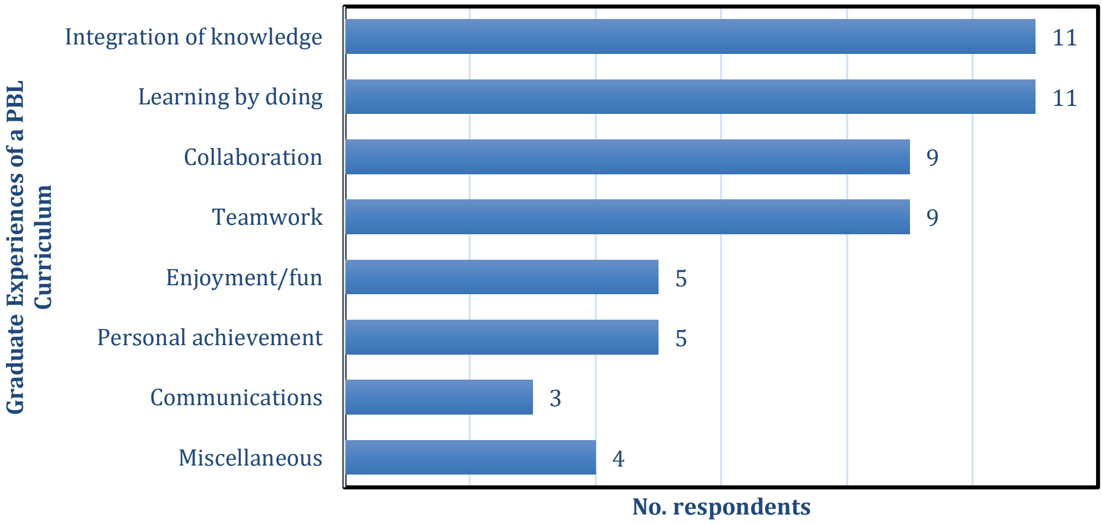

Figure 4: Classification of feedback linked to most impactful learning experiences (n=57)

Items falling under miscellaneous in Figure 4 include; a sense of being part of a unique educational experience, the value of learning from historic engineering failures, development of creative abilities, ownership (of the acquired knowledge), sharing ideas, passion for learning, integration of knowledge, leadership and an acknowledgement of the need to 'adapt' their (technical) language when interacting with non-engineers.

4 SUMMARY

The benefits of 'learning by doing' in engineering education features strongly in the graduate feedback. Graduates see it as a valuable tool in improving understanding of engineering design concepts and it also contributes to the development of the type of professional engineer discussed in section 1.1. Teamwork skills developed through PBL projects along with collaboration skills between different disciplines (architecture, construction management and law) are perceived by the graduates as being beneficial in preparing them for their professional lives. A sense of achievement from successfully completing open-ended engineering challenges is also reported in the feedback as is the enjoyment and fun experienced during the learning activities; one graduate described it as "*Working hard without it feeling like hard work."* Many graduates found the diverse nature of assessment tools employed throughout the programme for example, undertaking end of module interviews and presentations equipped them with good communication skills to succeed in industry. Finally, the graduates found being educated through PBL was a distinct advantage in developing their ability to tackle the types of problems they face in everyday practice (ie systems thinking, adapting, problem-finding, creative problem-solving, visualising and improving) along with becoming more proficient independent learners.

ASSESSING THE SHIFT IN ENGINEERING STUDENTS' INITIAL KNOWLEDGE AND FIRST-YEAR RESULTS OVER A DECADE

Keywords: *Transition, Skills & Attributes, Curriculum Development, Student Support*

ABSTRACT

Recent years have seen a shift in the qualifications students have before enrolling in undergraduate engineering programs in the UK. This shift includes numerous changes to the UK A-level syllabus, particularly in key subjects such as Mathematics and Physics. The Covid-19 pandemic also resulted in a reduction in the depth and breadth of the syllabus delivered at secondary school level several transitioning cohorts. Given these circumstances, it became crucial to review and compare the entry-level knowledge of recent students with their predecessors.

A decade ago, the authors, along with several collaborators from UK universities, initiated a project aimed at easing students' transition to university. The project entailed the development of an online questionnaire to quantify the knowledge, understanding, and attributes of incoming engineering students. This report draws on the transition results from that study and compares them with those of recent cohorts. The outcomes at the end of the first year were also compared. The results indicated a decline in performance on the transition survey in various areas, and particularly poorer performance in a mechanics module at the end of the first year. Interestingly, despite students from more recent cohorts achieving higher entry grades, the overall performance seems to have declined, accompanied by an increase in failure rates. This downward trend underscores the importance of addressing any gaps during the transition phase and necessitates a comprehensive review and remapping of the curriculum.

1 INTRODUCTION

1.1 Engineering Students Transitioning to University

The importance of robust mathematical and analytical skills for engineering students is universally recognised, with most undergraduate engineering degrees containing a high proportion of modules requiring skills and knowledge in these areas. However, studies reveal skills gaps between the expected knowledge of incoming students and reality, particularly in mathematics (Tsui and Khan, 2023) and (Kent and Ross 2003) and mechanics topics (Hawkes and Savage, 2000) and (Lee et al, 2008).

Beginning in 2010, a study at the authors' institution, in collaboration with other UK universities, identified gaps in transitioning students in these areas through means of a transition questionnaire which assessed new student knowledge and understanding of key fundamentals in Mathematics, Physics, Technology and Professional Skills. Despite high A-level grades, first-year students showed gaps in Mathematical, Mechanical, and Manufacturing knowledge (McCartan 2015). This insight informed curriculum changes at that time, highlighting the need for continuous review in light of significant shifts in secondary and higher education sectors.

Subsequent alterations to secondary level syllabi are believed to have impacted the foundational knowledge and skills of students transitioning into engineering undergraduate degrees, especially in A-level Mathematics and Physics. A review of these changes was scheduled for 2020 but was superseded by the Covid-19 pandemic. The potential long-term effects of the educational disruption caused by the pandemic (Pick et al, 2022), coupled with early anecdotal evidence of poorer outcomes for student cohorts transitioning to university post-lockdown (Francis and McClure, 2021), has now necessitated a review to determine if significant changes in student knowledge and skills had transpired over the past decade.

1.2 Rationale

The issues highlighted above have prompted a review of students' knowledge upon entry and their outcomes in the first year. The initial step involved reissuing the previously developed transition study to compare the knowledge and skills of recent first-year students with those from a decade ago. Results were then correlated with student outcomes as indicated by module averages and the number of resits at the end of the first year. The aim of the study is to establish if there have been changes in entry level skills and knowledge and in which areas, and to establish if these changes have impacted outcomes in first year. This should in turn provide preliminary insights for required curriculum modifications or support structures.

2 METHODOLOGY

2.1 Entry Profile

The School offers two main versions of the degree programmes in Mechanical and Aerospace Engineering: a 3 year Bachelor of Engineering honours degree (BEng Hons) and a 4 year integrated Master of Engineering honours degree (MEng). The entry requirements in 2011 and 2012, and from 2019 onwards are summarised in table 1. It can be seen that grade requirements have increased on the BEng pathway from BBC in 2011 to ABB in 2019, and on the MEng pathway from AAB to AAA.

Students have been required to have Mathematics at A level in all years, and at least one other mathematical/science related qualification from a selected range.

The A level grades at entry of the students from each of the cohorts were analysed. This was problematic for the students entering in 2021 as the group did not sit formal final A level examinations due to the pandemic, but instead were awarded grades based on a combination of performance in mock and previous examinations and work completed in school. For this reason, the entry qualifications for students for the academic year 2019-2020 (pre-pandemic) was also included for comparison to determine if there has been a shift in subject or grade profile.

Table 1: Entry Requirements 2011-2023

Entry year	BEng Hons	MEng Hons
2011	BBC including Mathematics and at least one from Physics (preferred), Biology, Chemistry, Design/Technology, Further Mathematics or Double Award Applied Science.	AAB including Mathematics and at least one from Physics (preferred), Biology, Chemistry, Design/Technology or Further Mathematics.
2012	BBB (including Mathematics + Physics/Chemistry/Biology/Technology/ Applied Double Award Applied Science)	AAB including Mathematics and at least one from Physics (preferred), Biology, Chemistry, Design, Further Mathematics or Applied Double Award Science.
2019	ABB including Mathematics and at least one from Physics (preferred), Biology, Chemistry, Further Mathematics, Technology and Design or Double Award Life & Health Sciences.	AAA including Mathematics and at least one from Physics (preferred), Biology, Chemistry or Further Mathematics.

2.2 Transition Survey

This work uses the original web-based questionnaire developed in 2010 and detailed by McCartan (McCartan, 2015). The questionnaire consists of forty questions on knowledge, skills and reasoning in Mathematics, Mechanics, Thermofluids, Nuclear, Electrical, Materials, Manufacturing, Technology, and Professional Skills. Each question permits a “not sure” response to minimise guessing and the rubric emphasises that it is not a test. The questionnaire is given to first year students on entry to the university. A copy of the questions can be found at this survey link.

The survey results give the percentage of successful responses for each of the years, 2011, 2012, 2021 and 2022 and for each of the relevant study areas. Each ten-year period is then compared (2011 & 2021, 2012 & 2022) to determine if there are any differences that can be identified in the pre-entry knowledge, skills, or reasoning over the ten-year period, for students transitioning into first year in Mechanical and Aerospace Engineering degree programmes.

Initially a statistical analysis was carried out to compare the numbers of students answering each question correctly using a two-sample z-test. The standard error (SE) was calculated according to *Eq. (1)*, where p_1 is the proportion of correct answers in group 1, where p_2 is the proportion of correct answers in group 2 and n_1 and n_2 are the sample sizes of group 1 and group 2 respectively.

$$SE = \sqrt{\frac{p_1(1-p_1)}{n_1} + \frac{p_2(1-p_2)}{n_2}} \quad (1).$$

The SE value was then used to calculate the *z* test statistic (the number of standard deviations away from the mean) from *Eq. (2)*. The *z* score was then correlated with *p*-values for each question. Increases or decreases were deemed to be significant with a *z* value of greater than 1.96 or less than -1.96, correlating with a *p*-value of less than 0.05, which is equivalent to a 95% certainty level.

$$z = \frac{p_1 - p_2}{SE} \quad (2).$$

The areas showing an improvement or decline in each of the ten-year periods were then highlighted and matched to the general topic areas.

2.3 Module Results

Students entering the programmes currently study four year-long core engineering and science modules (Mathematics, Thermodynamics and Fluid Mechanics, Mechanics of Materials and Dynamics) in addition to two more practical modules. In the 2011 and 2012 intake years, the modules were instead run as eight half modules, four in the first semester and four in the second semester. Results for the first-year students at the end of year exam board were analysed across 2011, 2012 and 2021, 2022. For the 2011 and 2012 years the results for the two half modules which were equivalent to current full modules were averaged to allow a comparison to be drawn. Results were also included for the pre-pandemic 2019 cohort to assess any differences that may be attributable to the issues caused by the 2021 intake students not having sat formal A level exams, as discussed in 2.1.

3 Results

3.1 Entry Qualifications

The percentage of first year students entering through the A level qualification with A levels in key subjects is shown in figure 1 for 2012, 2021 and 2022. A full breakdown is not available for 2011. A notable drop is seen in students offering Physics A level between 2012 and 2022, with some reduction also seen in the percentage of entrants with A levels in Chemistry, Biology and Technology and Design.

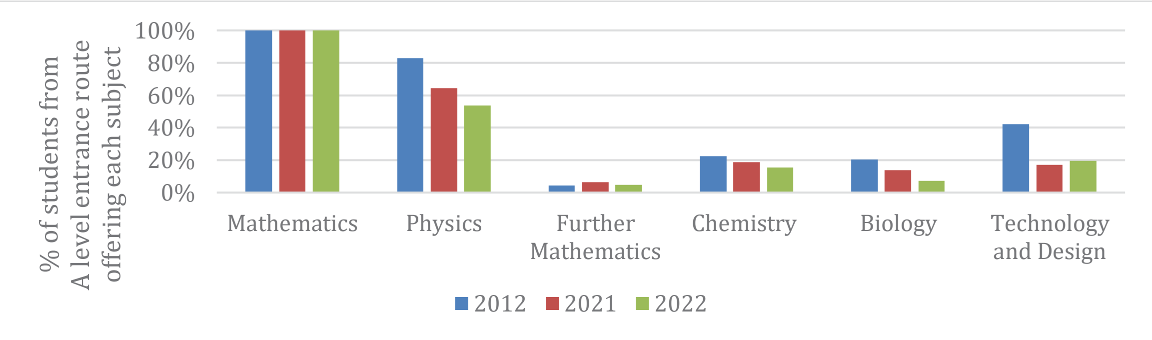

Fig 1: Percentage of A level entrants with key subjects

In line with the increase in entry requirements between 2012 and 2022, a shift in the grade profile of students can also be seen (figure 2). Comparing 2012 and 2022 shows an increase in the percentage of students with A and A* grades in Mathematics (45% in 2012 to 85% in 2022).

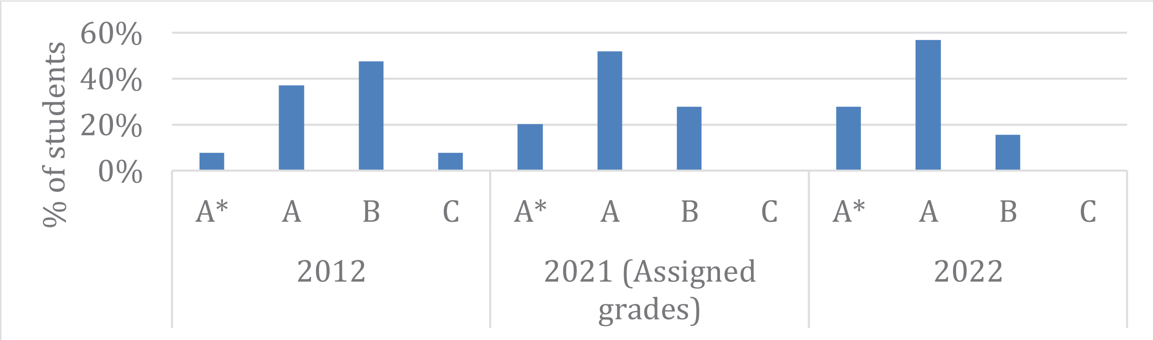

Fig 2: Grade profiles in A level Mathematics

While the number of students offering Physics at A level has fallen notably from 83% to 54%, the grade profile for those offering the subject has shifted slightly to higher grades, with 23% of students holding an A or A* grade in 2012 compared to 32% in 2022 (figure 3). Despite the 2021 entry students receiving assigned grades based on class work, the grade profiles are not out of line with 2022.

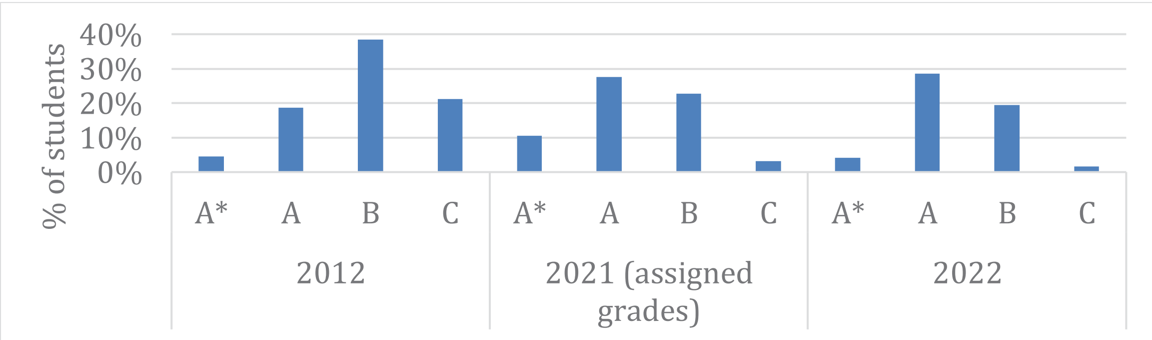

Fig 3: Grade profiles in A level Physics

3.2 Transition Survey Responses

Figure 4 shows a graphical representation of the results by question for the four years examined in the survey. The response rates out of the whole first year cohort for the survey were: 74% in 2011 (102 students participated), 86% in 2012 (124 students returns), 68% in 2021 (84 returns) and 42% in 2022 (62 returns). Overall average scores across the years were similar, at 61%, 62%, 66% and 64% from 2011 to 2022. For most questions, the results across all four years are also remarkably similar, however some clear differences can be seen when comparing the 2011/2012 individual question data to that of 2021/2022.

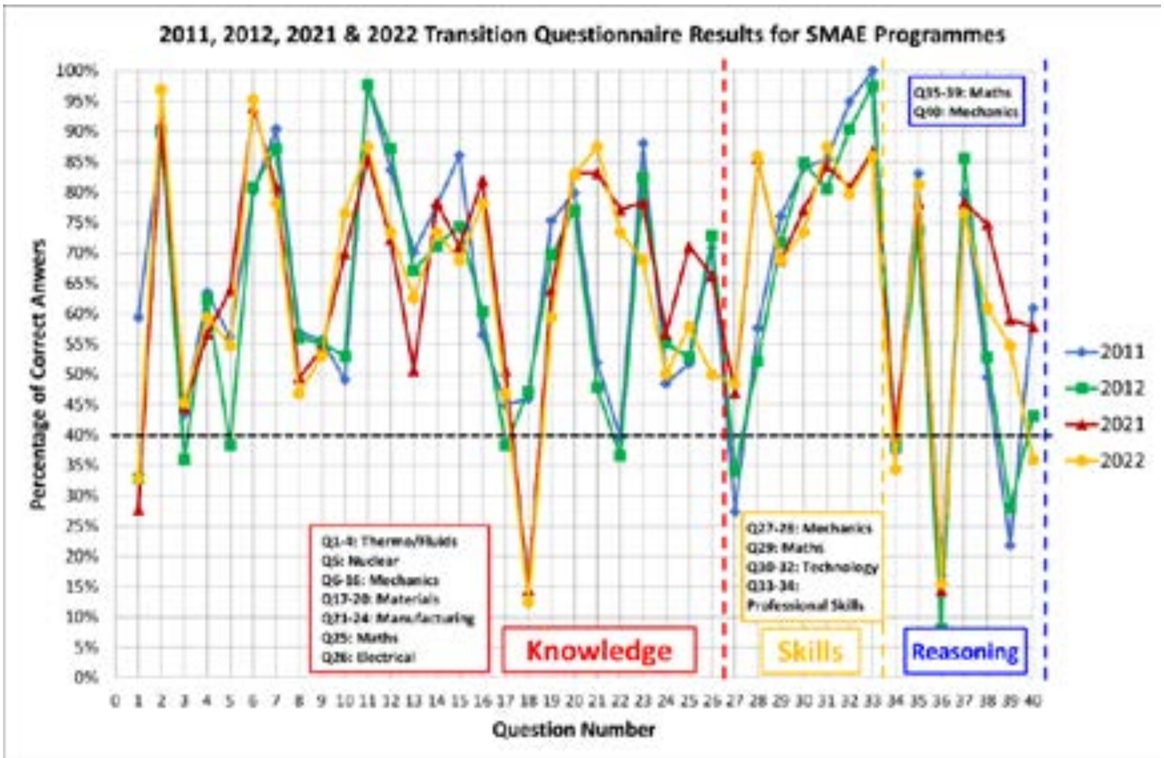

Fig 4: Scatter Plot of Transition Questionnaire Results

Table 2: Identified areas of changes in performance and statistical analysis.

3.3 Statistical analysis of changes in performance

Table 2 presents data on the performance in the survey over the four years. Questions are highlighted in red where a decrease is seen comparing both 2011/2021 and 2012/2022, and in green where a consistent increase is seen in both years. Seventeen questions show a decrease across the decade in both sets of comparator years. Of these, eight are mechanics questions, with the remainder spread across a variety of areas. Consistent statistically significant decreases to the 95% confidence level across both sets of years are only seen in three questions. Seventeen questions show an increase in student performance in both sets of years, five in mechanics, five in manufacturing and materials, and a spread across the other areas. Five questions showed statistically significant increases in both sets of years.

3.4 Performance at the end of year 1

The averages and standard deviations of module marks for the four core modules are presented in figures 5 and 6 for students on the BEng and MEng degrees respectively. Aerospace and Mechanical Engineering students are combined in the presented results. For Mathematics, the average values across the years analysed have remained relatively flat, although 2022-23 was the lowest year for both MEng and BEng students. Mechanics of Materials shows the most obvious drop in performance comparing the pre-Covid years to the latest two years analysed, and averages are out-of-line with the other modules. This may correspond to the reduction in performance in mechanics-related questions in the transition survey, and to the reduction in the percentage of students completing an A level Physics qualification coupled with a reduction in the mechanics content of the A level Mathematics syllabus. Dynamic Systems has been very consistent over the years. Thermodynamics and Fluid Mechanics showed a large drop in performance for the BEng students in 2018-19, but subsequent interventions and changes in the module have led to an upswing in results for these students.

It is notable that the attainment gap between MEng and BEng students seems to have narrowed over the years in the majority of the modules, potentially due to the entrance grade requirements to the degree programmes being raised and the difference in BEng and MEng requirements narrowing. However, it is clear that the uplift in intake requirements has not resulted in an uplift in performance, which is in fact slightly lower overall, and first-time failure rates are clearly higher (figure 7).

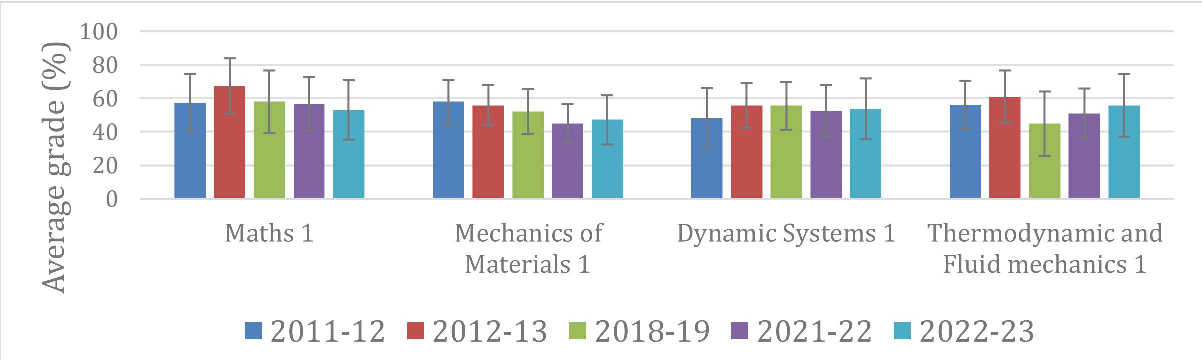

Figure 5: End of year 1 averages in core modules - BEng Students

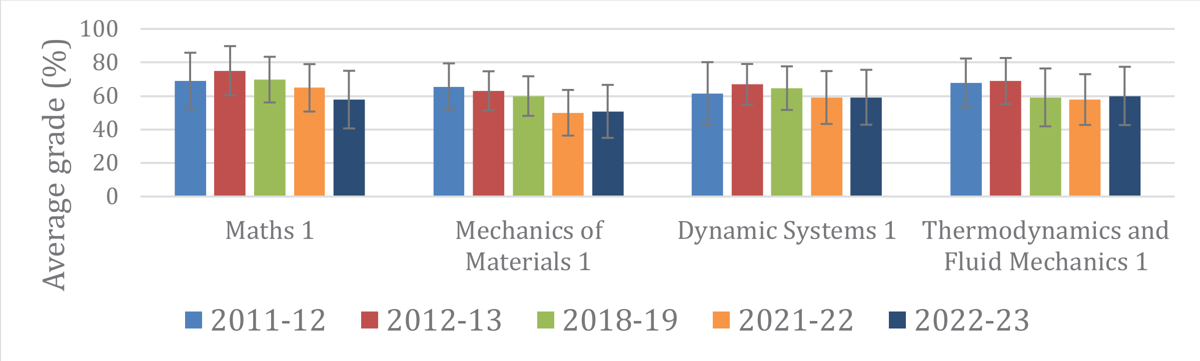

Figure 6: End of year 1 averages in core modules - MEng Students

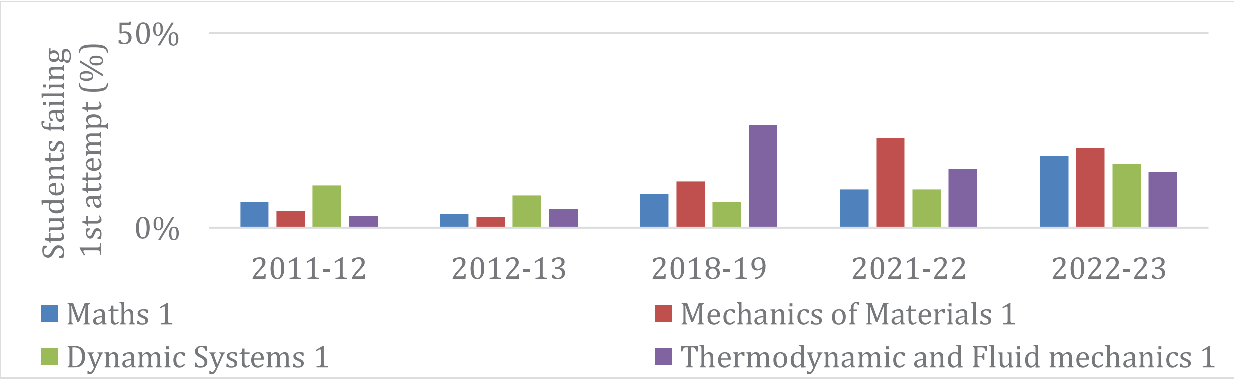

Figure 7: Percentage of students failing on first attempt

4 CONCLUSIONS

Overall, the results suggest that there are certain shifts in student entry level knowledge and understanding in some key engineering-related topics comparing recent years with a decade ago. The transition survey results indicate declines in performance in some areas, around half of which are in mechanics topics, but there are increases in others. Entry level qualifications of the students are higher than they were a decade ago, but most module averages show slight declines, and overall failure rates at the end of year 1 are higher. A reduction in performance in the year 1 Mechanics of Materials module in particular is likely due to the reduction in students entering the programmes with an A level Physics qualification, coupled with reduction in Mechanics content in the A level Mathematics syllabus. Some of this decrease may also be due to the incomplete coverage of the syllabus during and in the immediate aftermath of the Covid-19 pandemic.

Regardless of the reasons, the university has limited control over pre-entry knowledge, but must proactively respond to the needs of changing cohorts of students entering the programmes. This study has indicated that there is a need for a timely remapping of entry knowledge and skills, and recalibration of the current year one syllabus to be carried out to ensure that students transition successfully into their engineering degree programmes. However, the picture is a complex one, and it is difficult to present a fully controlled comparison of current and historical results given the variety of factors that have changed over the years and further in-depth analysis will be required to draw out clear causal factors and trends. The next steps in the work will involve a more detailed mapping of A level syllabi and student entry knowledge to the current stage 1 curriculum to identify any mismatches, and to identify other factors that may be at play. This will then allow some curriculum design recommendations to be made. Results of this study will be presented in due course.

ABSTRACT

In this exploratory study, we set out to reconstruct and critically analyse the history of two engineering education accreditation frameworks with a global reach: the Washington Accord (WA), and the EUR-ACE label. Because these two frameworks have significantly expanded over the last decade, such a historical analysis would be beneficial in outlining the values and motivations associated with each of them, contributing to a deeper understanding of their current and future efforts. To achieve

[1] *L. Pollettini Marcos,*
lpollett@purdue.edu

this, we analysed 35 of approximately 360 documents retrieved from current and previous versions of websites officially related to each of these frameworks. Documents from older versions of the websites were retrieved through the Internet Archive's Wayback Machine. Our analysis procedure started with descriptive coding of the documents, followed by a reflective analysis of the codes, which led to the identification of themes relevant for the focus of this work. In this paper, we report the preliminary results of our analysis. Our results suggest that both WA and EUR-ACE are motivated by economic aspects of mobility, competitiveness, and economic pressure. Framing our results through the geopolitics of knowledge and Fanon's zone of being/non-being reveals the colonial dimensions of these two frameworks.

1 INTRODUCTION

This paper provides an exploratory historical analysis of two global accreditation frameworks in engineering education: the European Accredited Engineer (EUR-ACE) and the Washington Accord (WA). Understanding the values embedded in these two dominant accreditation frameworks and their historical context is paramount to frame their current and future expansion efforts. This becomes important as global dynamics prompt more countries to uncritically consider implementing quality assurance systems originating in the Global North as they seek to remain globally competitive (Sánchez-Chaparro et al. 2022; Blanco Ramírez 2014). Such approaches, in addition to the colonial history of the engineering profession, lead to a risk of challenging or displacing the local values and strengths of existing engineering education systems (Nasr 2014; Eichhorn 2020). Therefore, historical research lends itself well to this topic, as it can expose the evolution of perspectives and approaches in these accreditation frameworks, allowing for a more critical perspective on accreditation platforms with global influence (Schrag 2021).

As a response to changes driven by globalization, the International Engineering Alliance (IEA) and the European Network for Accreditation in Engineering Education (ENAEE) emerged as two key international organizations that established equivalencies between engineering degrees in different regions through accreditation. These organizations' efforts gained traction because of ideas such as international competitiveness of engineering programs, facilitating the mobility of engineering students and professionals, and potential economic gains (Augusti 2009; Alam and Kootsookos 2021; Turhan, Sengul, and Koyuncu 2015; Mohd Said et al. 2013; Aoudia 2022). To establish such equivalencies, these two organizations maintain engineering accreditation frameworks that direct accreditation agencies in different countries to adopt similar learning outcomes and assessment procedures in engineering programs (IEA 2014; Alam and Kootsookos 2021; ENAEE 2021). The WA, originated in 1989, describes the accreditation framework maintained by the IEA, whereas ENAEE's accreditation framework is described through the EUR-ACE label, which originated in the mid-2000s. These two frameworks now have a large global presence, with the WA currently having over 20 full signatories and 7 provisional signatories (IEA 2023), while 15 different accreditation agencies are authorized to award the EUR-ACE label (ENAEE 2022).

Prior research on these two frameworks has tended to emphasize their technical aspects and not their historical backgrounds. For example, Aoudia (2022) compared the requirements for the two accreditation frameworks to understand which would be an appropriate entry point for engineering accreditation in Saudi Arabia. Other studies more directly compare the standards themselves, highlighting the similarities and different nuances in defining and assessing knowledge, skills, and competencies (Freeston 2009; Hanrahan 2009). Another type of work focuses on analysing specific aspects of these standards, for example in terms of degree outcomes related to engineering ethics (Jesiek, Zhu, and Vinod, Forthcoming). As a contrasting example, Alam and Kootsookos (2021) briefly compare the two frameworks while providing a more detailed historical background for each; however, their work on the history of these two frameworks was mostly descriptive. The current literature is still lacking in more detailed and critical historical analyses of these two frameworks.

To provide the historical and contextual analyses presented below, we collected and examined historical documents made available by the organizations (IEA and ENAEE) and their members at different points in time. The overarching research question guiding this study is: *What are the values and motivating circumstances for the establishment and expansion of the WA and EUR-ACE accreditation frameworks?* The specific research question we answer through our preliminary analysis in this paper is: *What are the factors used to justify the creation and expansion of the WA and EUR-ACE accreditation frameworks?* These factors could be of economical, political, or technical nature; and identifying them can help us critically examine what these frameworks have been accomplishing in a global scale.

2 LITERATURE REVIEW

2.1 Globalization and engineering

Due to its ties to economical activities and the development of technologies, engineering is a key part of globalization, simultaneously driving and being driven by it. Globalization can be understood as the process of changing the mobility of people, goods, behaviours, and services, as they encounter less or more barriers to traverse different regions or jurisdictions (Lechner and Boli 2015; Ritzer and Dean 2015). The globalization movement has been accelerated by the evolution of technology and the expansion of economic markets, creating a network of global interdependence (Ritzer and Dean 2015; Sen 2015; Sklair 2015; Weiss 1999). Engineering and other forms of scientific knowledge are frequently at the forefront of technological and economic development and can thus be strategically controlled by high-income countries to emphasize their role in global dynamics (Freeman 2010). Thus, globalization leads to concerns around the competitiveness of engineers in a global job market and the standardization of products, processes, and services that ensure global compatibility (Acosta 2010; Freeman 2010). Engineering education is, therefore, also affected by global influences such as transnational education (Alam and Kootsookos 2021), exchange or academic visitor programs (Freeman 2010; Downey et al. 2006; Johri and Jesiek 2014), and international validation of program structures and outcomes, frequently through accreditation (Nasr 2014).

2.2 Colonialism and engineering education

Although most forms of settler-based colonization came to an end after the end of World War II, colonial legacies remain and new forms of colonization emerged. Colonial legacies can be identified through systems and structures that were created during colonial times but persist to this day. In higher education (HE), for example, it is argued that universities were built in colonies to serve colonial interests (educating settlers and local elites, maintaining the status of universities in the colonizing countries as superior, and operating in ways disconnected from local problems and realities), which still shape how these institutions operate today in former colonies (Abrokwaa 2017; Guzmán-Valenzuela 2023). As for new forms of colonization, political and economic factors uphold structures and actions that maintain existing dynamics for the exploitation of natural resources and labour by former colonial powers (Pearson et al. 2019; Sayed and Agndal 2022; Wijesinghe, Mura, and Bouchon 2019). These new forms of colonization manifest themselves in HE through university ranking systems, quality assurance models, and recognition of only certain forms of knowledge (Blanco Ramírez 2014; Sánchez-Chaparro et al. 2022; Kells 1999). These issues extend to engineering education due to its place in HE and the previously explored connections between engineering and globalization. In a review of literature about decolonizing engineering education, Seniuk Cicek et al. (2023) identify that this type of work addresses an assumed superiority of Western engineering standards and the education of engineers to serve in a neoliberal system. Thus, decolonization in engineering education within HE institutions can take the form of revising program structures by incorporating indigenous knowledge and pedagogies that highlight the needs and values of local communities.

3 THEORETICAL FRAMEWORK

The theoretical approach used in this work is directly informed by the dynamics of globalization and decolonial thought in engineering education. More specifically, we use Shahjahan and Morgan's (2016) conceptualization of decolonial thought, based on geopolitics of knowledge and zones of being. The geopolitics of knowledge aspect comes from Mignolo's (2003) work, which establishes that the power relations embedded in knowledge systems derive from the social context in which those systems emerged. Thus, the expansion and domination of these knowledge systems is facilitated through these power relations, potentially shaping knowledge in a global scale. The aspect of zones of being (and non-being) derives from Fanon's (1967) work, which originally discussed these aspects in relation to racism. Fanon defines beings as people who are recognized through their social systems as worthy of having rights, while non-beings are those without such recognition. The existing structures compel those in the zones of non-being to seek recognition from those in the zones of being so they can be valued. Within global dynamics, Shahjahan and Morgan (2016) contextualize this idea in terms of peripheral countries seeking to emulate HE standards to be acknowledged in a global knowledge system.

In their original work, Shahjahan and Morgan (2016) utilized this framework to analyse OECD's Assessment of Higher Education Learning Outcomes (AHELO) initiative. The authors classify this initiative as a form of establishing global spaces of equivalence for HE, which they define as socially constructed spaces where various events can be described and compared according to standard norms. Moreover, they describe these spaces as "universalized, delocalized, and depoliticized so that they are seen as legitimate comparative measures." (pp. 92–93). Following this definition, we understand the accreditation frameworks of interest to this study as variations of global spaces of equivalence specific to engineering education, and thus we use this framework to contextualize our findings.

4 METHODS

This study uses historical research methods and qualitative analysis methods. The reconstruction of historical events was carried out through the analysis of documents related to the IEA and to ENAEE. In both instances, the document retrieval process started with the official websites for both organizations and snowballed to include publications historically included in their online material, using the Wayback Machine's archive as a source. Most documents retrieved using the Wayback Machine were located using the service's URL function, which lists all archived assets associated with the specified web domain. We filtered the assets for PDFs and office suite documents. For ENAEE, the domains were enaee.eu and feani.org; and for IEA, the domains included ieagreements.org and washingtonaccord.org. Additional publications were sought as we found names of relevant actors for the development of both frameworks and clear gaps in the documentation were found (e.g., no copy of the original 1989 version of the WA). The final breakdown of documents and their broad categories are reported in Table 1.

Table 1. Description and numbers of document types retrieved. Duplicates are not included in the document count.

Document category	Description	# of documents retrieved
Official document	Documents published by either IEA or ENAEE documenting their working procedures, guidelines, and other official manifestations. Also includes legal documents related to either organization.	157
Presentation	Presentations made during meetings or conferences held by the IEA or ENAEE.	71
Academic publications	Includes publications made by authors who attended the meetings and conferences held by the IEA or ENAEE. These publications typically have presentations associated with them.	47
Program documents	Documents that detail the topics and schedule of meetings/conferences organized by the IEA or ENAEE. Also includes commentaries and wrap-up documents discussing the events as a whole.	27
External documents	Documents created by external organizations (including accreditation agencies in the countries that are part of the accords) that reference activities done in partnership with the IEA or ENAEE, or that document certain	61
Total	-	363

For this paper, we analysed 36 (10%) of the retrieved documents using reflexive thematic analysis. We chose the documents analysed at first as to prioritize overviews on the current state and history of the frameworks. After examining some documents, we pivoted our focus to the presentation documents, which offered more insights into the principles that were guiding the discussions and decisions being made in the context of the two frameworks. To build a preliminary understanding of the general circumstances that led to the creation and the expansion of these accreditation frameworks, we started our analytical process with coding. Given this more general goal and our research questions, the first author mainly relied on descriptive coding strategies. As outlined by Saldaña (2013), descriptive coding identifies the general topic that each passage focuses on, and helps in identifying patterns within the data, which can be helpful when dealing with large amounts of data. Later, the first author engaged in reflexive analysis of the codes to identify themes relevant to the research questions, discussing the process with the other authors (Braun and Clarke 2012; Byrne 2022). After jointly discussing our findings, we were only confident in the evidence that we had to support one of these themes. The other potential themes shall be expanded upon in future versions of this work, when we are done analysing all the documents we retrieved.

5 RESULTS

This paper presents the results of an exploratory analysis of these documents. In this section, we will detail a single theme we identified that has been pertinent for the establishment and expansion of both accreditation frameworks. We call this theme “Pressure for Going Global”. The first element of this theme is the promotion of mobility for engineering professionals. Documents related to the WA consistently emphasize the ability of engineers who earned their degree from accredited programs in any of the signatory countries to have their education credentials recognized by other signatories—effectively enabling them to directly practice engineering or seek authorization from the local authorities. In other words, one of the main motivators of this accord is establishing a mutual recognition of engineering qualifications between signatories: “Through the Washington Accord, which comprises this Agreement, the Rules and Procedures, the signatories recognise the substantial equivalence of such programmes in satisfying the academic requirements for the practice of engineering at the professional level.” (IEA 2023a, 5). Similarly, ENAEE established mobility as a core goal for the EUR-ACE label, being particularly influenced by the effects of economic integration within the European Union. Additionally, the integration of HE across Europe through the Bologna Process motivated ENAEE to frame mobility not only for engineering professionals, but also for engineering students. For both organizations, maintaining the mobility of engineering students and professionals stands at the core of their mission, with recent expansion efforts further strengthening this aspect.

The second element of “Pressure for Going Global” is that of competitiveness for engineering professionals. Because of global economic integration, engineers are now frequently expected or encouraged to perform their work in different countries or regions. As such, it is the desire of both IEA and ENAEE to ensure that engineering graduates in countries that follow their accreditation frameworks remain competitive in the global job market. In a presentation given shortly after the establishment of ENAEE and the EUR-ACE label, Giuliano Augusti, who had a key role in leading ENAEE in its early years, wrote: “The lack of an European accreditation system, notwithstanding the prestige of many National systems and of some Academic titles, in a global job market puts the European engineer in a objectively weak position, when confronted with the several existing international recognition agreements.”

(Augusti 2008, 7). For the IEA, this idea is expressed more implicitly in their documents. In recent times, their concerns over competition are made implicit under globalization: “The international recognition and portability of both educational qualifications and professional competency is becoming increasingly important in this age of global interdependence but unbalanced global development, which requires movement of engineering skills around the world” (IEA 2014, 4).

The following quote from a paper presented at an ENAEE Annual Conference co-authored by Giuliano Augusti demonstrates the points just outlined: “...it must not be forgotten that the original motivation behind EUR-ACE was, and still is, to establish a pan-European accreditation system of quality engineering education, extensively accepted by the broad engineering stakeholders community: indeed, the lack of such a system still involves great difficulties in trans-national recognition and mobility of European engineering students and graduates, that EUR-ACE is trying to overcome.” (Augusti et al. 2013, 3).

The final element of our theme consists of economic pressures influencing the creation and expansion of the accreditation frameworks. An example of this is that the Washington Accord was drafted explicitly considering the development of the European Economic Community (EEC). Ray Meyer, the representative of Engineers New Zealand in when the accord was drafted wrote: “As a background to the deliberations, developments in Europe were also considered. The EEC becomes a single and important market in 1992 and access to this market for engineering goods and services will be important” (Meyer 1989, 38–39). For the expansion of the WA, the 25th anniversary document states that, after some years of the accord’s existence, “the growth in interest by other organisations indicated the need for more structure and formality” (IEA 2014, 10). This quote suggests that the WA was pressured by external accreditation agencies to consider expanding, potentially so that these other organizations could enjoy the indirect economic benefits of being part of this group—consequences of the mobility and competitiveness elements highlighted previously. More recently, the IEA has partnered with UNESCO and the World Federation of Engineering Organizations (WFEO) to promote their perspectives on quality of engineering education.

For ENAEE, economic pressures are more directly mentioned in their documents, guiding both the original establishment of the accreditation framework and its expansion. The initial development of EUR-ACE framework happened as a consequence of the Bologna Process, which is one of the key strategies in the economic development of the European Union. As a more specific example, their expansion efforts in Central Asian countries were carried out through the QUEECA (Quality of Engineering Education in Central Asia) project. One of the goals of QUEECA was to “promote the practice of transnational recognition of engineering qualifications and facilitate engineering graduates mobility, taking into account the Central Asian regional economy and integration also in the global educational space” (Augusti 2013, slide 20). This quote evidences how an interest in promoting the economic integration of Central Asia with the global economy partly drove the EUR-ACE expansion to that region. Similar goals and statements can be seen in the MEDACCR (On-line Quality Assurance and EUR-ACE Accreditation of Engineering Programmes in the Mediterranean Area) project.

6 DISCUSSION

6.1 Globalization and engineering accreditation frameworks

Many of the aspects of globalization outlined in the literature review were relevant in the documents analysed. First, the element of mobility identified as one of the main motivators for these accreditation frameworks is aligned with the of changing the flow of engineering students and professionals globally. However, as highlighted by Ritzer and Dean (2015), mobilities can also be hindered through globalization, and we should consider how the creation and expansion of these frameworks might also negatively impact the mobility of students and professionals who are trained outside of these accords. The conformity of certain accreditation agencies to one of the accords but not the other also has the potential of negatively affecting mobilities in certain regions, as the two frameworks coexist in some jurisdictions (e.g., Turkey, Peru, Russia). Second, the element of competitiveness directly relates to the literature in globalization because it represents instances of regions being motivated to ascertain their economic competitiveness by establishing mechanisms to dictate the value of engineering degrees. As established by Freeman (2010), strategic control of scientific and engineering knowledge constitutes a strategy that dominant countries can use to promote their long-term economic dominance.

6.2 Colonialism in engineering education accreditation

In light of the geopolitics of knowledge, it is important to highlight that the WA and EUR-ACE frameworks emerged in the Anglosphere and in Europe, respectively. As such, the social context on which these systems came to be conceptualized and developed is aligned with the dominant knowledge systems in engineering. Therefore, the establishment and expansion of these systems was facilitated on a global scale. Our analysis indicates that proponents of these systems were aware of such dynamics, as both systems were proposed, at least in part, to help maintain the epistemic and economic dominance of those regions. The expansion of these frameworks to regions outside their initial scope might be influenced by countries in the zone of non-being wanting to move to to the zone of being in the case of those joining the WA and those involved in ENAEE’s QUEECA project. In that sense, countries that adopt such frameworks outside the Global North continue the historical valuing of colonizer interests as they follow existing rules in hopes of having “world-class” institutions (Abrokwaa 2017; Blanco Ramírez 2014; Guzmán-Valenzuela 2023). However, a more complete analysis of the documents is needed to confirm this hypothesis. Finally, the theme we highlighted through our analysis demonstrates a significant alignment with findings from (Shahjahan and Morgan 2016): “the fetishized prizes of this [academic] Olympiad are primarily: a globally competitive labor force, credential mobility, and accountability practices.” (p.105). Our findings thus add to the literature by providing parallels between previous findings in other areas and in engineering education, specifically for a globally competitive labour force and credential mobility.

7 SUMMARY AND ACKNOWLEDGEMENTS

Accreditation frameworks in engineering such as the WA and EUR-ACE have been successfully established and continue to expand globally, providing mechanisms for enhancing the mobility of engineering students and professionals. However, these accreditation frameworks have social and political consequences that the engineering community needs to be conscious of. Thus, through an exploratory analysis of historical documents associated with EUR-ACE and WA, this paper provided an initial perspective on how these systems operate under globalization and colonialist perspectives. We highlight how the idea of global engineering education is currently enabling new forms of epistemic dominance. Even though some level of global cooperation on accreditation frameworks for engineering education would be beneficial for a multitude of reasons, we need to understand the impacts of doing so on local systems of engineering education to avoid losing their existing strengths. Due to its exploratory nature, only a portion of the documents retrieved were analysed, meaning that there are likely more nuances to some of the ideas discussed in here. In our future research, we intend complete the analysis of all documents we retrieved, looking to understand how much voice new accreditation agencies have over making their processes distinct and locally relevant. Additionally, we wish to further triangulate the findings of our analyses through interviews with current and past members of ENAEE and IEA. This paper can thus inform research to better understand the motivations of countries seeking to join the IEA or ENAEE, and what the dynamics between these organizations and incoming countries are.

ABSTRACT

Only about 54% of South African Engineering students graduate from the four-year professional engineering qualification within five years. One of the biggest stumbling blocks in many engineering programs is mathematics, which in South Africa often comprises a significant part of the first year of an engineering degree program. Research indicates that there is an articulation gap between student preparedness and institutional responsiveness in South Africa. In response to this articulation gap, the Diagnostic Mathematics Information for Student Retention and Success (DMISRS) project engages with mathematics educators from various South African higher education institutions to find solutions collectively and collaboratively to issues surrounding the retention and success of students in STEM programmes with a focus on the teaching and learning of Mathematics. It can be argued that South African higher education mathematics curricula do not consider sufficiently the preparedness of the students they teach and are not adequately responsive to the needs of students. This article reports on the results of a baseline survey of South African Mathematics departments undertaken as part of the DMISRS project, with participants teaching mathematics in engineering as well as other disciplines. The

[1] *RN Prince*
rprince@uj.ac.za

results show that while various student support mechanisms are implemented in first-year mathematics courses in South Africa, educators rate these as being of varying effectiveness. Overall, there appears to be insufficient attention given to questions of curriculum, content and student support in first-year mathematics courses, particularly where these are offered to engineering students.

1 INTRODUCTION

Throughput rates, or successful completion of university degrees, in South Africa have long been a concern for academics and society at large, and have been discussed by various authors (*inter alia*, Scott et al., 2007; Case et al., 2013; Du Plessis and Gerber, 2012; Frith and Prince, 2016). While access to higher education has widened in recent decades, many students fail to successfully graduate. In 2014, the number of students enrolled in South African higher education institutions was close to a million (CHE, 2016: p.3). However, about 40% of all registered students dropped out of their studies by the end of regulation time, and only 27% obtained their degrees in the regulation time (CHE, 2013).

It is acknowledged that "poor performance in Science, Technology, Engineering and Mathematics (STEM) Education and professional programmes is of particular concern, given the short supply of high-level skills in these fields" (CHE, 2013). The ratio of engineers to population in South Africa is very low compared to other countries: 1:3166 in South Africa, compared to 1:389 in the USA and 1:130 in China (Grayson et al, 2013: p.343). This is of concern, given the lack of high-level skills in the South African engineering field and the need for engineers in order for the country to achieve its developmental goals. A study in 2009 by the Council for Higher Education showed that only 54% of South African Engineering students enrolled for a four-year professional bachelor's degree in 2000 graduated within five years (CHE, 2009: p.36) and referred to a "growing gulf" between enrolment and graduation in Engineering between 1989 and 2010. In a further study in 2013 by the Council for Higher Education, it was shown that only 41% of the 2006 Engineering cohort graduated within 5 years (CHE, 2013: p. 47). This is substantially lower than what it was for the 2000 cohort.

Mathematics is fundamental to all STEM programmes. There is a growing need for capacity development and augmentation of the skills of mathematics educators in HEIs to effectively utilize innovative technologies and data-driven teaching methods, in the context of the challenges and changing landscape of Higher Education. There appears to be a lack of alignment between students' literacy practices and mathematical proficiency, on the one hand, and the academic practices of their chosen disciplines, on the other. This gap results in significant attrition, which continues to widen inequality, and impacts the economy and future development. Even in institutions where forms of curriculum responsiveness such as curriculum-integrated mathematics support are found to be necessary, this is generally not available. There remains a clear national imperative to address the problem of high failure and drop-out rates in STEM programmes, specifically in first-year Mathematics courses.

To this end, the Diagnostics Mathematics Information for Student Retention and Success (DMISRS) project was established to engage Mathematics educators with the needs of their students through investigating and sharing current practices in terms of curriculum-integrated support for mathematics in order to incorporate and facilitate further development and identification of ‘best’ practice in this regard. The project included diagnostic workshops, annual symposia and regular surveys of practice in mathematics teaching in higher education.

2 METHODOLOGY

A baseline survey was sent out to all South African mathematics departments participating in the DMISRS project. The focus of this baseline survey was on the support mechanisms that institutions make available to students in first-year mathematics courses. In total, 11 questions were included in the survey; a mixture of open- and closed-ended questions were included. Twenty-four lecturers from 16 universities completed the baseline survey. Half of the lecturers work directly in a Science faculty while the other half teach mathematics as a service module in other faculties, including many from engineering (as can be seen from Figure 1). Ethics clearance (CHED REC 2019_2) for the research associated with the Diagnostic Mathematics Information for Student Retention and Success (DMISRS) project was received from the Centre for Higher Education Development at the University of Cape Town.

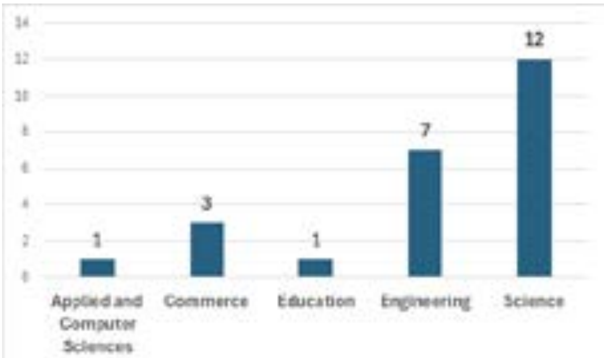

Fig. 1. Number of lecturer respondents per faculty

3 RESULTS

3.1. Admission and Placement

School-leaving mathematics requirements for entry into first-year mathematics courses ranged from level 3 (40-49%) to level 6 (70-79%) with the majority expecting a level 4 (50-59%) (see Figure 2). Of the 16 participating higher education institutions, 6 require their prospective students to write the National Benchmark Tests (NBTs), a set of South African higher education admission tests; only 5 require prospective students to write the NBT Mathematics test, specifically. The majority of the universities (88%) do not use the NBT results for student placement. 75% of universities do not use the results to identify student support needs.

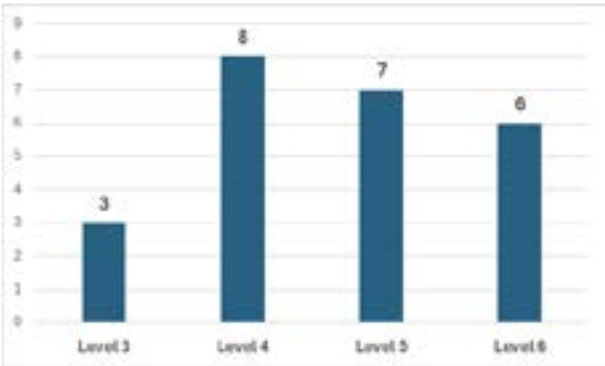

Fig. 2. Number of institutions per NSC mathematics level

Among those institutions who do use the NBTs to identify student support needs, this is done in the following ways:

“If the NBT results are poor, students are put into Extended Studies … with lots of support.”

“Our students are subjected to internal profiling test on academic literacy and mathematics which is then followed by an intense week programme on challenging sections / gaps identified in this test. Tutorial and extra classes are conducted throughout the year as a form of extra support.”

“Mostly with placement of students who need to decant from the mainstream mathematics course to a first semester course done over a year.”

“Organising help from Mathematics Centre.”

3.2. Content of Mathematics Courses

On the question about whether any topics could be excluded from mathematics courses, only 3 lecturers feel that certain topics can be omitted. Two of these lecturers argued the following:

“Topics that do not have any connection with contexts encountered in other non-mathematics disciplines can be omitted. Topics of a purely theoretical nature can safely be avoided.”

“From 1st semester: Applications of the mean value theorem. Anything beyond the basics of binomial theorem. From 2nd semester: Taylor series (or at least anything beyond the basics). The matrix representing a linear map. I am not familiar enough with all the places in the engineering degree where the content of these courses is required. I don't believe there is consensus among engineers on what maths should be taught in first year.”

Lecturers identified a wide array of topics that students generally struggle with. Basic high school competencies were commonly noted by 5 lecturers. Other gaps include: differentiability, curve sketching, logarithms, fractions, calculus, limits, absolute values, among others. Identification of these problems generally stemmed from multiple sources, including the students themselves, as well as test, exam, and assignment performance, and from lecturers’ and tutors’ observations.

3.3. Types of student support offered

3.3.1. Special sessions

Only seven lecturers reported implementing special sessions with their students. These sessions are not compulsory at the majority of universities and are mostly facilitated by the same lecturer who teaches the students in the module. Student participation is voluntary at three universities, forms part of first-year orientation at one university, and is performance-based at three universities. Lecturers' ratings of the effectiveness of these sessions' varied, as seen in Figure 3.

3.3.2. Tutorials

All but two universities report offering tutorials to students. Tutorials are compulsory at most of these universities (82%). The majority of universities cover current lecture material in their tutorials. Content is chosen based on the course outline, lecturer and tutor observations, and student needs. Tutorials seem to be generally well-attended, as reported by most lecturers. Attendance ranges from 60% to 100%. Tutors are most commonly undergraduate students, postgraduate students or lecturers, and undergo training at the majority of universities (90%).

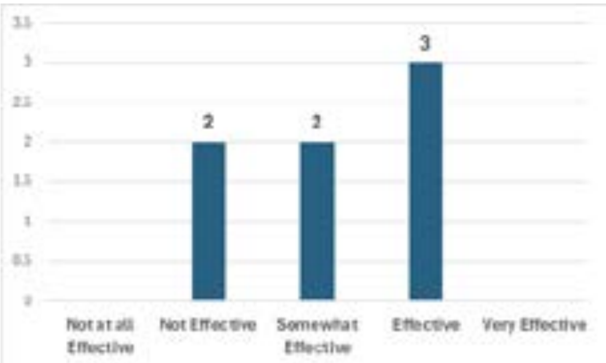

Fig. 3. Lecturers' rating of special sessions effectiveness

As for the effectiveness of this type of student intervention, most lecturers rated tutorials as *somewhat effective* in supporting students (see Figure 4). Thirty-six percent of lecturers offer additional tutorials to students (e.g. on the weekend) and these typically take the form of 'Whiteboard Workshops'. Most lecturers reported that tutors are *often*, or *sometimes*, available to answer student questions. If tutors are not available, students turn to lecturers with their questions (see Figure 5).

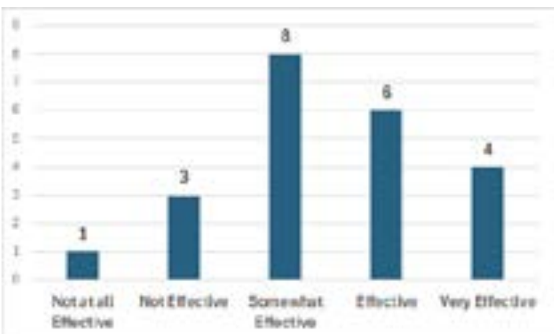

Fig. 4. Lecturers' rating of tutorials' effectiveness

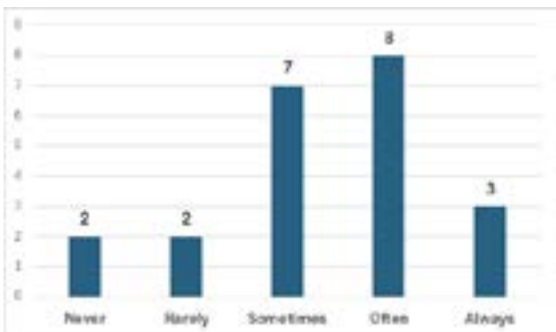

Fig. 5. How often tutors are available to answer students' questions (outside of tutorial sessions)

3.3.3. Additional materials

The majority of lecturers (75%) report that students are provided with additional material to help bridge knowledge gaps. These materials include: online content (e.g. blog posts and videos); additional study material (e.g. lecture notes, exercises solutions, and examples); and other textbooks. Lecturer observations, student requests and students' performance help to determine what materials are provided. These materials are typically made available to students through online platforms. Most universities (78%) monitor whether students access these materials, and report good levels of utilisation (60% - 100%). Generally, this intervention is viewed as an *effective* form of student support (see Figure 6).

3.3.4. Peer support

Just over half of the surveyed lecturers (58%) report that peer support is available to students, with most of these universities actively encouraging students to form peer-support groups. These groups are typically formed within tutorial groups, or universities have a residence mentor/tutorial system. Groups are mostly led by strong students. Students who join these groups are not necessarily weak students – respondents report a mix of strong and weak students. Current lecture/tutorial content is discussed in the groups. The majority of lecturers think that peer groups are a *somewhat effective* form of student support (see Figure 7).

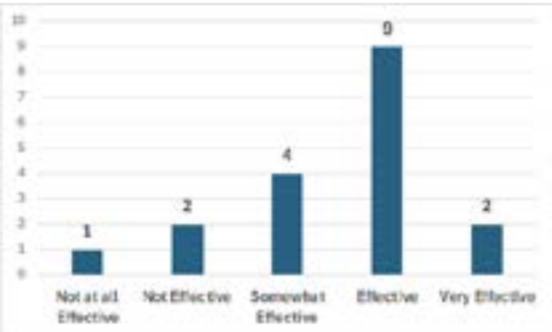

Fig. 6. Lecturers' rating of additional materials' effectiveness

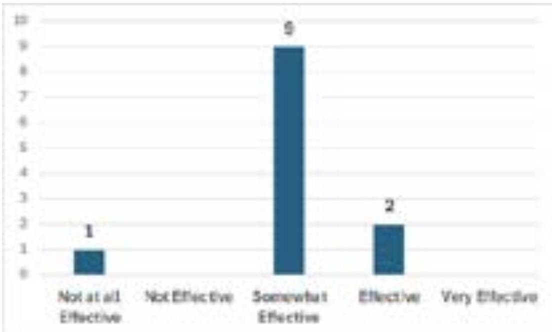

Fig. 7. Lecturers' rating of peer support effectiveness

3.3.5. Hot seats (dedicated one-on-one consultation with tutors and/or lecturers)

Fifteen lecturers (63%) implement hot seats; however, there is some variation in how lecturers understand what constitutes a 'hot seat'. Two lecturers said that they do not implement hot seats, but instead offer a Maths Centre. Another commented: "There are not official hot seats. All lecturers are available at all times" – this means that, in these cases, hot seats cannot be differentiated from lecturer support. Hot seats are mostly available to students every day. However, utilisation by students is fairly low (0% - 40%). When asked whether the person who runs the hot seat communicates with lecturers, they report mixed degrees of communication (see Figure 8). Lecturers rated hot seats as having varying degrees of effectiveness (see Figure 9).

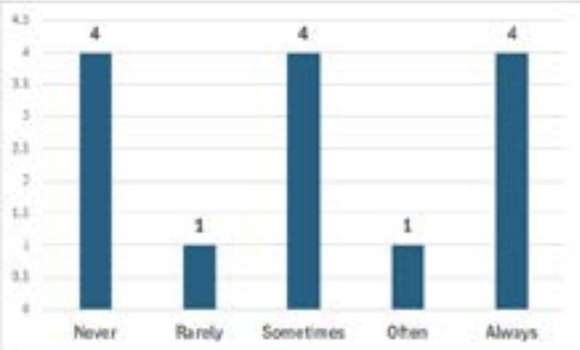

Fig. 8. Frequency of communication between lecturers and the person running the hot seat

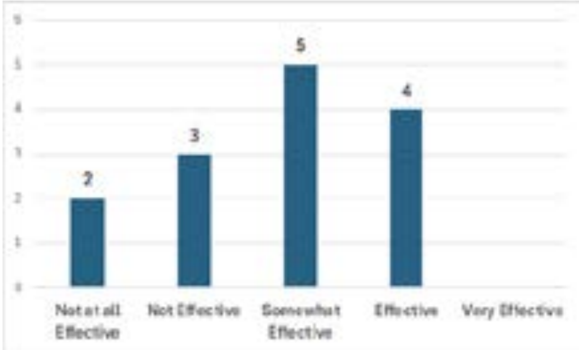

Fig. 9. Lecturers' rating of hot seat effectiveness

3.3.6. Lecturer support

Most universities offer lecturer support to students (92%) on a daily basis (68%). This can take the form of emails, consultations and drop-ins, WhatsApp, and online chat rooms. All students typically make use of this offering. Lecturers perceive this type of support to be manageable for themselves (see Figure 10), and think that this is an effective mechanism of support for students (see Figure 11).

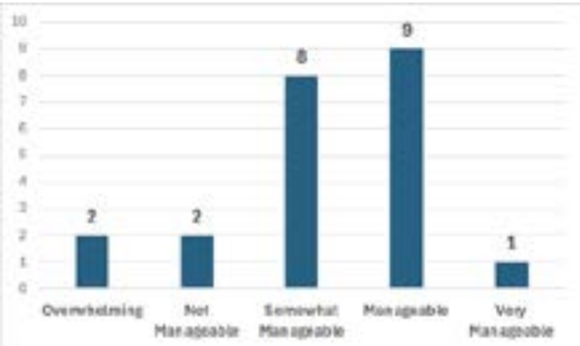

Fig. 10. Degree to which lecturers can manage this type of support

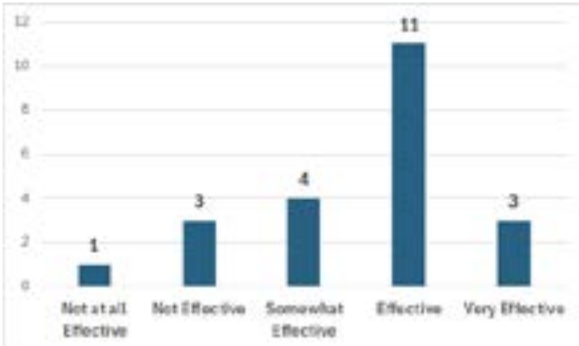

Fig. 11. Lecturers' rating of lecturers support effectiveness

3.3.7. Additional and alternative support

Three lecturers mentioned additional support available to students at their universities:

> "Student Development Support in each faculty."
>
> "The [University's] Learning and Teaching Development Department have workshops with the students."
>
> "Maths Centre available for students."

Many lecturers described the alternative mechanisms that their institutions have in place for those students not coping; most take the form of extended programmes.

3.4. Changes to student support

Half of the lecturers feel that no changes should be made to their current student support offerings, with one commenting: "students need to make more use of the current support services". Another lecturer also emphasised the need for improved self-monitoring among students, and a more meaningful understanding of students' cues among both staff and students:

“Students take time to realise that they are not coping. Often when they do realise it, it is often too late to remedy the situation. I feel we do not utilise assessments effectively and do not teach students how to assess themselves. I also feel that words such as ‘understand’, ‘yes’, ‘ok’ and signals such as nodding are used loosely by both teachers and learners and student[s] learn too late in the year that these cue[s] have [no] meaning in themselves.”

Among those who feel these services could be improved, the need for more tutors was commonly noted. One lecturer mentioned that this is difficult, as their engineering course does not produce enough postgraduate students. Focused attention on individual students was also noted, with one lecturer saying:

“One-to-one consultations are very valuable but time consuming. I suspect I would be more effective if I replaced 80% of my 8 am lectures with online lectures, and made it a requirement for students to make a 5-10 minute consultation with me once a week to report on their progress”.

One lecturer suggested that more online support could be made available, given students have access to adequate internet connectivity and infrastructure. Lastly, one lecturer noted that resource guides are not provided for common content problems. This is important, given how many students appear to struggle with high school competencies: “We have not yet developed resource guides for topics known to be problematic, especially topics done in high school”. Thirteen lecturers (54%) feel as though they need more resources in order to change their student support services. Most noted the need for more tutors. Other needs identified include:

Assessing the effectiveness of student support services;

Budgeting information that can support innovative strategies;

Links to helpful resources (e.g. Khan Academy, videos, free online quizzes, etc.)

Motivating senior students to become tutors; and

Time management skills.

4 DISCUSSION

Timely completion of university degrees, particularly in engineering, has been identified as a significant challenge; this is particularly so in South Africa (see Scott et al., 2007; Case et al., 2013; Du Plessis and Gerber, 2012; Frith and Prince, 2016), but is also present in Europe. For example, Mumenthaler et al. (2023) show that, at EPFL in Switzerland, the failure rate in the first year is close to 35%. Mathematics is fundamental to engineering programmes and often serves as a gatekeeper for students, with the focus often on the underpreparedness of students in terms of mathematics (Mumenthaler et al., 2003). There is, therefore, an imperative to address the problem of high failure and drop-out rates in Mathematics courses. This paper has reported on the results of a baseline survey of South African lecturers in Mathematics departments teaching mathematics in engineering as well as other disciplines.

As can be seen in the results section described above, few universities make use of the diagnostic information provided by university entrance tests to inform their mathematics curricula. This should be a first point of departure for ensuring mathematics courses respond appropriately to the needs of the students admitted therein. In addition, there is a lack of consensus over what content is important in a first-year mathematics course, particularly where these courses are offered to engineering students. This has long been a challenge for engineering education, as reported by the SEFI Mathematics Working Group as early as 1992 (SEFI Mathematics Working Group, 2013). Greater clarity and communication in this regard is required.

A wide array of support mechanisms are implemented in first-year mathematics courses in South Africa. However, the lecturers in this survey rate these support mechanisms as being of varying effectiveness. It is important to note that the lecturers were mathematics educators and therefore tended to more highly rate the support mechanisms they themselves offered. In addition, relatively few lecturers see a need for changes in the way student support is offered in mathematics, despite the poor results often seen in these courses. This is a significant challenge if mathematics is to cease to act as a gate-keeper within STEM programs in general and engineering in particular. Of course, “learning outcomes in mathematics are not dependent solely on good teaching, sufficient resources, or other external considerations” (Pohjolainen et al, 2018, p. 3) but are a result of all of these factors.

5 IMPLICATIONS

The way forward could be that mathematics lecturers need to be working collaboratively in order to deal with the complex problem of low throughput and high failure rates, particularly in mathematics. If mathematics is to become a gateway rather than a gatekeeper for engineering studies, mathematics lecturers will have to see this as a collaborative endeavour. They should also work alongside engineering disciplinary experts to ensure that the mathematics that is being taught is relevant to engineering disciplines. In this regard, it would be important to consider both the curriculum as well as the teaching, learning and assessment approaches employed to ensure alignment between the preparation of students and the demands of the degrees for which students are studying. As such, greater attention will need to be given, not only to providing more support within mathematics courses, but also to more creative and effective mechanisms for supporting first-year students. While this study has sought the views of lecturers, further investigation would need to be done to ascertain students’ perspectives on the effectiveness of the various support mechanisms offered.

ABSTRACT

Engineering education has immense potential in promotion of the types of competencies that are likely to help future engineers make responsible decisions. The written curricula play a significant role in the implementation of engineering education so how to integrate key sustainability competence developing activities in teaching should be clearly communicated in the course descriptions. Mainstreaming sustainability aspects as part of engineering education also calls for more robust means to identify sustainable development content in curricula.

This research examines a method for assessing the extent to which sustainability competencies are currently conveyed in course descriptions in engineering education. The findings suggest the tested method to be a good starting point for

[1] *L Routaharju*
liisa.routaharju@student.lut.fi /liisa.routaharju@xamk.fi

assessing sustainability competence developing content; however, more work to be necessary for a truly generalisable method. Clear challenge of identifying sustainability competence related content is the varied interpretations of the written curricula content. Supporting academic staff in the integration of sustainability competence developing content in teaching could be enhanced, for example, by arranging workshops that might also increase the understanding on the importance of offering sustainability content for engineering students.

1 INTRODUCTION

Engineering education offers a lucrative basis for the development of the competencies necessary for responsible decision making, as the traditional role of an engineer as a technical problem solver has evolved into a transdisciplinary specialist with a strong role in the sustainability transition (Karvinen, 2024, 23-24).

Responsible decision-making considers the various repercussions of the decision, even beyond temporal and spatial distances. Such consideration requires extensive understanding of the complexities and the causal relations of the potential consequences of the action decided on as well as a strong value base to lean on in the crossfire of conflicted interests (Karvinen, 2024, 18).

The ability to identify and influence the root causes of sustainability challenges is a clear foundation for true transition from unsustainable practises (Ehrenfeld, 2005, 23), yet currently formal education is falling short on equipping graduates with the essential abilities to succeed in this (Voulvolis et al., 2022, 2). A “competence” as a term can be defined as the matrix of “knowledge, skills and attitudes that together allow the competent individual to perform successfully” (Wiek et al., 2011, 204).

A consensus on the most essential competencies for enhancement of the sustainability transition is growing and many frameworks name systems thinking, anticipatory, normative, strategic, and interpersonal competencies as the key sustainability competencies (KSCs) (Wiek et al., 2011, Redman and Wiek, 2021, and Brundiers et al., 2021). Systems thinking competence refers to the ability to analyse complex systems across domains and anticipatory competence to the ability of analysing, evaluating, and drafting future vision (Wiek et al., 2011, 207-209). Normative and interpersonal competence refer to abilities of negotiating and communicating sustainability values (Wiek et al., 2011, 209-211) whereas strategic competence refers to the ability of implementing change by applying knowledge to finding solutions to sustainability challenges (Wiek et al., 2011, 210).

The assessment of the efficacy of initiatives aimed at fostering the growth of the specified Key Sustainability Competencies (KSC) among students presents a methodological challenge, since development of a competence, let alone a set of competencies, is highly subjective. Learning is always reliant on the pre-existing skillset, so the increase of KSCs is dependent on the existing competence set of the learner (Brunders et al. 2021, 23). Measuring the learning outcome and the efficiency of the activities aiming at learning is therefore challenging; the learning result being dependent on each learner’s initial level, personal learning abilities and a wide range of other variables. Allocation of the learning outcome to a specific activity is likewise challenging. The development of a competence is not limited to the confinement of a formal educational institution but is affected by all stimuli encountered by the learner. The dilemma of understanding the urgent need for KSC building content in education but lacking the tools for their promotion is a concern for higher education institutions (HEIs) that, for their part, carry the responsibility of mainstreaming education for sustainable development (UN, 2015).

The discussion on the types of competencies likely to promote responsible behaviour is ongoing. Even after reaching a clear consensus on the competencies to focus on, it is obvious that "*competencies are not naturally developed in teaching-learning settings, instead they require targeted and ongoing efforts*…" (Brundiers et al., 2021, 26). Engineering education commonly relies on the documented curriculum to lay the base for course content and learning assessment, so supporting the teaching staff in competence developing course implementation should be clearly communicated as elemental parts of course descriptions. If they are not, their integration in course implementation is dependent on the responsible teacher's personal interest, potentially resulting in polarization of learning (Routaharju et al., 2024, 125). Tangible and robust instruments for the assessment of sustainability competence development need more attention (Redman and Wiek, 2021, 128).

Educational content in HEIs is based on the course content and learning objectives defined in curriculum, which should provide the academic staff with the necessary instruments for integrating KSC enhancing activities in teaching. This research examines a method for assessing the extent to which sustainability competencies are currently conveyed in course descriptions in engineering education. The research questions addressed are:

1) "How do university engineering degree course descriptions support teaching *staff in sustainability competence integration in course implementation?*" and

2) "*Does curricula content analysis provide an adequate method for the assessment of key sustainability competence developing content in engineering education?*".

2 METHODOLOGY

2.1 Curricula mapping

Lappeenranta-Lahti University of Technology (LUT) offers studies in fields of technology, business, and social sciences (LUT, N.d.a.). The Faculty of LUT School of Energy Systems (LES) consists of departments in Energy technology, Electrical engineering, Mechanical engineering, and Sustainability science. (LUT, N.d.b.). The integration of sustainable development education should not be limited to students studying sustainability science. Instead, it should encompass the entire faculty. This broadened scope was applied to the empirical portion of our study. However, due to time constraints, it was necessary to establish a limit for data collection. The focus was specifically on the documented course descriptions that were acquired from the student information system LUT Sisu (2023).

Figure 1 presents a flow diagram of the course description selection procedure. The first inclusion criteria for course descriptions were set to be language ("courses taught in English") and organizer ("School of Energy Systems at LUT") resulting in 613 course descriptions. English language courses were selected to ease the analysis, as English is the language of the KSC description terminology. Initial screening for the exclusion of theses, internship, and orientation courses resulted in

555 course descriptions that were sampled to narrow the data for the analysis. The samples were decided from courses titled “Introduction to…” (29 course descriptions), “Advanced…” (27 course descriptions) and “Basic(s) of…” (14 course descriptions) in order to ensure examples of different level courses to be included. The remaining 489 course descriptions were randomly sampled for thirty more descriptions to include in the analysis. Some of the original sample course descriptions were excluded during the analysis iteratively, e.g., due to insufficient information given in the course description or being orientation or seminar courses, leaving the final sample size to be eighty-nine course descriptions.

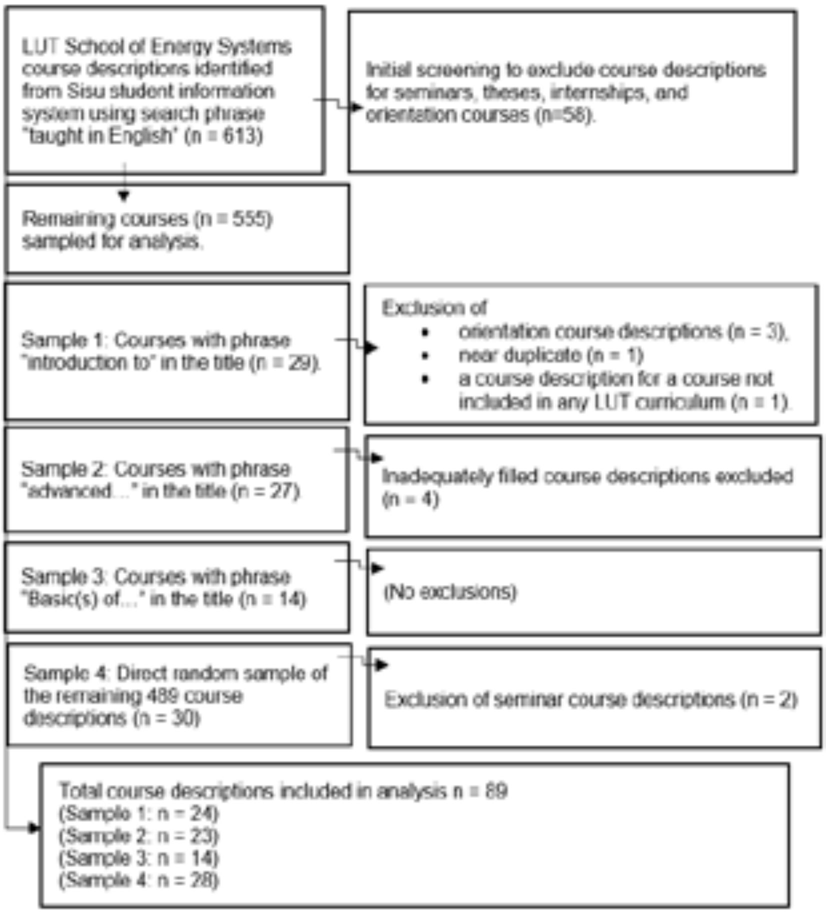

Figure 1. Course description selection procedure

The KSC definitions and examples presented in two framework suggestions (Wiek et al., 2011 and Brundiers et al., 2021) were used as a basis of a matrix (table 1) designed as a one-page guiding tool to be used in analysis of the selected course descriptions. Both the learning objectives (LO) and course content (CC) descriptions were included in the analysis, but due to the limitations of this paper these were treated as equal elements of the course descriptions. Comparing and analysing their different weights would make for an interesting topic for a further study.

The analysis was carried out as deductive content analysis (Elo and Kyngäs, 2008, 111) with the matrix content as units of analysis. Each selected course description was read and content relating to the KSCs was highlighted. The definitions of the KSCs and the guiding questions listed in the matrix were used to help the text analysis. Occurrences of each KSC as well as the justification of identifying each occurrence as a manifestation of a KSC related content were documented. Since the aim was to determine the number of course descriptions that were likely to support the teaching staff in integrating KSC developing activities in teaching, each KSC was only taken into account once per course description even in cases where a course description contained several mentions of the same KSC. The variation of course extents was not considered in the analysis either.

Table 1. Matrix used in course description analysis

	Key Sustainability Competence				
	systems thinking	**anticipatory**	**normative**	**strategic**	**interpersonal**
Condensed Definition (Wiek et al. 2011 and Brundiers et al. 2021)	The ability to collectively analyse complex systems across different domains and scales.	The ability to collectively analyse, evaluate and draft future vision.	The ability to collectively map, specify, apply, reconcile, and negotiate sustainability values ("values competence").	The ability to collectively design and implement interventions toward sustainability.	The ability to motivate enable and facilitate collaborative and participatory sustainability problem solving.
Learning objectives (LO) "Can this LO be achieved without these competencies?"	Does the LO include a reference to system understanding or identification? Is the LO linked to modelling or system analysis? Does the LO include requirements for system element or dynamic comprehension? Does the LO include other aspects linked to systems thinking competence?	Does the LO indicate the use of future envisioning tools (e.g. backcasting)? Does the LO include aspects of scenario building? Does the LO include other aspects linked to anticipatory competence?	Does the LO name identification of sustainability aspects in the course context? Does the LO include other aspects linked to normative competencies?	Does the LO demonstrate designing interventions towards more sustainable practises? Does the LO include an aspect of implementation? Does the LO include other aspects linked to strategic competence?	Does the LO include aspects of cooperation? Does the LO include aspect of self-reflection? Does the LO include communication development (incl. reporting skills)? Does the LO include other aspects linked to interpersonal competence?
Course content (CC) "Can the topic be covered without using these competencies?"	Does the CC include aspects that imply a link to systems thinking?	Does the CC include aspects that imply a link to anticipatory competence?	Does the CC include aspects that imply a link to normative competencies?	Does the CC include aspects that imply a link to strategic competence?	Does the CC include aspects that imply a link to interpersonal competence?

2.2 Matrix testing by comparison analysis

After the initial analysis, a set of twenty (five from each of the four samples) course descriptions were selected to be analysed by another researcher using the same matrix to test it for generalisability. Descriptions of courses taught by the second analyser were excluded prior to sampling and the second analyser did not have access to the original findings before or during the analysis. The course selection was based on the original findings to ensure all KSCs would be represented in the comparison analysis as extensively as possible. The second analyser carried out a text analysis of the selected course descriptions highlighting which part of the course descriptions manifested KSC related content as described in the matrix, and documented their justifications of which KSCs were in question and why. The findings were then compared to the original analysis findings of these twenty course descriptions to determine the frequency of similar findings and to compare the justifications given for identification of KSC related content in course descriptions.

3 RESULTS

3.1 Key Sustainability Competencies documented in course descriptions

The initial course description analysis indicated systems thinking competence to be the most commonly present KSC in course descriptions (70/89) with strategic competence being the second most common one (32/89). The frequency of KSC occurrences in the analysed course descriptions and examples of the key terminology listed as justifications for the selections are presented in Table 2.

Table 2. Course description analysis results

	Key Sustainability Competence				
	systems thinking	anticipatory	normative	strategic	interpersonal
Occurrence in all (n= 89) course descriptions	70 (79%)	15 (17%)	14 (16%)	32 (36%)	30 (34%)
Examples of content related to this competence.	Ability to identify system elements, control of systems, conversion of xxx system, identification and description of system elements, life cycle phases, structure of a xxx (system), system characterization, system component, system stocks, system understanding.	Envision alternatives, envisioning future, history and ongoing change, opportunity and challenge identification, scenario comparisons.	Identification of sustainability impacts in context, naming impacts in context, ethics, sustainability challenges in the context, understanding sustainability in context.	Noting restrictions and abilities, application of theory, application of xxx case study, applying knowledge, design and implement, design intervention.	Ability to communicate, communication and team working, communication and management, debate, network, explain the importance, express, research, critically evaluate, making judgements, collaboration, self-management.

The KSC analysis indicates the majority of course descriptions contain at least some elements related to the KSCs. Out of the eighty-nine analysed course descriptions no KSC related content was identified in only six descriptions (about 7 % of the analysed course descriptions). This suggests sustainability competence enhancing content to be relatively well represented in engineering education course descriptions, although for more reliable results the analysis should be extended to a larger number of course descriptions in several HEIs. In three of the cases the most likely reason for no identified KSC content was the difficulty of understanding the course description overall. Unfamiliarity with the terminology used to describe course contents and learning objectives was a clear challenge of the course description analysis suggesting a need to develop the method further. The use of such a tool could be coupled with interviews of the course description authors or the teaching staff responsible for organizing the courses in question to ensure more accurate interpretations of the descriptions. This could also help teaching staff in becoming more involved in the process of integrating sustainability competence developing content in teaching, which may be a more effective method of mainstreaming education for sustainable development than mere curricula alterations (Routaharju et al., 2024, 123).

The dominance of systems thinking competence in the number of KSC occurrences can reflect the nature of study content in the School of Energy systems, since engineering education generally relies on understanding of system elements. This may also lead to systems thinking being the most concrete and thus possibly the simplest to identify in written course descriptions. The same may explain why strategic and interpersonal competencies were identified in about one third of the analysed course descriptions: many engineering courses aim at helping students learn to design interventions and communicate their progress effectively. The results suggest anticipatory and normative competencies may not be effectively communicated in engineering course descriptions. Testing such an analysis on curricula of some other field and comparing the results would make for an interesting topic for further research.

Each course was treated as one unit not considering the variation in extents or level of studies. These would make interesting issues to consider should such a tool be tested elsewhere.

3.2 Comparison analysis

Only four out of the twenty course descriptions subjected to the comparison analysis returned the same result on all five KSCs (Table 3.). The same findings were at their lowest for anticipatory competence (13/20) and at their highest for interpersonal competence (18/20). The similar outcomes for systems thinking (14/20), strategic (15/20), and anticipatory competencies fluctuated within this range. While these results quantitatively suggest a relatively high similarity, the analysis of the justifications listed as the basis of each finding reveal a difference of thinking even in part of the course descriptions returning a similar result. This implies qualitative content analysis, even with the same set of units of analysis, does not return a generalisable result of the KSC content in course descriptions. Furthermore, this suggests teaching staff interprets course descriptions very subjectively so supporting them in integration of KSC developing content in course implementation should entail more than adding relevant terminology in course descriptions and learning objectives.

Table 3. Comparison analysis similar findings

	Justifications (A)	Justifications (B)
systems thinking competence		
Introduction to IoT-Based Systems (4 ECTS) (LUT Sisu, 2023)	identification of IoT systems	define systems, information, and communication
Advanced Course on Software Business (3 ECTS) (LUT Sisu, 2023)	models	connections between the economic system and the industry
anticipatory competence (no occurrences)		
normative competence (no occurrences)		
strategic competence		

Basics of Software Product Management (6 ECTS) (LUT Sisu, 2023)	design interventions	product strategy
interpersonal competence		
Advanced Course in Electronics (6 ECTS) (LUT Sisu, 2023)	communication, presentation	group discussion

3.3 Limitations

It is important to remember that course descriptions only provide the foundation for course implementations, and this research started with the assumption of course descriptions being used for this purpose by the academic staff responsible for course implementations, and the descriptions being accurate and up-to-date. A more thorough view on if this indeed is the case would improve the reliability of the findings. The different interpretations made in the content analysis highlight the challenge of qualitative analysis but can also be seen as an indication of how differently teaching staff interprets course descriptions. Thus, the results indicate course descriptions alone are not enough to support the academic staff in integrating KSC developing content in teaching. For a better outcome, the matrix should be coupled with other methods, such as workshops or informative sessions for the teaching staff, to help understand the nature of the KSCs and to allow a more comprehensive understanding of how they are manifested in courses of varied contextual contents.

Even if the curricula mapping matrix still needs to be improved to provide an adequate tool for assessing the degree of KSC developing content in engineering education courses, the matrix could serve as a basis for developing a guiding tool in course design when creating new curricula. This would require a more thorough analysis of the course description elements and a consideration of the course extents. The matrix could help engineering educators identify the connection between the pedagogical strategies used in their field of expertise and the KSCs with such a tool. The increase of such effort, after all, it required for the mainstreaming of KSC developing content in engineering education.

4 SUMMARY

This research set out to test a method of assessing the extent to which key sustainability competencies are currently conveyed in course descriptions in engineering education. Selected course descriptions were analysed using a guiding tool based on the KSC frameworks by Wiek et al. (2011) and Brundiers et al. (2021).

The examination of the KSC related content in written course descriptions revealed that while several course descriptions were found to contain content related to the KSCs, the method used for analysis still needs improvement. Comparing the content analysis results by two different researchers also indicates differences in how the course descriptions and the KSCs are interpreted. Such a matrix could be used as a starting point for designing course descriptions supporting the academic staff in their efforts to integrate more KSC developing content in course implementation, especially if the staff was also offered some other content helping them identify the KSCs related content in their field of expertise.

ABSTRACT

Engineering education has great potential to enhance the sustainability transition by ensuring future engineers possess the abilities to act as catalysts for the change. Contrarily to this aim, studies on environmental sustainability challenges can lead to increased eco-anxiety. This research delves into the intersection of learning and sustainable development, specifically examining how environmental engineering students engage with elements of their studies that foster a vision of a hopeful and sustainable future. Environmental engineering students were interviewed to allow them to express their views on sustainable development overall and in connection to their studies. The findings imply that environmental engineering students primarily interpret sustainable development in terms of natural resource use and the available tools, such as circular economy for enhancing resource efficiency. Students also

[1] *L Routaharju*
liisa.routaharju@student.lut.fi /liisa.routaharju@xamk.fi

associate the concepts of “circular economy” and “life-cycle thinking” with the sustainability transition and their future roles as catalysts for change. These practical instruments can help students develop a sense of sustainability agency.

1 INTRODUCTION

Sustainable development, although having been discussed for decades, is still a rather ambiguous concept especially in the context of education (Karvinen, 2024, 11, 46). The role of education is to promote both individual and societal development and give an insight into the happenings of the world around us. It is clear that the sustainability transition requires awareness and increased understanding of the sustainability challenges along with their potential solutions, but for genuine effectiveness the sense of sustainability agency is needed (Sterling, 2014, 90). Defining sustainable development (SD) as the type of development that allows current generations to fulfil their needs, without compromising the ability of future generations to do the same (The World Commission on Environment and Development, 1987, 16) can make it difficult to connect the aim with daily operations.

An environmental engineer is expected to have a thorough understanding of natural sciences and technology, as the basis of many environmental engineering applications rely on natural processes. The characteristics of the environmental engineering professional field seem to automatically facilitate development of holistic viewpoints and understanding of cause-effect relationships, which, in turn, should contribute to the strengthening of student and graduate sustainability competencies (Wiek et al., 2011, 207-209). Despite this, students and graduates of the field don’t automatically connect their studies to sustainable development (Karvinen, 2024, 54-55). Increasing awareness of exceeding the planetary boundaries (Richardson et al., 2023) may even lead to eco-anxiety (Vercammen et al. 2023, 13) that may decrease the sense of sustainability agency further.

This research delves into the intersection of learning and sustainable development, specifically examining how environmental engineering students engage with elements of their studies that foster a vision of a hopeful and sustainable future. The research questions addressed are: 1) “*How is sustainable development defined by environmental engineering students?”* and 2) “*Which elements of environmental engineering studies promote hopeful future scenarios for students?*”. Student views on sustainable development in connection to their professional field and the elements of their education that help them gain a sense of sustainability empowerment and hopefulness about their future can be used as a starting point in developing environmental engineering education towards better facilitating the sustainability transition on its part. Environmental engineering students were interviewed to collect data on their views on sustainable development overall and in connection to their studies. Both deductive and inductive qualitative content analysis were used for data analysis and interpretation.

2 EDUCATION FOR SUSTAINABLE DEVELOPMENT IN ENVIRONMENTAL ENGINEERING EDUCATION

An elemental part of education for sustainable development (ESD) is supporting the set of values likely to encourage transformative action towards a more sustainable future (Anastasiadis et al., 2021, 273). The process of sustainability agency building consists of steps from the value basis of common good to understanding brought about by increased knowledge and building up to empowered agency (Pacis and VanWynsberghe, 2020, 583, Sterling, 2014, 90). These elements of sustainability agency formation by increased awareness on sustainable development and the set of skills increasing the ability to act towards sustainable development are visualized in Figure 1.

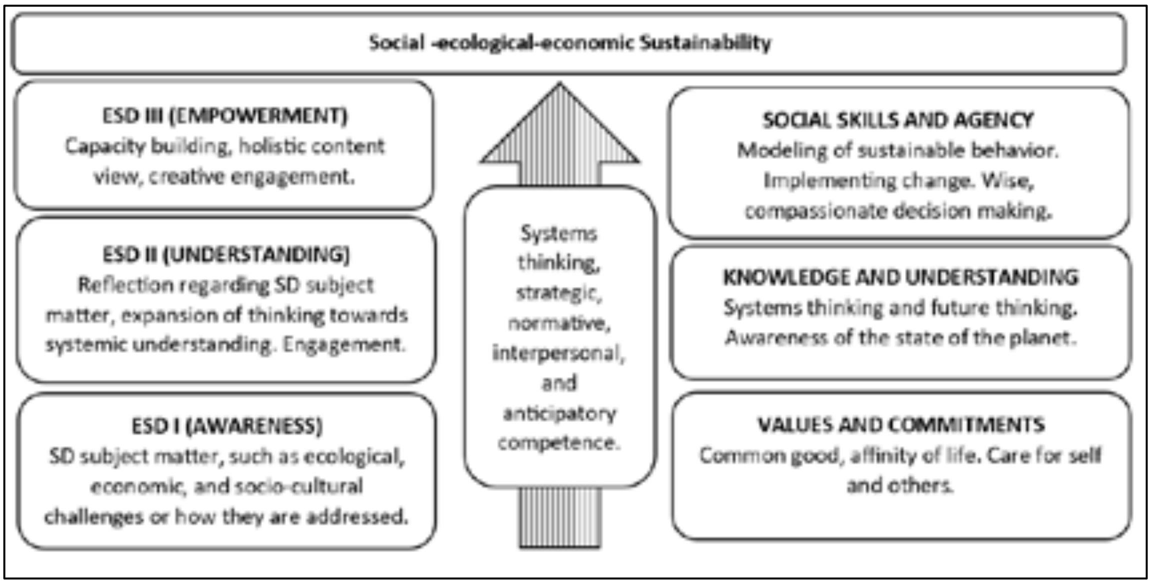

Figure 1. Visualisation of the connections of Sterling (2015, 98) ESD (on the left), Pacis and VanWynsberghe (2020, 583) LfS CCF (on the right) and the KSC (Wiek et al., 2011, 203) (in the middle) frameworks. Translated from Routaharju et al. (2024, 116)

The discussion on the types of competencies that could facilitate the transition to sustainability has identified systems thinking and anticipatory competencies as two examples of the key sustainability competencies (KSCs) (Wiek et al. 2011, 207-209). Advancing systems thinking competence of students will allow them to identify, analyse and understand challenges related to sustainability along with their root causes more effectively. Coupled with anticipatory competence they will become better equipped in envisioning sustainability supporting scenarios (Wiek et al. 2011, 207-209). These elements are important factors of hopeful future scenarios especially in the field of environmental engineering that understandably focuses on the environmental problems faced. Supporting the development of interpersonal, normative, and strategic competencies can also help push aside potential eco-anxiety by allowing students to communicate and share sustainability values and possibilities to apply their knowledge for a more sustainable future.

Mainstreaming education for sustainable development is far from complete. There is evidence that sustainability efforts in universities seem to focus more on the operational sustainability than educating sustainability (Karvinen, 2024, 45). Communicating efforts to improve campus energy efficiency or waste sorting can model organizational sustainability culture, but for a more robust impact sustainability content should be integrated in educational content.

3 METHODOLOGY

3.1 Data collection and the demographic

The data collection was focused on bachelor's degree in environmental engineering students at South-Eastern Finland University of Applied Sciences (Xamk). The degree is designed to be a four-year degree (240 ECTS CU) preparing students for a variety of professional roles (Xamk, N.d.). The focus was narrowed further to students enrolled on courses taught by one of the researchers during data collection. This focus was decided to ensure data availability, as previous experiences suggest students to be more willing to share their views with a familiar lecturer. The learning objectives and arrangements for these four courses had been prepared prior to the research data collection so no conflict of interest was assumed in this sense. A clear distinction between data collection participation and student evaluation on the ongoing courses was also made to avoid biased responses.

The sample of interviewees was opportunistic, as students were invited to a voluntary individual interview and asked to allow their course work product to be used as research data. Only a few students gave consent to using their course work product in the research, so this data was iteratively excluded to ensure anonymity of participants. The interview focus was on studies overall, not only the ongoing courses at the time of data collection. A total of 18 interviews were given, when 108 students were invited to give one, so about 17 % of the demographic was interviewed. A more extensive data collection (e.g. conducting similar interviews in several universities) would increase the generalisability of the results, but as the aim was to get an understanding of student views to be used for educational practice improvement and better facilitation of sustainability agency formation the sample was seen as an adequate starting point. Delving into the topic more extensively would make for an interesting topic for further research.

The majority of the interviewees were over halfway through their environmental engineering degree programme studies (Table 1). Two of the interviewees were completing a Finnish environmental engineering degree, the majority being from the international group with English as their teaching language. Age variation or other background information is not revealed to protect the anonymity of the participants.

Table 1. Interviewees

Gender	Stage of studies	Curriculum	Interview language
Male: 8	1st or 2nd year: 7	English environmental engineering degree: 16	English: 10
Female: 10	3rd year: 11	Finnish environmental engineering degree: 2	Finnish: 8

The interviews were semi-structured with the interviewees first being asked to define, in their own words, the phrases "*sustainable development*", "*sustainable development awareness*" and "*sustainable development skills*" and then asked to reflect on how their personal sustainable development awareness and skills had changed during their environmental engineering studies. These concepts were selected as they represent components of sustainability agency formation (see Figure 1.). Students were also asked to share examples of the types of educational activities they felt had facilitated this change and encouraged to share other thoughts related to the topic of education for sustainable development. The interviews were conducted on Teams collaboration tool and recorded to ease later transcription and data coding phases.

3.2 Data analysis

The transcripts were analysed using both inductive and deductive content analysis (Puusa and Juuti, 2020, 79). The inductive analysis was carried out first to reveal demonstration of learning for sustainable development in how students described their study experiences. Inductive analysis was selected to ensure all possible views would be included without the constraints of preselected analysis units. The initial in-vivo coding was followed by thematic grouping to identify central concepts arising from the data. These themes were then abstracted to facilitate interpretation into outcomes (Figure 2).

The interview themes (sustainable development, sustainable development awareness and sustainable development skills) were used as analysis units in the deductive content analysis. This analysis was conducted to ensure any outcomes possibly missed in the inductive analysis would be included in the conceptualization phase. Some quantification was also used for the presentation of the results.

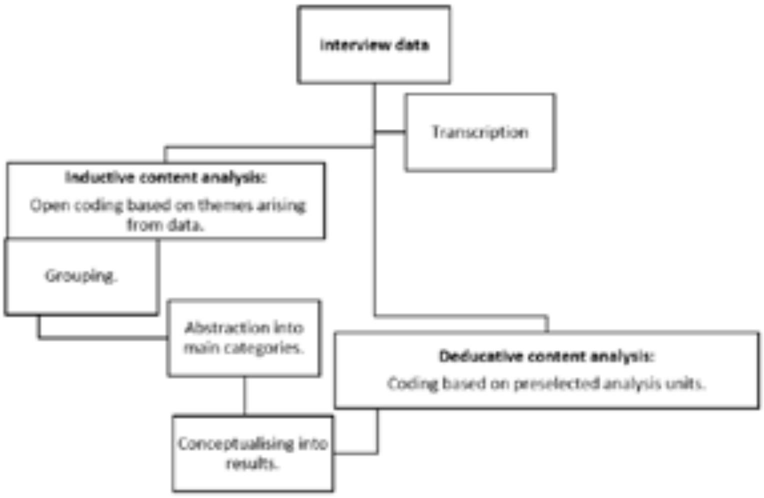

Figure 2. Flow diagram of the data analysis process

4 RESULTS

The interviewed students frequently associated "*sustainable development*" with concepts of "*circular economy*" or "*resource efficiency*", as presented in Table 2. This implies, as anticipated, that environmental engineering students define sustainability mainly from the perspective of natural capital and resource use. Some mentioned "the future" or "future generations", indicating consciousness of responsibility extending beyond the present. The term "Sustainable development awareness" was connected to the significance of understanding the overall need for sustainability. An aspect of personal involvement through taking action or spreading knowledge was also demonstrated. The aspect of taking action by applying knowledge and making informed decisions was also prominently featured in the definitions for "sustainable development skills".

Table 2. Definitions for sustainable development terminology by environmental engineering students. The number of interviewees (out of the total 18) using each phrasing indicated in parentheses.

Sustainable development	Sustainable development awareness	Sustainable development skills
Circular Economy (5/18)	Understanding the need for SD (consequences of past actions) (10/18)	Applying knowledge to practice (develop, improve, manage) (13/18)
Resource efficiency (4/18)	Personal ability to influence and to take action (CE) (5/18)	Making informed decisions (5/18)
Future (generations) (4/18)	Spreading knowledge and applying it into practice (3/18)	
Well-being (1/18)		
Decision-making (1/18)		
Damage minimization (1/18)		
Sustainable consumption (1/18)		
UN SDGs (1/18)		

The elements of sustainable development learning, as conceptualized from the outcomes of the interviews, are visualised in figure 3. Many of the interviewed students mentioned a personal motivation or interest in environmental or sustainability issues prior to the beginning of their studies, but emphasized this interest being increased further during their studies through subject matter studies and the peer group. The increased understanding of the sustainability challenges and their consequences coupled with the potential tools to take on these challenges were described to lead to believing a change for the better is still possible.

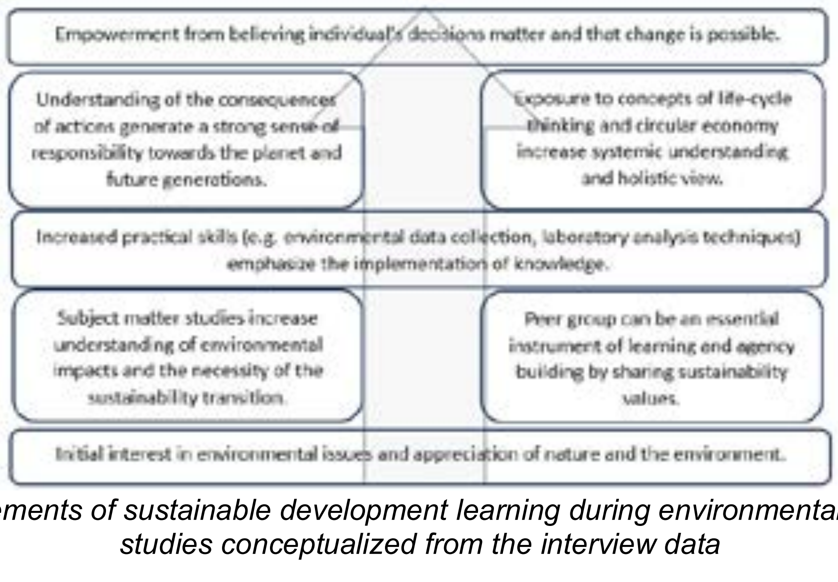

Figure 3. Elements of sustainable development learning during environmental engineering studies conceptualized from the interview data

Many students described a development of a sense of empowerment during their studies. The described process was quite similar to the steps visualised in Figure 1. starting with an initial value basis and awareness on the issues and though improved understanding leading to empowerment and agency (Sterling, 2015, 98, Pacis and VanWynsberghe, 2020, 583).

The interviewees described how studies on the subject matter had increased understanding of the need for a transition to sustainability. Understanding of the consequences of actions also led to a sense of responsibility for the planet and future generations. Several interviewed students identified practical, experimental courses, such as sampling, laboratory analysis and real or simulated working life projects as being effective in development of holistic and systemic understanding of sustainability issues. Introduction to the principles of life-cycle thinking and circular economy seems to not only increase understanding of the systemic nature and complexity of the sustainability challenges but also to assist students in their sustainability agency development. The increased need to apply sustainability values in decision-making from personal, professional, and societal perspectives was expressed by a majority (10/18) of the interviewees and it was often coupled with a description of how circular economy and the life-cycle approach could be used as instruments of the sustainability transition. It seems that studying these concepts can promote sustainability agency by reinforcing the belief in the potential for change. It may also allow students to feel their studies will eventually help contribute to the change for their part. Based on the results it seems focusing on concrete tools, such as the practical implementation of circular economy business models or life cycle assessments, can help students envision more optimistic future scenarios.

Students pursuing a career in environmental engineering can be expected to value ecological sustainability, which puts a strong emphasis on protecting the natural ecosystems, but the peer group was mentioned by many as strengthening this value base even further. The peer group had a strong role in sustainability agency formation for this part. Group-based learning tasks as well as learning sessions involving peer discussions were seen particularly beneficial especially in international student groups:

"…*that we have students from so many different countries…and different cultural backgrounds…that certainly expands our worldview*." (Interviewee 15)

The results that indicate presenting students with not only the challenges, but also actionable and preferably tangible tools for addressing them can benefit their agency formation:

"…*during these studies I realized that my two little hands and my little brain can help …to make something different…".* (Interviewee 11)

The results suggest the initial interest on ecological sustainability may play a major role in the selection of the study field, but the sense of sustainability agency is formed by learning about the possible ways to make a difference.

While the results indicate some directions on the elements of environmental engineering education, which can help students cope with the increasing environmental concerns, it should be noted the sample size is quite small due to resource constraints. Since there were only two interviewees following the Finnish environmental engineering curriculum, the possible differences between views of students following it and the English environmental engineering curriculum were not discussed. Inviting students to give an interview to a familiar lecturer also poses a possible source of bias, which could have been avoided by an external party conduct the interviews. The decision not to was based on previous experiences of students being very reluctant to take part in such data collection. A more extensive data collection would allow to make more transferable conclusions; however, the results already provide a starting point for educational practice development in environmental engineering development. The findings indicate environmental engineering students benefit from the types of educational activities that present them with opportunities for connecting theoretical information with hands-on assignments and sharing their thoughts with their peers. Applying these findings in other engineering education fields would make for an interesting topic for further research – after all, mainstreaming education for sustainable development only succeeds if all study fields are involved.

5 SUMMARY AND ACKNOWLEDGEMENTS

Environmental engineering students can be expected to have an interest in environmental issues and finding solutions to the current ecological sustainability challenges. Increased awareness on ecological problems; however, can lead to anxiety that may hinder sustainability agency development.

Understanding how environmental engineering students interpret sustainable development helps to identify the types of educational activities that may help them in developing sustainability awareness, understanding and empowered agency. Student interviews imply that environmental engineering students primarily interpret sustainable development in terms of natural resource use and the available tools, such as circular economy, for enhancing resource efficiency. Students also associate the concepts of “circular economy” and “life-cycle thinking” with the sustainability transition. Such concepts can help students identify their personal future roles as catalysts for change and strengthen their sense of sustainability agency. Such sense can be the primary component of seeing the future as hopeful.

We are very grateful for all the students taking the time to give an interview and allowing their views to be used as data sources.

ABSTRACT

Students' course learning and perception are crucial tools for evaluating the effectiveness of courses and the outcomes of school education. Previous research highlights disparities in college learning based on factors such as gender, family socioeconomic status (SES), and cultural backgrounds. However, the influence of these factors on STEM (Science, Technology, Engineering, Medicine) students' learning and perceptions remains unexplored. This study draws from cultural capital theory and Hofstede's cultural dimensions theory to examine the influence of these factors on students' perceptions in a multicultural course. We observed a course at a well-known US public university during the summer term of 2023, designed to improve STEM students' math teaching skills at the high school level. Through qualitative interviews, the study revealed that within a multicultural course: 1. There are no obvious gender differences in STEM students' encountering cultural problems and course learning expectations; 2. Culture factors influence students' teaching style perceptions and encountering cultural problems when attending class..3. Family SES might influence students' course learning expectations and encountering cultural problems when attending class.These findings emphasize the importance of culture factors and family SES on STEM students' learning.

1 INTRODUCTION

1.1 Background and Research Questions

Multicultural learning environments are prevalent in modern U.S. society. How do STEM students learn and feel in a multicultural class? Past studies have highlighted that international and immigrant students perceive differences in their courses compared to their local peers (Bal and Perzigian 2013). Specifically, these studies suggest that cultural differences can negatively affect students' participation in courses. Additionally, Reeder et al. (2004) found that different cultural communication patterns increase miscommunication, and the greater the perception of cultural differences between participants in an activity, the more frequent the incidents of miscommunication. Therefore, this poses challenges for educators. Parrish et al. (2010) argue that multicultural environments are vital for education, requiring culturally adapted teaching methods. Educators must not only meet students' needs but also adjust their teaching styles to suit diverse cultural backgrounds.

With the increasing presence of immigrant and international students in STEM education, it is crucial for STEM education providers to comprehend the diverse educational values and cultural expectations of students and their impact on learning. Consequently, there is a pressing need to develop new theories and conduct empirical research to offer guidance for the successful design and delivery of cross-cultural STEM courses.

To investigate the differences in learning perceptions among STEM students from diverse backgrounds and provide beneficial guidance, this study examines a summer course offered by a well-known U.S. university, designed for STEM students to learn how to teach high school math. The course utilized Environment-based Learning (EBL), emphasizing fieldwork, discussions, and teamwork It consisted of two parts: observation at a high school followed by lectures. The lectures introduced course content, followed by discussions in small groups. Six STEM students from diverse cultural backgrounds enrolled in the course, with over half being second-generation immigrants. Due to differences in cultural factors, family SES, gender and other factors, these students held varying opinions and attitudes towards learning perceptions in the course.

This study addressed the following three questions:

1. Are there any gender differences in STEM students' perceptions of a multicultural course, and if so, what are they?

2. Are there any culture differences in STEM students' perceptions of a multicultural course and if so, what are they?

3. Are there any family SES differences that influencing STEM students' perception of a multicultural course and if so, what are they?

1.2 Theoretical Framework

Cultural Capital Theory

Cultural Capital Theory, formulated by the French sociologist Pierre Bourdieu, emphasizes the role of various forms of "capital" beyond economic wealth in perpetuating social inequality (Bourdieu 1986). Bourdieu's theory, particularly relevant in educational contexts, examines how cultural capital influences educational outcomes (DiMaggio 1982). For instance, individuals from higher socio-economic backgrounds often possess greater cultural capital, such as familiarity with the educational system and access to extracurricular activities, providing them with an advantage in education (DiMaggio 1982; Huang 2019).

Hofstede's Cultural Dimension theory

Hofstede's cultural dimension theory stands as one of the most widely employed frameworks for the examination of cross-cultural communication. Hofstede developed a four-dimensional model of cultural differences, encompassing

power distance, uncertainty avoidance, individualism versus collectivism, masculinity versus femininity (Hofstede 1984; Hofstede 1986).

According to Hofstede's Cultural Dimension theory, China exhibits high power distance, moderate masculinity, low individualism, and uncertainty avoidance. South Korea, on the other hand, demonstrates high power distance, indicating acceptance of unequal power distribution, alongside low individualism, emphasizing group harmony. The country also displays a moderate masculinity score, balancing competitiveness with the quality of life, and high uncertainty avoidance, showing a preference for structure and stability.

The U.S. is marked by very high individualism, emphasizing individual rights and achievements, and high masculinity, reflecting a competitive culture. Meanwhile, Mexico exhibits high power distance, accepting hierarchical inequalities, and low individualism, valuing group loyalty. Mexico also shows a high masculinity score, valuing competitiveness and material success, and high uncertainty avoidance, preferring rules and predictability (Hofstede Insights 2024).

This framework is commonly employed to characterize cultural behaviors originating from different societies. Collis et al. (1999) proposed the "flexible" approach, suggesting that courses should be adaptable enough to encompass diverse cultural perspectives rather than rigidly adhering to predetermined content.

In our study, we integrate the aforementioned two theories to explore the genuine and precise differences in how family SES, gender, and culture factors influence STEM students' perceptions in a multicultural learning environment. The following figure 1 outlines the theoretical framework for our study. We use parents' occupation to measure family SES and consider teaching style, learning attitude, learning expectations, and if encountering cultural problems when attending class as aspects of course perceptions.

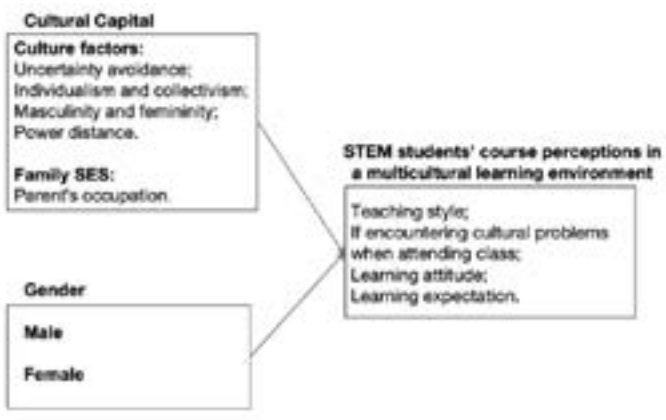

Fig. 1. Theoretical Framework

2 LITERATURE REVIEW

2.1 Course Perception Differences by Gender

Controversial claims exist regarding the influence of gender on students' learning.

Previous research indicates that gender impacts students' cognitive strategy usage (Wolters and Pintrich 1998). Moreover, gender emerges as a significant predictor

of learners' perceived learning, with female students often reporting higher perceived learning compared to their male counterparts (Rovai et al. 2005;Lee and Choi 2011; McCroskey et al. 1996). However, other researchers have found that female students perceive lower learning outcomes(Li 2019) and assert that gender does not affect the learners' levels of motivation and engagement in the classrooms (Almusharraf et al. 2023).

2.2 Course Perception Differences by Culture Factors

Previous studies affirm that cultural background does indeed influence students' perceptions about learning(Heath and Miller 2012; Munardji et al. 2020). While definitive conclusions about whether cultural differences lead to varying levels of satisfaction cannot be drawn, researchers have suggested that culture influences participants' perceptions of education and learning styles through communication, values, and educational systems (Morse 2003).

Furthermore, culture has been found to impact students' perceptions of the value of different forms of feedback (Evans et al. 2016). For instance, Kim et al. (2014) discovered within their cohort of first-generation Mexican immigrants that self-esteem was adversely affected by acculturative stress. They also noted that ethnic identity exacerbated the detrimental effects of the two identified types of acculturative stress (American-based and Mexican-based) on psychological well-being. The influence of stress and experiences of discrimination can lead individuals to become disengaged from the dominant culture. Zhang (2007) pointed out that Eastern cultural tradition, together with other social factors, has shaped a group-based, teacher-dominated, and centrally organized pedagogical culture. However, cultural identities are not fixed attributes; rather, they are adaptable and subject to change based on circumstances and situations (Deaux 2006; Oyserman et al. 2006).

Nevertheless, despite the importance of understanding the real differences in STEM students' course perceptions among different cultures, there is limited research on this topic.

2.3 Course Perception Differences by Family SES

Students' learning is influenced by their family's socioeconomic status (SES). Previous research indicates that individuals from different social backgrounds exhibit

variations in preferences, behavioral tendencies, and social norms (Liberatos et al. 1988). Contributing factors to these differences include parental educational background (Stephens et al. 2007), personal income, and personal educational attainment (Liberatos et al. 1988).

Research has shown that students from higher SES families often have higher expectations for their courses and might experience different learning outcomes compared to their peers from lower SES backgrounds (Sirin 2005; Reardon 2018). For instance, these students may be less engaged or challenged by the course material if it does not meet their elevated expectations (Bowen et al. 2005). However, it remains uncertain whether these trends hold true for students in STEM fields.

Given the distinct demands and characteristics of STEM education, further investigation is required to determine how family SES impacts STEM students' course perceptions and learning experiences (Musu-Gillette et al. 2016).

3 METHODOLOGY

3.1 Semi-structured Interview

The interviews comprised one-on-one in-depth sessions conducted in English for both the participants and the interviewer in August 2023. Each interview lasted around 10-30 minutes. The six participants were all undergraduates who attended and enrolled in the summer class held at a public university. Participants received a participant information sheet and a consent form. All interviews were recorded, kept confidential and anonymous, and the data were analyzed by using thematic analysis. This process involved familiarization, coding, and classification (Braun et al. 2006).

Initially, the interviews were transcribed and independently reviewed by the authors to record initial ideas and emerging themes. Subsequently, the transcripts were reread several times to refine the coded themes. The codes were then organized into discrete categories or themes, which are reflected in the structure of the findings section. For example, we combined and categorized all the interview data into different themes, such as positive worldviews, pessimistic worldviews, facing cultural problems, and not facing cultural problems, among others. The themes generated during the analysis were corroborated by data collected from all students who enrolled in the same class, thereby enhancing the credibility of the findings. All participants were STEM majors, with most aged between eighteen and twenty-five, totaling six students who attended the class and willingly participated in the interviews.

The following are the interview questions used in this study, which encompass students’ family backgrounds, their cultural values, and their attitudes towards the course. Additionally, they delve into their evaluation of the STEM course and the teaching style.

Interview Questions

1. Which country are you from? Are you an immigrant? What age range are you in? What are your parents' occupations?

2. What is your major? Which academic year are you currently in?

3. What are the most important values and beliefs in your culture, particularly regarding education? How do these influence your worldview?

4. Why did you choose to take this course? What is your perspective on the importance of mathematics and science? How do you typically approach studying these subjects?

5. Overall, what is your opinion of this class? How would you describe the teaching style? Can you identify three positive aspects and three negative aspects of the class?

6. Can you recall any other courses that left a strong impression on you? If so, why?

7. Have you ever encountered any cultural challenges while attending your courses? How did these challenges impact your comprehension of the material or your academic performance?

8. When students' cultural backgrounds, teachers' cultural backgrounds, and the culture of mathematics/science intersect in the classroom, what occurs?

9. How did this course enhance your problem-solving skills? What specific problem-solving techniques did you acquire from the course?

3.2 Participants

Table 1. Demographic information

No.	**Sex**	**Age**	**Parent's occupation**		**Immigrant or not**	**Major**	**Grade**	**If meet cultural problem in class**
			Father	**Mother**				
P1	Male	18-25	Engineering	Accounting	No	Physics	3	Y
P2	Female	18-25	/	Manager at laundromat	Yes, from central American	Bio-engineering	3	Y
P3	Male	30	Construction worker	Stay at home	Yes, from Mexico at 8 years old	Math	3	N
P4	Female	21	Retired	Design clothes at a clothing company	Yes, from South Korean, born in US	Applied mathematics with a concentration in economics	3	N
P5	Male	18-25	Unemployed	Retired	Yes, from Mexico, born in US	Double majors in physics and astronaut	5	Y
P6	Female	18-25	Worker	Worker	No	Education in Chemistry	4	Y

Table 1 shows the background information of all the participants. Among the participants, three are female students. P1 is a local American student. P2-P5 are second-generation immigrant students, hailing from Central America, Mexico, and South Korea respectively. P6 is an international student from China. The local American student has the highest family SES background, and the students from Mexico have the lowest family SES.

4 RESEARCH FINDINGS

4.1 Gender Differences

There are no apparent gender differences in encountering cultural problems when attending class and course learning expectations

When comparing P2 (Central American female) and P5 (Mexican American male), both have immigrant experiences and similar family SES backgrounds; their parents are both working class, and they share similar cultural values. P2 mentioned being "f*amily-oriented, kind, and honest*" while P5 emphasized "*treating others as you want to be treated*". Moreover, they both expressed discomfort in their STEM classes. For instance, P2 stated, "*Sometimes I'm the only woman there, and sometimes I'm the only person of color. It's intimidating. I was kind of afraid to speak*." P5 shared similar sentiments: "*I definitely feel it a lot with the physics courses I've taken here. All of my physics classes are very white-dominant, full of white students and professors. I don't really have much motivation to go to lectures. For the past few classes, we strictly learned from the book, not from the lectures. Some of the white professors have a very specific teaching style or tone, which I find unengaging.*"

These shared experiences suggest that factors other than gender, such as cultural background might play a more significant role in shaping students' course perceptions. Both participants displayed a positive attitude towards the course despite their challenges. P2 stated, "*The content is good but lacks placements*," while P5 mentioned, "*The concepts are all very interesting but lack placement*." Therefore, we assume that gender may not be an influential factor in encountering cultural problems and course learning expectations

4.2 Culture Factors Differences

Culture might be an influential factor in teaching style perceptions and in encountering cultural problems when attending class

When asked about the most impactful course in the past, P6 (Chinese international student) mentioned that she "*would like to express thanks to high school physics teacher, who was very strict with us. In this way, I could form a good habit and learned it well*."

The immigrant students (P2-P5) all expressed appreciation for teachers who were patient and enthusiastic. The local student (P1) mentioned a teaching style that combines practice and lecture, emphasizing hands-on activities.

When comparing P2 (Central American female) and P4 (Korean American female), both are immigrants with similar family SES backgrounds, their parents are working class. P4 emphasized self-effort in her family, saying, "*Everything is gonna be fine as long as you put in effort*." She also shared that she did not encounter any cultural problems when attending class. In contrast, P2 expressed a different experience: "*It's like navigating a game. It's kind of scary; you should find your support systems, like family. There are many challenges in life.*" She also noted, "*Sometimes I'm the only woman there, and sometimes I'm the only person of color. So it's intimidating. I was kind of afraid to speak.*"

Therefore, we assume that culture might be an influential factor in students' teaching style perceptions and in encountering cultural problems when attending class.

4.3 Family SES Differences

Family SES is an influential factor for students' course learning expectations and encountering cultural problems when attending class

During the interview, P1, a local white male student from a middle-class family, exhibited the most negative attitudes towards the course. His family background is the most affluent among all the participants. He expressed dissatisfaction, stating that he "*did not learn much from the course since it did not meet his standards, and the anticipated teaching method was not clearly expressed.*" In contrast, immigrant students and international students had a more positive appraisal of the perceived learning from the course, sharing that they learned a lot and benefited from it.

When comparing P3 (Mexican American male) and P5 (Mexican American male), P3 immigrated from Mexico at eight years old. The family SES of P3 is slightly lower than that of P5. P3 emphasized the unfairness of the educational resources available to them and insisted that only those with money could access a good education, highlighting "*unfairness*". They both shared a positive attitude towards the course. P3 reported not encountering any cultural problems in the class, while P5 held the opposite opinion.

Therefore, we assume that family SES might influence students' course learning expectations and encountering cultural problems when attending class.

5 SUMMARY AND DISCUSSION

The findings derived from the interview data highlight the influence of diverse cultural, gender, and family SES backgrounds on STEM students' perceptions of their courses. We found that there are no apparent gender differences in STEM students' encountering cultural problems when attending class and course learning expectations. However, culture and family SES could be influential factors for STEM students in encountering cultural problems when attending class. Also, culture might be an influential factor in students' teaching style perceptions and family SES might influence students' course learning expectations.

Specifically, Chinese and Korean students prefer strict teaching, while US and Mexican students prefer a patient and enthusiastic teaching style. Immigrant students from Mexico and Central America expressed struggles with assimilation into predominantly white mainstream society, affecting their willingness to participate in classroom activities led by white professors and their academic performance. All participants stressed the importance of learning STEM and the value of discussion-based teaching methods.

The research also has some limitations. Firstly, since the course is small, even though we interviewed all the students, the sample is still lacking. Secondly, the students who attended the class have diverse backgrounds, making it challenging to control for variables.

It's important to note that this study does not aim to determine which gender or culture has superior course perceptions or learning results. Rather, it seeks to analyze the differences among them. Although this study focused on course perception in only one summer course in the US due to resource limitations, it is hoped that the findings will contribute to understanding STEM students' course perception differences in multicultural environments. Ultimately, this article aims to offer suggestions and support to promote educational equity. Lastly, this research emphasizes the immigrant problem, especially for those from Central America or Mexico. Their children might encounter difficulties and obstacles in accessing educational resources and studying STEM majors.

ABSTRACT

Humility is important for learning because it allows individuals to acknowledge their limits, accept feedback and be open to changing their ideas. This paper examines the relationship between intellectual humility, empathy, and resistance to change among science and engineering students. Intellectual humility is defined as the willingness to recognize one's own cognitive limitations and openness to diverse perspectives. Empathy involves the ability to understand and share the feelings of others. Resistance

[1] J. Strobel,
jmstrobel@utep.edu

to change refers to the tendency to resist new ideas or ways of thinking. The study aimed to explore how these factors are interconnected. A survey was conducted among a sample of students from three universities in the USA to measure their levels of intellectual humility, empathy, and resistance to change. The results revealed that students with higher levels of intellectual humility tended to exhibit more empathy towards others and were more open to new ideas and change. Furthermore, the study found that humility played a significant positive role in mediating the relationship between empathy and resistance to change. These findings have important implications for educators and policymakers in promoting a culture of openness among science and engineering students. Suggestions for fostering intellectual humility and empathy in educational settings are also discussed.

1 INTRODUCTION

Learning requires an open mindset, yet research has shown that students seem to resist new ideas and have developed what Snelson (1992) calls an “ideological immune system”. In engineering education, prior research has shown that undergraduate engineering students carry a high level of cognitive rigidity and a high level of emotional attachment to their own ideas (Dyehouse et al., 2015), particularly regarding the nature of engineering as a human-oriented discipline. To better understand underlying mechanisms in students’ beliefs, cognition and their associated emotions, several lines of research have been pursued: A growing body of literature has researched empathy among undergraduate students (see e.g., Rasoal, Danielsson & Jungert, 2012) and within industry contexts (Strobel, Hess, Pan & Wachter Morris, 2013) showing particularly gender differences. Similarly, previous research has researched cognitive rigidity and emotional attachments to one’s own ideas (Dyehouse et al., 2015). Intellectual humility is briefly listed as possibly a virtue contributing to engineering students’ mindset and belief system (see Pierrakos et al., 2009), yet the connection to empathy and cognitive rigidity has not been explicitly studied. This paper represents a first step in a larger endeavor to understand the relationship between intellectual humility empathy, and resistance to change to contribute to a deeper understanding of existing worldviews, beliefs, and underlying mechanism at play when engineering students engage in the learning process. Longer term, this line of research could lead to rethinking learning outcomes, instructional and pedagogical approaches and understanding the complexity of individual learners.

The objectives of this research study are: (1) Researching how intellectual humility is related to perspective taking/empathy by identifying how the Intellectual Humility Scale (IH) is correlated with the Interpersonal Relativity Scale (a scale to measure perspective taking). (2) To identify the role of intellectual humility as a moderator between empathy and resistance to change. (3) To determine what sociodemographic variables presented any differences among the levels of intellectual humility and empathy in the engineering and science student sample and finally

2 PERSPECTIVE(S) OR THEORETICAL FRAMEWORK

The paper draws from three theoretical frameworks of which we argue are connected and benefit from being examined for their impact on student learning: Intellectual Humility, Empathy and Resistance to Change. Intellectual Humility is defined as "(a) having insights about the limits of one's knowledge, marked by an openness to alternative ideas, and (b) the ability to present one's ideas non-offensively and receive information non-defensively" (Wong & Wong, 2021, p.1) and falls in the broader category of emotion (Saroglou et al. 2008, p.168). Existing research shows that Intellectual Humility is positively associated with academic performance in post-secondary education (Wong & Wong, 2021) and has direct influence on how individuals process new information, remain open, change their conceptual understanding, and learn new competencies (Samuelson et al., 2015). In the context of engineering education, Intellectual Humility is briefly listed as intellectual virtue (Pierrakos et al., 2009) yet we have yet (a) to research to what extent Intellectual Humility is influencing engineering students' mindset and (b) to practically evaluate how Intellectual Humility as a quality can be taught (Leary, 2018). Empathy is broadly defined as "the reactions of one individual to the observed experiences of another" focusing both on the act of understanding and the capacity to enter the feelings of another and oneself (see Davis, 1980). The last two decades saw an increase in research on empathy and perspective taking (as part of empathy) in engineering education (Strobel et al., 2011; Strobel et al., 2013; Hess et al., 2016; Hess et al. 2017). Research shows strong connection to design thinking, communication, and other transversal skills (Sanz et al., 2023), ethical behavior (Hess & Fila, 2016), yet the connection to empathy and intellectual humility in engineering has not been explicitly studied.

This paper follows Oreg's (2003; 2018) model of resistance to change which conceptualizes resistance to change as "an individual's personality-based inclination to resist changes" (Oreg, 2018, p.89). We utilized particularly two dimensions: The emotional reaction to imposed change dimension captures the degree to which imposed change elicits anxiety and discomfort; and the cognitive rigidity dimension captures the degree of inflexibility in changing one's opinions or attitudes. Existing research shows that undergraduate engineering students carry a high level of cognitive rigidity and a high level of emotional attachment to their own ideas (Dyehouse et al., 2015) yet the connection between humility, empathy and resistance to change has not studied.

3 METHODS, TECHNIQUES, OR MODES OF INQUIRY

The research team constructed a survey using subconstructs of three independently developed validated survey instruments which each measured two sub constructs of our three main constructs: Intellectual Humility, Empathy (operationalized as interpersonal reactivity, see Davis, 1980), and Resistance to Change. The survey was administered in three universities in the U.S. Midwest and Southwest known for their STEM programs. We received 523 responses, and after data cleaning we had usable data from 369 respondents who had completed all items on at least three out of the six sub constructs we measured.

3.1 Sub constructs

We used the following sub constructs: from the Comprehensive Intellectual Humility Scale (CIHS; Krumrei-Mancuso & Rouse, 2016) we used two sub-constructs (a) Respect for Others' Viewpoints (IH-ROV: 6 items) and (b) Lack of Intellectual Overconfidence (IH-LIO: 6 items). The 12 items were rated on a scale from 1 (Does not apply to me at all) to 6 (Does apply to me very well). Sample items include 'I welcome different ways of thinking about important topics', and 'For the most part, others have more to learn from me than I have to learn from them'. A higher total score reflected a higher level of intellectual humility. In our study, the reliability of both subscales was good: α = 0.89 for Respect for Others' Viewpoints and α = 0.75 for Lack of Intellectual Overconfidence (Field, 2009).

To measure empathy, we used the Interpersonal Reactivity Index (Davis, 1980) from which we used two sub-constructs (a) perspective taking (IR-PT: 7 items) and (b) empathic concern scale (IR-EC: 7 items). The 14 items were rated on a scale of 1 (does not describe me very well) to 6 (describes me very well). Sample items include 'I try to look at everybody's side of a disagreement before I make a decision' and 'Other people's misfortunes do not usually disturb me a great deal.' A higher total score reflected a higher level of interpersonal reflectivity (empathy). In our study, the reliability of both subscales was good: α = 0.75 for Perspective-Taking and α = 0.74 for Empathic Concern.

To measure resistance to change, we used two sub-constructs of the Resistance to Change scale (Oreg, 2003) (a) Emotional Reaction to imposed change (RC-ER: 8 items) and (b) Cognitive Rigidity (RC-CR: 3 items). The 11 items were rated on a scale of 1 (Strongly disagree) to 6 (Strongly agree). Sample items include 'When things don't go according to plans, it stresses me out.' and 'My views are very consistent over time'. A higher total score reflected a higher level of resistance to change. In our study, the reliability of both subscales was good for Emotional Reaction to imposed change (α = 0.85) and borderline acceptable for Cognitive Rigidity (α = 0.63).

3.2 Data sources, evidence, objects, or materials

The research team administered an online survey to three institutes of higher education located in the Southwest and Midwest of the USA combining into one dataset. Recruitment happened through a network of colleagues supplemented with support from institutional offices such as associate dean of undergraduate studies. We deliberately recruited with a goal of reaching predominantly science and engineering (including computer science) undergraduate students. As recruitment followed a snowball principle, the study also includes graduate students, see the demographic information in Table 1.

Table 1: Demographics of Study Participants

		Gender			
		Female	Male	Other	Total

	Non-white	159	90	4	253
	Prefer not to say	1	6	2	9
	Missing				1

4 RESULTS

4.1 Relationships

A Pearson correlation analysis was conducted among IH-ROV, IR-EC, IH-LIO, RC-CR, IR-PT, and RC-ER. Cohen's standard was used to evaluate the strength of relationships (Field, 2009). The result of the correlations was examined based on an p value of .001. Table 2 presents the results of the correlation analysis.

Table 2 shows significant correlations between the two Intellectual Humility constructs, and the Interpersonal Reactivity constructs. The two Resistance to Change constructs have a weak, yet significant, correlation of .207, yet do not correlate with the other constructs. The only correlation we found between Resistance to Change constructs is between Cognitive Rigidity and Lack of Intellectual Overconfidence, and this correlation is negative, which means that if students score higher on Cognitive Rigidity, they score lower on Lack of Intellectual Overconfidence (LIO) and vice versa.

Table 2: Correlation Between Sub-constructs

		IH LIO	IR PT	IR EC	RC ER	RC CR
IH-ROV	Pearson r	.180**	.625**	.478**	.081	.069
	Sig. (2-tailed)	<.001	<.001	<.001	.128	.195
	N	352	348	339	354	354
IH-LIO	Pearson r		.238**	.351**	-.151	-.426**
	Sig. (2-tailed)		<.001	<.001	.004	<.001

	N		349	340	355	355
IR-PT	Pearson r			.604**	.068	.016
	Sig. (2-tailed)			<.001	.201	.763
	N			344	354	354
IR-EC	Pearson r				.134	-.085
	Sig. (2-tailed)				.013	.115
	N				345	345
RC-ER	Pearson r					.207**
	Sig. (2-tailed)					<.001
	N					361

**Probability level is <.05, ** Probability level is <= .001*

We ran a correlation analysis on the main constructs of the survey. We established a large correlation between IR and IH, and a small, negative correlation between IH and RC. This means that if participants score higher on Intellectual Humility, they score lower on Resistance to Change.

Table 3: Correlation Between Main Constructs

		IH	RC
IR	Pearson r	.611**	.022
	Sig. (2-tailed)	<.001	.691
	N	328	337
IH	Pearson r		-.145*
	Sig. (2-tailed)		.007
	N		347

**Probability level is <.05, ** Probability level is <= .001*

To test the mediating effect of humility on empathy and resistance to change, we performed a partial correlation test to determine the relationships between the variables, IH, IR, and IC. Partial correlation analysis is employed to control the effect that a variable has over the correlation of other variables. We conducted a Kolmorogov-Smirnov test for normality. This test yielded a non-significant result hence we assume the data is normally distributed meeting all conditions for partial correlation testing. The results of the partial correlation can be found in Table 4, which shows the correlations among the constructs and the partial correlations when we controlled for IH as an intermediating variable between IR and RC. When we did not control for IH, we found a nonsignificant ($p > 0.05$) relationship of .011 between IR and RC, which is negligeable. A positive correlation of .610 was observed between IR and IH, indicating a large effect size (p < .05). The correlation between RC and IH is negative and is weak yet significant at -.172 (p < .05). IH correlates with both other main constructs, while the other main constructs do not seem to correlate. When we control for IH the correlation between IR and RC increases to .149 (p < .05), which indicates that IH indeed is an intermediating variable between IR and RC. In other words, experiencing empathy for another person would not necessarily reduce the resistance to change one's perspective, yet people who score high on intellectual humility might be more willing to change their minds if they empathize with someone else's point of view.

Table 4: Partial correlations between main constructs

Control Variable			RC	IH
None	IR	Pearson r	.011	.610**
		Sig. (2-tailed)	.842	<.001
		N	321	321
None	RC	Pearson r		-.172
		Sig. (2-tailed)		.002
		N		321
IH	IR	Pearson r	.149*	
		Sig. (2-tailed)	.007	
		N	321	
Note: Partial correlations were calculated on data points without missing items.				

**Probability level is <.05, ** Probability level is <= .001*

4.2 Significant Differences between Groups

We tested for significant differences between *Year in College, Gender,* and *Fields of Study*. We did not find any significant differences for *Year in College*. The results for differences between gender are presented in Table 5. The differences between Male and Female students are striking, as we established moderate to large effect sizes for the sub constructs where we found differences. In all cases the Female students scored higher on the sub constructs.

Table 5: One Way ANOVA Differences based on Gender (only significant reported here)

		Mean	SD	F-value	p	Effect size*
IH ROV	Male	4.66	.963	5.655	.004	.33
	Female	4.96	.838			
IR EC	Male	4.09	.849	26.282	<.001	.79
	Female	4.71	.710			
IR PT	Male	4.14	.886	9.184	<.001	.44

	Female	4.51	.755			
RC ER	Male	3.52	1.09	14.761	<.001	.58
	Female	4.17	1.11			

**We used Hegdes' g for effect size calculations as the sample sizes differed strongly: Male: 106, Female: 193*

We tested for significant differences on our subconstructs between fields of study. We discern between Engineering (including Computer Science), Natural Sciences, and Other fields, e.g. kinesiology, neuroscience and nursing. For humility subconstructs, we did not find any statistically significance. We established significant differences for IR EC (F= 7.630, p= <.001), IR PT (F= 6.413, p= .002), RC ER (F= 5.955, p= .003) between Engineering, Science and Other fields (see Table 7 for details on the outcomes of this analysis) in so far that engineering students scored significantly lower on empathy subscales and the emotional reaction to imposed change subscale of the resistance to change construct.

Table 7: One Way ANOVA Differences based on major: Engineering, Science, Other (only significant reported here)

		Mean/ SD	Mean/ SD	F-value	p value*	Effect size**
IR EC	Engineering and Science	4.26 / .879	4.56 / .689	7.915	.005	.36
	Engineering and Other	4.26 / .879	4.75 / .727	10.145	.002	.57
IR PT	Engineering and Other	4.20 / .861	4.65 / .784	10.795	.001	.53
RC ER	Engineering and Science	3.71 / 1.14	4.12 / 1.15	9.028	.003	.35
	Engineering and Other	3.71 / 1.14	4.21 / 1.14	6.175	.014	.43

**We used a Bonferroni correction, which means that we consider p=.017 as the cut off score for significance.*
***We used Hedges' g for effect size, as the sample sizes between the fields differed in size: E= 196, S= 98, O= 56*

5 DISCUSSION

The aim of our study was to examine how intellectual humility is related to perspective taking/empathy and to determine what sociodemographic variables presented any differences among the levels of intellectual humility and empathy in the engineering and science student sample. Finally, to identify the role of intellectual humility as a moderator between empathy and resistance to change.

Our analysis has shown a positive and statistically significant relationship between sub-constructs of intellectual humility and empathy (interpersonal reactivity). We also established a small, negative correlation between Intellectual Humility (IH) and Resistance to Change (RC), meaning that students who score higher on empathy are also scoring higher on humility and that if participants score higher on Intellectual

Humility, they score lower on Resistance to Change. The finding does not come as a surprise as cognitive rigidity reflects a level of dogmatism and lack of overconfidence would rather indicate an intellectual doubt in one's own position – two juxtaposing positions. Findings here are consistent with existing literature on the inextricable relationship between cognitive rigidity and overconfidence (Cohen, 2017). The main outcome of this study pertains to IH as an intermediate variable between IR and RC.

As far as our significance testing between our constructs and Year in College, Gender, and Fields of Study it was surprising however that we did not find any significant differences for *Year in College* as it would indicate that humility and empathy are more stable traits. We also investigated gender differences and found that female students scored higher than males on all the interpersonal reactivity constructs (empathy, perspective-taking, and emotional reaction to imposed change) which is consistent with the literature on self-reported empathy data for students (Rueckert et al., 2011) yet not with results on engineers working in the profession (Hess et al., 2017).

For Fields of Study, we did not find any statistically significant differences when it came humility. We found, however, significant differences for Interpersonal Reactivity (empathy) subconstructs and the emotional reaction to imposed change (resistance to change) subconstruct based on fields of study. Engineering students scored statistically significantly lower on empathy subscales which is corroborated by research by Rasoal et al. (2012) and score lower on the emotional reaction to imposed change subscale of the resistance to change construct which confirms prior results by Dyehouse et al. (2017).

6 LIMITATIONS

The study has several limitations: The study surveyed students from three universities in the USA, which may limit the generalizability of the findings. The demographics, cultural backgrounds, and academic experiences of the participants might not represent the broader population of science and engineering students. In addition, the data collection relied on self-report measures to assess intellectual humility, empathy, and resistance to change. This approach is subject to social desirability bias, where participants may provide responses that align with perceived societal norms or expectations rather than their true attitudes or behaviors.

The study captured data at a single point in time, and the reliability of the CR construct could have been better. As a result, causal relationships cannot be inferred, and longitudinal studies are needed to examine how these constructs evolve over time and whether changes in one variable precede changes in another.

7 SCIENTIFIC OR SCHOLARLY SIGNIFICANCE OF THE STUDY OR WORK

Our research shows preliminary statistically significant correlations between multiple subconstructs and constructs of humility, empathy, and resistance to change. The results indicate differences based on gender and fields of study as well. In addition, our research shows that intellectual humility seems to be a mediator variable between empathy and resistance to change. Further research and the design of interventions are needed to improve intellectual humility of engineering students and change the cultural norms of engineering education.

ABSTRACT

As engineers play a central role in solutions for holistic sustainability, it is pivotal to ensure that our engineering graduates enter their careers with dynamic competency profiles - where core engineering skills are integrated with generic and value-based skills in a synergistic way. At present, the graduate competency discourse is driven by employers' and stakeholders' perspectives, thus overlooking those of recent graduates. In this study, we adopted a data-driven approach to study national survey data on recent graduates' (n=1976) perceptions on the importance thirty key competencies and the patterns underlying those perceptions. Our quantitative analysis revealed that while graduates perceive a variety of competencies as important within the first year of graduation, these competencies form five unique profiles where foundational and organizational skills are perceived as most

[1]*J. Sundman*
julia.sundman@aalto.fi

important. Furthermore, we uncovered that graduates' perceptions on these competencies are shaped by two key dimensions: generic versus discipline-specific skills, and analytical versus holistic thinking. Our results provide foundational insights for both educators and employers to enhance their collaborative efforts in supporting students' transition from studies to working life. Particularly, by adopting experiential learning pedagogies and providing mentoring, there is an opportunity to leverage graduates' competencies and novel insights for the benefit of the industry and society.

1 INTRODUCTION

Today's engineers are operating in a rapidly evolving landscape that is shaped by technological advancements and demands for sustainable solutions. Early-career graduates could hold a pivotal role within this context through their education and novel insights, however, this is perhaps not well recognized yet in the working life, nor promoted sufficiently in the education (Karvinen 2024; Craps et al. 2021b). At the same time, both educators and working life actors are encouraged to collaboratively ensure that engineering graduates are sufficiently supported to develop competencies to respond to the on-going sustainability crisis (Kolmos et al., 2016; Karvinen, 2024). Therefore, gaining a broader understanding on how graduates perceive various working life competencies and how those competencies interact with one another can shed light on areas where current educational and professional practices could better support graduates' transition from studies to working life, and lifelong learning.

1.1 Early-career competencies of engineers

The discourse on what type of competencies engineers need in the early career is not new. There is a long tradition of surveying the general needs of engineering practice, particularly from the employers' perspectives. The key expectations towards engineering graduates often emphasize a broad range of skills, ranging from subject-specific know-how to various generic and interpersonal skills (Passow and Passow 2017; Khoo, Zegwaard, and Adam 2020). This pattern can be observed across different cultural and disciplinary contexts. For instance, a recent study surveying employers' expectations in the water and environmental engineering field in Finland found that a mix of subject-specific, social, and problem-solving skills are emphasized when recruiting graduates (Renko et al. 2020). Similarly, another study focused on mechanical engineering field in the United Kingdom found that personal working attitude, professional conduct, willingness to learn, as well as technical and subject-specific skills to be crucial for employability (Souppez 2023).

From graduates' perspective, the subject-specific or "hard" skills are more relevant in the early career, but when moving forward in the career, "softer" skills, such as leadership, ethics and value-based thinking, become more important (Winters et al. 2013; Vehmaa et al., 2018). The emphases on what skills become relevant also depend on which career paths the graduate ends up taking: for instance, those pursuing managerial positions require competencies such as business knowledge and leadership and are less likely to rely on engineering tools and techniques (Brunhaver et al., 2013). This diversity of career paths, coupled with high and changing demands of the working life, often leads to debates on misalignments between education and practice – particularly when engineering curricula tends to favour technical and theoretical foundation, whereas working life also seek for attitudinal factors and transferrable competencies (Trevelyan 2019; Pyrhönen et al., 2019).

1.2 Towards a shared vision of competency profiles

Recent soaring demands to enhance sustainability in education have created a strong need to incorporate not only workforce concerns but also agency and value-based skills in the engineering curriculum (UNESCO 2021; Malmqvist 2020). As a response, various competency profiles and frameworks have emerged in literature to be promoted through education. Frameworks such as key sustainability (Brundiers et al., 2021) and transformative competencies (OECD, 2019) emphasize that competencies should be viewed as a cohesive unit of interacting abilities rather than lists of isolated skills to be developed. Viewing competencies through the lens of interconnected and synergetic abilities is encapsulated, for instance, through the T-shaped competency profile (Uhlenbrook and Jong 2012; Conley et al. 2017) and a recently proposed hybrid competency profile (Karvinen 2024). Both models call for combining the core engineering expertise with broader competencies. In particular, the hybrid profile, highlights the need to integrate broader competencies—such as interdisciplinary, comprehensive, futures, and values thinking—into the core engineering expertise. These competencies are essential for engineers to support the transition towards more just and sustainable societies (Quelhas et al. 2019).

The responsibility of developing the needed competency profile should not fall solely on the graduates. Engineering education is confronted with the need to keep their curricula up to date with a variety of competencies aligning with employability and sustainability agendas, and what the graduates themselves perceive as important for their career and wellbeing. Simultaneously, employers play a crucial role in fostering environments that support professional growth and embrace graduates' contributions (Karvinen, 2024). However, to adequately support engineers' transition to working life, there is a need for a more in-depth understanding on the interplay of various competencies in the early career. Few studies have explored recent graduates' perceptions on the importance of these skills, and even fewer have examined the interrelations between them. This gap hinders a comprehensive understanding of how competency profiles develop in practice, and thereby also the efficacy of collaborative efforts to support graduates lifelong learning. To bridge this gap, the following questions directed our research:

1. What are recent graduates' perceptions of the importance of various skills for their careers?
2. What possible underlying patterns characterize these perceptions?

2 METHODOLOGY

We adopted a quantitative approach to address our research questions. For this study, we acquired and received permission to utilize survey data collected by a Finnish professional organization and labor union for engineers "Tekniikan Akateemiset" (TEK). TEK collaborates with seven Finnish universities to conduct an annual "Graduate Survey" for academic engineers and architects who have completed their degrees during the past year. Given the varying time spans associated with the term "early-career," we adopted "recent graduates" to specifically refer to those who graduated within the past year.

2.1 Data description

The survey data used in this study is from the most recent TEK Graduate Survey (N=1976; TEK 2022). The survey collected information on respondents' study experiences, developed competencies, well-being, and employment situation (response rate 61%). Respondents were mainly male (N=1332, 67%), and on average 29 years (range 21-64, median 27). A total of 83 % (N=1481) of respondents were Finnish and this share was similar among men and female. In this study, we used responses to questions related to the perceived importance of thirty pre-defined skills for respondents' careers that were ranked on a six-point Likert scale (1 = not at all, 2 = very little, 3 = little, 4 = somewhat, 5 = much, and 6 = very much important). Notably, 94% of the respondents gained work experience during their studies, indicating some level of understanding about the work life needs, despite been fresh graduates.

2.2 Data analysis

We used R programming language to conduct statistical analyses using *stats* and *factoextra* packages (Kassambara and Mundt 2020; R Core Team 2024). Due to limitations of the methods, we removed respondents that left at least one of the skills unrated and performed analysis on a total of 1502 respondents. We conducted basic descriptive analysis, correlation analysis, hierarchical clustering, and principle-component analysis (PCA) of the skill ratings. For hierarchical clustering, we used the Ward method to minimize variance when merging clusters. At each step, the two clusters that result in the smallest increase in total within-cluster variance are merged. This process continues iteratively until all data points form a single cluster. For PCA, we used a correlation matrix of the thirty skills as input data to account for variability.

3 RESULTS

3.1 Graduate perceptions of working life competencies

Our results indicate that generally, recent graduates perceived most of the surveyed skills as rather important for their career (Table 1). Particularly, problem-solving (M = 5.79), retrieval of information (M = 5.65), independent work (M = 5.65), and an attitude towards developing one's skills (M = 5.56) were ranked high. On the other hand, entrepreneurial capabilities (M = 3.95), and knowledge of history and development of own field (M = 4.14), although still considered "somewhat important", received lower scores compared to the rest of the skills. Surprisingly, mathematics and natural sciences (M = 4.57), and business knowledge (M = 4.62) were perceived in the same manner. The perceptions on the importance of entrepreneurial capabilities, business knowledge, digitalization and utilization of data, and knowledge of the history and development of the field were more variable compared to other skills. The correlation analysis reveals that most of the skills are significantly correlated, except for business knowledge, which showed less correlation with other skills.

Table 1. Descriptive statistics of the surveyed skills, ordered by mean values (n=1502).

	Mean	St. dev.	Median	Min	Max
Problem-solving	5.79	0.46	6	3	6
Information retrieval	5.65	0.60	6	2	6
Independent work	5.65	0.58	6	3	6
Developing own skills attitude	5.56	0.63	6	1	6
Time management and prioritization	5.52	0.68	6	2	6
Teamwork	5.50	0.69	6	1	6
Analytical thinking	5.47	0.67	6	2	6
Know-how own field	5.46	0.72	6	1	6
Self-confidence	5.42	0.70	6	1	6
Own well-being	5.37	0.79	6	1	6
Project management	5.36	0.77	6	2	6
Social skills	5.35	0.77	5	1	6
Critical thinking	5.32	0.71	5	2	6
Practical application of theories	5.31	0.79	5	2	6
Career management capacity	5.26	0.79	5	1	6
Self-knowledge	5.22	0.73	5	1	6
Oral communication	5.21	0.79	5	2	6
International environment	5.12	0.91	5	1	6
Creativity	5.01	0.89	5	1	6
Visual communication	4.95	0.92	5	1	6
Ethicality	4.91	1.02	5	1	6
Leadership	4.81	0.97	5	1	6
Written communication	4.80	0.98	5	1	6
Sustainable development knowledge	4.79	1.10	5	1	6
Digitalization and utilization of data	4.69	1.14	5	1	6
Research knowledge of field	4.63	1.06	5	1	6
Business knowledge	4.62	1.15	5	1	6
Mathematics and natural science	4.57	1.09	5	1	6
History and development of field	4.14	1.13	4	1	6
Entrepreneurial capabilities	3.95	1.21	4	1	6

3.2 Five competency profiles

Hierarchical clustering revealed five unique profiles of graduate competencies, which we named according to their contents (Figure 1). The largest cluster, “foundational and organizational skills”, contains a broad mix of organizational, intra- and interpersonal, cognitive, and field-specific know-how that are important to recent graduates. The second major cluster, “values and creativity”, contains knowledge and skills related to creativity, communication, and values-based skills, such as sustainability and ethicality. Knowledge and skills related to business, entrepreneurship, and leadership formed their own cluster, “strategic leadership”. Finally, “academic knowledge” and “scientific and data proficiency” clusters are formed based on two individual skills, but later together form a statistically significant cluster.

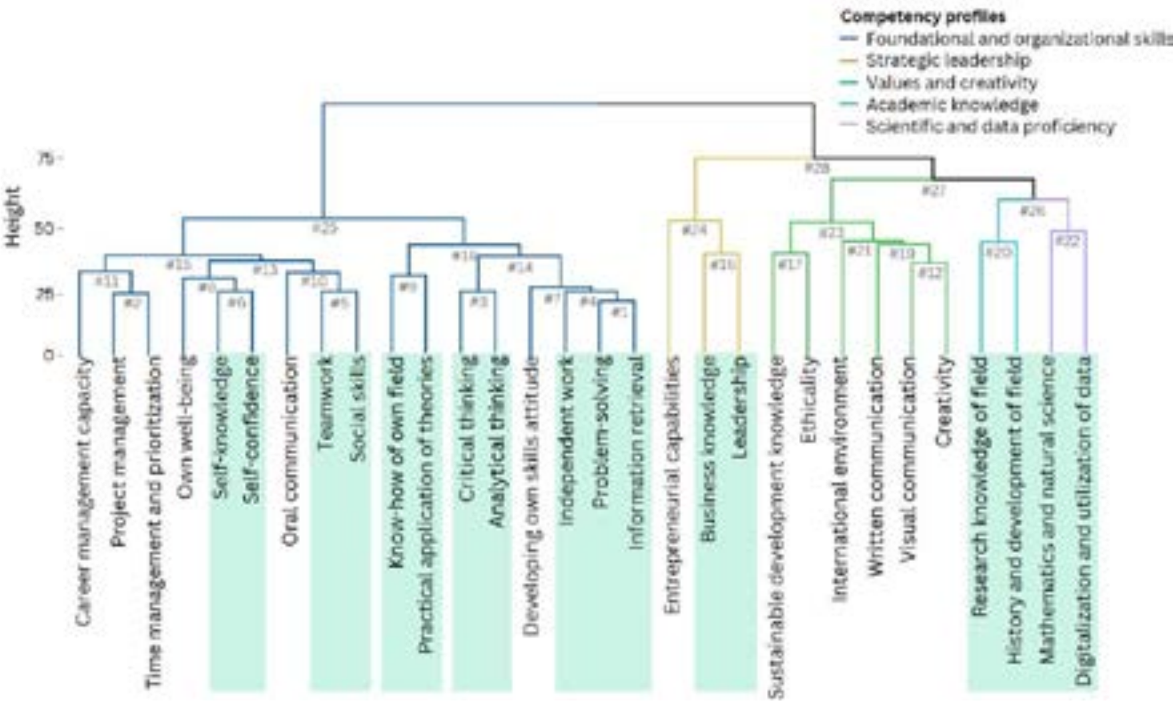

Figure 1. Hierarchical clustering of the surveyed skills, with statistically significant clusters (alpha ≥ 0.95) highlighted in teal, and the order of clusters formed indicated by running id.

3.3 Key dimensions of graduate perceptions

The principal component analysis (PCA) reveals the main dimensions of graduate perceptions and the loadings of each skill in these dimensions.The PCA highlighted the two most important dimensions, that explain 38 % of the total variation in the skill ratings (Figure 2). Based on the nature of the skills that had the most contribution to the variation, we intuitively named Dimension 1 “analytical vs. holistic thinking”, and Dimension 2 “subject-specific vs. generic skills”.

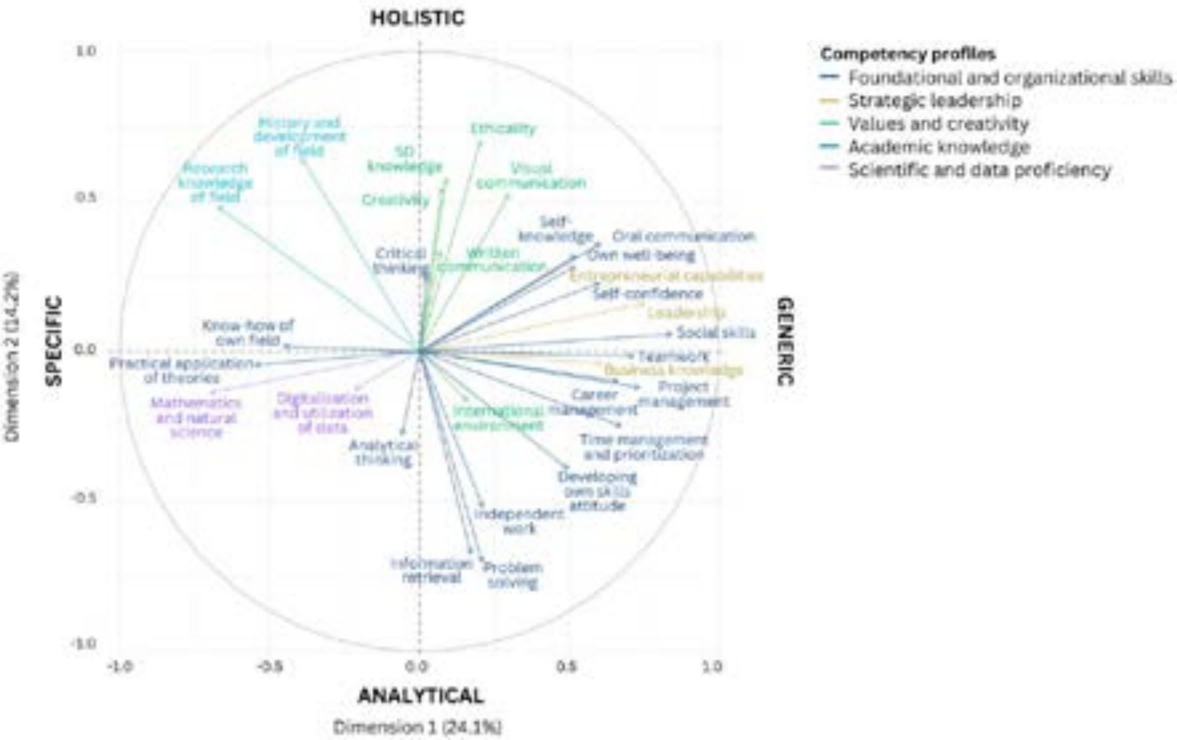

Figure 2. Principal component analysis biplot visualizing the loadings of the surveyed skills. The skills are grouped by the five competency profiles identified in hierarchical clustering.

The first dimension, “analytical vs. holistic thinking”, was strongly contributed by problem-solving and information retrieval on one end (analytical), and ethicality, knowledge on sustainability and history and development of the field in the opposite (holistic). The second dimension, “subject-specific vs. generic skills”, had a large contribution from social, leadership, and project management on one end (generic), and mathematics and natural science and practical application of theories on the opposite (specific). The positioning of these contributions indicates that recent graduates perceive a clear distinction in the importance between technical, discipline-specific abilities and broader, transferrable skills. Overall, it seems like the skills belonging to the five competency profiles previously identified tend to be positively correlated – in other words, rated similarly. Interestingly, it seems that some skills belonging to “foundational and organizational” group are oppositely correlated within the “specific vs. generic” spectrum.

4 DISCUSSION

To develop an engineering curriculum that delivers a competency profile aligning with industry needs and sustainability imperative, it is essential to understand graduate competencies from a holistic perspective. Although surveying learning outcomes of degree programmes is a prerequisite to identify what the graduates have learned in practice and possible competency gaps, this has been explored mainly through employer perspectives or stakeholder consultation. Graduate surveys are a common practice to monitor employment and satisfaction with education, but they can also be used to explore graduate perceptions on the importance and relevance of their working life competencies to inform educators, employers, and researchers. Our study therefore advanced the discourse on engineering competencies by incorporating the perspectives of recent graduates and patterns that underpin them by examining a national level survey.

Firstly, it seems that recent graduates value most competencies highly. Potential reasons for this could be that within the first year of graduation, graduates may feel uncertain about the professional roles as an engineer, the diversity of tasks in entry-level jobs and broad expectations of employers (Sheppard et al. 2015; Bennett and Male 2017; Jesiek et al., 2021; Craps et al. 2021a). Yet, given that problem-solving is a core competence for both employability and sustainability agendas of engineering education (Kolmos et al., 2016), our findings indicate that also recent graduates recognize its importance for their careers. **Secondly**, we identified five competency profiles that encapsulate the diverse skill combinations according to how recent graduates value them. While studying competency groups is not uncommon in engineering education research, it often lacks specificity regarding career stage or encompasses a broader timespan (Passow & Passow, 2017). Thus, our findings provide a unique perspective by highlighting groupings that are relevant within the first year of graduation – a crucial timeframe in transitioning to working life. **Finally,** our PCA revealed two distinct dimensions underlying graduate perceptions: the first dimension representing a spectrum from specific to generic skills, and the second dimension representing skills from analytical to holistic thinking. The explained variance (38%), along with the spread-out nature of the skills in the plot, suggests wide heterogeneity in how recent graduates prioritize and perceive them.

Understanding graduates' perceptions on competencies and their interrelations can provide a common grounding for educators and employers to support the development of a hybrid competency profile – integrating core engineering expertise with broad inter- and intrapersonal, thinking and value-based skills (Karvinen, 2024). Interestingly, it seems like recent graduates perceive the importance of few key competencies in an opposite manner, for example sustainability knowledge and problem-solving. While these perceptions could be explained through factors such as education background and career trajectory, it is important to not overlook the potential synergy among these skills within a competency profile. Thus, it is essential to recognize both the diversity in graduates' perceptions and the interconnectedness of these skills within a comprehensive competency framework. For example, engineering students' competence development and career readiness could be supported through experiential learning approaches resembling authentic engineering practice and its complexity (Mann et al. 2021). Employers can complement these efforts by providing training and mentoring aimed at supporting graduates' socialization and journey as lifelong learners (Davis et al., 2017; Korte et al., 2019).

Our primary limitation lies in analysing graduate perceptions in isolation from potential explanatory factors such as demographic, educational, and career characteristics. However, we believe that our findings offer foundational insights for moving forward: by incorporating additional variables and further exploring the variations of the identified patterns, future studies have an opportunity to yield a more holistic understanding on the development of graduate competency profiles across diverse engineering disciplines and cultural contexts within Europe and beyond.

5 ACKNOWLEDGEMENTS

We would like to thank Tekniikan Akateemiset (TEK) for collecting and providing us with the data used in this study, and Maa- ja vesitekniikan tuki ry for funding this study.

ABSTRACT

The 'gender mathematics gap' which persists in many countries means that women students may, on average, have less high school preparation in mathematics than men students entering engineering education. This in turn could impact their performance in first-year exams and thus reduce women's participation in engineering programs. One factor that has been a focus of some interest in addressing equity issues in education is time-limited exams, which have been found

[1] *R. Tormey*
roland.tormey@epfl.ch

to give rise to unfairness with respect to underrepresented students in a number of domains. In mathematics, time pressure has been found to be linked to increased student stress and to the use of less effective problem-solving strategies in assessment conditions. We sought to explore, therefore, the impact of reducing time pressure in a first-year engineering Linear Algebra course. We had 275 participants, of which 192 (69.8%) were men and 83 (30.2%) were women. Using a pseudo-experimental design in real-word conditions which controlled for teacher effects and assessment effects, we found that, when there was reduced time pressure, students with less prior mathematics performed better than when in a more time-pressured exam. Our results show that these students can learn the required Linear Algebra and can demonstrate their learning under appropriate conditions. This leads us to conclude that reducing time pressure in first year mathematics exams may contribute to improving the retention of women students in engineering education, particularly in cultural contexts in which a gender mathematics gap is prevalent.

1 INTRODUCTION

1.1 Exam length and equity in engineering education

Equity remains a persistent issue to be addressed in engineering education. Lichtenstein et al. note that in the US, for example, while the proportion of women enrolled in higher education has grown substantially since the 1980s, ‘‘minimal progress has been made in recruiting and retaining …women and minorities, into engineering programs’’ (Lichtenstein et al. 2014, 314). Similar patterns are evident in European engineering education (Barnard et al. 2012; Powell et al. 2012).

One factor which plays a role in this is the place of mathematics in the initial education of engineers. Lower prior performance in math has been found to be a factor in non-retention of students in engineering education (Takahira et al. 1998; Falkner et al. 2010; Falkner et al. 2014). This in turn is linked to gender since, despite a narrowing of the gap, boys continue to have, on average, higher mathematics achievement at upper secondary school level in many countries (OECD 2019). Indeed, the comparatively better performance of boys in mathematical attainment is actually higher than the OECD average in many European countries including Switzerland, Luxembourg, Austria, Germany, France, Italy, Portugal, Belgium, Ireland, Spain and the United Kingdom. This ‘gender mathematics gap’ is not something that should be taken for granted or accepted, however: girls actually outperform boys in mathematics in other nearby European countries including Sweden, Norway and Iceland (OECD 2019, 25-26). Rather than linked essentially to sex, gendered differences in attainment are linked to persistent cultural beliefs about gender and mathematics, as well as to educational practices (OECD 2023). The issue is, therefore, not a biological one, but one linked to culture and social and educational structures.

If there are differences in average high school performance in mathematics, this in turn impacts on those same students when they enter university. Differences in prior knowledge like this can be understood in two different ways: either as a ‘deficit’ in some students that needs to be addressed through the students changing what they learn before coming to university, or as a ‘difference’ between students that needs to be taken into account in pedagogical choices of institutions. There is evidence that framing equity issues as one of ‘difference’ is productive insofar as changing the way we teach and assess in university can have an impact on equity in student success without simply transferring the burden for change onto the student themselves. For example, specific pedagogical choices such as the use of flipped classes (Hardebolle et al. 2022) or interactive teaching (Theobald et al. 2020) have been identified as having an impact on reducing attainment gaps for women and other underrepresented students in undergraduate science, technology and mathematics courses. It makes sense, therefore, to look at other aspects of teaching and assessment that may be contributing to attainment gaps for women and other under-represented groups.

One such factor that is worthy of consideration is examination time pressure. Although time-limitations in assessment are widely accepted as a normal practice, there is evidence that time-limited tests discriminate unfairly against students who are learning in a second language (e.g. immigrant students), those who are older than average, and those from other underrepresented backgrounds (see Gernsbacher et al. [2020] for a review of evidence). Caviola et al. (2019) found that there is a substantial body of literature that suggests that the imposition of time limits can increase stress associated with challenging tasks. Specifically looking at mathematics problem solving, there is also evidence that, as is expected from stress reactions, shorter time limits can lead to a shift to using suboptimal (heuristic rather than analytical) solution strategies (Gillard 2009). Since there is a known association between mathematics anxiety and gender (e.g. Hart and Ganley, 2019; Vos et al. 2023) this suggests that examination time pressure may well play a role in contributing to gender differences in performance.

In light of such findings, it is surprising to see that there are few studies which have explored the impact of time pressure on equity in mathematics learning. Caviola et al.'s review, for example, found only a handful of studies looking at university students, most of which were relatively small, and which typically did not use the kinds of mathematical problems being solved by engineering students in first year courses. Furthermore, while experimental studies have the benefit of being designed for internal validity, their findings often do not transfer into real world settings. Kim (2019) for example, found that in one review of trials aimed at transferring a previously validated educational intervention into real-life settings, only 11 of 90 trials yielded positive results. This suggests a need to test such ideas beyond experimental settings, under real-world conditions.

This, then, gives rise to our research question: does reducing time pressure in first year university mathematics exams have an impact in reducing the gender gap in attainment for engineering students?

1.2 Context of this study

As noted above, gendered patterns of mathematical performance differ depending on the education system and culture of the wider society. This study took place in Switzerland, where almost all students come from France and Switzerland, two countries in which the 'gender-mathematics gap' (i.e. boys having higher mathematics scores than girls on average) in high school is a little bigger than the average for the OECD as a whole (OECD 2019, 25-26).

In the technical university in question, women make up circa 29% of the first-year intake. While the students coming from France all had a scientific baccalaureate (French BAC) (and therefore substantial prior studies in mathematics), not all Swiss students have substantial mathematics in their high school. Of the students entering this university who had a Swiss high school diploma, over the years 2014-20, 56% of the men had taken the physics and mathematics option in high school (Swiss PAM), as compared to 33% of the women. In the same time period, counting all students (i.e. including both Swiss and others) 70% of first year men passed exams to allow them to enter second year, as compared to 65% of women.

2 METHODOLOGY

The purpose of this study was to explore if reducing time pressure in first year university mathematics exams would have an impact in reducing the gender gap in attainment for engineering students. This was done through a pseudo-experimental study. In the academic year 2019-20, the number of questions in the Linear Algebra exam for first year students was reduced, without reducing the time allocated to the exam, the difficulty of the questions or the amount of material covered in the course. This, therefore reduced the time pressure on students in the exam, while retaining other factors as constant. Students who took the exam in 2018-19 were identified as a control group (normal time pressure condition), while those who took the exam in 2019-20 were identified as the experimental group (reduced time pressure condition).

2.1 Participants

Table 1. Student participants, the examination condition and their high school diploma type

	French BAC	Swiss PAM	Swiss Other	Total
2018-19 (Control condition)				
Men	34	17	11	62
Women	19	7	9	35
2019-20 (Reduced time pressure condition)				
Men	57	45	28	130
Women	25	8	15	48
Total	135	77	63	275

As the university was interested in researching aspects of mathematics pedagogy at that time, students were invited to volunteer to be part of a study on pedagogical innovations. A total of 660 students volunteered to participate in the years 2018-19 and 2019-20. In the university at that time, the Linear Algebra course in the first semester of first year was taught by nine different teachers. Since one of the classes had a different pedagogical condition than others (a flipped class) it was excluded from this study. This study is then based on data from classes with eight different teachers (effectively ensuring that any findings are not simply the result of a factor related to a single instructor). We therefore retained for this study (a) students who were not involved in the flipped class condition, (b) students who had not previously taken first year (i.e. repeating students were excluded) and (c) students whose high school experience we could meaningfully categorise (i.e. those who studied for a high school diploma in France or Switzerland). This gave us 275 students, of which 192 were registered as men and 83 were registered as women (the university registration system did not allow students at that time to identify with a gender other than these two). The breakdown of students in terms of their registered gender and high school diploma type (i.e. French scientific BAC, Swiss PAM, Swiss Other) is in table 1.

2.2 Measures

The Linear Algebra exam was 80% multiple choice questions (common to all teachers) and 20% developed response questions (different across different teachers). The multiple choice questions were set by the teachers collectively and validated to ensure that the difficulty level was the same from year to year (this effectively controlled for assessment-related factors). Students who did not achieve a grade of 3.5 out of 6 on their mathematics and physics subjects in the first semester are not permitted to proceed to semester two and are instead redirected into a 'foundations reboot program' which must be passed before they can be readmitted to first year (it should be noted 3.5 is not a 'passing' grade – students need 4 out of 6 on average over two semesters to pass first year). Since our focus was on retention of students in the first year we focused on two measures. The first is grade, scored on a scale of 1 to 6, with 6 being the highest. The second is achieving a grade of 3.5 or higher (since lower grades mean not being allowed continue in the first year unless the 'foundations reboot' is passed).

In the control condition there were 24 multiple choice questions. In the reduced time pressure condition there were 22 multiple choice questions. The exam time in both cases was 3 hours and the 20% of developed response questions did not change.

2.3 Ethics

Students had all volunteered to take part in research on pedagogical innovation in mathematics education and had given their informed consent for their data to be used in research. The decision to reduce the time pressure in the exam was taken by the teachers and was done for all students to ensure fairness and equity of treatment for all. Thus, while the mathematics test condition was the same for all students (those who volunteered to participate in the research on pedagogical innovation and those who did not), only data from students who volunteered to have their data used in research was included in this study.

3 RESULTS

Table 2 presents the overall average grades for students on the Linear Algebra exam including both the 80% common part and the 20% questions individual to each teacher. As table 2 shows, the average grade went being below the level which barred students from entering the second semester (3.5) to a grade above that level in the reduced time pressure condition. This difference is statistically significant ($t = -2.11$, $df = 193.98$, $p = .03$).

Interestingly, the additional time made effectively no difference to the performance of those who had substantial mathematics in their high school experience (French BAC and Swiss PAM diplomas), for whom the final grade in the control condition was very similar to under the control condition (see the dashed grey line in Figure 1, below). There is however a clear difference in those who had a non-mathematical Swiss high school diploma, who had a higher grade average in the reduced time pressure condition (t = -3.18 df = 41.16, p <.01). In the control condition only 4 out of 20 participants with a non-mathematical Swiss high school diploma scored 3.5 out of 6 and were thus allowed proceed to the second semester (20%); in the reduced time pressure condition this rose to 22 out of 43 (51%).

Table 2. Grades of participating students in control and reduced time pressure conditions

	N	Mean Grade	Median Grade	Grade St. Dev.
Control (2018-19)	97	3.38	3.5	1.25
Reduced Time Pressure (2019-20)	178	3.71	3.75	1.22

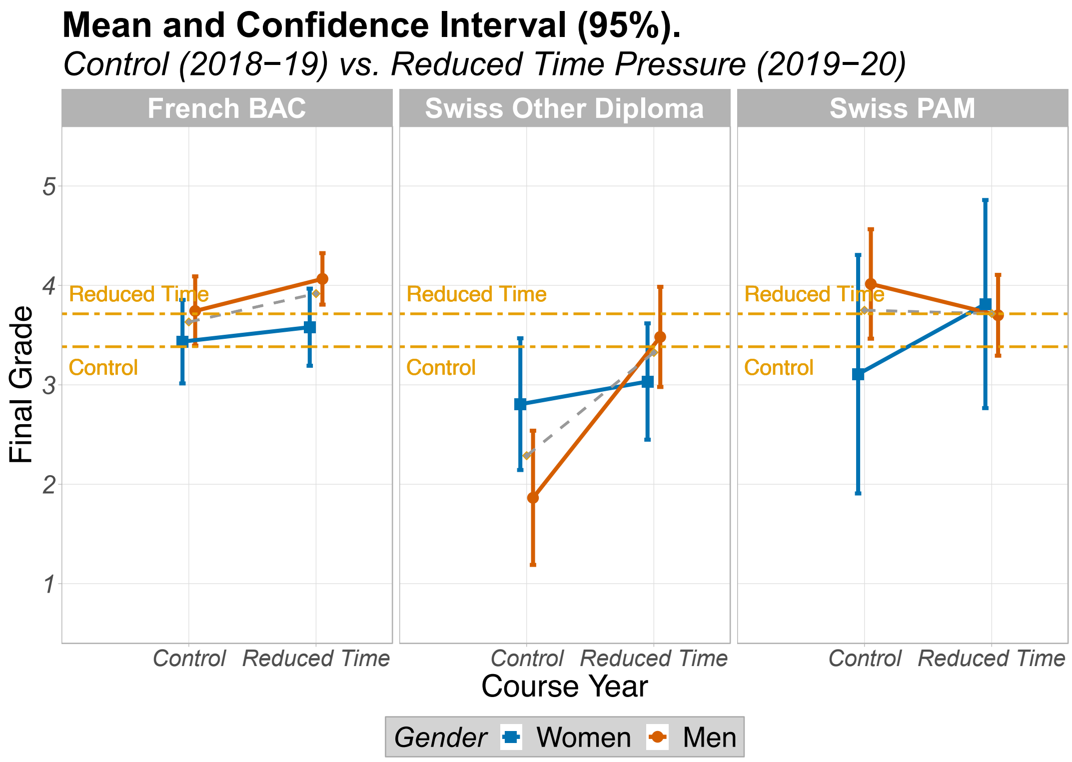

Fig. 1. Grades by gender, condition and high school diploma (including 95% confidence interval). The mean grade across groups is represented by dash-dotted horizontal lines. Dashed grey lines represented the weighted means for each condition and group.

Figure 1 (above) shows how the interaction between gender and prior mathematical experience in high school impacts upon this change. The improved performance of those who do not have substantial mathematics in their high school diploma (Swiss Other) is experienced by both men and women. This is reflected in the overall performance of women on the exam: their mean average grade rose from 3.21 (st. dev. = 1.11) in the control condition to 3.45 (st. dev. = 1.15) in the reduced time pressure condition (t = -0.96, df = 74.76, p = .34). This is reflected in an increase in the rate of women having a grade (3.5) that would allow them to enter the second semester: the rate in the time pressured condition was 15 out of 35 (42.9%). In the reduced time pressure condition this rose to 26 out of 48 (54.2%). Although Figure 1 shows a slight decline in grade for men with Swiss PAM backgrounds in the reduced time condition, and shows different levels of increased attainment between conditions for men and women with Swiss Other backgrounds, these differences are small enough that they are neither notable nor statistically significant.

4 ANALYSIS

The data shows that the difference in time pressure in the exam does appear to make some difference in student success in the exam. As Figure 1 shows, however, this improvement is not evenly distributed across all groups: the benefit is felt most acutely by those who have less mathematics in their high school diploma (Swiss Other Diplomas), a group in which women are over-represented. Unlike those who had more prior mathematics in high school, the grades obtained by this group are significantly higher in the reduced time pressure condition ($t = -3.18$, $df = 41.15$, $p < .01$). The specific psychological processes that explain this was not the subject of this study. It may be that students who have less prior mathematical practice have less fluency and therefore need more time to demonstrate their mathematical skills and knowledge. It may be (as studies cited by Caviola et al. [2019] found) that the time pressure increases stress and therefore leads to the use of less efficient solution methods for those students.

Whatever the actual psychological processes involved, the findings do seem to show that students with less prior mathematics (such as those with a Swiss Other diploma) can learn the required linear algebra knowledge and skills and can demonstrate that learning under the right conditions (such as a reduced time pressure exam). This in turn can be seen in a notable increase in grade by women students in our study, and an increase in women having the grades required to progress to the second semester. Unfortunately, the average grade for women in the reduced time pressure condition is still only 3.45, below the passing grade (4) and below the grade at which students are allowed to progress to the second semester (3.5). So a change in exam time, on its own, will not constitute a magic bullet to solve the 'gender mathematics gap'. However, it seems likely that there is no magic bullet to address this and rather there are only a range of strategies which each have an incremental effect and which together can have a meaningful impact. This data does suggest that time pressured exams may be one factor leading to the exclusion of both women and men students who did not have a strong background upon entry to university, and addressing this may be part of the solution.

This has clear implications for equity issues and the retention of women students in engineering education. As noted above, in the context of our study, the wider culture and the structure of high school education means that women, on average, come to engineering education with less prior mathematical experience than men. Creating assessments that allow those with less mathematical prior knowledge to show the mathematical knowledge and skills they have learned during the course is, therefore, one potentially important factor in improving equity. Reducing time pressure may well be one way of doing this.

As with any study, ours has some limitations. Our study is a real-world pseudo-experiment, which means we do not randomly assign students to control and reduced time pressure conditions. While the study effectively controls for multiple factors (teacher effects, assessment effects, prior mathematical background and gender), we cannot rule out some other factor impacting on the data. We would note however, that while this is a limitation, it is also a strength: the findings of the majority experimental studies do not survive transfer to real-world conditions (Kim, 2019) and what we have found is an impact in real-world conditions. A second limitation is that the number of women present in our study is relatively small, which means that we do not have enough power to find statistically significant differences. This is a function of the lower enrolment rates of women in our programmes: in fact we began with 660 participating students but once we controlled for prior study, gender, pedagogical differences and having repeated first year we were left with 24 women with a non-mathematical high school diploma. This highlights, once again, the challenges of doing real-world studies on gender and attainment in engineering education. Our study focused on the experience of women students. We are unable to say if this experience is shared by other under-represented groups, and thus this should be a focus of further research. A third limitation to be aware of is that gender differences in mathematics performance are not uniform across education systems and cultures, and so the findings from one place should not simply be applied in a different cultural context. A fourth limitation is that only one method of reducing time pressure in assessment (having fewer questions in the same time period) was studied here. There are other strategies for reducing time pressure, such as having more time and the same number of questions. These other strategies may also merit consideration.

5 CONCLUSION

Equity remains a persistent issue to be addressed in engineering education, including the retention of women students. Since, in many cultures and contexts, women come to engineering education with, on average, lower prior levels of mathematics education than men, one dimension of how we retain more women in engineering education is by ensuring that the impact of prior knowledge on their attainment in first year examinations in mathematics is minimised. In this study we sought to explore how we could adapt assessment to ensure more equitable outcomes for our diverse student intake.

Although time-limited assessments are a widely unquestioned part of the ritual of university mathematics, there is some evidence that these kinds of assessments can be unfair (Gernsbacher et al. 2020). There are also specific reasons for thinking that they might contribute to gender inequities in mathematical attainment (Caviola et al., 2019). Using a real-world pseudo-experiment, we explored the impact of time pressure on students' attainment in a first year Linear Algebra exam. We found that in a less time pressured condition, students with less prior mathematics can demonstrate the required linear algebra knowledge and skills while similar students in a more time pressured situation did not demonstrate the same learning. Students with a strong mathematical background do not benefit nor suffer from such a measure.

Creating assessments that allow those who had less mathematical experience in high school to show the mathematical knowledge and skills they have learned in university is, therefore, a potentially important contribution to improving women's retention in engineering education.

ABSTRACT

That inclusion is fundamental to sustainable engineering is reflected in the professional standards engineers work to, and the educational frameworks that underpin them. However, educational frameworks do not state how the skills, knowledge and aptitude related to inclusive engineering should be taught and assessed. For educators of engineers this poses the question, how can students learn about inclusivity and inclusive engineering, and what activities can be used to teach these? We asked the question: will a discipline specific inquiry based learning (IBL) group task to investigate inclusive engineering improve student's confidence, knowledge and understanding in relation to inclusion and inclusive engineering? To answer it, an inquiry based learning approach was used to develop an inclusive engineering workshop for undergraduate students to facilitate learning in a discipline relevant way. Survey results showed the workshop successfully improved student's knowledge, understanding and confidence in relation to inclusive engineering. Further use of a case study based IBL approach will allow for effective teaching and

provide a means of assessment of inclusive engineering across undergraduate curriculums in engineering.

1 INTRODUCTION

1.1 Professional Attributes for Engineers

Engineers are trained to solve problems using new or existing technology. It is widely acknowledged that to do so successfully engineering and technology must be developed in a sustainable manner, and inclusivity is fundamental to sustainable outcomes. Professional engineers are expected to work to standards that embody principles of sustainability and inclusion. Specifically, in the UK, these are provided by the UK Standard for Professional Engineering Competence (UK-SPEC) (Engineering Council 2020b).

UK-SPEC specifies that engineers should understand and take into account societal and cultural structures outside of their own, and actively contribute to the development of sustainable communities. It states they should minimise adverse sustainability impacts during the design stage of engineering solutions, they must be aware of the conflicting unmeasurable elements of sustainability, and be prepared to challenge the status quo that often is not inclusive. They must seek multiple opinions by proactively engaging with those who will be affected by engineering solutions and involve those who have not traditionally been considered during development and design stages. They must seek and value the perspective of others, and should utilise multi-disciplinary perspectives (Engineering Council 2024).

The values and commitments of UK-SPEC underpin the Accreditation of Higher Education Programmes (AHEP 4), the framework of Learning Objectives for engineering education. In the accreditation framework it is explicitly stated that students “Adopt an inclusive approach to engineering practice and recognise the responsibilities, benefits and importance of supporting equality, diversity and inclusion” (learning outcome C/M11) (Engineering Council 2020a) and it is a requirement that this is assessed. Similar values and standards are embodied by professional engineering bodies across the world (International Engineering Alliance 2021) or are implied with reference to sustainability (European Network for Accreditation of Engineering Education, 2022.), and are integral to the UN sustainable development goals (The United Nations 2015). What is not provided by these documents are guidance as to how the skills, knowledge and aptitude related to inclusion and diversity should be taught and assessed. For educators of engineers this poses the question, how can students learn about inclusivity and Inclusive Engineering, and what activities can we use to teach these?

1.2 Inclusion and Inclusive Engineering

In this work, inclusion is taken to mean the extent to which people feel valued for who they are (their personal and professional background, experience, and skills) and the extent to which people feel they belong or ‘fit’ in the engineering profession and their organisation (Royal Academy of Engineering 2023). Inclusive engineering is taken to align with the British Standards Institute definition of inclusive design as “the design of mainstream products and/or services that are accessible to, and usable by, people with the widest range of abilities within the widest range of situations without the need for special adaptation or design” (British Standards Institute 2005).

Issues related to inclusion are a persistent problem in engineering and higher education. For example, women have been under represented in the engineering profession (Walker 2001), and the problem persists, as illustrated by relatively low numbers of female engineering graduates in the US (National Center for Science and Engineering Statistics. 2021). In 2023, a 9.4% attainment gap was reported between black and minority ethic students compared to their white counterparts for first class or 2:1 degree classifications in Science, Engineering and Technology degrees in English and Welsh Higher Education Institutions (Advance HE 2023). Improving inclusion and diversity in those who study, teach and work in engineering has long been a priority for educators (Baillie et al. 2011; Borrego and Bernhard 2011). By explicitly introducing inclusive engineering teaching into the curriculum, it is likely the profile of inclusion will be elevated and it could become a topic of debate and discussion among more engineering educators.

In this work, inclusive engineering is used as a concept to aid students and teachers in the development of their knowledge and understanding of issues relating to inclusion. Inclusive engineering can best be understood through examples, and oftentimes, these are where engineering solutions have turned out to not be inclusive. For example, the use of pulse oximeters to measure saturated oxygen levels in blood. Pulse oximeters are convenient, non-invasive, medical devices that are placed on a patient's finger or ear lobe, however, the accuracy of the measurement is reduced in non-white patients. During the Covid-19 pandemic, this led to worse clinical outcomes for non-white patients infected with SARS-CoV 2 (Fawzy et al. 2022; Sudat et al. 2023). This is a high profile case study that is relatable to current students who have lived experience of the Covid-19 pandemic. Although it is easy to understand the problems with this case, it is complex and multi-faceted, making it a good to learn about, discuss and critique.

1.3 Inquiry Based Learning

In Inquiry Based Learning (IBL) the learner is guided through an activity in which they address an open ended question or problem. It is a learner centred approach that requires them to take responsibility for directing the learning and for the construction of new knowledge and understanding (Spronken-Smith and Walker 2010; Aditomo et al. 2013). By setting learners the challenge of addressing open questions and giving them agency in the questions they answer, learners are required to critique knowledge and information, and to reflect on how these intersect experience and context. This process fosters independent thinking, and through practice, self-belief and confidence in learners is improved (Levy et al. 2010). The educational attributes of IBL are well aligned with the training needs required for individuals to meet the professional requirements specified by the Engineering Council in relation to Sustainability (Engineering Council 2024). Given that there are conflicting unmeasurable elements of sustainability, and that feeling included and the sense of inclusion are subjective and personal, the person centred and open ended mode of IBL (Spronken-Smith 2012) is well suited for learning about inclusion and inclusive engineering.

In engineering inclusive design principles can be seamlessly integrated into teaching related to the design of a product or system, as highlighted by the case studies investigated in the Cambridge Inclusive Design Toolkit (University of Cambridge, 2017.). The use of case studies allows learners to develop a better understanding of how their theoretical disciplinary knowledge links to real world problems, and thus support learners to develop an identity and sense of place within their discipline. Use of case studies for teaching engineers are well established and exemplified in the high quality, structured tool kits available to support teaching of Engineering Ethics and Sustainability (Engineering Professors Council, 2024a; 2024b). Similar toolkits do not exist for inclusive engineering; we aim to provide structured educational activities that utilise case studies.

1.4 Research Question

In order to develop methods for teaching the skills, knowledge and aptitude related to inclusive engineering, we asked the question: Will a discipline specific inquiry based learning group task to investigate inclusive engineering improve student's confidence, knowledge and understanding in relation to inclusion and inclusive engineering?

2 METHODOLOGY

2.1 Participants

A cohort of Materials Science and Engineering (MSE) students from the Faculty of Engineering at the University of Sheffield took part in the case studies workshop developed in this work during the Autumn semester of 2023. These students were sitting their first semester of graduate level study and they undertook the workshop during a non-credit bearing 'Skills Week' during which they took classes related to study skills, professional skills and employability.

23 students took part in the workshop, 13 of whom completed the start and end survey and consented to be included in this study. These responses are the data that underlie the results of this work. The other students were excluded from the analysis because they did not provide consent to be included in this research, they did not complete the survey fully, or they have a timestamp that disqualifies the response they gave because they completed the start survey after the workshop.

2.2 Ethics Approval

This work was carried out following The University of Sheffield Good Research and Innovation Practices policy, with ethical approval obtained (application number 049730).

2.3 Development of case studies workshop

The workshop activity and session plan were developed over a couple of years by the lead researcher in collaboration with students. The proposed approach was reviewed and critiqued by MSE undergraduate students who were members of a Task and Finish group, during the 21-22 academic session. Case studies of inclusive engineering (Table 1) and the structure of a IBL workshop was developed based on the discussions and feedback from that group, and were finalised by an undergraduate project student employed by the Faculty of Engineering Diversity Confidence in Engineering (DiCE) project (University of Sheffield 2022).

Table 1: Case studies offered in the workshop

Name of Case Study	Keywords
Non-inclusive aeroplane seats	Design, Corporate Policy, Body Shape
Discriminatory car safety testing	Legislation, Safety Testing, Society, Body Shape
The case for inclusive hip implants	Materials, Medical Regulation, Corporate Governance
Discriminatory automatic soap dispenser	Design, Skin Colour, Testing and Calibration, Corporate Policy
Vaccine hesitancy and racism in healthcare	Vaccines, Racism, Healthcare, Clinical Trials
Facial recognition bias	Racial Bias, AI, Facial Recognition, Procedural Failure

The facilitated workshop (Figure 1) included an introductory talk, in which the reasons for the workshop and research were described, key terminology explained and ground rules set. Key terminology included definitions of terms used during the workshop, descriptions of professional attributes of engineers, and about the Equality Act 2010 (United Kingdom Legislation, 2015.), as well as the concept of inclusive engineering with supporting examples. The students were assigned to groups, each of which was given the task of choosing a case study. The groups were given time for discussion and debate, guided by the questions in a pro forma (Appendix 1). The questions asked them to consider the who, how when and wider implications of the case study, and the group was expected to complete the pro forma. Each group then presented their critique of the case study to the other groups, with the assistance of the facilitator, an academic in the MSE department.

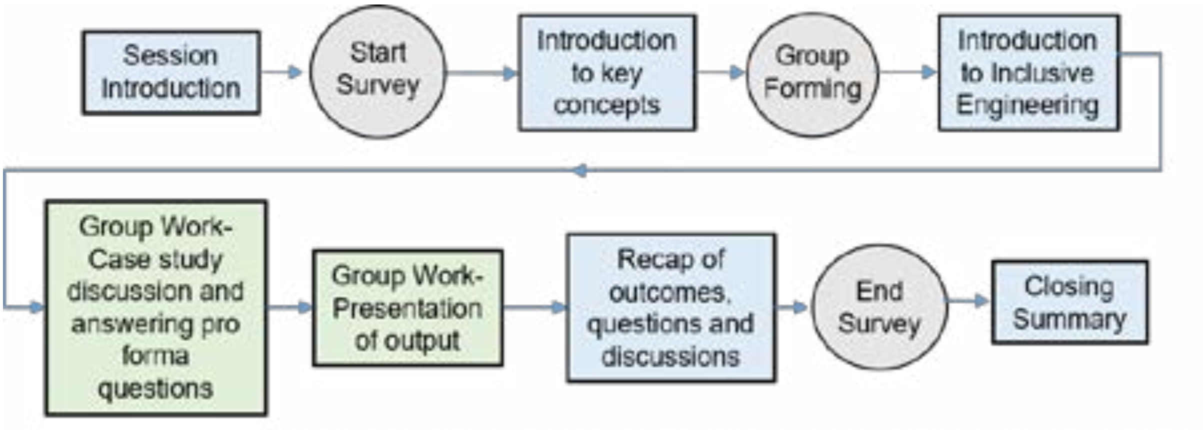

Figure 1: Inclusive engineering workshop structure. Background colour indicates different activity during the two hour long workshop. Blue: led by the facilitator; grey: activity or action; green: group work. The output of the group work was a completed collaborative Google Doc pro forma containing prompt questions completed by each group (Appendix 1).

2.4 Data collection, presentation and analysis

The students were surveyed using Google Forms at the beginning of the workshop, and again immediately after the workshop (Appendix 2). The form was designed to be quick and easy to complete to maximise the probability that participants would complete the survey. Informed consent was sought, and any student who declined consent in either of the surveys was excluded from the analysis. Numerical data collected from the survey was tabulated and analysed in GraphPad Prism (version 10.2.1). The survey included optional text responses. These were not systematically analysed due to the low number of responses but have been summarised in the Results section.

3 RESULTS

3.1 Quantitative outcome of the workshop

Comparison of the survey results before and after the workshop provided evidence that the workshop had a positive influence on student knowledge, understanding, confidence and opinions in relation to inclusive engineering.

When the students were asked to report their confidence in their Engineering (Figure 2A), Maths (Figure 2B) and Materials Science (Figure 2C) skills, there was no significant change in the numbers reported before and after the workshop. These questions were included to allow for comparison, given that there was no expectation that they would change because of the workshop.

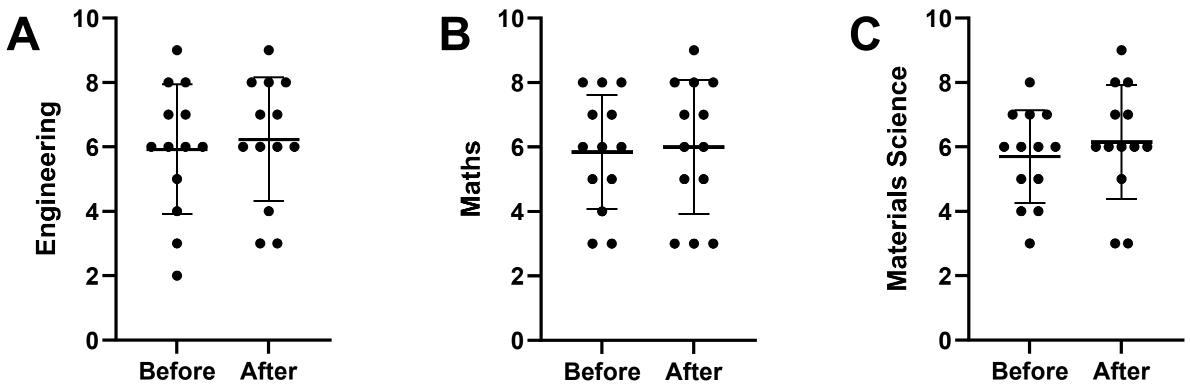

Figure 2: Self reported confidence in subject specifc skills. Students were asked to report their confidence of **A** Engineering, **B** Maths and **C** Materials Science skills before and after the workshop. Each point is an individual participant response, with the mean value and standard deviation indicated by lines and whiskers respectively. Two-tailed, paired t-tests performed for each question revealed no statistically significant differences, N=13 (A: p= 0.0395, t= 2.309, df= 12; B: p= 0.6130 t= 0.5193, df=12; C p= 0.1902 t= 1.389, df= 12).

When student scores were compared for attributes related to inclusive engineering, all measures increased (Figure 3). The largest change was in relation to student's reported knowledge of inclusive engineering which increased by an average of 1.8 (Figure 3A). The next largest change was in student's understanding of inclusive engineering (Figure 3B), which increased by an average of 1.4, followed by student's confidence to discuss inclusive engineering (Figure 3C) which increased by an average of 1. Student's opinion of how important inclusive engineering is (Figure 3D) increased by an average of 0.7.

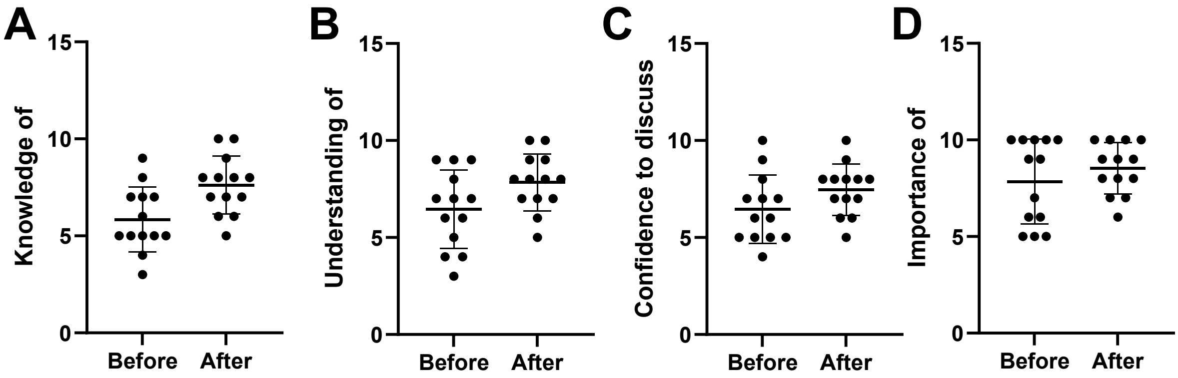

Figure 3: Self reported attributes in relation to inclusive engineering. Students were asked to report their **A** knowledge of inclusive engineering, **B** understanding of inclusive engineering, **C** confidence to discuss inclusive engineering, and **D** opinion of how important inclusive engineering was, before and after the workshop. Each point is an individual participant response, with the mean value and standard deviation indicated by lines and whiskers respectively. Two-tailed, paired t-tests performed for each question revealed statistically significant differences between the before and after responses for A-C with p values of <0.0001 (A, $t=6.299$, $df=12$), 0.0088 (B, $t=3.207$, $df=12$) and 0.0075 (C, $t=3.122$, $df=12$). There was no significant difference for (D, $p=0.1079$, $t=1.737$, $df=12$).

Despite the absolute low numbers of responses, the relatively high proportional number of completed responses (74%) is evidence that the survey design was effective for encouraging these. In future work using this survey method, an anonymised survey design, and other action or reassurance may encourage more students to consent to being included in the work. Repeating this work with bigger and different engineering disciplines would provide evidence of the wider applicability of the approach. Furthermore, the workshop could be carried out with cohorts that have differing proportions of home and overseas students, or studying at different levels to determine when inclusive engineering teaching is most impactful.

3.2 Qualitative feedback for the workshop

24 text responses were given, most of which were constructive. The salient points in response to question one were that two respondents liked the workshop, and four expressed a desire for inclusive engineering case studies to be embedded across the curriculum. One respondent indicated a desire for more ethnic diversity in professors.

When asked what was good about the workshop, five respondents gave reasons that they liked learning about the real world examples, and four that they liked discussion and the people in the workshop. These responses are further evidence of the strengths of using a case study IBL method, indicating that the students had to develop and discuss their ideas with others (Aditomo et al. 2013). To improve the workshop, one respondent desired more case studies, and another that they would like to develop case studies of their choosing, an idea that could be developed in future work.

It is important to consider these comments in context of the research design, because they were not anonymous, and the cohort was small. These factors may have resulted in respondents not wanting to give negative comments, and so the feedback here may not be fully representative. Regardless of these limitations, the comments provide useful insight and ideas for improving teaching of inclusive engineering. Specifically, by embedding it across the curriculum, which would ensure inclusive engineering is not regarded as secondary to theoretical or technical knowledge, although that approach would require teachers to develop skills, knowledge and understanding of inclusive engineering. Giving students the opportunity to develop their own case studies would allow for development of more skills and knowledge, as well as ownership of knowledge and an identity in the discipline, although would require more time and support for the learners.

An important consideration for using this approach is to ensure that students have the requisite skills to work inclusively in groups. Although it is related to inclusive engineering, inclusive group work, and the skills required to support this are a completely different topic, but should be acknowledged by the facilitator. This is particularly important where there might be a lack of diversity in the classroom, and where there is a danger that individuals might feel isolated or excessively burdened because they feel excluded by their group.

The workshop provides an activity and outputs that enable assessment of student skills, knowledge and understanding of inclusive engineering, although this was not manifest in this work. The inclusive engineering workshop was used to support learning in a separate group of 114 Automatic Control and Systems Engineering undergraduate students, prior to them performing a stakeholder analysis for a module in which they utilised the Engineering V- model (Walden and International Council on Systems Engineering 2023) to design and build a burglar alarm. The design process loosely followed the ‘Discover’ phase detailed in the Cambridge Inclusive Design Toolkit (University of Cambridge, 2017.), and the workshop helped students to consider an inclusive approach towards user and stakeholder requirements. In contrast to the assessment in previous years, inclusive engineering was evident in work submitted by the groups. Future work could investigate the link between the workshop and other activities to support student learning of inclusive engineering and assessment, by comparing submitted work between current and previous cohorts. This approach would identify the most impactful teaching to support learning of inclusive engineering.

3.3 Future developments

To build upon this work and to better integrate inclusive engineering into disciplinary curriculum, the ideas detailed here could be taken forward into new activities. The case study IBL approach is suitable for integration throughout the curriculum, and could be directly assessed, or used to support assessment of Learning Objectives. Supported learning tasks could be developed in which students make their own case studies, further helping them find their place and identity in their discipline. These approaches have the potential added benefit of being a vehicle for development of skills, knowledge and confidence in teaching staff, and would potentially improve awareness of and actions towards inclusivity in the academy (Liyanage 2020; Dale-Rivas 2019). The work also provides a template from which more extensive toolkits to support the learning of inclusive engineering could be developed, to compliment those that already exist (Engineering Professors Council, 2024a; 2024b).

4 SUMMARY AND ACKNOWLEDGEMENTS

We have demonstrated a successful educational intervention for teaching inclusive engineering, that gained positive written and verbal feedback from students who took part. The approach could be used to support assessment of Learning Objectives related to inclusion. Embedding inclusive engineering in disciplinary teaching requires development of new skills and knowledge by engineering specialists and a long term strategic approach. Practical and actionable teaching methods are a means to support this in engineering education.

We would like to acknowledge Professor Rachel Horn, Dr Matt Mears and Professor Stephen Beck for the generous and invaluable support and encouragement for the development of this work.

ABSTRACT

An intrinsic case study explores the personal and professional support provided to international science, technology, engineering, and math (STEM) postdoctoral scholars through postdoctoral offices at colleges and universities across the United States (US). Semi-structured interviews were conducted with 20 US postdoctoral office directors to explore this topic. Participant interviews were analyzed inductively and resulted in four themes: (1) Understaffed and underfunded; (2) Identification and communication challenges; (3) Social and professional development programming; and (4) Targeted support through specialized programs. The identified themes could be particularly instructive to US postdoctoral office directors and international faculty sending Ph.D. graduates to the US for postdoctoral training.

1 INTRODUCTION

1.1 Overview

In the United States (US), over half of the science, technology, engineering, and math (STEM) postdoctoral scholars are international (Camacho and Rhoads 2015). Colleges and universities that host international postdoctoral scholars are uniquely positioned to support international scholars personally and professionally during their employment tenure in the US. However, little information is known regarding the ways in which university postdoctoral offices support international STEM postdoctoral scholars. An intrinsic case study design is employed to explore interviews conducted with 20 US postdoctoral office directors inductively. The research question guiding this study is: What personal and professional support do US university postdoctoral offices offer international STEM postdoctoral scholars?

1.2 Literature Review

International STEM postdoctoral scholars comprise a substantial part of the US academic labor force, and their presence not only diversifies American academia but also furthers high-quality, world-class research (Cantwell and Taylor 2013). However, international postdoctoral scholars have identified challenges they face when working in the US, such as immigration concerns, strains to find a community, pressure to publish and secure funding, and inadequate career counseling (Mendez et al. 2023). In addition, international postdoctoral scholars often report negative postdoctoral scholar-advisor relationships, complicating their postdoctoral experiences (Burt 2019; Van Benthem et al. 2020). Also, US institutional resources, such as postdoctoral offices, have been criticized for lacking adequate funding and personnel (Gunapala 2014) despite research indicating that a successful postdoctoral experience depends on whether a scholar has been provided with appropriate resources and support (Burke et al. 2018).

US postdoctoral and international offices are designed to combat these challenges and to provide academic, career, and personal support to international postdoctoral scholars (Ferguson et al. 2017). The National Postdoctoral Association (2019) publishes best practices for US postdoctoral offices, which includes offices providing an orientation to welcome new postdoctoral scholars; issuing a postdoctoral handbook outlining institutional benefits, policies, and opportunities; and providing career counseling and other professional development opportunities. However, research indicates a lack of universal orientation programs to help prepare postdoctoral scholars for their work responsibilities (Burke et al. 2019; Cutright et al. 2018). Moreover, few international postdoctoral scholars report familiarity or awareness of available resources (Ferguson et al. 2017). Thus, the extent to which these best practices are implemented is unclear, so more research on the personal and professional support available to international postdoctoral scholars in the US must be investigated.

2 METHODOLOGY

2.1 Research Design

An intrinsic case study (Stake 1995) was implemented to explore the personal and professional support provided to STEM international postdoctoral scholars by US college and university postdoctoral offices. Intrinsic case studies are valuable when seeking to provide insight into a particular issue in which the case is secondary. Interviews with 20 US postdoctoral office directors were analyzed inductively (Silverman 2019). The research question guiding this study was: What personal and professional support do US university postdoctoral offices offer international STEM postdoctoral scholars?

2.2 Participants

A diverse group of 20 postdoctoral office directors from public and private colleges and universities across the US was recruited via email. Most directors were in part-time positions, and some held dual faculty roles. The number of postdoctoral scholars working at the colleges and universities included in this study ranged from 400 to 1000. Nearly half of the postdoctoral scholars were categorized as international, and almost all of the international postdoctoral scholars were in STEM fields.

2.3 Data Collection

Following Institutional Review Board approval, all participants were provided with a consent form detailing the purpose of the study, interview procedures, and safeguards in place to protect their privacy and confidentiality. A semi-structured interview protocol was created to examine the personal and professional support offered to international postdoctoral offices by US postdoctoral offices and the extent to which they implemented best practices identified by the National Postdoctoral Association (2019). Open-ended probing questions were included so the researchers could seek clarification and meaning during the interview. Interviews averaged 60 minutes in length. All participants were given pseudonyms, and only de-identified interview transcripts were stored. Participation was incentivized with a $50 e-gift card.

2.4 Reflexivity and Positionality

Throughout the study, the research team engaged in individual and collective reflexivity by reflecting upon, bracketing out, and dialoguing about experiences and beliefs concerning the ways in which US colleges and universities support international STEM postdoctoral scholars. In qualitative research, reflexivity is a crucial component of inquiry, positioning researchers to consider their bias and its potential impact on meaning-making and interpretations during data analysis. Additionally, researchers must disclose their positionality so readers know the unique perspectives they bring to the study (Lincoln and Guba 1985). The research team comprised social science American women trained in qualitative research methods within educational settings. Two are professors, and the other is a doctoral student who is an international student. All are engaged in STEM education research, particularly in efforts to diversify the engineering professoriate and broaden success in academia. This study was approached as a matter of social justice; therefore, empathy and humility were integral to the data collection and analysis processes.

2.5 Data Analysis

Inductive thematic content analysis techniques (Silverman 2019) were employed to explore the personal and professional support provided to international STEM postdoctoral scholars by US postdoctoral offices. The transcripts were coded individually through three review rounds, leading to 25 unique codes. Next, the researchers collectively cross-referenced the codes and identified five initial themes through consensus. Following consensus-building, the themes were refined for parsimony and to ensure the themes captured the entirety of the data and could be applied broadly. This refinement led to four final themes: (1) Understaffed and underfunded; (2) Identification and communication challenges; (3) Social and professional development programming; and (4) Targeted support through specialized programs. Multiple verification strategies ensured the results were trustworthy by attending to credibility, transferability, dependability, and confirmability (Lincoln and Guba 1985). This occurred by including participant direct quotes, the researchers engaging in reflexivity and positionality, and involving multiple feedback loops in the data analysis process.

2.6 Limitations

As in all research inquiries, this study has several limitations. First, the researchers did not conduct member checks because arranging and conducting interviews was difficult due to participants' demanding schedules. Member checking might have provided more complex and nuanced depictions of their challenges. However, theoretical saturation was achieved by the sixth interview, so these results appear to adequately represent the viewpoints of postdoctoral office directors at large. This study attended to researcher bias through reflexivity and positionality, its potential to influence the results and interpretations cannot be guaranteed. Last, this inquiry is primarily approached from an outsider's vantage point, as none of the researchers hold a STEM academic background, but one has served as a postdoctoral scholar, and another holds an international student demographic.

3 RESULTS

3.1 Understaffed and Underfunded

All postdoctoral office directors shared that they lack the adequate personnel, resources, or financial means to support their international postdoctoral scholars. As Becca described, she has an "absurdly small budget," which limits her ability to provide the personal and professional support she desires and knows would benefit the international STEM postdoctoral scholars at her institution. Furthermore, they are often the only person managing the postdoctoral office for hundreds of postdoctoral scholars. With this personnel structure, the directors felt they were doing all they could but could not possibly reach nor help all postdoctoral scholars with such limited resources. Many of the postdoctoral office directors collaborate with others in their state or surrounding areas, such as the "Big 10" universities in the Midwest, to create postdoctoral coalitions that provide more professional development opportunities, advertise faculty and research positions, and offer connections for postdoctoral scholars across institutions.

3.2 Identification and Communication Challenges

All the participants stressed the importance of international STEM postdoctoral scholars finding connections and community within the university to ensure they were satisfied and productive in their positions. However, all expressed difficulty in identifying postdoctoral scholars at their institutions. As Travis said, "Defining what even constitutes a postdoc is a fraught question." Across US colleges and universities, there is no solid definition of a postdoctoral scholar, as it depends on the funding of their position, their research and teaching role, and their employment status. Some are classified as staff, some as faculty, and some as visiting professors. Therefore, it can be difficult for postdoctoral offices to identify and communicate with all the postdoctoral scholars employed at their institutions.

Most directors depend on their Human Resources departments to identify postdoctoral scholars, and then they reach out via email to welcome and connect with them. Some institutions offer a postdoctoral orientation, usually a virtual meeting; however, many depend on the "new hire" orientations provided by Human Resources due to their lack of funding and resources. Most postdoctoral offices post handbooks on their websites and send regular newsletters and emails with information regarding professional development offerings, grant opportunities, social events, and other university news. However, as Allison said, "It's passive," meaning they are not actively recruiting postdoctoral scholars to participate in these opportunities but rather providing information for consumption. If the postdoctoral scholars do not respond, they cannot connect with them. Furthermore, as Jessie expressed, "How can I know if I'm capturing everybody?"

3.3 Social and Professional Development Programming

All the postdoctoral office directors highlighted the importance of offering social and professional development programming for the international STEM postdoctoral scholars at their institutions. Because their resources are limited, almost all rely on postdoctoral associations to facilitate social events, such as monthly coffee hours; "field trips" to museums, art galleries, and local attractions; and international potlucks, where postdoctoral scholars bring food from their home country to share. The directors also indicated they partner with their institutional international office to ensure international postdoctoral scholars receive visa and immigration guidance, as well as language and cultural services. Also, many postdoctoral offices provide professional development opportunities with topics ranging from effective lab practices, finding funding, career preparation, enhancing professional communication skills, and health and wellness tips. Many of these professional development opportunities are also connected with the graduate school at their institutions, but some work with the National Postdoctoral Association or the National Institute of Health for programming. Many directors said they offer one-on-one career counseling and job material support to international postdoctoral scholars, but they do not publicize this service because they are understaffed. Thus, "word of mouth" often spreads this specific support activity.

3.4 Targeted Support through Specialized Programs

Some universities created unique grant-funded programs for postdoctoral scholars interested in entering the professoriate job market. These programs offer targeted personal and professional support, but only a handful of scholars participate in these programs, and only some are available to international postdoctoral scholars, as most are designed for minoritized US citizen populations. In these programs, postdoctoral scholars are provided mentoring, training, and coaching throughout their experience. As Tim described, the purpose is to diversify the professoriate, train excellent future faculty members, and "support the research scholarship and creative works as a larger intellectual community." The programs intentionally provide individualized support, so postdoctoral scholars can identify and meet their specific career goals, such as securing grant funding for their research or improving their instruction. Since these programs are grant-funded, there is limited funding to support the number of participants interested in these specialized programs. Directors indicated that these programs have successfully supported postdoctoral scholars in securing tenure-track positions at their institutions and beyond.

4 DISCUSSION AND CONCLUSION

4.1 Discussion

This intrinsic case study aimed to explore the personal and professional support provided to international STEM postdoctoral scholars by US postdoctoral offices. The participants in this study indicated that they are aware of the support, resources, and activities they want to provide, such as targeted professional development, community, and connection points, but their limited personnel and financial resources are a constraint. Furthermore, the difficulty in even identifying the postdoctoral scholars working at their institutions limits their ability to make initial contact and build relationships. All the directors indicated that they are doing what they can with their allotted resources, and they all communicate regularly with postdoctoral scholars via email and website postings.

Due to limited resources, they must rely on their postdoctoral association, the institutional international office, graduate school programming, and external opportunities to provide personal and professional support. As Allison described, international postdoctoral scholars "just need a sherpa…someone to help them navigate…and plug them into all the resources." However, as one director described, there is a severe lack of guidance and support for postdoctoral scholars when only a "skeleton crew" is in place. Specialized postdoctoral programming that provides personalized and targeted mentoring and coaching is successful, but it is impossible to scale without adequate funding. With more financial and personnel resources, US postdoctoral offices would be better positioned to support their international STEM postdoctoral scholars, but until greater advocacy for this large part of the academic workforce is more prevalent, support is unlikely to increase.

4.2 Implications

Implications abound for US postdoctoral office directors and international faculty sending Ph.D. graduates to the US for postdoctoral training. It is evident that postdoctoral office directors want to provide more support to their scholars; however, they are constrained by a lack of resources and personnel. The US depends on international postdoctoral scholars to diversify the academic workforce, produce world-class research, and staff universities and colleges nationwide, but their personal and professional needs are often going unmet. Every office director interviewed stressed the need for more financial and personnel resources to reach more scholars. For international postdoctoral scholars to have their personal and professional needs met, they must self-identify and advocate for themselves, which is an unfortunate undertaking for individuals to take on in the bureaucracy of American higher education.

4.3 Future Research

Future exploration is warranted to understand whether these personal and professional supports and connected challenges in offering them are unique to international STEM postdoctoral scholars or indicative of larger postdoctoral training trends. In order to do so, additional interviews with postdoctoral scholars, both international and domestic, could be administered to broaden and strengthen the results and implications of this study.

4.4 Conclusion

This intrinsic case study provides a deeper understanding of the personal and professional support international STEM postdoctoral scholars are provided by US postdoctoral offices. Data analysis of the interviews resulted in four main themes: (1) Understaffed and underfunded; (2) Identification and communication challenges; (3) Social and professional development programming; and (4) Targeted support through specialized programs. It is clear that more intentional support for international STEM postdoctoral scholars is needed, but this will only occur if more resources are directed to this large population within the academic workforce. This is an investment that is necessary if the US is going to support the careers of these scholars and advance diversity, equity, and inclusion in US academia.

ABSTRACT

Microcredentials (MCs) are gaining increasing interest in continuing education and life-long learning in higher education institutions. MCs are often used within informal

[1] *H.K. Väätäjä*
heli.vaataja@lapinamk.fi

learning context and are related to microlearning entities, but they can also be used within formal learning and when delivering degrees. Our goal was to develop an approach and model for micro-learning and DCs to be piloted in two 5 ECTS continuing education MOOCs. We aimed at supporting student engagement by a gamified approach to motivate learners, and to give feedback on the competence development as well as to show the gained competences. We developed an initial stackable three-level framework for DCs, starting from nanocredentials related to microlearning entities, and ending at highest level with metacredentials for successful course completion. We describe the designed framework and its connection to pilot course design and implementation. The number of applications for the open digital badges was relatively high (60-70%) for both the nanocredentials and the metacredentials. The results of an online questionnaire after the pilot show that most of the students that responded (N = 36) reported that the used assessment method for the competences related to micro-credentials gave feedback on their learning, DCs showed development of their skills and competences, and getting a DC was found to be motivating and encouraging. However, about one fifth of the respondents saw no value in DCs. Further studies are needed to understand the factors affecting the perceived value of DCs, and to develop and test DC models in CEE.

1 INTRODUCTION

1.1 Background

Microcredentials are gaining increasing interest in continuing education and lifelong learning in higher education institutions (Ahsan et al. 2023, Smith and Kalman, 2023). They can be used for separate microlearning entities, or more recently, integrated to be part of course offerings (Brauer, 2020). In the latter case, microcredentials can be used as a means for gamification as well as for acknowledging the assessed skills and competences in the learning process, for example (ibid.). Microcredentials, and digital credentials generally, are typically issued electronically as digital open badges (DOBs) to identify and promote excellence and mastery of competences (Abramovich, Schunn and Higashi 2013). DOBs include detailed knowledge, competence, and expertise criteria as well as a description of the evidence like assessments (Brauer, 2020; European Commission, 2020).

Designing and implementing digital credentials in higher education calls for pedagogical design, which takes into account the specifics related to microlearning and credentialing in the course design and implementation. There is no consensus on what size, volume and depth microlearning actually has, meaning that the amount of time used for learning and showing the competences, and therefore gaining the microcredentials may vary (Varadajanan et al. 2023). Besides MC being a micro-unit, it can also be a sub-unit of a credential or qualification (European Commission, 2020). Therefore, when planning the use of MCs, it is important to consider what are the motivations and goals of implementing microlearning and microcredentials, how they are connected to course, program or degree components, learning objectives and competences, as well as to other credentials and qualifications provided.

1.2 Prior research on learner interest and value for digital credentials in HE

One of the important motivations for developing microlearning approaches in Higher Education (HE) is to supplement traditional degree programmes (Varadajanan et al. 2023). Learners are interested in short, practical, and up-to-date courses to support their career paths (ibid.). Similarly to findings by Varadajanan et al. (2023), Kiiskilä et al. (2023) report based on 19 learner interviews that learners place utility value in short and long term to digital credentials in job searching, for example. Furthermore, the clear description of the skills and competences associated with the digital credentials was appreciated and described to help in credit transfer to a different institution (Kiiskilä et al., 2023). In addition, learners expressed enjoyment and interest in digital credentials, as expression of their intrinsic value (ibid.). The factors that weakened the value of digital credentials for learners were related to the low number of available digital credentials at the institution at the time of the study, as well as the low awareness of them by industry (ibid.).

2 DEVELOPMENT OF THE MICROLEARNING MODEL AND FRAMEWORK FOR DIGITAL CREDENTIALS

2.1 Goals of the development

Our goal was to develop, implement, and trial a model for microlearning and a framework for digital credentials in two master's level (EQF-7) continuing education MOOC courses. Our specific interest was to study, how students participating in the two pilot MOOC courses perceive DCs as part of the course implementations, and whether adult learners who are upskilling or reskilling themselves will find them interesting and motivating. Furthermore, one of the identified challenges in MOOCs is the high drop-out rate of students and therefore the low percentage of those who complete the courses (Semenova, 2022). We were therefore interested, whether we could develop a model for HE with microlearning content and a stacked framework for DCs that could engage students with smaller learning entities as an alternative to taking a 5 ECTS course.

2.2 Modular structure for MOOC courses

We designed the two pilot MOOC courses as follows. First, we identified the skills and competences relevant for working life to define the learning objectives for each work-life related course. We then used our prior knowledge on students' preferences for developing the MOOC implementation as self-paced individual learning, but including also some asynchronous social learning activities. To create a modular structure for the five (5) ECTS courses, we identified five main themes related to learning goals that we grouped to form the skill and competence goals for the two five (5) ECTS courses, aiming for five one (1) ECTS sized thematic units within each course (Fig. 1).

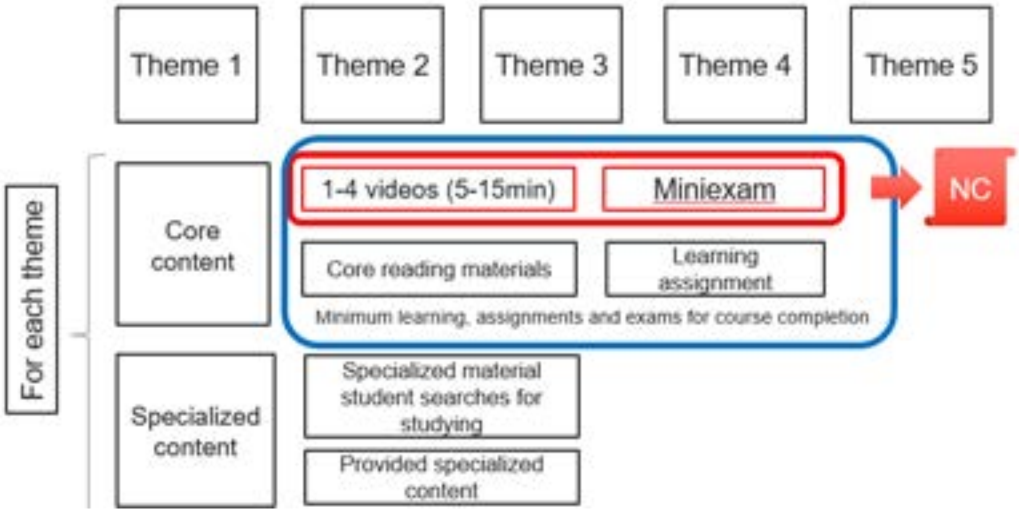

Fig. 1. Modular structure for a designed course with nano-credential (NC) application for successfully completing a microlearning entity.

For each of the five themes we created a modular structure, with short videos as core content, related mini exams that were automatically graded, as well as additional core reading materials and a larger learning assignment that was evaluated by the course instructors. In addition, specialized content was provided and/or searched by the student related to the theme that could be also used in doing the learning assignment. Application for a nanocredential (open digital badge) was possible with a successful mini-exam passing with at least 80% score of maximum points. The application for the DOB opened automatically for only those students that passed the minimum acceptance level for the mini-exam with a maximum of two attempts for passing.

2.3 Designing the initial framework for digital credentials

Designing the initial framework for the digital credentials was based on the following goals. We aimed to create a structure that supported the stacking of the credentials from thematic microlearning unit related nanocredentials (approximately 0.5-2 hours) to microcredentials equivalent to 1 ECTS. In addition, we aimed at creating course level metacredentials equivalent to 5 ECTS. In Finland, microcredentials are aimed to be used for 1-59 ECTS (Digivisio, 2022). Nanocredential is therefore suitable as a concept to be used for smaller microlearning related digital credential. We use here the notion of “metacredential” for the course level digital credential to differentiate between the levels and to clearly distinguish the three levels to nano-, micro- and metacredentials based on the amount of study time used on each level. The planned three levels of digital credentials are presented in Figure 2. In the pilot study, we focused on implementing and piloting levels 1 and 3 to test the idea and implementation, and to gain knowledge and experiences on the use, usefulness, and perceptions and preferences of students.

Fig. 2. Initial framework for digital credential levels.

Next, we present the pilot study, within which the digital credentials were available for the students to be applied for after successful completion of the thematic microlearning units and the completion of the courses. We report the findings on student interest based on the applications for the credentials in comparison to course completion statistics. This data is complemented by an online questionnaire covering the perceptions of students on microlearning, in terms of mini-exams used for competence development assessment, and related digital credentials.

3 METHODOLOGY

3.1 Participants of the pilot MOOCs

Altogether 100 students enrolled to the two pilot MOOC courses that were organized as open continuing education offering, and marketed in social media as well as on university web pages. Most of the students were enrolled to both courses, but some took part only to either of them. 57 students completed the first MOOC, and 46 students completed the second MOOC. MOOCs were open for anyone to enrol with no participation fee, as the MOOCs were developed and piloted within an educational project funded by an external funder. There were no entry requirements, including no requirements for prior knowledge on the course topics.

3.2 Implementation of the Open Badges in pilot MOOCs

The two pilot MOOC courses were implemented in Moodle learning management system. The digital credentials were offered as open digital badges through Open Badge Passport platform (https://openbadgepassport.com/). The digital badges created in the Open Badge Factory (https://openbadgefactory.com/en/) by the course instructors included the information on the name of the badge, issuing organization, date of issuing, name of the person the badge is issued to, short description of the skills and competences, the criteria for receiving the badge, including the learning objectives and how the skills have been demonstrated. Both Open Badge Factory and Open Badge Passport are certified to the Open Badges v2.0 standard.

The students could apply for the open badges as follows (see also Figure 1). The microlearning unit included watching short video(s) and passing a mini-exam related to the video content with a minimum of 80% correct answers. The mini-exam could be taken twice, but with a minimum of one hour between the first and second attempt. After successfully completing the mini-exam, the learner was opened a new section in Moodle, from which he/she could apply for the nanocredential. The learner could apply for the open badge issued for the nanocredential in question from Open Badge Passport. The issuing was done automatically based on the passed mini-exam. The learner then received an email on the issuing of the badge to his/her registered email address for the Open Badge Passport. Students, who had completed either of the courses, were also offered by an email an opportunity to apply for a metacredential for the course in question. The email included a link to the application form in Open Badge Passport.

3.3 Online questionnaire and respondents

We conducted an online questionnaire after the two pilot courses had ended. Questionnaire was implemented with Webropol survey tool and answering to it was voluntary. The link to the students was sent via an email in November 2023. The questionnaire included questions on student background, such as age, gender, and educational level.

There were 36 respondents to the questionnaire. 78% of the respondents were female, which may be due to fact that the courses were related to knowledge management in technology sector. The average age of the respondents was 46 years (min = 32, max 62). 94% of the respondents had a degree from tertiary education. All of the respondents expressed that they participated the courses to gain competences to be applied in work life. Only 6% of the respondents wanted to include the completed courses to their ongoing higher education studies, indicating that most of the respondents were adult learners in continuing education.

4 RESULTS

4.1 Interest towards digital credentials

First, we report the interest of students towards the nanocredentials for microlearning units and metacredentials issued for the whole course completion with a passed grade (see Table 1). We use as an indicator for the interest the number of applications compared to the number of course completions. In the first MOOC (MOOC1), the interest towards digital open badges decreased from slightly from 70% to about 60% for the nanocredentials after the first thematic microlearning unit with a nanocredential. However, the metacredential issued after the course for the 5 ECTS MOOC 1 completion increased again the number of applications to about 68% of the students who completed MOOC 1. For MOOC 2 the interest towards nanocredentials was about on the same level as for MOOC 1. The interest towards the metacredential for MOOC 2 course completion slightly decreased compared to MOOC 1. 60% of the students, who passed MOOC 2, applied for the metacredential.

Table 1. Number of students who applied for open badges based on completing successfully nano-credential sized microlearning units and course completion related meta-credentials.

Course	No. students, who passed MOOC	NC-1	NC-2	NC-3	NC-4	NC-5	meta-cred.
MOOC 1	57	40	34	35	34	34	39
MOOC 2	46	33	29	28	28	27	28

4.2 Student perceptions on digital credentials and mini-exams

In the online questionnaire we asked the respondents to rate their agreement on the following two topics: seven (7) questions on digital credentials and five (5) questions on mini-exams (see Table 2). Questions were formulated as statements, and respondents were asked to rate their agreement with a 6-point Likert scale (1 = strongly disagree, 6 = strongly agree). Table 2 shows the statements, with white cell background for statements related to digital credentials, and with grey cell background for mini-exam related statements. Besides the descriptive statistics, Table 2 also presents the percentages for scale values 1-6. For discussing the results, we discuss also sums of percentages for perceptions for agreeing (scale values 4-6), and with disagreeing (scale values 1-3) with the statements.

Over half of the respondents agreed with statements on the value of digital credentials perceiving them as encouraging and motivating as previous research suggests (statements 3, 5, 9). Digital credentials were perceived by over half of the respondents as showing increase of own competence, as well as generally showing the competence gained (statements 2, 4). In addition, getting a metacredential for the course completion was perceived as meaningful by over half of the respondents (statement 6). Over half of the respondents disagreed, that they were not interested in the digital credentials (statement 6). It should be noted that the agreement (disagreement for statement 7) varied between 58-72% depending on the statement. However, the results also show, that digital credentials divide opinions among the respondents. 17-25% of the respondents do not see value in digital credentials by completely disagreeing with the value statements 2-6 and 9, and completely agreeing with statement 7. Results are on one hand encouraging in terms of taking the digital credentials into use in HE, and even within master's level (EQF-7) MOOCs. This also encourages to develop and test options for micro-learning with digital credentialing in both degree and open learning in addition to their use in MOOC courses. One the other hand, as opinions are clearly divided on the value of digital credentials, further studies are needed to identify the appropriate application contexts and models for digital credentialing, and what factors affect the perceived value of digital credentials.

Passing a mini-exam was the prerequisite for applying for a related nanocredential. Mini-exams were felt to give feedback on own learning (78%, statement 1), testing own knowledge on the basics of a theme (78%, statement 11), as well as were perceived as meaningful on the basics of a theme (81%, statement 10). Over half of the respondents agreed, that the requirement level of the mini-exams was suitable (69%, statement 8). On the contrary, over half of the respondents agreed that the mini-exams were too easy (58%, statement 12). This clearly raises a development need for the future implementations – what is the suitable requirement level for a mini-exam and how to design the micro-learning entities with nanocredentials overall from the learning objectives to the ways of assessment and assessment criteria. On the other hand, the engagingness and motivational value of digital credentials, especially regarding nanocredentials, needs to be carefully considered.

Table 2. Perceptions on value of digital credentials and related mini-exams on 6-point Likert scale (1 = strongly disagree, 6 = strongly agree; N = 36). Statements with white background are on digital credentials, and with grey background on mini-exams.

	Mdn	min	max	1	2	3	4	5	6

1.Mini-exams give me feedback on my learning.	5	1	6	6%	8%	8%	20%	22%	36%
2.Digital credential shows increase of my competence.	4.5	1	6	17%	5%	14%	14%	22%	28%
3.Getting a digital credential encourages to continue learning.	4	1	6	17%	14%	11%	11%	22%	25%
4.Digital credential shows the competence I have gained.	4	1	6	22%	3%	17%	11%	28%	19%
5.Getting a digital credential is motivating.	4	1	6	22%	9%	8%	14%	25%	22%
6.Getting a digital credential for completing the course is meaningful to me.	4	1	6	25%	8%	8%	20%	8%	31%
7.I am not at all interested in the digital credentials.	2	1	6	28%	25%	5%	14%	11%	17%
8.Mini-exam to show the competence gained related to the basics of a theme was at a suitable requirement level.	4	1	6	6%	8%	17%	22%	33%	14%
9.Meta-credential given for the course completion is encouraging.	4	1	6	17%	8%	3%	25%	22%	25%
10.Mini-exam on the basics of a theme is meaningful.	5	1	6	11%	3%	5%	22%	31%	28%
11.Mini-exam tests my knowledge on the basics of a theme.	5	1	6	11%	3%	8%	22%	25%	31%
12.Mini-exam was too easy.	4	1	6	8%	14%	20%	31%	8%	19%

5 SUMMARY

We developed and tested an initial framework for digital credentials to be used within MOOC course implementations at a HEI. We aimed at a modular course structure within which the successful completion of thematic microlearning entities would result in nanocredentials that could be stacked to equal a microcredential, e.g., equivalent to a 1 ECTS entity. We also included an option for students to apply for a meta-credential on successful completion of the 5 ECTS course. The number of applications for open badges showed that students were interested in the badges both on the implemented nano- and metacredential levels. The results of the online questionnaire confirmed the interest. Furthermore, most questionnaire respondents found getting the digital credentials as open badges motivating and encouraging, and showing their competence. However, opinions were divided, and about one fifth of the respondents reported to see no value in digital credentials. The mini-exams were felt to be meaningful, give feedback on own learning, and testing basic knowledge on the theme, but they were perceived to be too easy.

The results indicate that including microlearning components with nanocredentials to a MOOC course is a promising approach in continuing education and life-long learning worth further development, testing, and studying, also to better understand the factors that affect the perceived value of digital credentials. Furthermore, microlearning seems to offer future potential as HEI offering. Microlearning units can, for example, be offered separately or as small entities to support adult learners own learning goals and objectives in up- and reskilling for new work-life competencies. The modularity in designing the course implementations in connection with microlearning and digital credentials offers an opportunity to increase the effectiveness and engagingness of providing different types of learner groups offerings that suit their needs.

ACKNOWLEDGEMENTS

This research and development has been conducted in “Tiedolla johtamisen osaajakoulutuksella tuottavuutta työelämään” project, funded by the European Union's Recovery and Resilience Facility (RRF), which is the key instrument of the EU's Recovery Facility (NextGenerationEU). The financing has been granted by the Service Centre for Continuous Learning and Employment. The Service Centre promotes the competence development of working-age people and the availability of skilled labour. The operations of the Service Centre are overseen by the Ministry of Education and Culture and the Ministry of Economic Affairs and Employment.

ABSTRACT

The workplace demands continuous learning to keep up with technological advancements and evolving labour market requirements, emphasizing the importance of lifelong learning (LLL) competencies for engineers. Preparing engineering students for their future career and for LLL is the responsibility of the engineering programmes. To support this, the TRAINengPDP project developed pilot interventions focusing on LLL while using a cyclical personal development process (PDP) based on literature reviews, a perception survey, and an analysis of learning outcomes in engineering programmes. Three diverse interventions were implemented, namely an e-portfolio, a self & peer assessment, and digital storytelling, with each intervention strategically emphasizing different LLL competencies and PDP steps. Student experiences were collected after the pilots using quantitative and qualitative feedback measures. While the e-portfolio fostered pragmatic quality, students desired less time-intensive reflection tasks. Peer & self-assessment interventions prompted behavioural changes and enhanced awareness. Digital storytelling interventions heightened awareness, understanding, and agency among participants. Finally, students' definitions of LLL post-intervention highlighted aspects of lifelong learning, including motivation. Challenges and adaptations for each intervention were identified, underscoring the importance of contextual understanding in implementation. Overall, the interventions showed promise in cultivating LLL competencies, with implications for engineering education's longitudinal integration of LLL and PDP across curricula.

1 INTRODUCTION

Today's workplace is characterized by continuous technological advancements and shifting requirements in the labour market, increasing the need for lifelong learning (LLL) competencies for engineers. By focusing on LLL in the curriculum, engineering students are made aware of the importance of LLL competencies, preparing them for their future as an engineer in the working field (Galanis et al. 2017; Sankaran and Rath 2021). LLL is, however, considered to be a container concept, consisting of a variety of competencies. In their systematic review, Cruz et al. (2019) lists the most frequently used criteria for LLL competencies in engineering: (1) self-reflection, (2) willingness, motivation and curiosity to learn, (3) self-monitoring, (4) locating and scrutinizing information, and (5) creating a learning plan. Lifelong learning is in this review defined as "the intentional and active personal and professional learning that should take place in all stages of life and in various contexts with the aim of improving knowledge, skills and attitudes" (Cruz et al., 2019, p.737).

Although there is clear agreement about the need for LLL and LLL competencies, a previous study showed that LLL competencies are currently not really embedded in the learning outcomes (Beagon et al., 2022, Dujardin et al., 2023). Self-reflection, Willingness, Motivation and Curiosity to learn, and Creating a Learning Plan were the least represented in the learning outcomes of the reviewed engineering programmes and are therefore the priority competencies to be developed. In addition, the presence of LLL competencies is mostly limited to the first and final year of the engineering study programme. Hence, there is value in developing separate pilot projects at Bachelor and Master level as the focus of competence development changes significantly within each programme.

Since learning outcomes are not always a perfect representation of what goes on in the lecture hall and in the minds of students (Armstrong and Niewoehner 2008; Maher 2004; Orón Semper and Blasco 2018), a survey to capture engineering students' and lecturers' perceptions about LLL competencies was distributed (Authors 2023). The results of the survey indicate that both students and lecturers find all the different competencies either important or very important. Additionally, the results show that students and lecturers perceived these LLL competencies only taught to a limited extent and evaluated even less (Van den Broeck et al., 2023). When asked about the educational practices in the context of LLL, lecturers believe that (1) Creating an inclusive, safe, and curious environment, (2) Reflective practice, and (3) Self-regulation tools will become crucial in the future. These practices are, therefore, included in the case studies of the current paper.

But how to support the development of students' LLL competencies? A scoping review distinguished four types of LLL interventions (Van den Broeck et al., 2022), namely (1) interventions focusing on self-regulation like (e)Portfolios, (2) reflective journals or reflective practice, (3) student-centred teaching methods like problem-based learning, and (4) the use of peer and self-assessment. Another approach is the use of personal development process as a method to stimulate LLL. The Personal Development Process (PDP) is a more dynamic and interactive adaptation of the popular Personal Development Plan. The latter is a tool in which students give an overview of the competencies they have been working on (looking back) and is planning to further develop (looking forward). Patel et al. (2013) distinguish five steps in this plan: Identify, prepare, act, monitor, and reflect. These five steps can be mapped on Zimmerman's (2000) cyclical self-regulation model: identify and prepare (forethought); act and monitor (performance/volitional control) and reflect (self-reflection). When reviewing the literature on PDP interventions (Van den Broeck et al., 2022), five PDP intervention types are described in the literature: (1) e-portfolios, (2) reflective writing, (3) digital storytelling, (4) progress file interviews – tutor or role play and (5) online resources about PDP. PDP and LLL interventions show considerable overlap, which was expected considering the theoretical overlap between the two concepts. Both literature reviews distinguished interventions with a focus on self-regulation such as e-portfolios and on self-reflection such as reflective journals. LLL interventions can also entail student-centred teaching methods and peer and self-assessment, which were not found in the literature on PDP interventions.

During the TRAINengPDP project, three pilot interventions were developed, implemented, and evaluated. The current paper focuses on (1) how the interventions were designed, specific attention is given to clearly reporting about the characteristics of the interventions, which are often neglected in papers, (2) students' experiences with the intervention, and (3) students' perception on LLL after the intervention. Effectiveness measurements and lecturer feedback are not covered in this current study, but will be analysed in the next phase of the project.

2 METHODOLOGY

The methodology part consists of a section to elaborate on the different intervention designs. A second section provides more information about how students' experiences with the interventions were captured and the final section describes how students' perception on LLL was analysed.

2.1 Intervention design

Based on the analysis of learning outcomes, survey results, and literature review, three pilot interventions for the different institutions were designed. Table 1 provides an overview of the different pilot characteristics and Table 2 gives a more detailed description of how the different LLL competencies and PDP steps are embedded in the pilots.

2.1.1 Pilot – Belgium (KU Leuven)

The pilot interventions are carried out on the first-year engineering students at Flemish University. The use of an e-portfolio is embedded in the course Engineering Experiences (9ECTS) in which challenging and authentic assignments are implemented thanks to the integration of the competencies acquired in other courses. Both technical and professional competencies need to be addressed as will be the case later on in professional practice. The portfolio focuses on students' professional competencies, their strengths, weaknesses, and interests.

2.1.2 Pilot – Ireland (TU Dublin)

The pilot interventions are carried out on the first year of a General Entry Engineering Level 8 (Ireland NFQ, EFQ=Level 6) programme at Irish University. The first year typically has 160 students who are separated into four groups of 40, to undertake a Design Project Module over semester 1 and 2. The Design Project module has 10 ECTS, but includes 3 projects, Electrical and Electronic Engineering (Robosumo = 5 ECTS), Mechanical Engineering Energy Cube (2.5 ECTS) and Civil and Structural Bridge Design (2.5 ECTS). The intervention will take place within the Civil and Structural Bridge Design project for each group of 40 students. The project already contains aspects of good practice in relation to LLL competencies, so the pilot projects will focus on bringing explicit attention to specific LLL competencies and embed this in the current student-centred teaching method. The pilot intervention also consists of the use of peer- and self-assessment with emphasis on specific LLL competencies.

2.1.3 Pilot – Finland (LUT University)

The pilot intervention was carried out on a master level engineering course module related to research planning and methods. The intervention was voluntary and students gained extra points which were counted towards their final course grade. The pilot was introduced in the last lecture of the module after which students had four weeks to produce and submit their digital stories. The pilot aimed at the improvement of students' reflection skills and students were instructed about digital storytelling with a collection of materials in the course module learning management platform.

Emphasis on LLL & PDPTable 2 gives a more detailed description of how the different LLL competencies and PDP steps are embedded in the pilots. To develop diverse interventions, it was decided to use different approaches for the three pilot interventions:

(1) The e-portfolio intervention aimed to encompass all the different PDP steps, as described by Patel et al. (2013), since the cyclical aspect was determined as a valuable advantage of an e-portfolio. Specifically, three LLL competencies: creating a learning plan, self-monitoring, and self-reflection, were intentionally incorporated to reinforce the cyclical aspect.
(2) In the self & peer assessment intervention explicit emphasis was placed on two specific LLL competencies (willingness, motivation, and curiosity to learn, and locating and scrutinizing information) by systematically going through the different PDP steps.
(3) The digital storytelling intervention prioritized the LLL competency of self-reflection and the PDP step of reflection. By focusing on the act of reflection itself, students were prompted to critically evaluate their experiences.

Table 1. Pilot characteristics

Characteristics	**Belgium**	**Ireland**	**Finland**
Intervention Type	e-portfolio	Peer and Self-assessment	Digital storytelling
LLL or PDP focus	LLL & PDP intervention	LLL intervention	PDP intervention
Target Group	First-year engineering students (n=80)	First-year engineering students (n=40)	2nd year M.Sc. (eng) students (electrical engineering & energy technology) (n=90)

Duration	12 weeks (explanation in a lecture, filling the portfolio in three times during the semester)	6 weeks (explanation in first lecture, self-assessment of two LLL competencies, including it in the team charter)	4 weeks (one-time intervention with 4 weeks to complete)
Extra/intra curricular	Intra curricular	Intra curricular	Intra curricular
Course/Cross curricular	Cross-curricular	Embedded in course	Embedded in course
Voluntary/Obligatory	Obligatory	Obligatory	Voluntary
Feedback from lecturer	Yes	No	No
Part of course assessment	Yes	Yes	Bonus point
Individual/Team task	Individual	Individual & team	Individual
Explicit/Implicit PDP	Explicit	Explicit	Explicit
LLL competencies	Creating a learning plan, Self-monitoring, Self-reflection	Willingness, Motivation and Curiosity to Learn; Locating and Scrutinising Information	Self-reflection

Table 2. Detailed description of PDP steps in pilot intervention

PDP steps	E-portfolio	Self & peer assessment	Digital storytelling
Identify	Self-assessment: first assess your own ability for the competencies below (communication, social competencies, self-management, innovative thinking). Then choose one to focus on during the project.	Self-assess individual ability for the two LLL competencies identified.	
Prepare	Creating a learning plan: Discuss the reason for your choice and a proposal of specific approach to develop this competency.	Develop team charter with group and identify individual roles. Think about how the two LLL competencies could be developed during the project.	
Act	Act on the learning plan	Work through project and assess how LLL competencies are being developed.	
Monitor	Self-monitoring; Peer and self-assessment	Peer and self-assessment	

Reflect	Self-reflection after peer feedback: Select one competency and discuss your response to the feedback received (this can be from your peers, coach, or technical expert), What specifically had you paid attention to regarding this competency? Did the others notice? Was there something you could have done differently? What specifically will you do to further develop this competency?	Complete Team Charter and assess how individual performed with respect to the competencies identified. - Willingness, Motivation and Curiosity to Learn (Are you motivated to learn new things by yourselves?) -Locating and Scrutinizing Information (How do you find and examine information to help progress the project?)	Self-reflection in the end of the course "How the course X has affected you as an engineering student and future engineering professional"

2.2 Students' experiences

In order to capture students' experiences with the interventions, a combination of quantitative and qualitative measurements was employed, tailored to the nature of each pilot. Given the necessity to maintain students' willingness to share their experiences, the questionnaire format was kept concise, considering that students also completed pre- and post-tests to gauge the effectiveness of the interventions (not included in this paper).

2.2.1 E-portfolio

The User Experience questionnaire (Laugwitz, Held, and Schrepp 2008) was used to make a quantitative assessment of students' experience with the e-portfolio. This questionnaire uses bipolar items ranging from -2 to 2 and consists of six factors. A subset of four factors was used because they respond the most to our concerns. Firstly, the items from the *attractiveness* factor are included to estimate the students' general feeling towards the e-portfolio. Secondly, the factors *perspicuity, efficiency* and *dependability* are included because they measure the pragmatic quality of the e-portfolio, which gives us insight in if the e-portfolio was easy to use. The factors *Novelty* and *Stimulation* were not used.

Additionally, students were given a list of possible changes to the e-portfolio and asked to select three and rank them. To analyse this data, each response was given a score (not chosen = 0; rank 3 = 1; rank 2 = 2; rank 1 = 3) and these were added up to a final score for each of the possible changes. How higher the final score, how stronger the students feel that this change should be made.

2.2.2 Peer & Self-assessment

Students were asked to answer one open-ended question regarding their experience with the intervention: *"We asked you to add two competencies to your team charter*

'Willingness, motivation and curiosity to learn' and 'Locating and scrutinizing information". How did you feel about this? Did it have an impact on how you engaged in the project?"

Their answers on this question are categorized in the following categories: awareness, understanding, agency, behaviour, or not applicable (NA).

2.2.3 Digital storytelling

Students were asked to answer one open-ended question regarding their experience with the intervention: *"Which benefits (besides the extra points towards the course grade) did you receive from doing the task?*

Their answers on this question are categorized in the following categories: awareness, understanding, agency, behaviour, or not applicable (NA).

2.3 Capturing students' perception on LLL

Students were also asked to give their definition of LLL after the interventions. The answers of the students are analysed according to the LLL competencies: (1) self-reflection, (2) willingness, motivation and curiosity to learn, (3) self-monitoring, (4) locating and scrutinizing information, and (5) creating a learning plan. The results were compared to determine if there are differences between the year of study (First year and Master students), and the intervention type (i.e. focus on specific competencies more present in students' definition).

3 RESULTS

3.1 User-feedback

3.1.1 Quantitative measures from e-portfolio pilot

Regarding the *attractiveness* of the e-portfolio the mean was lower than the midpoint of the scale of 3 (M = 2.41; SD = .71). However, the pragmatic quality is above the midpoint of the scale (M = 3.16; SD = .82). The students' ranking of possible changes of the e-portfolio can be found in Table 3. How higher the final score, how stronger the students feel that this change should be made (see 2.1.2. for score calculation details).

Table 3. Ranking of changes pilot

Change	Score
Less time intensive	22
Less reflection questions	19
More questions about professional competencies	17
Having to fill in less often	16
More feedback	15
Less frequently having to assess competencies	12
Faster feedback	10

More information about the grades	10

3.1.2 Qualitative measure from Peer & self-assessment and Digital storytelling pilot

A total of 15 students from the Finnish pilot and 13 of the Irish pilot answered the open-ended question regarding their experience with the intervention. The results of the analysis are in included in Table 4. The students in the Digital storytelling pilot report, equally distributed, an impact on their awareness (27%), understanding (27%), and agency (27%) after participation in the intervention. An impact on the students' awareness is the most present in the answers of the students in the peer & self-assessment intervention (31%). Notably, in the peer & self-assessment pilot, 23% of the respondents report an impact on their behaviour after participation in the intervention.

Table 4. Categorisation open-ended questions

Categorisation	Finland - Digital storytelling	Ireland - Peer & self-assessment	Total
Awareness	4 (27%)	4 (31%)	8 (29%)
Understanding	4 (27%)	2 (15%)	6 (21%)
Agency	4 (27%)	3 (23%)	7 (25%)
Behaviour	1 (7%)	3 (23%)	4 (14%)
NA	2 (13%)	1 (8%)	3 (11%)

3.2 Analysis of LLL definitions

All of the students who responded on the question what LLL means to them, provided at least a basic definition or understanding of LLL. When linking this to the earlier given definition "the intentional and active personal and professional learning that should take place in all stages of life, and in various contexts with the aim of improving knowledge, skills and attitudes" (Cruz et al., 2019, p.737), students indeed mentioned time related aspects in their definitions such as: "learning every day", "lasts for life", and "never stops". Some students also directly link it to the professional context (e.g. "for my career", "during my job") whereas others look at LLL in a broader way (e.g. "personal development", "learning from life experiences"). A vast majority of the Finnish students (73%) mentioned an aspect of willingness, motivation or curiosity in their definition, in comparison to only a smaller group of the other two pilots, both with first-year students (23% and 30%). In the Irish pilot, 15% of the students also defined self-monitoring as an aspect of LLL. The Belgian students mentioned the least LLL competencies, but two of them mentioned both self-monitoring and self-reflection in one definition, which are two of three elements of the cyclical approach of PDP.

Table 5. Students' LLL definitions

Analysis definitions	Total LLL definitions (N)	willingness motivation curiosity (N)	self-monitoring (N)	self-reflection (N)
Belgium	17	4 (23%)	2 (12%)	2 (12%)
Finland	15	11 (73%)	1 (7%)	1 (7%)
Ireland	27	8 (30%)	4 (15%)	0 (0%)

4 DISCUSSION

The pilot interventions are promising; however, an extensive approach is required to successfully support students in the development of LLL competencies and guide them through the PDP. This approach entails integrating various embedded interventions not only within a specific course but also across the curriculum. Students have to be reminded of the existence and importance of LLL and PDP in different contexts and at different times throughout their curriculum. An e-portfolio has the potential to be used as a longitudinal and cross-curricular intervention. However, along with these substantial and longitudinal interventions, LLL competencies can also be triggered by making small tweaks to the curriculum to make LLL and the LLL competencies more explicit.

Student-centred teaching methods such as problem-based learning are embedded in plenty of engineering programmes and are a perfect environment to make the LLL competencies more visible. Students tend to see the value of these methods for their further career, possibly making it easier to introduce the LLL competencies in this context. Additionally, student-centred teaching methods in the engineering context often include multiple assignments where LLL and PDP can be introduced (team charter, peer-assessment, …) and often span over multiple weeks allowing for a longitudinal implementation. For example, in the Irish pilot the LLL competencies were made more explicit in the already used peer and self-assessment.

When implementing an intervention, understanding the context is crucial. While all interventions offer substantial benefits, it is essential to also acknowledge their drawbacks. The e-portfolio requires support from educators in guiding the students and providing feedback. This can be a daunting task without experience with PDP and LLL. With the use of a feedback rubric, the time for giving feedback to an individual student was approximately 15 minutes for one semester. The e-portfolio, and other interventions such as a reflective essay, require students to write about their thoughts, behaviour and sometimes also their emotions. As can be seen in the results of the ranking question, engineering students are not always a fan of self-reflection and they can encounter difficulties in writing reflections. A possible adaptation to the e-portfolio could be to to submit their self-reflection in a different format, similarly to what was done in the Digital storytelling pilot. Although not applicable to the current pilot, a challenge with the digital storytelling intervention would be that the diverse formats make it challenging to assess. Nevertheless, using digital storytelling allows students to be creative, which is also an important trait for an engineer. Although peer & self-assessment is already commonly used, with having the advantages of being embedded in a course, of including all types of competencies, and of partly replacing lecturers' feedback, it also has the risk of being influenced by team dynamics or social desirability. Using the peer & self-assessment in the project-based course in Ireland resulted in a direct impact on students' behaviour (23%), according to their experiences.

When looking at how students define LLL, some differences were noted. The majority of students from Finland mentioned an aspect of willingness and motivation in their definition on LLL. This can be explained by the fact that the pilot was voluntary and that the students are master students. Consequently, it could be that the participants were already intrinsically more motivated, more prepared for LLL, or more aware of what it means. Two specific LLL competencies were not included in the students' definition, namely creating a learning plan and locating and scrutinizing information. This could be explained by the fact that these are the two most specific LLL competencies and that definitions are kept more general.

5 SUMMARY AND ACKNOWLEDGEMENTS

LLL is crucial in preparing engineering students for the dynamic demands of the contemporary workplace. PDP emerges as a promising way to foster LLL, offering a cyclical approach that aligns with the iterative nature of learning. Explicitly including LLL competencies in learning outcomes of engineering programmes enhances their visibility and importance. Selecting interventions tailored to specific contexts enables targeted competency development, addressing the unique needs of students and programmes. While longitudinal interventions are essential for sustained impact, smaller tweaks in curricula can also yield significant benefits and employing a combination of interventions allows for a multifaceted approach to LLL.

This work was supported by the Erasmus+ program of the European Union (grant agreement 2021-1-BE02-KA220-HED-000023151) and is part of the TRAINeng-PDP project.

ABSTRACT

This exploratory study investigates the integration of Artificial Intelligence (AI) in undergraduate engineering education in the US and UK by focusing on engineering academics' perceptions from two prominent universities in each country. Responses were collected from three academics through semi-structured interviews, and these responses were organised into four key themes: AI curriculum integration, faculty perceptions of AI, ethics and biases in AI education, and interdisciplinary AI topics.

The preliminary findings, which were compared to those from prior research, suggest a mix of caution and optimism towards AI regarding pedagogical innovation, highlighting the need for responsible AI usage. The study highlights various pedagogical practices for AI in engineering, from explicit AI-focused material to the use of AI tools in assessments and projects. In addition, some of the academics interviewed mentioned the significance of project-based learning (PBL) in teaching AI topics to engineering students due to its ability to foster hands-on learning and real-world problem-solving skills. Furthermore, the study found that there is a growing demand by students for AI-related engineering topics or 'AI-engineering' to be incorporated into traditional engineering classrooms, implying a need for curricula development to meet future industry needs.

gouri.vinod.20@ucl.ac.uk

These insights provide a foundation for further research and aim to inform current engineering educators on how they can generate strategies for incorporating AI into undergraduate engineering curricula. This study lays the groundwork for future research to explore how AI can be integrated into engineering education so that educators can bridge the gap between current demand and future practices.

1 INTRODUCTION

1.1 Overview

The research described in the paper delves into the perceptions of undergraduate engineering faculty members and students in the US and UK regarding Artificial Intelligence (AI) in their curricula. Specifically, the project explores how these perceptions impact their career choices post-graduation and if students are aware of biases in AI. It focuses on current undergraduate or Generation Z students, as this generation is currently entering a workforce heavily influenced by AI technology. Most current undergraduate students belong to Generation Z or Gen-Z, defined as those born after 1995 (Seemiller and Grace, 2016). The definition of AI that will be utilised throughout the project comes from Russell, Stuart, and Norvig (2016), as it captures the interdisciplinary nature of the AI technologies discussed.

As engineering programmes incorporate AI modules into their curricula (AI-engineering), it is crucial to understand how these topics are being taught to Gen-Z engineering students, whether they recognise the biases embedded in AI technologies, and whether these students are interested in pursuing a career in AI. For the first phase of my thesis, I interviewed six faculty members from two universities, one in the US and the other in the UK.

For this exploratory paper, I will discuss the responses of three of the six academics interviewed. My preliminary findings indicated that faculty members' attitudes toward integrating AI into the curriculum varied significantly across all six academics. However, the three academics chosen for this paper had particularly unique positionings based on how much they interacted with AI within engineering education.

1.2 US and UK: Motivations for Innovation

The intersection between global economic competition, technological innovation, and the rise of AI, particularly within the fields of Science, Technology, Engineering, and Mathematics (STEM), positions AI-related engineering or ‘AI-engineering’ education in the US and UK at a critical time for maintaining the two countries’ historical leads when it comes to technological advancement. This calls for exploring national policies that promote innovation for economic growth and societal advancement (Kennedy and Odell 2014; Liu 2022) to improve both countries' current engineering and AI contexts.

At the same time, as highlighted by (Chu, Tu, and Yang 2022), the use of AI in higher education has also become more prevalent in recent years– specifically among undergraduate, engineering, and Gen-Z students across a variety of subjects– calling for the importance of understanding how current engineering faculty are even more imperative

In the US, the science, technology, and innovation (STI) policy, under which AI would fall, has been intricately linked with political decisions that often dictate the direction of funding for technological advancements (Liu 2022). This has revealed a historical trend where the funding for large-scale projects has been influenced by governmental interests– reflecting the country's consistent challenge of aligning scientific progress with political interest.

In 2020, in the UK, the government published its 'Research and Development Roadmap' highlighting the various issues and policies the country aimed to tackle by 2025 (UK Government 2020), for example, the lack of long-term funding, which has hindered essential projects due to the government not allowing researchers enough time to complete their projects. As opposed to countries like the US, where the majority of technological funding is privately sourced, the UK government has noticed that British businesses presently invest less in STEM when compared to other Western nations and hopes to console this by seeking international investment.

1.3 AI in Undergraduate Engineering Education

The above-mentioned motivations for AI innovation, in the US and UK, led me to decide that the prevalence of AI in engineering curricula was an important topic for exploration. A review of AI in higher education conducted by (Crompton and Song 2021) identified undergraduate computer science and engineering students as having significant exposure to AI compared to other degree subjects. Another systematic review conducted by (Crompton and Burke 2023) showed the growing interest in AI applications for teaching, specifically in computer science and engineering, and outlined the diverse roles AI plays in assessment, prediction, and personalised learning.

It could be argued that the AI profiles and motivations for AI innovation for both countries can be summarised as such: the US's desire to maintain the lead in technological innovations and the UK's goal to be on par with the advancements of similar countries serve as the two countries' main incentives to rise in order compete with Asia's– specifically China's (Lee 2018)– massive AI investments for both national prestige and increasing AI human capital. These drivers have resulted in AI being more prominent in engineering and computer science education, as literature has supported. As a result, this paper will focus on the perceptions of academics currently working in the US and UK contexts to learn more about how they navigate AI-engineering education with their Gen-Z students.

2 METHODOLOGY

2.1 Positioning Within Project

To understand how the integration of AI in engineering curricula is perceived by AI-engineering academics, with the US and UK AI-engineering contexts in mind, individual interviews were conducted with engineering faculty before interacting with the student participants. This was done to gain a better idea of the current state of AI and engineering at both universities, in addition to learning which programmes are viable for recruiting student participants. The faculty interviews also provided further insight into current student perceptions about AI and whether their students have expressed confidence in working with AI after undertaking the proposed recruitment modules.

2.2 Participant Recruitment

The academics were initially contacted through email to conduct the interviews and they were discovered using online university engineering department directories which summarised their teaching and research interests. The faculty members who expressed interest were sent scheduling links through Microsoft (MS) Teams along with the decided date and time, the consent form, and participant key information sheets for them to complete before the interview. Before starting the interview, participants were also informed that the interview would be audio-recorded and transcribed.

2.3 Interview Structure and Analysis

As this phase of the data collection was an opportunity to develop questions for the forthcoming survey and individual student interviews, semi-structured interviews were conducted with academics to allow for new topics and themes to be addressed in the next phases of the study. Kallio et al. describe the semi-structured interviews as “... conducted conversationally with one respondent at a time, the semi-structured interview employs a blend of closed- and open-ended questions, often accompanied by follow-up why or how questions" (Kallio et al. 2016, 493). The authors also mention how this style of interviewing allows the interview to meander around various topics as opposed to a standardised open-ended interview where a set number of questions are asked to the participants in the same order. Semi-structured questions also allowed for exploring ideas that were not previously considered for the thesis– allowing it to have a greater breadth.

A pool of 32 open-ended questions was developed and conversationally delivered to the faculty members at both universities. The six academics interviewed were anonymised by labelling them Academic A, Academic B, Academic C, Academic D, Academic E and Academic F. The interviews were structured in three sections and the participants were debriefed on how the interview would be conducted. The first section (1) related to general thoughts on AI before going on to AI and teaching (2) and concluding with AI and students (3).

I reviewed the transcripts generated from MS Teams and marked the recurring topics and issues that were discussed by the academics during the interviews. Then, I created mind maps to identify the possible relationships and connections between these topics. As a result of this analysis, I developed six themes based on the responses of the six academics, out of which four will be discussed in this paper.: **Theme One:** *AI Curriculum Integration and Pedagogical Approaches*, **Theme Two:** *Faculty Perceptions and Interactions with AI in Higher Education*, **Theme Three:** *Ethics and Biases in AI Education*, and **Theme Four:** *Interdisciplinary AI Topics and Demand for AI Education*

As mentioned in the introduction, six academics were interviewed for the thesis. The three participants chosen for this paper are Academic A, Academic C, and Academic E. The three academics were chosen for analysis due to their unique roles in AI-engineering education due to the different ways they interacted with AI. Table 1 describes the three academics who were chosen and their roles:

Table 1. Faculty Participants Overview

Academic	Country	Discipline	Role in AI Engineering Education

A	US	Robotics Engineering	Explicitly teaches AI modules, at both an introductory and advanced level for undergraduate students
C	UK	Chemical Engineering	Does not teach AI explicitly but utilizes AI for grading assessments and for showing students how to use AI tools
E	UK	Mechanical Engineering	Supervises AI-related student projects and is currently developing an AI module for engineering students

The main messages that emerged from these interviews for each theme were also shown in Table 2, so that major findings could be visually represented and summarised in a table for ease of interpretation.

2.4 Theme One: AI Curriculum Integration and Pedagogical Approaches

Academic A:

"... the courses I teach are AI courses—not necessarily robotics courses. There are two courses I teach…one is an introductory course… it is kind of a ... broad overview of AI, and the other is a senior-level course that is…more advanced AI tools for autonomous agents."

"The advanced course is a project-based course, a group-based, project-based course... the introductory course is... individual programming and written assignments. Both of them have final exams, but the bulk of the learning is done through assignments… programming-based assignments."

Academic C:

"No, I don't teach AI explicitly... it comes in at least for me mainly when it comes to assessment... I bring that (AI) in to show students how they might use certain AI tools to help them... that's really probably as far as it goes."

Academic E:

"In the projects that I propose for the third year… students are mainly data analysis and machine learning. So, I supervise students on projects that they use machine learning... I don't teach modules that are machine learning if that makes sense."

"For the AI topics that I interact with at the moment, they are projects. So, you have third year projects which is an individual year-long project...students do this project all year long and at the end they need to submit a report... have a presentation... it's not like lecture, lecture, exam... it's about regular meetings and their responsibility to pull off the project."

Findings:

The context for the deployment of AI in all three of the academics' cases was project-based learning (PBL). CDIO defines PBL in engineering education as "…an instructional method in which students learn a range of skills and subject matter in the process of creating their own projects. Sometimes, these projects are solutions to a real-world problem. But what is most important in project-based learning is that students learn in the process of making something. They work in groups and bring their own experiences, abilities, learning styles and perspectives to the project” (CDIO Initiative, “What is CDIO?”).

Academic A explicitly used PBL in their advanced AI module through project-based group projects, e.g. requiring students to complete large, programming-based projects in groups. Academic E oversaw projects that encouraged students to use AI in a practical way– similarly to how it would be used in an engineering workplace– by incorporating machine learning and data analysis. However, Academic C’s use of AI tools is rather different from the other two. Academic C shared a more implicit use of PBL by demonstrating how AI tools could be used for some assignments, e.g. showing students how to use an AI chat engine to generate an outline for an essay. This aligns with how Díaz Lantada discusses how PBL should evolve with technology– namely AI– within a modern engineering education framework, stating, “the employment of artificial intelligence tools for supporting educational practice” is just one of the ways engineering educators can use technology to support student understanding (Díaz Lantada 2022, 5).

These findings of the academics implementing AI in different ways also align with those found by (Zawacki-Richter et al. 2019), who explored the various ways AI is currently being implemented across higher education and emphasised the need for flexibility when it came to catering to AI in different educational contexts. However, as (Adeyeye and Akanbi 2024) found, as useful as diversification is to ensure AI engineering can be implemented in different contexts, without the collaborative efforts of educational institutions, AI developers, and policymakers, the full potential of AI in engineering may never be reached.

2.5 Theme Two: Faculty Perceptions and Interactions with AI in Higher Education

Academic A:

"...I think it (AI) is going to have a very large impact on education, both in terms of the tools that people can use, such as CoPilot for computer science…ChatGPT… in terms of personalising education... things like smart tutors and being able to personalise the types of education that you get in terms of… personalised exams or personalised assignments that can be automatically generated.”

Academic C:

“Yeah, so recently what I've gone and done is I've gone and... kind of made a draft of a coursework using AI to show the students the quality that they get out of it. If they did choose to go down that road..."

“It's, I think, as with a lot of things it is useful. Dangerous if misused. I think I perceive it one way as an educator or as... for my personal use, and I perceive it another way when applied to how I teach students.”

Academic E:

"It's a tool that should ease a lot of our tasks... we need to benefit from it. We need to learn how to use it... especially in higher education... we need new guidelines… we can’t ignore these tools... these tools are a part of our lives whether in academia or… industry… or even our personal lives. So, we need to embrace them. But we need to know how to control them, or we need to know how to use them.”

Findings:

The academics agreed that AI will significantly impact engineering education, and Academic C and Academic E emphasised its responsible use. Furthermore, they highlighted the dual nature of AI's role: as a personalised tool to teach students engineering topics and as a pedagogical tool for providing feedback. In addition, their perspectives differed in tone regarding the different applications of AI in engineering education. Academic A suggested AI could lead to personalised learning experiences– sharing an optimistic viewpoint for future students. Conversely,

Academic C and Academic E suggested a more cautious approach and even highlighted how AI is still at an experimental or introductory stage in engineering education– similar responses were also found in several previous studies. For example, (Mandal and Mete 2023) found that while educators understood the benefits of AI in the higher education workplace– such as simplifying administration tasks– they were also aware of issues concerning data privacy. Similarly, (Slimi 2022) found that while faculty members appreciate the efficiency AI can offer, they are still concerned about what over-reliance on AI can bring and the 'human' elements in teaching that can be lost due to its implementation in the classroom.

2.6 Theme Three: Ethics and Biases in AI Education

Academic A:

"…so, in a machine learning course, we'll talk about…bias and privacy...the course I have in autonomous agents, we focus on human autonomy and liability of the autonomous system… so yeah, the different courses take different aspects of… ethical dilemmas that... AI engenders and tries to look at things in that specific lens…"

Academic C:

"…we also show them or give them examples of… where there are biases with information that is generated…especially because a lot of the information generated is from, say Western society. And that they may be missing out perspectives of, you know, the wider world…so we do touch on that as well."

Academic E:

"… it's technical for sure; students need to know what each algorithm does and the math behind each algorithm… I think the technicalities are important…"

Findings:

Evidently, the academics had very different views about AI and ethics issues. Two broad views were identified– AI and ethics as a module topic and AI and ethics as a passing issue in a module. This is evident in the responses, with Academic A being the only faculty member who mentioned that they explicitly teach ethics and biases surrounding AI alongside technical topics, Academic C teaching how AI-generated information can be biased, and Academic E not discussing AI biases at all. Even though Academic A and Academic C do discuss AI biases in their modules, they differed on how they taught these topics– with Academic A discussing bias and ethics issues directly related to the technical topics of the module and Academic C highlighting the importance of recognising biases in AI-generated content in general.

Though the academics interviewed had mixed approaches to incorporating AI ethics and biases into the engineering classroom, the need for these topics to be introduced has been understood by professional and governing bodies in both the US and the UK. In their recent statement of how professional engineers should approach AI ethics, a key policymaking body in the US, the National Society of Professional Engineers (NSPE) stated that engineers should prioritise ethical standards in the development and deployment of AI-engineering technologies (NSPE 2023). Similarly, (UK Government 2020) shared a similar sentiment, more so focusing on the need for AI technologies to benefit society as a whole– which calls those developing it, potentially current engineering students, to be aware of the technology's shortcomings and inherent biases.

2.7 Theme Four: Interdisciplinary AI Topics and Demand for AI Education

Academic A:

"Yeah, definitely (there is student demand for AI topics within engineering)."

Academic C:

"…the demand is there, but the demand is also being met because they have optional modules that they can take…where if they wanted to focus more on AI and other digital tools, they can do that... so yeah… the demand is definitely there and being met as well."

Academic E:

"…because there... have been numerous requests from students…that they are interested in this topic…we thought that it's time now to propose this module…later on we can have an advanced or an intermediate level module…but this module is like an introductory module for machine learning and how to use it… and… the math behind it…maybe later on we …can improve this."

"…very important remark here is that we are a mechanical engineering department…not a computer science department, so… we need to be more focused on the applicability of these algorithms rather than… how complicated these algorithms are."

Findings:

All the academics recognise student demand for AI topics to be taught to them during their engineering degrees, with Academic A having a short response due to them already teaching AI-engineering modules. Academic C mentioned that the demand is also being met by highlighting that students could take optional AI modules outside their degree programmes. Although Academic A and Academic E did not discuss their plans for expanding AI- engineering within their departments, Academic E specifically highlighted how they are introducing a new AI module, which directly responded to students' interest in AI. This academic also mentioned how this new module is engineering-based and focuses on the practical applications of AI for solving engineering problems.

My findings align with a larger survey conducted by (Balabdaoui et al. 2024) to investigate the usage of AI by students at a technical university. Their study, similar to what the academics shared, found that the majority of students expressed a strong desire for AI topics to be further integrated into their technical curricula, calling for current AI tools to be more curated for technical subjects to better supplement STEM topics. Furthermore, the study, which surveyed 4,800 students, found significant demand across technical subjects- with computer science students and engineering students showing the most demand and natural sciences students showing the least, emphasising the interdisciplinary nature of AI student demand in not only engineering as the academics highlighted but a variety of technical subjects.

2.8 Summary of Findings Table

Table 2. Main messages from each theme summarised from the academics' interviews.

Theme One: *AI Curriculum Integration and Pedagogical Approaches*	**Theme Two:** *Faculty Perceptions and Interactions with AI in Higher Education*
• AI integration in engineering education is predominantly project-based. • Different approaches to AI education include structured group projects, individual projects, and the use of AI tools for specific assignments. • Project-based learning (PBL) frameworks are effectively used to teach AI, with students gaining practical skills applicable in real-world engineering contexts. • The findings align with Díaz Lantada's (2022) discussion on evolving PBL with AI and Zawacki-Richter et al.'s (2021) emphasis on flexibility in AI integration.	• AI is recognised as having significant potential to transform engineering education. • AI is seen as a tool for personalising learning experiences and increasing efficiency in educational tasks. Faculty members acknowledge the dual nature of AI's role: beneficial for providing pedagogical support yet requiring careful implementation to address ethical and practical challenges. • Mandal and Mete (2023) and Slimi (2022) found that educators appreciate AI's efficiency but are concerned about data privacy and the loss of human elements in teaching.
Theme Three: *Ethics and Biases in AI Education*	**Theme Four:** *Interdisciplinary AI Topics and Demand for AI Education*
• Academics had varying views on AI ethics, with some incorporating ethics and biases as a core part of their curriculum while others only touched on these issues briefly or not at all. • There is a need for a consistent approach to teaching AI ethics and biases, recognising the importance of these topics in engineering education. • Professional and governing bodies in the US and UK emphasise the importance of ethical standards in AI development and deployment.	• There is strong student demand for AI topics in engineering education. Different approaches to meeting this demand include optional AI modules and the introduction of new AI-focused courses. • Balabdaoui et al. (2024) found a significant desire among students for AI topics to be integrated into technical curricula, with the highest demand among computer science and engineering students. • The interdisciplinary nature of AI education is highlighted, with demand across various technical subjects.

3 CONCLUSION: EARLY FINDINGS AND FURTHER RESEARCH

This paper took an initial look into the perceptions of engineering faculty members in relation to AI curricula integration in the US and the UK. Though the thesis is primarily concerned with the perceptions of undergraduate engineering students, the phase of data collection explored allowed me to gain engineering academics' perceptions. It served as a way for me to gain access to the students later in the project. Through the conversations with the six faculty members– three of which were examined here– I was able to gain a foundational understanding of how academics from both the US and the UK are currently implementing AI into their engineering curricula and was able to generate six themes– four of which were highlighted– from their responses. From the interviews, I was also able to develop summaries of emerging messages related to each theme to allow for the main messages from the interviews to be apparent to readers in Table 2. The academics' insights, in addition to supporting findings found by previous researchers, pointed towards the various ways AI and engineering education are currently positioned– calling for further research and the need for student perceptions for a comprehensive understanding within the bounds of the thesis. In addition, some of the academics interviewed mentioned the significance of project-based learning (PBL) in teaching AI topics to engineering students due to its ability to foster hands-on learning and real-world problem-solving skills. Furthermore, the study found that there is a growing demand by students for AI-related engineering topics or 'AI-engineering' to be incorporated into traditional engineering classrooms, implying a need for curricula development to meet future industry needs.

My thesis is timely, as recent literature from the past three years has identified a general gap in knowledge regarding AI and engineering education, calling for further investigations (Xu and Ouyang 2022; Zhai et al. 2021). However, Aditya Johri's ongoing research (McDonald et al. 2024) and his webpage have been incredibly helpful resources in navigating the evolving discourse around this topic. They have allowed me to build a compelling case for my thesis objective, which is to understand the perceptions of academics and students in a cross-national context. Ultimately, the exploration discussed in this paper laid the groundwork for me to learn more about AI's nuanced and ever-transforming role in engineering education and how it is being introduced to the students who took part in my study.

Conference Key Areas: *The attractiveness of engineering education, Diversity, equity and inclusion in our universities and in our teaching*
Keywords: *Career Choice, Information Technology, Gender, Higher Education, Mixed Methods Research*

ABSTRACT

The popularity of studying computing disciplines has varied considerably over the last decades. The low share of female students, however, has remained constant. The issue extends beyond educational institutions to society as a whole, as the growing Information Technology (IT) industry requires more IT professionals, and IT faculties fail to supply enough proficient graduates with diverse backgrounds.

The aim of this study is to consider attraction to higher education IT studies from the perspective of IT majors. Students are regarded as experts by experience in the study. In developing pedagogical, administrative, and recruiting practices, their voices should be heard.

The online survey utilised a novel dialectical three-phase question method (D3P) combining open and closed questions to elicit initial, informed, and prioritised opinions of the respondents. Mixing qualitative and quantitative methods provides diverse perspectives to the phenomenon under study.

Students' opinions on factors attracting into IT studies underlined high employment rates, interest in IT, good salary, and versatile career options. The study revealed significant differences between genders. Women emphasised good salary and interest in problem solving while men were more interested in IT and technology in general.

The dialectical three-phase question method proved to be informative: It combined the benefits and limited the issues of both qualitative and quantitative approaches.

1 INTRODUCTION

As the abundance of services, tools, entertainment, and gadgets is getting new digitalised forms, there is a growing demand for a workforce capable of designing and implementing creative and reliable software solutions. Information and Communication Technology (ICT) know-how is the prerequisite for digital and digital-enabled innovations and plays a key role in modern technology-fuelled economies.

In 2023, 9.7 million people in the EU worked as ICT specialists, representing 4.8% of the total EU workforce. From 2013 to 2023, the number of ICT specialists in the EU grew by 59.3%. (Eurostat 2024) In 2022, 5.3 million people in the US worked in 'Computer and mathematical occupations'. This occupational group is estimated to grow from 2022 to 2032 at the second fastest rate of 15.2%. (US Bureau of Labor Statistics 2023) The shortfall of computing graduates who could fill current and future computing jobs is a serious concern of industries, governments, and educational institutes (Nager & Atkinson, 2017; Stephenson et al., 2018).

The popularity of majoring in IT has varied widely over the decades. The number of IT students started to grow in the 1980s and even more so in the late 1990's along with the www boom. In the 2000s the popularity waned following the burst of the IT bubble, but begun to rise again in 2010s. (Zweben and Bizot 2016; Nager and Atkinson 2017; Zweben and Bizot 2023)

Today, IT is a profession of white males (Jaccheri, Pereira, and Fast 2020; Myers 2018). The profile of IT workforce reflects the profile of IT majoring students. In OECD countries less than 18% of ICT students are females. As seen in Figure 1, the share of new female entrants into higher education was the lowest in Information and Communication Technologies (ICT) compared to all other educational fields. Even other STEM fields are more attractive to women. (OECD 2021)

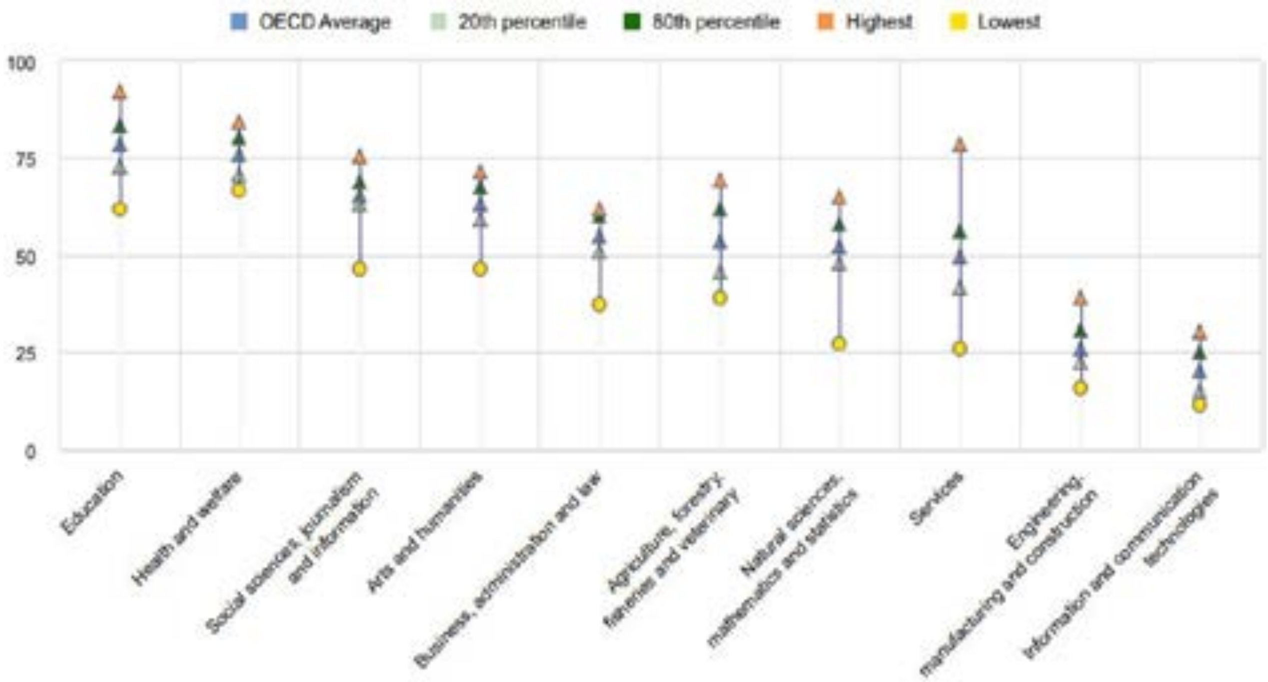

Fig. 1. Share of female new entrants into higher education by field of education in 2019 (OECD 2021)

Women earned the majority of all bachelor's degrees (58%), and nearly 50% of bachelor's degrees in science and engineering, but accounted only for 22% of bachelor's degrees in the computing disciplines in the US in 2021 (DuBow and Wu 2022) and 23% in the OECD (OECD 2023). The share of women in computing disciplines reached its peak in the US in 1985 with 37% of bachelor degree diplomas (DuBow and Wu 2022). The share declined steadily close to 15% in 2009. Since then only modest growth has been observed (Zweben and Bizot 2016). This unsettling imbalance has persisted for decades, and no significant progress has been observed, either in Europe (Informatics Europe, n.d.) or in the US (Zweben and Bizot 2023).

Increased diversity in computing would increase diverse voices and perspectives in research, development, and innovation, thus resulting in products and services that are usable and attractive to a diverse population. (Hunt et al. 2018; Fountain 2000) Attracting and retaining more diverse population to IT degree programmes is a persistent concern in IT institutes (Stephenson et al. 2018; Nager and Atkinson 2017). However, efficient measures to balance the distribution have not yet been established (Jaccheri, Pereira, and Fast 2020).

To shed additional light on the issue, the aim of this study is to elicit the opinion of IT-majoring higher education students on which factors attract youth to study computing. Students are regarded as experts by experience in the enquiry (Jasanoff 2016, Fisher, Margolis, and Miller 1997). The research question guiding this study is: Which factors attract students into bachelor-level computing education according to students majoring in Information Technology - and do these factors differ by gender?

The paper is organised as follows: Section 2 takes a look at factors identified as attracting to computing education. Section 3 describes the study design, and section 4 presents the results. Section 5 discusses the results and implications.

2 ATTRACTION TO STUDY IT

The Universities and Colleges Admissions Service (UCAS) in the United Kingdom conducted an impressive survey in 2020 covering more than 27,000 first and second year students aged 18 and 19 accepted to higher education in 2019 and 2020. According to the survey, students chose their major mainly based on the enjoyment of a subject (74%). High graduate employment rates were the second most important factor influencing the choice of the major (54%) (UCAS 2021).

Motivation refers to the psychological factors steering our actions. Intrinsic motivation refers to the internal drive to engage in an activity for its own sake, without the need for external rewards or incentives. Interest and enjoyment are typical manifestations of intrinsic motivation. Extrinsic motivation refers to the drive to engage in an activity in order to attain external rewards or to avoid negative consequences. Employment, status, and competitive salary are typical extrinsic motivators. (Järvelä and Renninger 2014) Both intrinsic and extrinsic motivation guide career choices.

In addition to motivational factors applicants' beliefs about their own skills shape their career choices (Savickas 2008). Success in studies and interest typically enhance each other. Students are generally interested in careers that allow them to utilise and develop their abilities. Youth with strong mathematical background are more likely to choose STEM fields as their major than ones with less competence. The problem with computing disciplines is that there is no undisputed consensus on what predicts performance, with math and verbal skills dominating the discussion. (Virkki 2021)

Values and perceptions behind career choices are susceptible to external influences. Societal and cultural influence from family, friends, career counsellors, media, social media, and role models may guide, support, or discourage career aspirations of the young. (Sanders 2005; Wang et al. 2015) In spite of decades of work towards gender equality, the world doesn't appear the same for women and men. Discourses in the gender-biased societies will likely teach youth to have gender-stereotyped interests. (Adam et al. 2006; Clayton, Hellens, and Nielsen 2009; Trauth 2002)

Factors that cause women not to choose IT as their career have been studied more than factors that attract women to IT. The stereotypical images of IT professions and culture do not appeal to women (Cheryan, Master, and Meltzoff 2015; Thomas and Allen 2006; Wolff, Knutas, and Savolainen 2020). Motivational factors for both men and women appear quite similar: high employment, interesting job opportunities, good salary, and interest in IT. (Corneliussen 2024)

Factors characterising women in computing fields were studied by Lehman, Sax and Zimmerman (2017). Women intending to major in computing in the US earned higher high school grades than their male counterparts. They outperformed men on the SAT verbal tests but scored less on the SAT math. Women in Computer Science (CS) self-rated themselves lower than male students on intellectual self-confidence, computing skills, math ability, competitiveness, leadership ability, public speaking ability, and social self-confidence. On the other hand, women rated themselves higher than men on writing ability, artistic ability, and creativity.

In comparison to women in other STEM fields, CS-pursuing women rated themselves highest on computing skills and artistic abilities. On the other end, women in CS rated themselves lowest on intellectual self-confidence, leadership ability, drive to achieve, and math. However, their actual scores on the SAT math were the same as in other STEM fields, and they scored better on the SAT verbal. (Lehman, Sax, and Zimmerman 2017)

Previous studies indicate that young women tend to rate their IT and math abilities lower than men, even if they had similar levels of academic achievement. Women's lack of confidence and low self-efficacy in their math and IT abilities may contribute to women's decision not to pursue an IT major or to drop out from the IT degree programme (Fisher, Margolis, and Miller 1997; Wilson 2002; Dempsey et al. 2015; Lishinski et al. 2016; Pappas, Giannakos, and Jaccheri 2016; Herbert et al. 2020). Interest and confidence in computing are key components in developing an identity as an IT professional and a sense of belonging in IT. (Dempsey et al. 2015)

Different career choice theories emphasise various factors in the career decision process. Parson's early talent-matching approach emphasised the skills and abilities of a person and the attributes required in particular jobs (Savickas 2008). Holland's theory highlights the congruence between vocational personality types and job environments (Holland 1985). The Social Cognitive Career Theory is based on Banduras concepts of self-regulation and self-efficacy according to which individuals' beliefs in their capabilities in a particular domain influence not only the choices they make, but even the goals they cherish (Bandura 1991). Our study was not committed to any single theory but sought a dialogue between theories and the survey data.

3 METHODOLOGY

The study was conducted as a survey. This chapter presents the sampling, question construction, execution, and analysis of the survey.

3.1 Sampling

The population under investigation consists of higher education students majoring in IT. Second year students were chosen as the sample. They already have experience of studying IT, but limited experience of working in IT. The survey was conducted in Haaga-Helia University of Applied Sciences in Finland in 2021.

In the academic year 2019-2020, 200 students began their studies in the Information Technology Degree Programme of Haaga-Helia University of Applied Sciences. After the first year of studies 20 of them (10%) had discontinued their studies. Thus, the sample size was 180 students (131 males and 49 females). The sample represents a cross-section of the IT majors at the university, which accommodates an average of 650 IT majors (75% males, 25% females). Sampling ratio was 28%.

3.2 Question Construction

A good question produces answers that are valid and reliable measures of what is under investigation. In this context, reliability means that the questions are consistently comprehended by both respondents and researchers. Validity means that answers correspond to the genuine opinion of the respondents. (Fowler and Cosenza 2009)

A novel questioning format, the dialectical three-phase question method (D3P), was applied in the survey. The study was interested in the experiential knowledge and conceptualisations of the respondents. On the other hand, generalisable results were sought as well. By collecting and analysing both quantitative and qualitative data, more comprehensive evidence can be gathered, and more robust and nuanced results achieved (Jick 1979).

In D3P the same question is presented three times with distinct formulations (Virkki 2023): The first question is an open question to elicit answers that express respondents' initial responses on the topic, unaffected by the conceptualisations of the researcher. Thus, answers to the open question have high validity (Sue and Ritter 2016). Respondents' own wordings involve rich information content, such as sincerity, feelings, and rationales. Answers to the first question are referred to as Initial Opinions.

The second question is a multiple-choice question with several response options allowing respondents to select as many options as they prefer. The response options were drawn from scientific literature by the researcher. The last response option was "Other", with a fill-in text-field, to offer a suitable response option for everyone. Answers to the second question are referred to as Informed Opinions.

In the third question, respondents were asked to identify the three to five most important factors, after being exposed to the multiple response options of the previous question and the thought process initiated by the first question. In other words, respondents were encouraged to reconsider and prioritise their views. Answers to the third question are referred to as Prioritised Opinions.

The rationale for the three-phase question method was to overcome the issues of one question type (open versus closed) with the counter-balancing strengths of the other. Open questions catch what crossed the respondent's mind when presented the question. However, respondents may not consider their answers thoroughly but utter the first thought entering their mind. The responses are influenced by the situation of the respondents, their knowledge, emotions, and mental states. Respondents' interpretations of open questions often vary, too (Peterson 2013).

On the other hand, a closed question with predefined response options may bias and restrict participants' answers (Fowler and Cosenza 2009). The choice and phrasing of the response options are done 'a priori' by the researchers and not by the respondents (Deetz 1996). Emerging and unanticipated answers are easily forgotten when faced with the battery of ready-made options. Furthermore, closed questions can only capture factors the researcher is already aware of, and nothing new may emerge.

Finally, prioritising opinions encourages respondents to reconsider and evaluate their views. Both researchers and respondents perceive the world from their own perspectives. Given the chance to even peak into the world of the other, both of them may encounter something new that allows them to learn and refine their views (Rock 2001). The D3P opens a dialogue between respondents and researchers.

Question quality and validity were ensured through a review and a field pre-test (Fowler and Cosenza 2009; Hardy and Ford 2014). Three university professionals in IT reviewed all questions and response options, and adjustment were made as needed. A pre-test involving 24 first-year students was also conducted. A group discussion with these students addressed the clarity, atomicity, and unambiguousness of the questions and response options, as well as the comprehensiveness and relevance of the response options. Insights from students' responses to open questions were utilised to add new response options to the questionnaire.

3.3 Survey Execution and Analysis

The questionnaire was deployed in 2021 using Webropol online survey tool. The survey was presented to the students by the researcher during online classes allotting 10 minutes for completion to encourage participation. Responding to the survey was voluntary and had no bearing on course assessment ("The European Code of Conduct for Research Intregrity" 2017). Two reminders were sent to non-responding students with one-week intervals.

There were 89 respondents, 61% males and 39% females. (In the target population, gender distribution is 75% males and 25% females.) The response rate was 49,4%. The median age of the respondents was 26 and mode 23, the youngest were 19 years, and the oldest 48 years old. Other diversity aspects of the respondents were not recorded. No responses were eliminated.

Responses to open questions expressing initial and prioritised opinions were catalogued and broken into atomic expressions with synonyms harmonised. The atomic expressions of initial opinions were synthesised under themes using inductive thematic content analysis (Braun and Clarke 2008). Prioritised opinions were analysed statistically as the format of the responses was list-like. Responses to multiple-choice questions, expressing informed opinions, were studied statistically.

4 RESULTS

4.1 Initial Opinions on Factors Attracting to IT

Both women and men emphasised interest in IT, high employment, and salary in Initial Opinions. External influences, personality types, or skill congruence were only rarely expressed. Responses brought up less diversity than expected, and no significant differences between genders emerged. Initial opinions are illustrated with representative quotes from the respondents (Eldh, Årestedt, and Berterö 2020).

"Interest in IT, reasonable salary, high employment."

"*Salary, employment, interest In IT and the nice combination of logic and creativity in software development."*

4.2 Informed Opinions on Factors Attracting to IT

In Informed Opinions, students selected as many of the response options as they pleased. High Employment was the most popular factor attracting youth to study IT. The multiple-choice questions of Informed Opinions added diversity in views and revealed differences between genders. The difference was considered significant when it was at least 10 percentage points. Men valued Interest in IT and Interest in Technology clearly more than women. Women appreciated Good Salary, IT as a Field of Future and Interest in Problem Solving more than men as seen in Fig. 2. Women also found that Media affected their career choice more than men perceived.

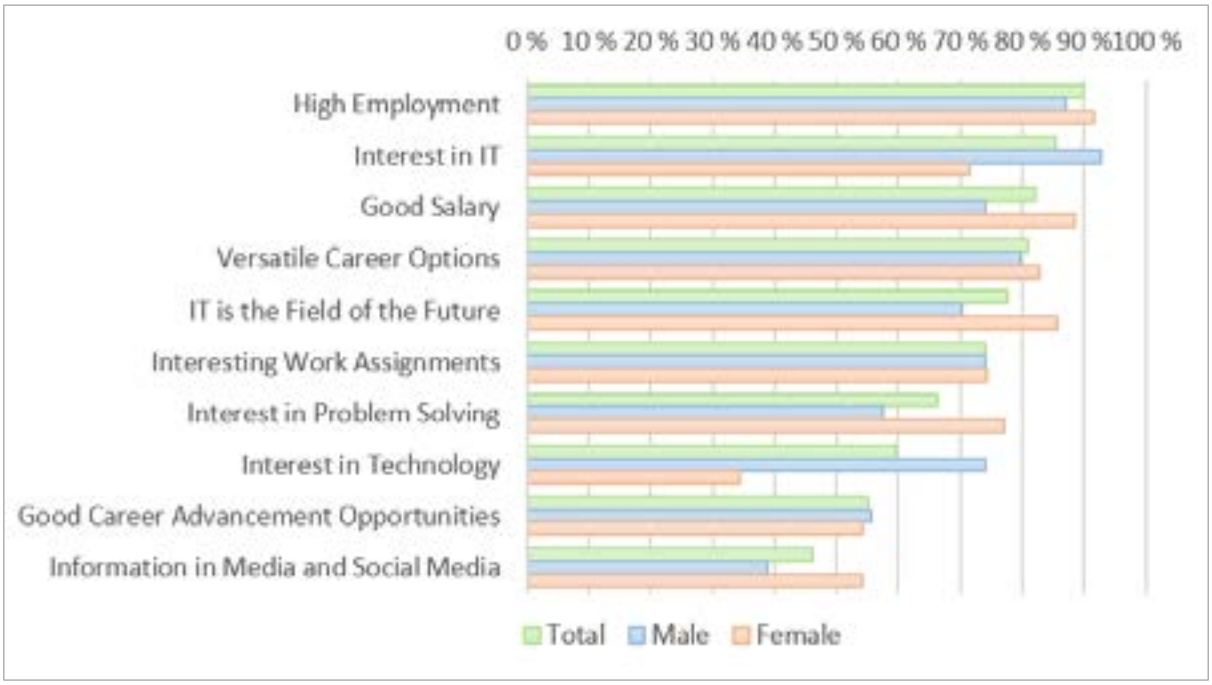

Fig. 2. Top 10 Informed Opinions on Factors Influencing the Choice of IT as a Major

For men the most popular intrinsic motivator was Interest in IT as for women the most popular intrinsic motivator was Interest in Problem Solving. In general, extrinsic motivators were more popular among women than men.

4.3 Prioritised Opinions on Factors Attracting to IT

When asked to prioritise and write down only three to five most important factors contributing their career choice, the first four factors stayed the same as in Informed

Opinions. However, three new factors appeared at the bottom of the list as seen in Fig. 3: Remote Work Possibilities, Interest in Design and Creativity, and Family and Friends. Women appreciated extrinsic motivators the most: High Employment, Good Salary, Versatile Career Options and Remote Work Possibilities. The most important intrinsic motivators for women were Interest in IT and Interest in Problem Solving.

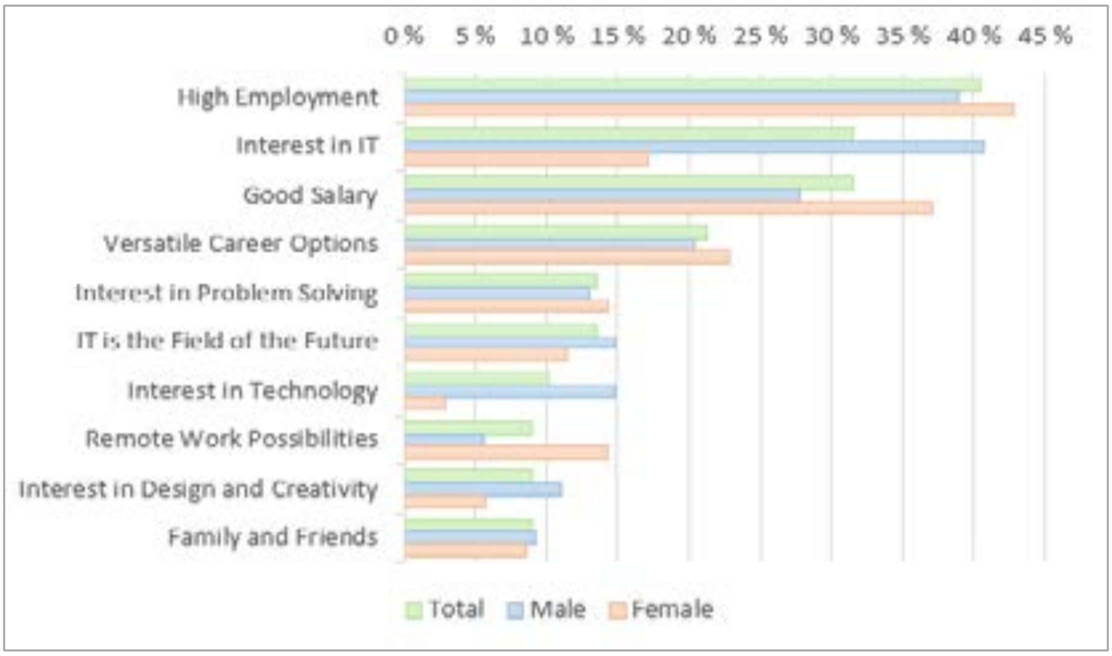

Fig. 3. Top 10 Prioritised Opinions on Factors Influencing the Choice of IT as a Major

5 DISCUSSION

The study gathered student opinions. However valid the opinions are, they may not capture the reality as it is, but opinions about it. Nonetheless, opinions matter as they affect the way people behave. All three question formulations of the D3P provided a slightly different perspective on the topic. Open questions enabled respondents' own conceptualisations. The multiple-choice question options broadened the response sphere. Prioritising brought forth the most important factors. By opening a dialogue with the experiential knowledge of the students and the science-based knowledge of the researchers, more sound and holistic evidence could be gathered. The sample sizes were modest for drawing definitive statistical inferences, but plentiful for qualitative analysis. Both theoretical and pragmatic implications are discussed succinctly.

Intrinsic and extrinsic motivators dominated students' responses. External influences, personality types, skill congruence, or self-efficacy were rarely expressed by students in this study. Bringing out one's personality features or issues may feel uncomfortable to students. On a general level, reasons to study IT are similar for women and men. But when the topic was elaborated further, considerable differences emerged. Interest in Problem Solving is the most popular intrinsic motivator for women. Men are more inclined to Technology Interest. These results are novel yet congruent with previous research. The difference may imply that women perceive IT more as a means to an end, while men are more intrigued by technology itself (Clayton, Hellens, and Nielsen 2009).

The study revealed that extrinsic motivators like high employment, good salary, and time- and location-independent work are essential to women. This may follow from the fact that women's financial independence is still not on par with that of men (UN Women 2024). Media has the potential to influence the stereotypical images of IT professions and work culture and thereby impact women's perceptions of IT as a career choice. Policies and practices to increase the attractiveness of IT studies and professions to young women could be refined with the outcomes of this study.

ABSTRACT

Despite extensive research on women in engineering, the retention of women engineers in the workforce remains a persistent obstacle to diversifying the engineering workforce. To confront this issue, empowering women engineers with the requisite skills for seamless integration into the workforce is essential. This study utilized an asset-based framework to examine the competencies employed by early career women as they transitioned from school into their engineering careers. Through qualitative methods involving both inductive and deductive analyses, we conducted initial and follow-up interviews with seven early career women (1-2 years into engineering careers), enabling them to reflect on the skills needed and advice they wished they had received during their transition. Findings indicated that prioritizing a good work-life balance, seeking guidance or support, and cultivating self-assurance, confidence, assertiveness, and resilience were essential for successfully navigating the transition into the engineering workforce. This work offers

[1] *E. Volpe*
Evolpe1@ufl.edu

insights into how to best prepare and empower women as they transition into the engineering workforce.

1 INTRODUCTION

In the United States, it has become a national imperative to include the ‘missing millions’ in science and engineering, referring to the absent voices and identities of underrepresented groups like women and Black engineers (“National Science Board: Vision 2030” 2020). This call resonates globally, as women constitute only 16.5% of engineers worldwide (“International Women in Engineering Day 2022” 2022). Research suggests that discrimination against women engineers persists in many workplaces, particularly within the construction and civil engineering industry (Enshassi et al. 2008). Workforce sustainability involves fostering an environment that prioritizes the safety and well-being of all individuals to generate optimal engineering solutions. Engineering careers often entail demanding work conditions and stressful environments (Loosemore and Waters 2004; Jensen and Cross 2021). Furthermore, there are calls for enhanced professional development for civil engineers, leading to increased global responsibility in reducing corruption and advancing sustainable development (Chance et al. 2020). The engineering workforce is in dire need of amplifying the voices that have been historically underrepresented. The transition into the workforce is a pivotal time in career decision making, and it is during this critical time that efforts must be concentrated to foster diversity and inclusion. Supporting the development of skills tailored to help women navigate this stressful period can significantly contribute to increasing diversity and creating a more inclusive engineering community. Empowering women engineers with a skill set for successful transition to the engineering workforce is key to establishing more sustainable careers in engineering.

1.1 Early Career Women Engineers

Early career experiences lay the groundwork for progression and significantly shape career choices and decisions (Francis and Michielsens 2021). In the field of engineering, positive early career experiences are associated with increased persistence and retention in the profession (Marinelli et al. 2022). The transition to the workplace requires early career engineers navigate how their existing skills and knowledge can seamlessly integrate into a workplace that presents new challenges for them to address (Smit 2023). The transition from academia to industry presents challenges to all engineers including high stress, demanding workloads, learning new information, and depending more on others (Beddoes 2019; Jensen and Cross 2021), and women often face additional challenges including isolation, harassment, stereotypes and stereotype threat, imposter syndrome, underrepresentation, exclusion, pressure to work harder to prove themselves, and negative interactions (Beddoes 2019; 2022; Chew et al. 2020; Buse et al. 2013).

1.2 Asset-Based Approaches and Empowerment

In studying underrepresented populations within engineering, it is important to avoid using deficit based approaches or situating the problem within the individuals themselves (Harper 2010). Therefore, our work implements an asset-based approach and seeks to empower these individuals by examining what skills and competencies they brought to this critical transitional time that helped empower them to be successful in navigating challenges in their career. Further, they identify advice they wished they had received as an early career woman entering the civil engineering workforce and additional skills they are working towards developing.

1.3 Professional Development in Engineering and Leadership Enabling Competencies

To excel in their professions, engineering students need an extensive array of competencies (i.e., knowledge, skills, and attributes) (Bae et al. 2022). Effective professional development, or preparedness for the workforce, is crucial for achieving successful and sustainable career growth (Bae et al. 2022). A study of construction industry leaders identified critical leadership-enabling competencies that engineering students should develop for successful transitions to construction and engineering careers (Simmons et al. 2020). These competencies include communication skills, professionalism, critical thinking/problem-solving, self-awareness, ambition/drive, time management, management, ethics/responsibility, big-picture thinking, humility, teamwork/collaboration/networking, quality control, adaptability, computer skills, safety/risk management, assertiveness, people focus, legal knowledge, and economic principles and trends (Simmons et al. 2020). These leadership-enabling competencies provided a framework to guide the analysis of the data to understand which competencies were most useful for women transitioning into careers in civil engineering.

1.4 Research Question

This study was guided by the following research question: What competencies and skills do early career women identify as empowering to navigate challenges as they transition to careers in civil engineering?

2 METHODOLOGY

2.1 Data Collection

Qualitative narrative techniques were employed to gather data, involving the comprehensive collection and synthesis of individual participant narratives. The data collection process consisted of bi-weekly reflection journals and initial and follow-up semi-structured interviews, each lasting between 40 to 90 minutes. Interviews were conducted in person or over Zoom, recorded, and transcribed verbatim. Participant narratives were then individually constructed using the process of restorying (i.e., reordering participants' stories chronologically) (Creswell 2020). The participants were then asked to review the final narratives as a form of member checking. Due to the nature of narrative inquiry, participants' individual identities, background and educational experiences, work experiences, and stories were allowed to emerge naturally, and interviews often shifted to follow up on participants' individual paths. As a part of the follow-up interview process, participants were prompted to describe responses to the following questions: “What advice would you give to your younger self before you embarked on a career in engineering?” and “How would you mentor or support other women navigating transitions into engineering careers?”.

2.2 Participants

Participants for this study were recruited by convenience sampling using the first author's network and industry connections. All participants identified themselves as women with engineering degrees in their first 1-2 years of work, working at highly reputable civil engineering firms across the southeastern United States. Five participants identified themselves as Black, one identified as White, and one participant chose not to identify their race. During this investigation, we acknowledge the principle of intersectionality, where the convergence of diverse identities can profoundly shape an individual's experience. It is important to recognize that an individual's experience cannot be exclusively attributed to a singular aspect of their identity. Participants selected pseudonyms to protect their identity.

2.3 Data Analysis

Thematic analysis was employed to analyze, examine, and present patterns from the data (Braun and Clarke 2006). Our analysis consisted of a combination of deductive coding, using the leadership-enabling competencies established by (Simmons et al. 2020), which was used as a conceptual model through which the data was analyzed. We also used inductive coding, which allowed emergent codes to arise from the narrative data. Thematic analysis of qualitative narrative data consisted of repeated readings (Saldaña 2013), restorying, and initial coding (Creswell 2020). Following a comprehensive examination of each participant's narrative, the researchers distanced themselves from the data and conducted a broader review across all participant narratives. This process aimed to construct a synthesis of competencies that empowered women to effectively navigate challenges during their transition into the engineering workforce. Codes were then complied into themes using the qualitative analysis technique and sorting and reviewed to assure they aligned with the participant data (Saldaña 2013; Creswell 2020; Braun and Clarke 2006). Finally, member checking was implemented as the findings were checked with the original participants to improve the trustworthiness of the findings (Creswell 2020).

3 RESULTS

3.1 Tables

Competencies identified through inductive and deductive coding are listed in Table 1.

Table 1. Competencies Identified by Early Career Women Empowering their Transition to Careers in Engineering

Leadership-enabling Competencies as Identified by Industry Leaders			
Communication	Professionalism	Self-awareness	Humility
Time management	Computer skills	Assertiveness	Teamwork/collaboration
Emergent Competencies from the Data			
Initiative	Continual learning	Confidence	Asking questions
Self-assurance	Setting boundaries	Prioritizing mental health/ wellbeing	Seeking mentorship/ guidance
Balance	Destressing skills	Resilience	Self-esteem

3.2 Themes Across Participant Narratives

Theme 1: Early career women value prioritizing mental health, boundary setting, and engaging in hobbies outside of work to maintain work-life balance and prevent burnout as they transition to engineering careers.

All participants described experiences of increasingly demanding workloads and a struggle to find work-life balance as they entered the engineering profession. Individuals highlighted the importance of prioritizing mental wellbeing especially when entering a career that is so mentally challenging. One participant advised,

Yes, you're here to work. You also have a life outside of work. Your mental health comes first. In engineering, you're constantly using your brain. It can be mentally *exhausting*. So prioritizing mental health would be one of the biggest things that I do to avoid burnout. (Victoria)

In addition to prioritizing mental health, some participants recommended adjusting personal schedules and engaging in de-stressing activities and enjoyable hobbies to counteract the stressful nature of engineering and project-based work. One participant shared,

Honestly, leaving school and starting work full time has been challenging [...] When I first started [work], it was really hard having that work-life balance because I would come to work and then be tired after and just go home and not do anything. So it's finding time just to take for yourself and do stuff for yourself, like waking up earlier to work out and then going home and cooking a meal and… just work-life balance is the hardest part. (Sam)

Sam emphasized that carving out even small portions of the day to commit to self-care had been impactful in helping her create a better work-life balance.

Another challenge that arose across all participant narratives was the pressure they felt as underrepresented engineers (i.e., women or Black women) to work harder to prove themselves and their abilities. This often resulted in taking on too many tasks and working hours and an internal fear of speaking up to ask for support or assistance. This resulted in increased stress and even feelings of burnout early in their career. One participant shared that setting boundaries and asking for help when needed was something she believed would help her succeed in the field.

I need to set more boundaries. My supervisor will ask me to do something, and I will do it. But I tend to be like 'No worries, I could do it right now.' And not like take a step back and be like *Can I?, Do I need anything else before I start doing it?, Do I need to tell them anything?* [...] I'm still trying to figure out how to get into the groove of working which is still very fresh. (Sandy)

Sandy reflected that she often immediately agrees to complete tasks right away to please her supervisor. However, she recognized it might be helpful to pause and evaluate the nature of the tasks and decide if there is any support or resources she might need.

Theme 2: Early career women recognize the significance of self-assurance, confidence, assertiveness, resilience, and seeking guidance or support for successfully navigating the transition into the engineering workforce.

In addition to battling external pressures associated with demanding workloads and high stress cultures in engineering workplaces, the early career women in this study were grappling with internal thoughts and pressures to prove themselves and their worth in the engineering workplace. One participant shared that having self-assurance and challenging these negative thoughts were useful skills in overcoming some of these internal challenges. She shared,

Just reminding myself I'm doing a good job. Honestly, I don't need to make up problems that don't exist. Like no one has said to me, ‘Hey, can you do this faster?’ ‘You're not learning fast enough.’ And I think internally I just need to remind myself that if a problem does arise, it will be brought up. My team is very communicative. I don't need to make it up in my head that I'm not doing a good enough job if they’re not telling me that. (Sandy)

Sandy emphasized that there were problems and challenges occurring in her head that were not being communicated to her directly by her team. She emphasized the importance of reminding herself of her skills, abilities, and past successes. Another participant emphasized the importance of gaining confidence in her engineering abilities and competence through work experiences. She shared,

Going into my first internship, I felt like a little baby[…] I didn't know anything about having a real job. The main theme of everywhere I've worked and my growth throughout my career thus far is just *gaining confidence*. And I have had some good mentors who have pushed me along my way and helped me realize that I have a voice that my education can apply to what they're doing, and that I can be independent and not have to worry about completely messing everything up. Little by little, *just gaining that confidence and that knowledge that I am capable and worthy of the spaces that I'm in*. (Brittany)

Brittany shared that she felt inexperienced and shy coming into her first engineering internship and work experiences. However, over time she identified solid mentors who helped support and empower her in these settings. This mentorship and maturity in her career resulted in her gaining confidence around her capabilities, worth, and belonging in engineering settings. Brittany further emphasized the importance of identifying role models and developing relationships with them to build confidence.

There's one girl. She was just very outspoken. Just very confident, not afraid to voice her opinion. And I think people really respected her for that. And I thought she was cool. So I've actually kept a relationship with her. (Brittany)

Brittany emphasized that identifying role models and mentors that shared a similiar identity was essential when entering an engineering career as an underrepresented engineer.

In a corporate [engineering] office settings just having those mentors and people that you can go to and voice concerns without fear of judgment, someone unbiased, is really important. And then just seeing examples of other women and people who look like you doing higher level work and not just… sitting on the sidelines […] just having that mindset of being open to everyone being friendly. And just being willing to work with people. (Brittany)

Across all participant narratives, establishing strong personal relationships and activating social capital by reaching out and asking for help when needed was critical to the success of these women in engineering spaces. Sam shared, “They toss you into the deep end, but that's the best way to learn. You ask a lot of questions and get exposed to a lot. That way you progress”. Another participant, China, emphasized the importance of resilience and asking for help. Even after negative interactions with her coworkers and feelings of exclusion, China expressed resilience and dedication to building relationships and seeking guidance. She shared,

You have to be willing to try again and not be so close minded as far as making relationships on the team. I even asked the guy that I don't like a question and he actually helped me. I had to push myself to do it because honestly, I didn't want to ask him, but I'm growing and I'm maturing and, I asked him and he helped me [...] I think just doing my part to develop stronger relationships, it's going good. I know it's going to take time with some people versus others, but I feel like it's going good direction. (China)

China emphasized the importance of strengthening team relationships and asking for help and support when needed. Kelsey reflected that to be successful as a new engineer requires overcoming fear of failure, trying new things, taking risks, getting comfortable with discomfort, and learning from mistakes. She shared,

One thing that a lot of students have is a “fear of failure.” I feel like women especially are scared to be wrong, so they are scared to try. This can really hold you back, so it’s important for new engineers to be willing to make mistakes as long as they are trying new things otherwise you won’t grow at all. You have to be willing to make yourself uncomfortable and put yourself in new/unfamiliar situations. (Kelsey)

4 SUMMARY

4.1 Discussion

This study highlights potential antecedents of positive outcomes for women in the engineering workforce, emphasizing the importance of work-life balance, self-confidence, assertiveness, resilience, developing strong relationships, and seeking guidance. These insights are crucial for empowering women during their transition into the engineering workforce. It also aligns with prior research highlighting the significance of relational factors, such as collaboration and feedback, for women's early career success (Marinelli et al. 2022). This study adds to the literature on the importance of relational empowerment (i.e., interactions that promote or prohibit autonomy in engineering work) and promoting student agency to practice and develop skills in the workplace (Lutz et al. 2019). Relational empowerment can be improved by granting early career individuals more control over decisions, tasks, and assignments (Lutz et al. 2019).

Additionally, the study reveals the internal challenges faced by early career women, including self-doubt, imposter syndrome, and pressure to excel. These challenges disproportionately impact underrepresented groups, notably Black women, who often experience heightened self-doubt and external pressures (Ross 2016; Smith et al. 2019). To sustain their engineering careers, these women found skills such as boundary setting, prioritizing stress-relieving activities, and seeking mentorship as useful in transitioning to engineering careers. These strategies helped participants navigate the invisible labor challenges associated with their underrepresentation and enhance career sustainability.

Recommendations for industry leaders and educators include providing positive reinforcement, mentorship opportunities, and support during the transition into the workforce. Engineering educators, faculty advisors, and mentors should provide opportunities for students to hear from and interact with women in engineering who have successfully navigated the transition from school to the engineering workforce and who are willing to share skills or advice they wish they had before they entered engineering careers. These encounters can contribute to fostering positive outcomes for early career women and emphasize the importance of social capital (i.e., access or availability of social networks that result in outcomes such as resources, jobs, information, support, or guidance (Lin 1999)) as students transition to the engineering workplace. Despite being based in the US, these findings are relevant globally, as studies in Europe also reveal similar challenges and disparities faced by women in engineering (Powell et al. 2012; Cannaerts et al. 2023).

In summary, this study underscores the internal and external challenges faced by early career women in engineering, offers skills and strategies for overcoming these challenges, and calls for comprehensive support systems to promote their success and inclusivity in the engineering workforce.

4.2 Limitations and Future directions for research

This research examined the lived experiences and reflections of a small sample population. Although the data's generalizability to all populations is limited, the findings may be transferable to those with similar identities working in similar fields. Future research should explore how, as part of their educational experience, women might develop competencies needed for a successful transition to the workforce. Further research could explore these transitions in different engineering disciplines and cultures.

4.3 Acknowledgements

The authors would like to gratefully acknowledge the participants for their thoughtful reflections and participation and interviews as well as the contributions made by Alison Bower to organize and edit this paper.

Keywords: *Diversity, equity, equality, inclusion,*

ABSTRACT

It remains the case that the engineering profession fails to reflect the diversity of people impacted by its work, and issues of diversity, equity and inclusion (DEI) continue to be a key area of interest within engineering education research (EER). In this work we aim to understand the focus of DEI within engineering education: we applied a scientometric content analysis to EJEE and JEE articles published in 2023. Three authors independently screened each publication (using the title and abstract) for inclusion in the subsequent analysis and synthesis stage. The abstract of each paper was then evaluated to determine the primary DEI issue(s) covered. Findings indicate that DEI is currently a major focus for US scholars with 42% of the 71

[1] *B Williams*
bwbillwilliamsbw@gmail.com

publications in JEE addressing DEI in some form. Articles studying underrepresented racial groups (43% of DEI articles identified) made up the largest part of these publications while 23% considered gender related under-representation. In the case of EJEE there were fewer DEI related papers overall in 2023: 15% of the 86 publications addressed DEI in some form. Of these publications 77% referred to gender related under-representation, which suggests that this area of DEI is currently the most studied by EJEE-published researchers

1 INTRODUCTION

Issues of diversity, equity and inclusion (DEI) have long been discussed within engineering education and practice, with the rationale for work in the area including a variety of arguments based on social justice to economics. Terms such as inclusion, diversity, equity, and equality, while commonly used within engineering education, tend to be used interchangeably and their meaning both evolves over time, and varies significantly across context and institution. Such changes and variation have implications for the areas in which efforts towards DEI, are focused, as well as our ability to learn from good practice and monitor progress. One way in which to gauge the areas of DEI that are of current interest is by understanding the common issues researched. This work therefore describes an analysis of papers published within the Journal of Engineering Education (JEE) and the European Journal of Engineering Education (EJEE) in 2023, to determine the DEI issues studied.

Scientometric methods have been used to understand the engineering education research (EER) publication landscape previously. For example, when mapping global trends in engineering education research, Jesiek et al. (2011) analysed the categories of research published in a range of journals and conferences between 2005 and 2008 and found that Diversity, classified as including Gender, Masculinity, Minority, Race, Underrepresentation and Women, appeared as 13th in a ranking of the most studied areas (the first three places in their ranking were occupied by Learning, Assessment and Educational Technology respectively).Previous EER in this area includes a content analysis of gender-related research published in JEE over a fourteen year period (1998-2012) whereby scientometric and other classification categories were developed and applied (Pawley, Schimpf, & Nelson, 2016). Articles primarily focused on quantitative studies of undergraduate students in university settings and applied a variety of theories. More recently, in their bibliometric review of papers published within JEE over a 53 period (1969-2021), encompassing 1251 articles, Qiu and Natarajarathinam (2022) identified diversity and inclusion as a major theme that was covered in 106 papers. Topics were found to include gender, student characteristics affecting enrollment and retention, value system and personal identity, and race and ethnicity, among others.

More recently, in a ‘Statement on Diversity and Inclusiveness’, the American Society for Engineering Education (ASEE) claims that “diversity and inclusiveness is essential to… innovations that drive the development of creative solutions in addressing the world’s challenges”. Similarly, in the ASEE & SEFI (French: Société Européenne pour la Formation des Ingénieurs, English: European Society for Engineering Education) Joint Statement on Diversity, Equity, and Inclusion (2020), the organisations claim that “engineers have not consistently made informed judgements that consider equitably the far-reaching societal impacts of engineering solutions" and that "history has shown that new technologies benefiting one part of society sometimes have less fortunate impacts on other segments" saying that "these unintended consequences partially result from an engineering profession with a limited diversity of lived experiences" (p.1). In a Position Paper on Diversity, Equality and Inclusiveness in Engineering Education (SEFI, 2018), SEFI states that "recognizing and supporting diverse individuals is more than a moral or ethical obligation. It is also the logical choice to improve the practice of engineering and its impact on society".

Despite such efforts, the lack of diversity within engineering continues to exist, with our ability to monitor changes in demographics being impacted by our changing and varying understanding of diverse characteristics. Such differences in semantics have been highlighted in the work of Pineda and Mishra (2023) who made use of computer-assisted content analysis to explore the extent to which the term 'diversity' appears to be global and universal within 2378 publications. Their findings reveal that diversity discourses are dominant within the USA and Canada, UK and Ireland and Europe, but not Asia, Africa, the Middle East and Latin America. They found academic literature on diversity to have emerged in the mid-1970s in both the USA and Canada, primarily in relation to race and gender, this extending to other English-speaking countries by the mid-2000s, with inclusion, gender, ethnicity and cultural diversity being referenced. Within Europe, diversity appeared later in the decade, often framed as inclusion and gender. They concluded that the interpretation was influenced by the local socio-political settings and that the semantics of diversity had not become global or universal.They subsequently proposed the use of new methods that allow and support the ability to view different regions simultaneously.

Given these differences in interpretation, it is encouraging that ASEE & SEFI call for a commitment to "deepen and broaden our understanding of inequities, so that we are prepared to take action to transform our institutions, universities, and the whole of the engineering community" (p. 2) within their Joint Statement on Diversity, Equity, and Inclusion (2020). The organisations claim that "steady gains have been made" in terms of "decreasing imbalance for white women" but acknowledge that progress is needed with respect to "all segments of our society, including minoritized races, immigrant populations, disabled persons, and economically marginalized groups". claim that it is "our engineering duty that no one is disadvantaged or receives less favourable treatment because of age, disability, neurodiversity, gender, gender identity and expression, sexual orientation, race, ethnicity, religion or belief, socio-economic status, national status, pregnancy and maternity, marriage and civil partnership, or any other minority status" (p. 3)

In keeping with such commitments, it is interesting to note that (what was) the SEFI *Gender and Diversity* Special Interest Group (SIG), changed their name to *Diversity, Equity and Inclusion* saying that they "embrace a broad understanding of diversity, equity and inclusion and work to better represent all SEFI members and the wider engineering education community. It is our experience that definitions of diversity, equity and inclusion vary considerably between different contexts and institutions, and that many initiatives have been primarily concerned with widening the participation of women in engineering".

As pointed out by Meija and Martin (2023) the fact that researchers use the same terms, whilst defining them and measuring them in different ways, makes it difficult to discuss DEI work meaningfully. Considerations for these broad understandings are of significance in terms of our ability to learn from best practice and make use of research findings within our own context, but also in supporting our ability to monitor progress and inform strategy and policy in the area. It is subsequently of interest to investigate and compare the focus of DEI research within engineering education. Consistent with this aim, here we present initial findings of a study involving the analysis of EJEE and JEE articles published in 2023 in terms of the primary DEI issue(s) covered.

This study aims to determine the current DEI issues under focus in two leading journals in the EER field. It poses the research question:

- what are the DEI topics addressed in the European Journal of Engineering Education and the Journal of Engineering Education in 2023?

2 METHODOLOGY

Adopting a scientometric content analysis approach (Hassan & Mathiassen, 2009), a list of all publications (including articles, editorials and erratum) in EJEE and JEE during 2023 were downloaded from the Scopus web interface. There were 86 EJEE publications and 71 JEE publications in 2023. We limit this work to the main EER journals, namely JEE, and EJEE which, as Jesiek et al. (2011) observe, have committed to publishing and disseminating high quality EER work, are highly cited journals. They are published by the American and European Societies for Engineering Education respectively, both of whom collaborated on the ASEE & SEFI Joint Statement on Diversity, Equity, and Inclusion (2020). We therefore chose JEE as a representative of US and EJEE of European EER journals. Furthermore, both journals specifically refer to EER in their scope.

Publications were vetted for inclusion in two main stages.The purpose of the first stage was to restrict the list to only those that discussed at least one DEI issue (Direito et al., 2021). The second stage focused on classifying the included papers into specific DEI categories that would subsequently be used for statistical analysis.

First, three authors independently screened each publication (using the title and abstract) for inclusion in the subsequent analysis and synthesis stage. Publications were tagged by the author for inclusion included using a binary yes/no inclusion criteria; publications that explicitly referred to any DEI issue within the title and/or abstract were tagged as ‘yes’. Following this, the authors met to compare their evaluations and any disagreements were resolved during discussion in which a consensus as to whether each article was to be included or excluded, was reached. Following this, the authors then evaluated each abstract together to inductively determine the primary DEI issue(s) covered, and allocated publications to these categories.

Editorials were included as they were considered to reflect emerging and significant areas of interest within the context. They have, alongside review papers, been separated from research papers in terms of analysis (see Table 3, Table 4). Abstracts in which DEI was not mentioned as a primary aim or focus of the research, but in which elements of DEI were mentioned or reported in the findings were included on the basis that they demonstrated an understanding of the impact of diverse characteristics on research outcomes. However, results are again presented separately (Table 2 and Table 6). Papers focused on belonging were also included to reflect the (often lesser used) term DEIB (Diversity, Equity, Inclusion, and Belonging), which originated in organisations in the 1960s and which recognises sense of belonging as associated with inclusion. Finally, abstracts which referred to 'mental health' were included as they were considered to relate more directly to ableism and disability as opposed to those who broadly referenced wellbeing.

The full-text of each paper was not evaluated, as it was outside the intended scope of this paper. We thus acknowledge that our analysis may have excluded papers that discuss diverse characteristics, for example within the findings, without this being mentioned in the abstract. The findings reflect the focus of journal articles published within 2 journals during a year one period and the degree to which they reflect wider trends is thus limited. We also recognise that published work only reflects a small amount of DEI work conducted within engineering education, and the validity of our findings are thus limited by the extent to which trends in published articles reflect the situation more widely.

3 RESULTS

Papers were assigned an individual ID (e.g. EJEE-3, JEE-18) based on the row in the spreadsheet exported from Scopus. e.g. EJEE-15 refers to the publication on the fifteenth row of the exported spreadsheet. The results below are presented first showing the results from EJEE, then the results from JEE.

3.1 European Journal of Engineering Education

There were 86 EJEE publications in our sample from 2023. A total of 9.3% of the publications primarily focused on addressing at least one specific DEI issue, with 7.0% focusing on gender related issues, 1.2% focused on belonging or inclusion, and 1.2% focused on diversity of nationality (Table 1). There were also another 6.8% of the publications which did not primairly focus on DEI issues, but included metrics or information related to DEI in the results or findings (Table 2).

Table 1. EJEE Articles which primarily focused on a DEI issue(s)

DEI Issue	%	Publications
Gender	7.0%	EJEE-02 Rokooei (2023) EJEE-09 Vellamo (2023) EJEE-11 Maji, Mitra, and Asthana (2023) EJEE-23 Chan, Rottmann, Reeve, Moore, Maljkovic, and Radebe (2023) EJEE-28 Qadhi, Du, Chaaban, Al-Thani, and Floyd (2023) EJEE-52 Moloney and Ahern (2023)
Belonging/Inclusion	1.2%	EJEE-38 Holmegaard, Madsen, and Nielsen (2023)
Diversity of Nationality	1.2%	EJEE-30 Bergman, Negretti, and Apelgren (2023)

Table 2. EJEE Articles which primarily focused on other issues, but included DEI in the results or findings

DEI Issue	%	Publications
Gender	4.6%	EJEE-22 Lockhart, and Rambo-Hernandez (2023) EJEE-37 Apostolellis, Taggart, and Schwartz (2023) EJEE-55 Behera, Alves de Sousa, Oleksik, Dong, and Fritzen (2023) EJEE-64 Chédru and Delhoume (2023)
Access/ Participation	1.2%	EJEE-73 Wint (2023)

3.2 Journal of Engineering Education

There were 71 JEE publications in our sample from 2023. A total of 30 (42%) publications primarily focused on addressing at least one specific DEI issue (Tables 3, 4, 5), with marginalised racial groups (18.3% total - articles 14.1%, review 1,4%, editorial 1.4%) gender (7.0% total - articles 7.0%), belonging (4.2% total - articles 4.2%) and mental health (4.2% total - articles 2.8%, review 1.4%) being the largest categories. Smaller categories included diversity of nationality, disability, historical marginalised groups only having 1.2% each. There were also another 5.6% of the publications which did not primarily focus on DEI issues, but included metrics or information related to DEI in the results or findings (Table 6). Overall, 43% of the 30 articles identified, were dealing with under-represented racial groups while 23% gender-related under-representation.

Table 3. JEE Editorials which primarily focused on a DEI issue

DEI Issue	%	Publications
Marginalized Racial Groups	2.8%	JEE-08 Secules (2023) JEE-12 Paige, and Morton (2023)
Diversity of Nationality	1.4%	JEE-14 Xu, Wei, and Cao (2023)

Table 4. JEE Review Papers which primarily focused on a DEI issue

DEI Issue	%	Publications
Marginalized Racial Groups	1.4	JEE-39 Reeping, Lee, and London (2023)
DEI (generally)	1.4	JEE-53 Andrews, and Boklage (2023)
Mental Health	1.4	JEE-71 Asghar, Minichiello, and Ahmed (2023)

Table 5. JEE Articles which primarily focused on a DEI issue(s)

DEI Issue	%	Publications

Gender	7.0	JEE-21 Patrick, Andrews, Riegle-Crumb, Kendall, Bachman, and Subbian (2023) JEE-24 Davis, Nolen, Cheon, Moise, and Hamilton (2023) JEE-25 Garriott, Pinedo, Hunt, Navarro, Flores, Desjarlais, Diaz et al (2023) JEE-37 Halkiyo, and Hailu (2023) JEE-59 Chen, Usher, Roeder, Johnson, Kennedy, and Mamaril (2023)
Marginalized Racial Groups	14.1	JEE-21 Patrick, Andrews, Riegle-Crumb, Kendall, Bachman, and Subbian (2023) JEE-24 Davis, Nolen, Cheon, Moise, and Hamilton (2023) JEE-25 Garriott, Pinedo, Hunt, Navarro, Flores, Desjarlais, Diaz et al (2023) JEE-37 Halkiyo, and Hailu (2023) JEE-39 Reeping, Lee, and London (2023) JEE-47 Coley, and Thomas (2023) JEE-52 Henderson, Junqueira, Benjamin, Hines, Alarcón, Davis, and Cavazos (2023) JEE-61 Taylor Jr, Mastrogiovanni, Lakin, and Davis (2023) JEE-66 Fleming, Coloyan, Patrick, Grote, Denton, Knight, Lee, Borrego, and Murzi (2023) JEE-68 Fletcher, Jefferson, Boyd, Park, and Crumpton-Young (2023)
Belonging	4.2	JEE-21 Patrick, Andrews, Riegle-Crumb, Kendall, Bachman, and Subbian (2023) JEE-63 Buckley, Robinson, Tretter, Biesecker, Hammond, and Thompson (2023) JEE-68 Fletcher, Jefferson, Boyd, Park, and Crumpton-Young (2023)

Marginalized Racial Groups	1.4	JEE-27 Misra, Kardam, VanAntwerp, and Wilson (2023)
Belonging	1.4	JEE-27 Misra, Kardam, VanAntwerp, and Wilson (2023)

4 DISCUSSION

Given that the researchers whose work is published in JEE are predominantly US-based (Williams, Wankat & Neto 2018), our findings suggest that DEI is currently a major focus for US scholars with 30 of the 71 (42%) publications addressing DEI in some form. Underrepresented racial groups (43% of DEI articles identified) made up the largest part of these publications while 23% considered gender related under-representation. Other DEI contexts appearing in JEE included belonging, disability, mental health and diversity of nationality.

In the case of EJEE there were fewer DEI related papers overall in 2023: 15% of the 86 publications addressed DEI in some form. Of these publications 77% referred to gender related under-representation, which suggests that this area of DEI is currently the most studied by EJEE-published researchers. While authors in EJEE predominantly are Europe-based, they also include researchers from the US and other international contexts (Williams, Wankat & Neto 2018). Other DEI contexts appearing in EJEE included diversity of nationality and belonging.

The methodology presented here can be readily adapted to analyse a larger sample of journal articles and the authors plan to do this in future work.

CONCLUSION

While DEI issues were 13th in the ranking of the most studied areas in EER in the period 2003-2008 (Jesiek et al., 2011), they have become a high-priority area in recent years with race and gender issues being the most addressed in JEE publications and gender the most in EJEE. These findings will be helpful to inform the work of groups like the SEFI Special Interest Groups on Diversity, Equity and Inclusion and on Ethics as well as the ASEE ASEE Commission on Diversity, Equity and Inclusion.

Conference Key Areas: *Building the capacity and strengthening the educational competences of engineering educators*
Keywords*: Engineering education research evolution, European Journal of Engineering Education, oral history*

ABSTRACT

This paper uses an oral history approach to present an account of the evolution of the European Journal of Engineering Education over the last 16 years. In the words of two Editors-in-Chief it traces the process whereby the journal has become a home for high quality research in engineering education both in Europe and globally. The journal has adapted to a notable increase in submissions by broadening its editorial staff and defining its aims and scope to attract research that combines scholarliness and usefulness. At the same time, EJEE has consciously worked at building a broad community of scholars through the SEFI conferences and its networks. In addition it has assumed a role in pro-actively guiding and sharing research by introducing a new special-issue process.

1 INTRODUCTION

1.1 Engineering Education Research: historical context

While formal education in engineering began in France with the establishment of the École Polytechnique in 1794, publication of research into engineering education (EER) gathered impetus in the1980s (Wankat et al. 2014). Early this century its status as a field of inquiry was the subject of debate among engineering educators, particularly in the US (Froyd & Lohmann, 2014) and by 2006, researchers began calling for "rigorous research" in engineering education (Loui and Borrego 2019).

Today research in engineering education is supported through the same structures as research in older academic disciplines: university departments, doctoral programs, research centers, academic journals, specialized conferences, and groups within professional societies.

The EER field has been represented as comprising five categories (Loui and Borrego 2019):

Engineering epistemologies

Engineering learning mechanisms

Engineering learning systems

Engineering diversity and inclusiveness

Engineering assessment

These five categories define the overall organization of the Cambridge Handbook of

Engineering Education Research (Johri & Olds, 2014), which provides a comprehensive overview of the field.

In addition to these five categories the importance of a meta research approach to study the historical evolution of the field and curate data and artefacts is being increasingly recognised (Froyd & Lohmann, 2014), Loui and Borrego 2019).

A recent example of this historical approach can be found in the Journal of Engineering Education (JEE) where interview data were presented from three recent editors in chief of that journal: Jack Lohmann, Michael Loui

Lisa Benson (Williams et al. 2023). Under Jack Lohmann, there was a shift in the journal's mission to a research journal aimed at highlighting rigorous engineering education scholarship. During Michael Loui's editorship, there was a significant increase in the number of qualitative and mixed-method studies appearing in the journal. Lisa Benson's tenure as editor-in-chief was a period when the journal made a commitment to supporting more inclusive practices in the engineering education community and to a more international and diverse editorial board.

1.2 SEFI: historical context

SEFI was founded in 1973 and in 1976 it decided to publish a quarterly journal, European Journal of Engineering Education, devoted to the presentation and discussion of important developments in higher engineering education, focusing on the European scene, but open to contributions from everywhere in the world.

The editorial board (Editorial Board, 1975) positioned the journal to include:

(1) scholarly articles and documented analytical reports,

(2) descriptions of institutions and of systems in member countries,

(3) editorials and letters to the editor to engender discussion,

(4) in-depth reviews of books, and

(5) news and features on SEFI.

Thus, SEFI apparently did not originally intend for EJEE to become the major research journal into which it has matured. By the beginning of this century, under the leadership of Jean Michel, EJEE had changed and the journal had the look and feel of an international research Journal (Côme et al., 2013). There were significantly fewer reports about engineering education at a specific institution or in a specific country – and an analysis in 2013 showed that by that year all the articles being published in EJEE could be classified as research (Wankat, Williams and Neto, 2014).

Given that SEFI recently celebrated its 50th anniversary and that in 2026 EJEE also will, we believed it would be instructive to capture the perspectives of the two editors -in-chief at the helm of the journal this century.

2 METHODOLOGY

Adopting an oral history methodology (Lambert and Frisch 2013) we interviewed Erik de Graaff (2008 to 2017) and Kristina Edström (2018 to the present). This approach is frequently applied in historical research (Janesick, 2020) although as yet it is not common in EER.

The procedure followed was in line with the Principles and Best Practices of the Oral History Association (2018). The interviews lasted between 40 and 60 minutes. They were conducted online, recorded and transcribed. The transcriptions were then sent to the interviewees who could refine their statements.

3 INTERVIEW DATA

Erik de Graaff (2008 to 2017)

“Somehow it appealed to me to have this position as journal editor. I thought I could improve the editorial process - when you're young and energetic, you have a lot of fantasies, how you can change things. And the biggest challenge was simply how to run the journal. Because it had been run in quite a traditional way where the EiC relied mainly on his personal network with much of the editorial process being done manually by the editor himself and so all dependent very much on knowing not only the system, but also all the people involved.

It really took quite some time before I had it sorted out in a way that we could communicate with the authors via email and run everything regularly. So actually, we had a problem in the first year to get six issues out and ended up missing one issue. That was a source of frustration later as it is likely to have delayed the process of our receiving a Web of Science Impact Factor.

After two years, we had everything running, having transferred to an electronic system with the help of the publisher Taylor and Francis. And with that system, I actually was able to manage the whole journal on my own with the help of a team of associate editors I brought on board. So that was that was the main challenge of getting started in the role of EiC.

And we had a different policy to that of the ASEE publication the Journal of Engineering Education (JEE). Jack Lohmann, the JEE EiC at that time had a policy of emphasising rigorous research whereas for EJEE our focus was on research that was relevant for engineering education practice. And I believe that spirit still prevails at EJEE today - I know that my successor is committed in that same way.

The electronic system we introduced allows you as an editor, to have access to everything from wherever you were on the world, every hour. And you could very easily communicate with all the reviewers, you could select them and have the preferences of people saved along with their knowledge and skills. So it was much less dependent on the personal network on your own individual knowledge. Of course, it always helps that you know people , and you know someone to be very, very strict, and another to be more lenient as that is not recorded. So you have to build that personal knowledge base. But it is more layer on top of a system that that works, independent of the people who operate it.

By 2017 when I was coming to the end of my term there were more and more papers coming to the European Journal and it had become hard for me to manage on my own. I had indicated that I would finish my term in 2018 and in the year before, we started the search for a new editor in chief. My aim was to hand it over in such a way that that there was a smooth transition. I have collaborated with my successor, Kristina Edström who could call on me if there were any questions or any things I could do. She still inherited a backlog of over a year by that time. And she took off differently, organising it much more as a team effort then as an individual effort. And that was the necessary kind of change that I could not have made. It was necessary, because the journal had grown so much and it was essential to organise the tasks in components that could be delegated to other people. And she started doing that right from the beginning.

I think that during the 10 year period that I was in charge, the scientific standard became more important - there was a growth of development and quality. Now, that is very difficult to measure that but if I look to the older issues, the ones before 2007, there were many articles presenting small scale classroom initiatives and this is no longer the case. The other changes I note are the transition to the online platform and the enormous growth in submissions from all over the world.”

Kristina Edström (2018 to present)

“When the call went out for a new Editor-in-Chief for EJEE, it was time for the journal to take a new step. Some colleagues had experienced delays when publishing in EJEE, which was particularly difficult for PhD students. The engineering education field had developed to a state where people were having careers. It was then imperative to have a well-functioning journal that could enable *and drive* the development of the field. Journals have the important function to help define the field and uphold quality standards, by selecting and highlighting work according to their aims and scope and their quality criteria. Without journals, you don't have a field.

At that time, seniors like Anette Kolmos, Erik de Graaff and Jonte Bernhard had been actively supporting my development for years. Now I thought it was my turn to support the new generation, and the journal would be a great platform for that. I understood that I would publish much less myself, because the editorship takes so much time and mental energy. In a way, being an editor is a dirty job, but someone has to do it. But I was over 50, had a permanent position and support from my university, so I could take one for the team here. I also saw it as an inherently stimulating task and was excited about actively shaping and furthering the field.

Beginning my editorship, the number one challenge was to build editorial capacity. Submissions had increased so much that handling them was a major effort, and there was a substantial backlog. I recruited two heroic deputy editors, Jonte Bernhard and Maartje van den Bogaard. Together we got the machinery up and running, reaching a healthy steady state during our first year. Affectionately, we called this period of hard work our “spring cleaning”. Perhaps a better metaphor would be “pulling off the bandaid”, because it meant that we raised the quality threshold immediately and significantly, with tough implications for many authors.

During our first months we also formulated the new aims and scope for the journal (Edström, Bernhard & van den Bogaard, 2018). The fundamental quality criteria state that the work should *combine scholarliness and usefulness*. In other words, the ambition was to raise the academic quality, while still emphasizing that the work had to be relevant and useful for engineering education. This positioning of the journal did not come out of the blue. The usefulness criterion meant staying firm on the course held by Erik de Graaff. My thinking on these matters had been developing since 2012, in relation to the CDIO initiative and my own motivation as a researcher (Edström, 2020). We see now that these criteria have been stable since we formulated them. They resonate with people and define a legitimate aim for the journal, and by extension for engineering education research.

During the years there were questions about EJEE not having a journal impact factor, but that was never a big worry for me. I always felt secure that we would eventually get it – as indeed we have. Especially since the matter was not in our control, my focus was only on developing the quality of the journal. It is the quality that drives the impact, whether it is formally listed as a journal impact factor or not. If the official impact factor had come in 2018 it would only have been 0,8 – but when we did get it in 2023, it was 2.3.

Looking back, I am particularly pleased to see the vibrant community that we have cultivated around the journal. When the journal was in steady state, we started recruiting. By now we have about a dozen associate editors, and another heroic deputy editor, Shannon Chance. It's such a pleasure to work with this brilliant editorial team. The fine relationship with SEFI is another strength of the journal. SEFI has supported its journal in thick and thin, and it would not be the same to publish a journal without a mother organization. The journal team is now a big group of people who are active in the SEFI conferences. We are all approachable and transparent about the journal, we give workshops for authors and for reviewers, and we participate in the SEFI doctoral symposium. One particular aspect of that is to encourage the PhD students to become reviewers. It is a relevant learning experience for them, as it helps them understand the peer review process. We think of it as inviting them to be members of the field.

Reviewers are a very special part of the journal community; there cannot be a journal without reviewers. We are so grateful for the amazing support they provide, and they do it anonymously, behind the scene. My worst frustration is also related to this: I am puzzled when people who publish in the journal still decline to review the work of others. My kindest interpretation is that they may not understand how a research field works. Reviewing is an integral part of being a scholar and people who want the advantages without contributing will undermine the system.

Another exciting development is that we have used special issues proactively. Rather than accepting incoming proposals and using them a means to unburden the Editor-in-Chief, I see them as a way to call for important work and to support the development of people and networks. We start by identifying a timely topic and shaping a guest editor team around it. Ideally, we combine younger scholars with key seniors, connecting different international groups. We require the team to contact potential reviewers upfront, already when the call-for-papers is being drafted. Finding reviewers must be done at some point anyway, and this way it alerts and involves key scholars within that topic. This approach has produced strong special issues that capture the state-of-the-art. It also strengthens the community around the journal, and some guest editors have stayed on as associate editors after their special issue is published. I've really enjoyed making this shift – recognizing that it is one way that the journal can take initiative and make good things happen.

Strengthening the community in all these various ways is a seamless and long-term activity. This is also the community in which it will be easy to find our successors as we turn over the editorial team."

4 Discussion

In this brief account of the evolution of EJEE over the last 16 years we have seen that the journal has become a home for high quality research in engineering education both in Europe and globally (De Graaff 2013, 2014, 2017). It has adapted to a notable increase in submissions by broadening its editorial staff and defining its aims and scope to attract research that combines scholarliness and usefulness (Edström, Bernhard & van den Bogaard, 2018; Edström 2020). At the same time, the journal has consciously worked at building a broad community of scholars through the SEFI conferences and its networks. In addition it has assumed a role in pro-actively guiding and sharing research by introducing a new special-issue process.

Overall while the EJEE evolutionary process described in these interviews has much in common with that of JEE this century as was referred to in the Introduction (Williams et al. 2023), the two journals differ somewhat in their aims and scope in that while EJEE aims to publish research that combines scholarliness and usefulness, JEE sees its main role as cultivating, disseminating, and archiving scholarly research.

5 Conclusion

As the European Journal of Engineering Education approaches its 50th anniversary, the journal will no doubt continue to evolve in tandem with the community it serves and we present this history in the hope that the Editor-in-Chiefs' observations set out here will contribute to the 50th anniversary reflections and will serve as a reference for future editors and readers of the journal.

ABSTRACT

Research highlights the influence of faculty on educational change in engineering education, emphasizing the need for interdisciplinary research and strategies aligned with individual perspectives. This study investigates the role of motivational and hindering factors among faculty engaged in engineering education across different

[1] *A Winkens*
ann-kristin.winkens@rwth-aachen.de

European universities as part of the ENHANCE alliance. For this purpose, a survey was developed and distributed to faculty engaged in engineering education from the ENHANCE universities. Statistical analysis of 391 responses reveals intrinsic motivation as the most relevant factor for engaging in engineering education, with varying perceptions of extrinsic motivation and hindering factors among universities. Further analysis indicates financial constraints, bureaucratic challenges, and political influences as common barriers, with differences attributed to national policies and institutional contexts. The results underline the relevance of considering local and national contexts in addressing motivational factors and barriers to quality engineering education. Further research is needed to explore correlations with political frameworks and individual beliefs, aligning with strategies for educational change in engineering education.

1 INTRODUCTION

In the rapidly evolving landscape of engineering, engineering education stands as a cornerstone in preparing the next generation of engineers. Central to this endeavor are motivated and pedagogically skilled faculty members, shaping not only the technical skills of their students but also their professional identity and ethical outlook. A wide range of research reports on motivating and challenging factors of people engaged in engineering education, referring to several drivers and barriers to pursue educational change or to adopt effective teaching practices (e.g., Cutler and Coso Strong 2023; Finelli et al. 2014; Graham 2012; Henderson et al. 2011; Matusovich et al. 2014; Shadle et al. 2017). At the same time, Cutler and Coso Strong (2023) highlight an often-overlooked influence of engineering faculty on engineering education, as “Faculty can be the enactors of educational change practices” (p. 302). Faculty members, as teachers and supervisors, influence students’ ways to learn as well as their development of the engineering profession and belonging (Finelli et al. 2014). Moreover, engineering faculty has not only an influence on their classroom activities, but also on their participation in projects on educational change, curriculum design and the support and supervision of students (Cutler and Coso Strong 2023). Thus, pedagogical beliefs, positions, perspectives and institutional context may vary in terms of how faculty members as people influence students’ educational experiences (Cutler and Coso Strong 2023; Matusovich et al. 2014).

Graham (2012) identified common features in successful educational change in engineering education, such as leadership and faculty engagement or educational design and implementation. To initiate successful curriculum change requires especially a common goal between faculty and senior management (Graham 2012). In their literature review on change in undergraduate STEM practices, Henderson et al. (2011) highlight often discipline-siloed research on educational change (i.e., STEM education-, faculty development- and higher education-focused researchers) and call for more interdisciplinary research. In their review, they derived four categories of change strategies that include disseminating curriculum and pedagogy, developing reflective teachers, enacting policy and developing shared visions. The authors found that effective strategies for change are aligned with individual beliefs, long-term interventions, the understanding that universities are complex systems and the design of strategies that fit to these systems (Henderson et al. 2011).

However, research has shown that there are several barriers for engineering faculty members to educational change, where especially time constraints are cited frequently (Finelli et al. 2014; Henderson et al. 2011; Shadle et al. 2017). Other reported barriers are, for example, instructional challenges, such as large class sizes, loss of autonomy, resistance to change, funding opportunities, lack of support or lack of recognition (Henderson et al. 2011; Shadle et al. 2017). In contrast, factors such as encouraging collaboration and shared objectives, alignment with existing resources, flexibility, an actual improvement of students' outcomes or a faculty desire for students' success are reported as motivating and driving aspects (Finelli et al. 2014; Shadle et al. 2017).

In the context of the extensive and collaborative "Teaching Cultures Survey" (Graham 2020, 2022), the culture and state of the art of teaching in higher education worldwide is captured, where participating universities commit themselves to improve the state of the art of their teaching and education. The results of the previous two surveys show that most respondents perceived university teaching as widely undervalued and even career-limiting, where only a quarter of participants perceived spending time on teaching positively impacts their career advancement (Graham 2020). Moreover, participants did not perceive university teaching as being a priority area in their institutions. At the same time, most participants want university teaching to have a greater priority, where especially university leaders seem to be committed to change.

The context of this study is a joint research project on engineering education between Chalmers University of Technology, the Norwegian University of Science and Technology (NTNU) and RWTH Aachen University as part of the ENHANCE alliance. ENHANCE is an alliance of ten European technical universities, aimed at fostering collaborations between the universities at different academic levels (ENHANCE no date). The aim of this joint project was to explore teaching and learning experiences, attitudes and motivational aspects of people involved in engineering education from different countries and thus, different national and political frameworks. For this purpose, a survey was developed aimed at people from the ENHANCE universities involved in engineering education, i.e., teaching and educating engineering students. In this paper, we first focus on the analysis of motivational and challenging factors, i.e., this study refers to and uses only part of the data collected in order to expand and build on it in a next step. The focus of this paper is on the following research question: *What role do different motivating and hindering factors play in faculty engagement in engineering education across different universities?*

In doing so, we build on the existing literature on motivational and hindering aspects and focus on local differences between universities in different European countries, with each different national and policy frameworks, that have jointly committed to improving teaching in higher education as part of the ENHANCE Alliance.

2 METHODOLOGY

2.1 Survey Design and Data Collection

The survey was designed partly based on motivation and hindering factors mentioned in the literature (see section 1), and partly with the addition of our own factors. In total, the survey contains 19 items on motivating factors and 15 on hindering factors. Participants were asked to indicate to what extent they perceive the above aspects as motivating or hindering factors for engaging in engineering education. Further, the participants could add other aspects and there was also a section for free comments. The answers on the items based on a five-point Likert scale, ranging between strongly disagree and strongly agree.

Moreover, we asked for demographic information, such as employment status and duration and the academic discipline. All statistical analyses were performed using the statistical software R.

A pre-test, which was performed with test subjects to improve the questionnaire, verified the quality of the survey design. As described above, the survey was aimed at people who are engaged in engineering education at the ten member universities of the ENHANCE alliance. The invitation email to participate in the survey was sent to the university representatives for further distribution to people engaged in engineering education. The survey was available at SoSci Survey (https://www.soscisurvey.de/) between July and November 2023.

In total 489 persons, who stated that they are currently engaged in engineering education, from five ENHANCE member universities, namely Chalmers University of Technology (Sweden), Gdańsk University of Technology (Poland), Politecnico di Milano (Italy), RWTH Aachen University (Germany) and Warsaw University of Technology (Poland) participated in the survey. An analysis of the demographic data shows that 81 percent of respondents state that they are a professor (full, associate, and assistant professors). Due to the low proportion of other employment statuses, e.g., postdocs 2.2 percent or PhD students 4.7 percent, we only use the data sets of professors, which are 391, for the further analyses in this study in order to ensure comparability.

2.2 Data Analysis

In this study, we analyze which motivating and hindering factors are perceived by participants in engineering education and what differences exist between the universities surveyed. Before making any comparisons, we performed an explorative factor analysis. The analysis resulted in a model with two factors each for the motivating and hindering factors. Table 1 shows the assignment of the items to the respective factor. The factors *extrinsic motivation* and *extrinsic hindering* each comprise eight items with high factorial reliability (Cronbach's alpha = .89). The *intrinsic motivation* factor contains eleven items with equally high factorial reliability (Cronbach's alpha = .83) and the *intrinsic hindering* factor contains eight items with acceptable factorial reliability (Cronbach's alpha = .78). The item *lack of time* is not assigned to one of these factors and is therefore considered as a separate hindering factor, as it is also an established hindrance to the quality of teaching (e.g., Finelli et al. 2014; Henderson et al. 2011).

Table 1. Factor structure, associated items and internal consistency of the factors

Dimension	Factor	Item	Cronbach´s Alpha
Motivation	***Extrinsic***	Recognition from my colleagues Recognition from my line manager	.89

		Recognition from my department/faculty Recognition from my university senior management Recognition from my research community Funding opportunities The university supports an educational change	
	Intrinsic	Combining teaching and research Freedom to determine what and how to teach Motivation of the students The pleasure I get from teaching Responsibility for students´ skills development The desire to positively impact students´ skills development The desire to positively impact students´ future engineering career To apply best practice examples in my own teaching To educate students with newest teaching methods/approaches To bring actual research to the students To motivate and inspire students for the subjects of research To exchange with younger generation	.83
Hindering	***Extrinsic***	Lack of recognition from my colleagues Lack of recognition from my line manager Lack of recognition from my department/faculty Lack of recognition from my university senior management Lack of recognition from my research community Lack of funding opportunities Lack of climate for an educational change	.89
	Intrinsic	Difficulties in combining teaching and research Freedom to determine what and how to teach Lack of students´ motivation Lack of personal motivation Potential failure in teaching students Lack of confidence in my teaching skills Lack of practice examples from teaching to apply myself	.78
	Lack of time	Lack of time	-

We performed descriptive statistics for each factor and group (university). As Shapiro-Wilk tests showed that no normal distribution can be assumed for all factors except the factor *intrinsic hindering* ($p < .05$), the requirements for a parametric procedure were not satisfied. For the comparison between the universities non-parametric Kruskal-Wallis tests were therefore performed, followed by post-hoc paired Wilcoxon tests if the Kruskal-Wallis test proved to be significant. A significance level of $p < .05$ was used for all tests. All statistical analyses were performed using the statistical software R.

3 Results

Overall, the descriptive analysis shows that the intrinsic motivational factor is considered as most relevant for the participants (see Table 2).

Table 2. Means, standard derivations and Kruskal-Wallis test for the motivation and hindering factors

Factor	University	n	Mean	SD	p-Value
Extrinsic Motivation	Chalmers University of Technology	11	2.65	1.07	<.001
	Gdańsk University of Technology	152	3.06	.82	
	Politecnico di Milano	110	2.66	.78	
	RWTH Aachen University	50	2.34	.71	
	Warsaw University of Technology	66	3.21	.69	
Intrinsic Motivation	Chalmers University of Technology	11	4.05	.49	.766
	Gdańsk University of Technology	152	3.98	.50	
	Politecnico di Milano	110	4.01	.46	
	RWTH Aachen University	50	4.02	.44	
	Warsaw University of Technology	66	4.04	.47	
Extrinsic Hindering	Chalmers University of Technology	11	2.93	.97	<.001
	Gdańsk University of Technology	152	3.20	.72	
	Politecnico di Milano	110	2.65	.87	
	RWTH Aachen University	49	2.35	.89	
	Warsaw University of Technology	65	2.99	.82	
Intrinsic Hindering	Chalmers University of Technology	11	2.71	.77	<.001
	Gdańsk University of Technology	152	3.03	.65	
	Politecnico di Milano	110	2.74	.75	
	RWTH Aachen University	49	2.19	.47	
	Warsaw University of Technology	65	3.03	.73	
Lack of time	Chalmers University of Technology	11	3.45	1.21	.017
	Gdańsk University of Technology	149	3.95	.94	
	Politecnico di Milano	110	3.52	1.11	
	RWTH Aachen of Technology	49	3.67	1.11	
	Warsaw University of Technology	61	3.89	1.02	

For the intrinsic motivational factor across different universities, we observe mean values ranging from 3.98 and 4.05. Moreover, the Kruskal-Wallis test reveals no significant differences in *intrinsic motivation* levels among the universities ($p = .766$), indicating a rather uniform distribution of perceptions. In contrast, the analysis of *extrinsic motivation* yields more varied results that are generally lower compared to intrinsic motivation. Specifically, respondents from Warsaw University of Technology report a mean value of 3.21, with Gdańsk University of Technology slightly lower at 3.06. Considerably lower mean values are shown by participants from RWTH Aachen University ($m = 2.34$), Chalmers University of Technology ($m = 2.65$), and Politecnico di Milano ($m = 2.66$). The Kruskal-Wallis test confirms that the disparity among universities in terms of extrinsic motivation is statistically significant ($p < .001$). The subsequent post-hoc paired Wilcoxon tests reveal significant differences in extrinsic motivation between most pairs with varying effect sizes r. The effect is large for RWTH and Warsaw ($r = .55$), moderate for RWTH and Gdańsk ($r = .38$) as well as for Milano and Warsaw ($r = .38$), and small for Gdańsk and Milano ($r = .26$) as well as RWTH and Milano ($r = .19$). The effect sizes for all other pairs were not statistically significant. Notably for Chalmers, we mainly attribute this result to the comparatively low number of respondents limiting our ability to draw robust conclusions for this university.

Our analysis of hindering factors suggests a more homogeneous pattern across the universities. The mean values for the *intrinsic hindering factor* range from 2.19 to 3.03, with RWTH reporting the lowest, and both Gdańsk and Warsaw presenting the highest values. *Extrinsic hindrances* show a similar range of mean values between 2.35 and 3.20. Again, RWTH records the lowest mean value ($m = 2.35$), while Gdańsk has the highest ($m = 3.20$), followed closely by Warsaw ($m = 2.99$). The Kruskal-Wallis test indicates significant differences between universities in both intrinsic and extrinsic hindering factors ($p < .001$). Further analysis utilizing paired Wilcoxon tests shows moderate effect sizes in the differences of extrinsic hindering factors between RWTH and Gdańsk ($r = .41$) and Warsaw ($r = .36$) and between Milano and Gdańsk ($r = .32$). For intrinsic hindering factors, only RWTH and Milano show a significant moderate effect ($r = .35$). Moreover, no significant differences between the universities are found. As discussed in chapter 2.2, the item *lack of time* was evaluated as separate hindrance, as it does not fit into the two-factor model established through explorative factor analysis and Cronbach's Alpha. As single-item factor – widely recognized in literature as a critical barrier to quality teaching – lack of time shows mean values ranging from 3.45 to 3.95 across the universities. Although the Kruskal-Wallis test indicates significant differences ($p = .017$) between the universities, the post-hoc paired Wilcoxon tests only reveals a small, significant effect for Milano and Gdańsk ($r = .20$) and none of the other pairs. Notably, the standard deviations for this factor were relatively high across all universities (between .94 and 1.21), underscoring the variability in perceptions of time as a barrier to education.

4 DISCUSSION AND IMPLICATIONS

The results suggest that intrinsic motivation is considered the most relevant factor across all universities, indicating that regardless of the university, participants general value intrinsic factors similarly. In contrast, extrinsic motivation is deemed less relevant with varying mean values and significant differences across universities. Moreover, the results of the statistical analysis showed some significant differences between the universities. However, as these only provide limited information about the reasons for these differences, we also looked at the free comment fields in the survey with regard to extrinsic motivation and hindering factors. Both institutional and structural influencing factors were identified here.

Social responsibility of people involved in engineering education was added as a further motivating aspect, such as the "ability to shape the future of our society" and "making a positive social impact in the world". Moreover, the main recurring motivational barriers mentioned here among all universities were financial constraints in the context of low salaries, limited funding or a lack of financial incentives in general, bureaucratic challenges and a lack of support, a lack of recognition for teaching, and political influence in terms of negatively impacting political frameworks on teaching and research. However, these similarities with regard to motivational barriers vary when comparing different universities which can primarily be attributed to different political framework conditions.

The quantitative results have shown, for example, that the two Polish universities of Gdańsk and Warsaw often differ significantly from the results of the others. This can presumably be attributed to the Polish education system. Free comments in the survey, such as "*You did not ask if teaching in a given system is even considered important. Well, in Poland it is not*." and "*Any political force is actually not interested in improving the general level of society education*" also point to this aspect. Moreover, an emphasis on teaching load and university policies seem to differ between the universities, where, for example, no participant from Chalmers mentioned any barrier in terms of teaching load, participants from Warsaw frequently criticize the large number of teaching hours mandated by law.

Overall, the results not only confirm existing research in terms of motivating and hindering factors of engineering educators (e.g., Graham 2020; Henderson et al. 2011; Shadle et al. 2017), but also highlight the relevance of considering national and even local differences in higher education systems and their policies (see also Finelli et al. 2014; Henderson et al. 2011). Since the political framework conditions of the respective countries as well as university policies seem to have a decisive influence on the motivation of teachers in the field of engineering education, a further in-depth analysis is expedient here and the next step in our research. Considering that all the universities studied are part of the European Higher Education Area, the respective political implementation seems to pose challenges in individual countries. As our results are based on a survey, limitations must be taken into account accordingly. The data represent the self-perception of teachers, which may be biased. Confirmation bias cannot be ruled out here either. In addition, we have only considered the answers of the professors for reasons of comparability. In a further analysis, the perspectives of other people working in teaching, such as PhD students and research associates, could be included, especially as there are country-specific differences in teaching commitments, particularly for PhDs. Moreover, we acknowledge the small sample size for Chalmers, which restricts the generalizability of findings. Additionally, high standard deviations indicate variability within responses, particularly for extrinsic motivational factors. Further research will be necessary to analyze not only correlations and comparisons between the political framework conditions, but also teachers' attitudes and individual beliefs towards teaching in general as well as their knowledge and use of different teaching and learning methods, as these aspects are aligned with promising change strategies in engineering education (Henderson et al. 2011). A comparison of the country-specific structural and political conditions of engineering education in Europe could provide explanations for the identified differences in extrinsic motivating and hindering factors.

In summary, this study highlights the importance of intrinsic motivation across different universities and identifies significant differences in extrinsic motivation and hindering factors. These findings underline both to take a closer look and the need for local and national context-related approaches and political frameworks to address motivational factors and barriers to quality teaching in engineering education. Moreover, the results stress the need for establishing and strengthening alliances like ENHANCE to be able to create a common framework for European education and research by also being aware of different local and national contexts that may influence teacher's motivation in engineering education.

ACKNOWLEDGEMENTS

This study was funded by ENHANCE as part of the ENHANCE.R research funding.

We would like to thank Malin Kjellberg and Reidar Lyng for their input in the development of the survey. We would also like to thank all the vice rectors who supported us in distributing the survey in the ENHANCE network.

ABSTRACT

In recent years 'resilience' has increasingly been framed as contributing towards success within higher education (HE), particularly within engineering degrees which prepare students for a profession and thus place emphasis on graduate attributes. Engineering degrees are commonly associated with heavy workloads, high rates of attrition and, increasingly, with growing concerns about student mental health. This raises questions regarding the degree to which a focus on resilience can help students manage the pressures associated with their study, whilst also preparing them for the rate of technological advancement and societal change they will experience as graduates. There is currently a lack of research which focuses on how students perceive this apparent need for them to demonstrate and develop resilience. In this work we thus take a qualitative approach to understanding how engineering students conceptualise resilience. In so doing, we make use of data

nat.wint@ucl.ac.uk

collected from semi-structured interviews with twenty-three engineering students at one UK-based university. Interview transcripts were analyzed using reflexive thematic analysis (RTA). Students described resilience and their resilient responses. Workload, the freedom of university, and peers were seen as the biggest threats to resilience, with teamwork being the most frequently cited learning experience in which resilience was required and developed. Participants primarily focused on the need for a plan and goals to aid motivation. Findings may be used to inform future interventions.

1 INTRODUCTION

From a psychological perspective 'resilience' is defined as "the process and outcome of successfully adapting to difficult or challenging life experiences, especially through mental, emotional, and behavioural flexibility and adjustment to external and internal demands" (American Psychological Association, 2019).

In recent years, particularly since the COVID-19 pandemic (Brammer, 2020), there has been an emphasis placed on the benefits of resilience to student success within HE (Beltman, Mansfield, and Price 2011; Brewer et al. 2019; UCAS, 2018; UNITE, 2017). Much of the literature focuses on resilience as necessary for successful navigation of the workplace (Sant 2013), focusing specifically on 'graduate resilience' (Morgan, 2016; Hodges 2017), 'academic resilience' (Hunsu, Carnell, and Sochackam 2021; Martin and Marsh 2006), and 'career resilience' (London 1983).

This perceived need for students to be resilient seems particularly pertinent within engineering. Firstly, because of the reported heavy workload (Armstrong 1996; Brainard, Staffin-Metz, and Gillmore 1999; Godfrey and Parker 2010; Rosenblatt and Lindell 2021; Seymour and Hewitt 1997; Stevens et al. 2007; Stevens et al. 2008) and high rates of attrition (Hunsu, Carnell and Sochacka 2021). Secondly, engineering degrees traditionally prepare students for a profession and therefore place additional emphasis on employability and graduate attributes (Lucas, Claxton and Hanson; Targetjobs), particularly the 'career resilience' (ECITB 2020; NAE 2014; Nieusma and Johnson 1996) needed for technological advancement and change.

In a systematic literature review on how engineering education research (EER) addresses resilience, Winkens and Leicht-Scholten (2023) found the term linked to engineering students as a personal attribute with the reasons for resilience being: persistence in completing studies; adapting to changes to educational settings during COVID-19; learning from failures/errors; coping with stress, adversity and challenging situations; and resilience as a desired attribute, outcome or competence. Within EER more widely, Huerta et al. (2021) describes resilience as the "enhanced ability to manage or bounce back from stress" (p. 652). Hunsu, Carnell, and Sochacka (2021) introduce the more specific term of 'academic resilience' (Martin and Marsh 2006) as a theoretical framework to explore how students react to academic challenges. Elsewhere the term has been associated with 'coping with stress' (Ssegawa and Kasule ,2017), an 'internal thriving competency' (Gesun et al., 2021), self-regulation (Concannon et al. 2019*)* and self-efficacy (Anthony et al. 2016; Concannon et al. 2019*)*. Finally, the term has been used in relation to equity, diversity and inclusion, with studies focused on the resilience of underrepresented students (Khilji and Pumroy 2019; McGivney 2007; Ross, Huff, and Godwin 2021; *S*ervant-Miklos, Dewar and Bøgelund 2021; Samuelson and Litzlerb 2016).

Mapaling, Webb and du Plooy (2023) made use of data from semi-structured interviews to understand students' perceptions of their own resilience in the South African context. Participants alluded to personal resources, and social resources. Students also expressed tension between maintaining self-care and academic attainment, something associated with a lack of acknowledgement for the systematic, structural nature of issues they faced. In a different study (Mapaling, Webb and du Plooy, 2021) in the same context, students identified language and cultural barriers, as well as their educational background, as impacting their ability to adapt to university. In terms of facilitators of resilience, they identified support of lecturers and peers. Finally, in quantitative work into self-perceptions of resilience among 167 first-year engineering undergraduates, white males and females were found to have slightly higher levels of perceived resilience than underrepresented groups (Moreno-Hernandez and Mondisa, 2021).

However, concerns regarding this discourse within HE more widely (Russell-Watts & Stringer, 2018; Stevenson, 2016; Turner et al., 2017), highlight the use of deficit-based approaches which fail to recognize wider structural inequalities (Stevenson, 2016). Within EER, Pawley (2018) describes how the burden of developing resilience is placed on the individual. Such concerns are significant considering the increasing focus on the mental health of engineering students (e.g., Danowitz & Beddoes, 2018), with barriers to seeking mental health support including a stigma, and cultural norms that suggest "engineering students (should) be resilient through mental health challenges" (Jensen et al., 2023, p.13). Such tensions point to a need to further understand the perceptions of engineering students.

As pointed out by Mapaling, Webb and du Plooy (2023) in their work into academic resilience, "there is a lack of literature that engages engineering students to draw on their own perspectives and lived realities" (p. 178). In this work we address the gap in the literature by taking a qualitative approach to understanding how engineering students conceptualise resilience and how university supports its development.

2 METHODOLOGY

The study is situated within a qualitative research paradigm allowing and focusing on understanding the meaning participants drew from experiences over a variety of contexts. It adopts an interpretivist constructionist approach (Denzin and Lincoln 2003; Lincoln and Guba 2005; Smith 1992). In-depth semi-structured interviews were selected as the method for data collection as they provided the opportunity to explore subjective meanings, experiences, and specific details of each participant (Guba and Lincoln 1994). A semi-structured interview protocol was developed to ensure coverage of key research questions and dimensions of resilience identified in the literature, but also allowed the opportunity for the interviewer to guide the discussion in directions that had not previously been considered and/or that were interpreted as meaningful for the interviewee. Questions thus focused on participants' prior educational experience, their understanding of resilience, examples of times they had demonstrated or developed resilience, and their views regarding the need for resilience in education and the workplace.

Ethical approval was obtained. A call for participants was distributed via internal departmental mailing lists within a public research university located in Wales, UK. As of 2021/2022 the student population was approximately 22,000 students, 81 % of which were home students, and 15% of which studied engineering (HESA, 2022). Twenty-three individuals (see Table 1) provided informed consent to participate. Participants varied in terms of engineering discipline studied and year of study (foundation year, undergraduate/UG and postgraduate/MSc). 17 identified as male and six as female, nine being classed as 'home' students and 14 as international. Interviews took place online or in person according to the preference of the participant and lasted between 20 minutes and one hour. Interviews were recorded and transcribed by the first author and analyzed using reflexive thematic analysis (RTA) following the six-stage process proposed by Braun and Clarke (2006).

Table 1: Participant Characteristics

ID	Gender	Age	Nationality	Engineering Discipline	Year of Study
1	M	20	Zimbabwean	Civil	Year 1 UG
2	M	26	Indian	Nanotechnology	MSc
3	M	26	Indian	Power	MSc
4	M	21	British	Materials	Year 1 UG
5	M	39	Iranian	Civil	MSc
6	M	21	Polish	Chemical	Foundation Year
7	M	25	Indian	Mechanical	MSc
8	F	19	British	Electrical & Electronics	Foundation Year
9	F	22	Nigerian	Aerospace	MSc
10	F	20	British	Biomedical	Year 1 UG
11	M	33	Nigerian	Aerospace	MSc
12	M	24	Sri Lankan	Nanotechnology	MSc
13	M	20	British	Electrical and Electronics	Year 3 UG
14	M	25	Indian	Power	MSc
15	M	21	British	Aerospace	Year 2 UG
16	M	23	British	Mechanical	Year 2 UG
17	F	20	Italian	Aerospace	Year 2 UG
18	F	18	Nigerian	Electrical and Electronics	Year 1 UG
19	M	21	British	Mechanical	Year 2 UG
20	F	23	Kenyan	Civil	Year 2 UG
21	M	18	British	Aerospace	Year 1 UG
22	M	32	British	Power	MSc
23	M	23	Polish	Aerospace	Year 3 UG

A limitation is that participants were self-selected. The findings reflect perspectives of students in one university and transferability is limited.

3 RESULTS

Three themes were generated. This paper focuses on themes 1 and 2. Excepts are labelled (1) to (23) to allow readers to identify quotes from the same participant.

3.1 What exactly is a resilient response?

This theme focuses on differences in views and judgements pertaining to resilience and is split into two subthemes. The first (*A. To change or not to change?)* describes differences in how resilience was conceptualised. The second (*B. "it depends on the situation…different situations demand different things from us")* relates to varying ways participants react to situations that require resilience.

A *To change or not to change?*

For participants, resilience was necessary, firstly *"because failure will happen at some point"* (2), and secondly due to the rate of change. In the former case, students generally described resilience by making use of terms such as 'overcome', 'failure', 'setbacks', 'hardships' and 'challenges', and characteristics such as 'strength', 'courage', 'determination', 'perseverance', and 'capacity' were typically considered as prerequisites to a resilient response. One participant made use of engineering-based analogies, for example, by comparing resilience to *"Newton's third law…equal and opposite reactions"* (16), and describing *"pushing, pushing, kind of like Kaizen in the Toyota production system of this constantly iteratively improving"* (16). Resilience was considered particularly relevant within engineering which was *"harder than most degrees"* and *"challenging"* (20). Engineering industry was considered a *"cut-throat environment"* (16) whereby companies were *"highly selective"* (17) and in which resilience was necessary as it is *"not always going to be a good environment"* (1). This sense of hardship was considered to have increased in a world that is *"changing fast"* (22), and in which *"hard work yields less"* (17), with one participant saying that *"it's getting harder, there are more expectations to meet"* (20).

This notion clearly links with the second reason to demonstrate resilience, which was associated with change. Participants made use of terms such as 'flexibility', 'adaptability' and 'transferability', particularly when referring to transitions between education and the workplace. In the workplace, resilience was deemed as beneficial in terms of innovation, creativity, and the flexibility to transfer knowledge to unfamiliar problems. In relation to this, one perspective was that *"resilience would be what we actually learn in this class, and how useful these newly taught for use in the industry"* (5), with one student saying *"you're going to look up and say, okay. I've never seen this before. I don't have a reference to start from, but I'm going to look at it, and I want to find the solution. I'm going to find a way. I'm going to keep looking at it "(*1). In comparison, a different participant who had worked in India, explained that industry did not require resilience as *"you are not allowed to think outside the box…you need to go as per their regulations and rules"* whereby managers have *"power in their hands"* and in which you *"needed to be loyal to the organization"* (7).

However, there was some variation in views as to what resilience was. For example, on the contrary to those who spoke of flexibility and adaptability, one participant believed that resilient people were *"very steadfast in how they think about their own ideas... you could equate it to being a little bit stubborn in resisting change"* (15).

B "It depends on the situation…different situations demand different things from us"

Participants described different responses to failure, this being articulated clearly by one student who said that how they react *“depends on the situation because different situations demand different things”* (3). For many, their response involved stages, the first involving stress and emotion, with one student saying *“I also do allow myself to be down and to feel sad. …maybe, after a few days get back to my thing because I feel like life must go on”* (20) and another that they *“stress out a lot at the beginning. Then, after that I’d kind of calm down, and actually do something about it”* (10). This stage was typically followed by *“putting it into perspective”* (6) and a more philosophical approach, which was sometimes linked to religion and faith. For example, students told themselves *“there are more opportunities”* (5) and that it’s not *“the end of the world”* (6). This helped them look forward, with one saying that *“once something is done, it is done, and you're not getting back that time, so make sure you do that thing better the next time”* (2), and another that you have to *“accept the past is in the past. You can only change what happens in the future” (*15). For one participant, not moving on “*would somewhat cost in the future as well”* (9). This more philosophical approach was often related to having a growth mindset, for example *“the idea that instead of focusing on the fact that last time when I did a lot of work, it didn't go so well, like its instead trying to build on what I did” (*6). One participant described asking themselves *“are you happy with what you have done? If you die tomorrow, are you happy with where you are”* (12), using this as motivation.

A third, more strategic phase was then required, or what one student referred to as *“sober decisions…when I’m in a very clear mind and I know what I am doing”* (12) and involved making use of strategies, and techniques, for example determining *“what the steps are, and how to get it done”* (4) or making use of time management by *“chart(ing) it out on a priority basis”* (3). In some cases, participants described the stages involved, for example questioning *“what could you have done differently?”* (19) and another that they would *“try to understand what might have gone wrong….and if it makes sense to me, I would like really change the way that I do it, because I just it's all about learning from your mistakes”* (3). The need to analyse the situation was mentioned by several participants, one described the need *“to analyze it to the point where I cannot analyze it”* (8). The mix of approaches was perhaps articulated most clearly by one student who said that sometimes *“you just have to accept the situation… look at myself, try and improve myself the best way I can. Also look at the other lens of sometimes there’s nothing more you can do, you’ve done the best you can”* (1). To this end, there appeared to be some level of judgment required in terms of response, for example if *“It’s a lost cause I don't worry about it. But if there is something we could do about that's when I stress out.”* (10).

3.2 Facilitating factors and inhibiting influences

This theme focuses on factors impacting resilience levels and is split into two subthemes. The first (*C. The cohort effect*) focuses on the degree to which resilience depends on individuals compared to others around them and the second (*D. Failing to plan and planning to fail*), on the role of planning in enabling resilience.

C. The cohort effect

Many participants spoke of resilience as an individual characteristic. One student said it must *“come from like inside…an internal sort of mental mindset”* (16), another describing it as being *“able to internalize things”* (20). These views were linked to accountability and responsibility, with one participant saying *“I’m not treating this as* *someone else's mistake. I rather try to take it as my own"* (23), another believing that *"a lot of engineering students just don't really except that reality"* (16).

Despite this focus on the individual, peers were seen as influential, this being unsurprising considering the time spent together in university. One participant claimed that *"if this group of students has a negative outlook, that does not help an individual at all"* (12) and another that *"if I'm surrounded by people who are lazy, then I'll tend to be same"* (21). Another student said, *"say our peers are not succeeding, that would mean the resilience of the group is lower"* (23). A different participant added that it was problematic *"if you have people around you that just are in a perpetual self-doubt situation, and they come to you for confidence"* (16). On the contrary, *"if you're with a group of people that is very studious and resilient… I would be more likely to be like that"* (17). Likewise, one student stated that they *"try to find the people that are resilient and that just gives a boost of morale"* (18) and that if friends show *"show resilience, you kind of want to do the same"* (19).

It is perhaps unsurprising therefore, that teamwork was the main learning activity that was considered to require and help develop resilience. For example, one participant claimed that *"working in a team can help you better understand resilience and learn from the views around how to handle tough situations"* (3) and another that *"when you're in a group you've got the motivation of working with people around you"* (13). Another participant alluded to the accountability involved saying that they had to think *"about the group as a total…so I should deliver this"* (23).

D. Failing to plan and planning to fail:

Participants mentioned several factors influencing resilience including diet and physical health as well as past success. For some, external *"distractions"* were considered as *"test(ing) you a lot"* (1). These distractions were seen as particularly problematic for those new to university *"because now you can do whatever you want to… so like that's also kind of one that pushes my resilience because now I have to keep my morals"* (1). Many participants also mentioned a need to be resilient because of the distraction of social media.

Most of those interviewed spoke about their motivation or goals. For one participant, you were able to be resilient *"once you have goals, no matter what you go through. Sometimes you do slip…. but as long as you have goals"* (20). Perhaps unsurprisingly given the context, the majority of students spoke about career plans, with one speaking of having *"had all the career paths, everything set in plan …. And I didn't want to give up my dream of…I had that mental picture of me*" (2), this meaning that they were motivated to react in a resilient manner when encountering failure. However, sometimes having a clear plan was considered detrimental, with one participant saying that you could be more upset when encountering failure *"if you're a very, planning oriented person and don't like things to not go to plan"* (17). A different student added that *"planning is an important part, but to be too rigid in your planning can also, you know, impacts negatively. So, I'm happy to change the way, to analyze and plan and change the way that I do things"* (3).

For many, it was these goals, and the consequences of not meeting them, which enabled them to take *"a bit of pain for that pleasure later"* (19) with one participant saying that **"***having consequences as well helps build that resilience"* (1) and another explaining that sometimes *"the consequences can be quite big if something goes wrong"* (22). Another mentioned that they thought they were *"far more resilient since*

I've come to university because there is almost a lot more on the line" (21). However, one participant claimed that unfair consequences "kind of messes with your resilience" (1) explaining that *"there were multiple times I was punished for nothing, and that pushed me to be resilient"* and that *"sometimes I'd work hard in high school, and the reward wouldn't come. But then that would push me to work harder. And then, now that I'm here I sometimes don't work hard but then I get more reward than I deserve… I mean I did the wrong thing"* (1).

4 SUMMARY

The findings suggest the existence of inconsistencies in the way resilience is conceptualised, from being flexible and dealing with change, to being 'steadfast' and 'stubborn'. Participants all saw the benefits of being resilient, this often being discussed in relation to how fast the world was changing technologically, but also in terms of competitiveness. Students described dealing with failure in several ways: by letting themselves feel emotion, by taking perspective, and by planning for the future. How they reacted appeared to depend on several factors including the importance of the situation and how motivated they were. Peers were seen as one of the most influential factors impacting individual resilience, with teamwork being the primary learning experience in which students claimed to develop and demonstrate resilience. Together, the findings point to a need to support students in understanding the situations in which it is desirable to be resilient, as well as assessing the short- and long-term benefits and costs of resilience at an individual level, something which would require students to have an understanding of their own values and moral beliefs.

Conference Key Areas*: The attractiveness of engineering education*
Keywords*: Attractiveness, recruitment, admission systems, educational pathways*

ABSTRACT

Reported shortages within the engineering workforce have resulted in significant efforts to promote engineering facilitating education pathways across Europe, particularly to those underrepresented within the sector. Such work has become significant in recent decades because of global demographic changes which are

[1] *N Wint*
nat.wint@ucl.ac.uk

likely to have increasing impact upon higher education (HE) systems. Given contextual differences between countries, understanding opportunities and barriers to recruitment of students requires a comparative approach which considers differences in education systems and admissions processes. At this initial pilot phase of this exploratory study, we have focused on understanding national education systems and admissions practices in three European countries, namely Belgium (Flanders), Czechia, and the UK. The analysis of the data provided is guided by research questions focused on 1.) the main education paths into an engineering career and any remedial routes, 2.) the qualifications and prerequisites required to study engineering within HE, and 3.) details of any exposure students have to engineering, both within and outside the curriculum, prior to university. Findings from this work in progress study will be used to inform design of large-scale research project to identify practices across SEFI.

1 INTRODUCTION

Europe faces demographic issues associated with an ageing population and low birth rates which influence the population at working age, and thus economic growth (United Nations, 2022). At present, impact on higher education (HE) systems is limited. However, the (at least) 18-year gap between birth and university enrolment means this is likely to change. Universities may take several approaches to such situations, for example focus efforts on widening access and participation.

Such challenges are particularly pertinent within engineering, for which attraction and retention of students has long been an issue. The 2023 annual review of the ‘Employment and Social Developments in Europe’ report identified engineering as an occupation/sector expected to face shortages in labour (European Commission, 2023). Furthermore, the report describes the persistent labour shortages in sectors with low percentages of female[1] workers, directly attributing this to differences in study fields of qualifications (particularly at tertiary level) held by women and men (European Commission, 2023). In keeping with this, the European Strategy for Universities articulated a commitment to strengthening women’s and girls’ participation in STEM (European Commission, 2022).

At such times, the role of admission processes become significant. Orr et al. (2017), consider how admissions systems are understood in different social, cultural, political, and economic contexts (such as those found across Europe). Within this perspective, they describe three ways in which schools influence students’ access to HE: by assigning grades; by streaming by academic ability; and by providing careers information, and guidance. With respect to higher education institutes (HEIs), they highlight differences in autonomy over selection processes, and assessment of academic ability. Finally, they describe the complexity of student decision making.

1.1 Typology of Admissions Systems

Orr et al. (2017), defined a four-field matrix to produce a typology of admission systems based on a comparative study of 36 European countries. Within this, one

[1] Whilst the report cited primarily focuses on the gender employment gap, the authors acknowledge the underrepresentation of students with several characteristics within engineering, for example by disability, age, sexual orientation, ethnicity (e.g., see Mejia and Martin, 2023)

dimension represents the freedom of HEIs with respect to their ability to set their own criteria to select students. The other dimension focuses on the pathways to HE and streaming within the secondary system (i.e., whether all streams lead to HE).

- Type 1 (selection by schools) includes countries in which HEIs cannot select with additional criteria and where students are placed in various streams where at least one stream does not allow access into HE.
- Type 2 (selection by HEIs) is used for contexts in which all pathways allow access to HE and in which HEIs can typically select with additional criteria.
- Type 3 (least selection) is similar to Type 2, but HEIs have less autonomy to select additional criteria.
- Type 4 (double selection) is the same as Type 2, but at least one of these stream qualifications do not allow access into HE.

They used this typology to examine admission systems in terms of three dimensions: (1) equity dimension (who gets into HE), (2) efficiency dimension (how many complete studies), and (3) effectiveness dimension (final attainment and outcomes). Their analysis revealed differences in unemployment, job mismatches, participation rates, graduation/completion rates across the types of systems, some of which could be linked to selectivity. The research highlights both the relationship that education systems and admissions processes have with recruitment and retention of students, and the way in which systems vary between country. It may therefore be expected engineering students' demographics vary between countries characterised by different education typologies. Table 1 shows typology and student characteristics for the three countries considered in this study.

Table 1: Country typology and engineering student characteristics

Country/ Typology	CZ (Type 2; selection by HEIs)	Flanders, Belgium (Type 3; least selection)	UK (Type 4; Double selection)
Engineering student demographics	58% male, 42% female 85% Czech 15% non-Czech	74% male, 26% female 85% Belgian, 15% non-Belgian	80% male, 20% female 63% UK, 37% non-UK (HESA, 2023)

Understanding the opportunities and barriers with respect to attracting students to engineering within Europe thus requires a comparative approach which considers differences across contexts. As such, this work in progress study aims to improve our understanding of how education systems and HEI admissions practices vary across Europe. Such data will be used to identify trends and patterns across systems and the resultant admissions and retention figures in engineering.

2 METHODOLOGY

At this initial pilot phase, we have focused on three European countries in which the authors of the paper reside, namely Belgium (Flanders), Czechia, and the UK.

In mapping the education systems and admissions processes within Europe, we position ourselves as 'experts' in our own contexts. In the initial stages the authors shared context specific information pertaining to 1.) the primary and secondary education systems and educational pathways to becoming an engineer and 2.) the admissions processes of universities within their context. This process allowed for initial comparison and identification of relevant contextual factors previously omitted. It also provided an opportunity for authors to engage in critical reflection regarding perceptions, enhance understanding and interpretation, and examine the limits of reflexivity. The Flemish context was analysed by two authors independently and compared to decrease the impact of author's own perceptions. The limited disagreements were discussed and resolved.

Data was subsequently combined, with publicly available information allowing for triangulation and ensuring creation of a comprehensive picture. Data analysis was guided by the following research questions (RQs) and Orr et al.'s (2017) typology.

1.) What are the main educational pathways/'remedial routes' into engineering?
2.) What are the qualifications/prerequisites required to study engineering in HE?
3.) Do students have exposure to engineering during secondary education?

The complexity of school education systems, in terms of starting age, grouping of ages, organisation of the school year/week/day, geographical accessibility, admissions systems, funding models, governance and teacher profile, amongst other factors, has led to the development of a variety of different methodologies by which to compare them. For example, one may make use of philosophical, social, historical, quantitative/statistical, descriptive or scientific methods. In this work we focus on the pathways into engineering, with particular focus on routes to studying engineering in HE. In so doing, we make use of Orr et al.'s framework (2017) because of its focus on university admission processes. In doing this we acknowledge inherent limitations of our work which does not include consideration for aspects such as societal and cultural perceptions of HE, and the engineering profession, as well as other factors which impact transitions into engineering.

3 RESULTS

Belgium: Flanders:

In the Flemish system, a certificate of upper secondary education grants unrestricted access to HE (Eurydice, 2024). It can therefore be considered a Type 3 system.

As shown in Figure 1, at 12 years old, pupils start secondary education, the majority in the A stream (84.25%) (Onderwijs Vlaanderen, 2024), a general stream leading to different pathways at 14 years old. The secondary education system in Flanders used to be divided into general, technical, arts and vocational secondary education but, recently, the system was reformed offering three pathways. Tracks in the first pathway '*transfer*' lead to HE studies, tracks in the second '*vocational*' pathway lead to the labour market, tracks in the third pathway '*double'* can lead to both HE and labour market. Each pathway consists of different study domains (STEM, Arts and Creation, Language and Culture, Cross-domain, etc.) with more discipline specific study tracks. Students from the cross-domain and STEM domain tracks are attracted to, and best prepared for, engineering. The first important study domain and track choice is at 14 years old, with a more discipline specific track choice at age 16.

Depending on the chosen study track, the weekly hours of mathematics vary. Also, students' experience with engineering varies, ranging from limited or no experience with an integrated STEM subject in the cross-domain tracks, to whole subjects titled ‘engineering’ available in some of the STEM domain study tracks. Despite the availability of study tracks focussing - to a larger or smaller extend - on technology and engineering, the main recommendation for successful study completion in an academic engineering programme is a prior education with at least four, preferably six, weekly hours of mathematics (Pinxten et al., 2017). Despite open HE access and flexibility for late commitment to study engineering, students’ choice for study tracks and domains with few math hours (e.g., languages and arts) decreases the chance to continue in engineering.

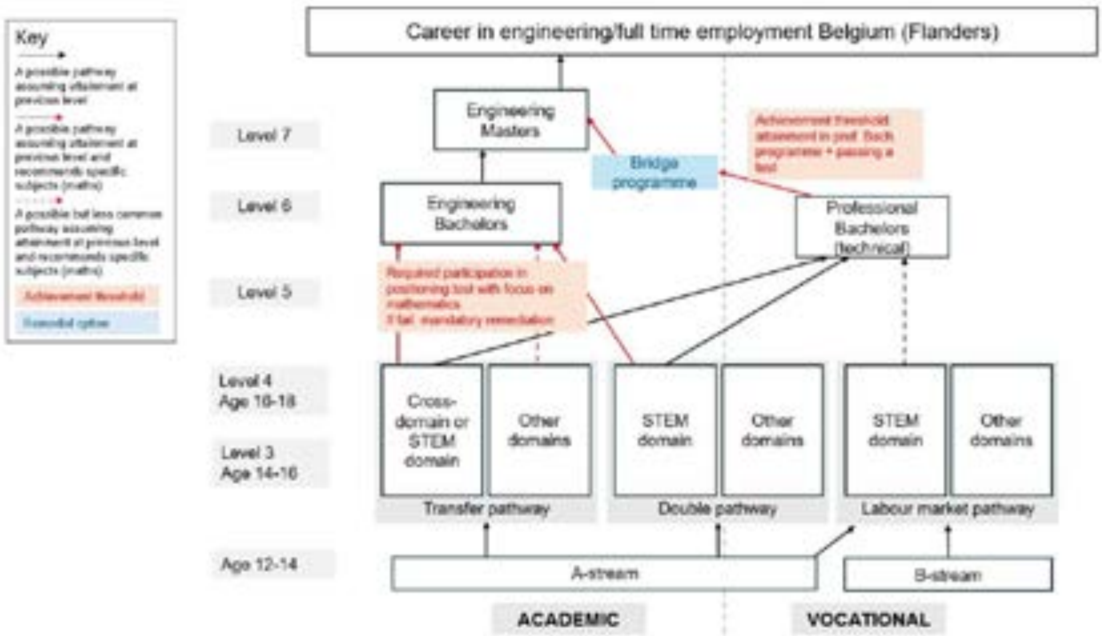

Figure 1: Schematic showing pathways to engineering in Belgium (Flanders)

To emphasize the importance of mathematical mastery, all engineering science and engineering technology HE programmes across Flanders initiated a positioning test in 2013 (Vanderoost, 2014; Hanssens, 2024). Although these tests are perceived as useful for students to assess their level of starting competencies, and for HEIs to identify students-at-risk, the test may also create unrealistic expectations of the engineering programme by creating feelings of high anxiety or overconfidence to start the programme (Hanssens et al., 2023). Students who fail follow a mandatory remedial programme in the first year of HE. The university foresees remedial routes for students obtaining vocational STEM undergraduate degrees in university colleges. After successful completion of bridge programmes, students who fulfil access requirements have permission to start an academic engineering programme. Although this route into engineering is often presented as attractive by university colleges, the bridge programmes have relatively high dropout rates. The different HEIs in Flanders reorganised these programmes recently and made access criteria stricter and programmes longer (60 to 90 credits). When choosing HE studies, students are often not aware of this.

The title “engineer” is not legally protected. A professional title is only granted to Master graduates of Flemish engineering HE programmes in Engineering Sciences (ir) or Bioscience Engineering (ir), and in (Bio)Engineering Technology (ing).

Czechia

The route to being granted the Ing. (engineer) title is not strictly defined but it mostly involves education in technical fields (with some historical exemptions e.g., economic fields) at master level. The Czech education system (Type 2) includes two main recognised pathways leading to engineering at a HEI (see Figure 2): academic and vocational (CNAIER, 2023). The first is by general secondary education (e.g., lyceum) which offer a more theoretical approach to scientifical and technical fields in comparison to full vocational secondary education programmes, which are more focused on practical aspects. Students need to make their choice at age 15. Students of both pathways have different background knowledge and skills entering HE and remedial courses are often offered as a part of bachelor programmes.

According to current statistics published by the Czech Ministry of Education (MSMT, 2024), the distribution of graduates of secondary education system in Czechia between these pathways has been fairly constant for the last decade as 43% of students graduated in full vocational secondary education programmes and only 25% at general education schools. The rest of secondary education students in Czechia graduated secondary education programmes with vocational education training certificates, with no direct possibility of continuation to tertiary education.

The official statistics pertaining to HEI *engineering* programmes applicants show that 57% come from full vocational secondary education programmes and 41% come from general secondary education (MSMT, 2024). These statistics are different in the Prague's metropolitan area where 60% of applicants come from general secondary education and only 40% come from full vocational secondary education.

This trend may result from 1.) differences in programme portfolio at technical universities that are more academically oriented and/or 2.) composition of secondary education in this region in favour of general secondary schools. The percentage of students admitted to, and graduating from, HE engineering programmes are similar for each pathway and there is not considered to be a significant difference in terms of graduate success rate from different secondary education paths.

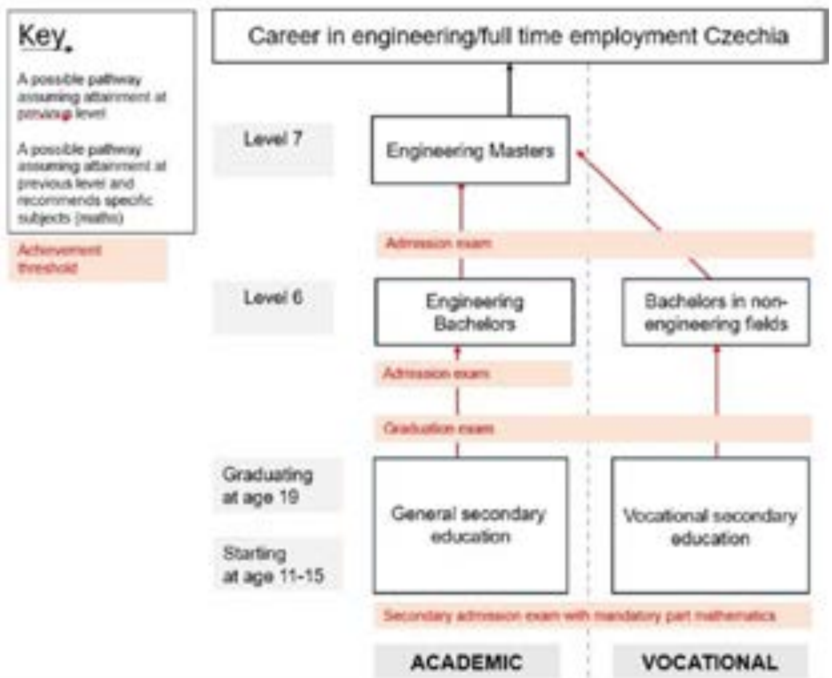

Figure 2: Schematic showing pathways to engineering in Czechia

United Kingdom (UK)

The UK is a Type 4 system, in which at least one stream of qualifications do not allow access to HE and in which HEIs typically select with additional criteria.

Professional titles of Engineering Technician (EngTech), Incorporated Engineer (IEng), and Chartered Engineer (CEng) can only be used by those to whom they are granted through registration with the Engineering Council. The CEng is open to anyone demonstrating the required competences, the application process being more straightforward for those with academic qualifications to masters level. In 2019, 23.4% of those working in engineering occupations studied engineering degrees with 33.9% having a degree or equivalent as their highest qualification and 39.4% having A-Levels or equivalent (ONS, 2019).

Defining the parameters of what constitutes an ‘engineering-facilitating educational pathway’ is difficult as shown in Figure 3. The options chosen at each point have long-term implications and potential to restrict future opportunities. This is considered particularly detrimental to engineering which does not feature in the national curriculum. Young people not aware of engineering are less likely to consider it as a career or understand the educational pathways required to pursue it (Engineering UK, 2020). Access to engineering is therefore seen as correlated with access to high-quality careers advice and guidance (teachers and peers). It is unusual for STEM teachers to have experience or expertise in engineering, and it is likely only to be mentioned by teachers with a specific personal interest.

Subjects and qualifications required to study engineering vary between HEI, with some (often those of lower status/ranking) accepting vocational qualifications. Non continuation data published by HESA (2022) shows the percentage of entrants to

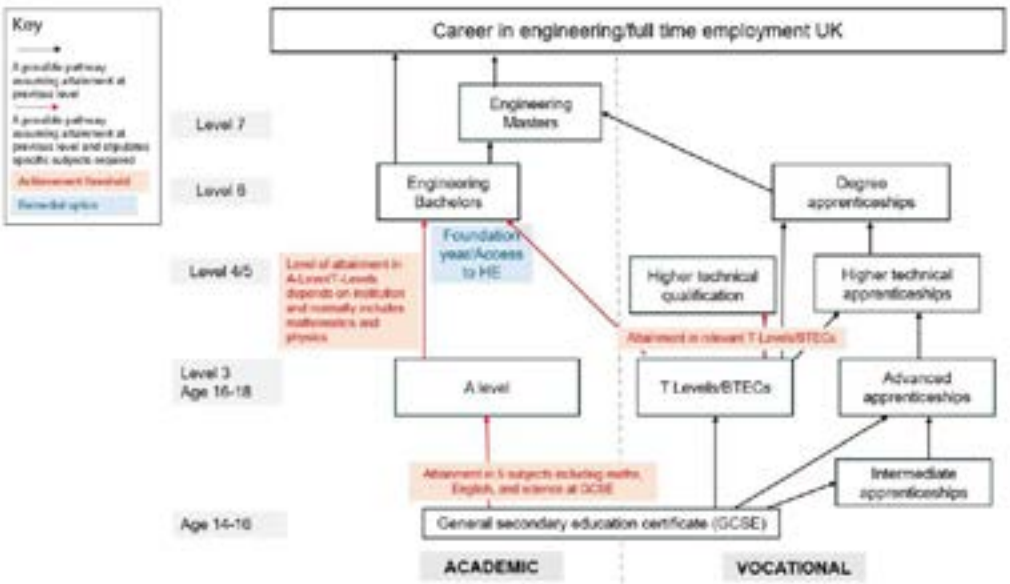

Figure 3: Schematic showing pathways to engineering in UK

engineering degree courses who are no longer in HE is relatively high for those entering with vocational BTECs, compared to A-Levels as well as compared to

those with BTECs entering other degree disciplines. Despite the variety of qualifications held by the engineering workforce, there is some consensus on the most relevant subjects recommended to keep options open. It is widely accepted that mathematics and physics are important at secondary level and are often prerequisite at A level to study engineering and technology degrees.

4 SUMMARY

The findings demonstrate that despite differences, all three education systems feature important crossroads in the trajectory into engineering at ages 14-16 and 18. These are important moments to raise awareness of the consequence of choices. Remedial routes are considered important (e.g., in Belgium, the route recently became more difficult), but are difficult to maintain in light of increasing student numbers and pressure for quality education, particularly in open admission systems. Exploration of pathways via apprenticeship, like in the UK, may be beneficial.

This paper presents findings from an initial pilot phase of an exploratory study focused on understanding national education systems and admissions practices in the three European countries in which the authors reside, namely Belgium (Flanders), Czechia, and the UK. In future it would be beneficial to extend analysis to include more countries. It would also be of interest to explore any relationships between education and admissions systems, and factors such as cohort diversity, retention, attainment, and employment opportunities, particularly pertaining to reasons different groups are lost at various crossroads. It is also of interest to further understand pathways to becoming a chartered engineer and levels of retention within the workplace having completed an engineering degree. Obtaining an understanding pertaining to countries within Europe would allow for identification of patterns which may be used to inform future practice in engineering attractiveness.

Keywords: *Emotional intelligence, EQ, EI, diversity, and inclusion.*

ABSTRACT

In recent years there has been an increase in research focused on the role that emotion plays within engineering practice. Of the related themes present within engineering education research (EER), emotional intelligence (EI) is reported as one of the most researched, its development being associated with multiple benefits. However, it is also claimed that emphasis on EI justifies an expectation for students to conform to norms, something which can result in inequality, and retention of power hierarchies. It can thus be argued that although the inclusion of emotion, and indeed EI, may, at first, appear advantageous in terms of diversity, it can act to sustain the status quo. This work is intended to examine the underlying assumptions associated with the inclusion of EI in engineering curricula. In so doing, a review of the literature is completed with the aims of understanding the way in which EI has been introduced within engineering education, as well as the reasoning behind its inclusion. 34 research articles were reviewed, with most motivated by the general benefits of EI in the context of the workplace. Whilst the majority of studies included use of EI measurement tools, the type varied significantly. Test results were typically used to identify domains of EI in which students scored least, this informing future course design, or student personal development plans. There was a lack of evidence to suggest that interventions included critical analysis of EI within a wider context, something which should be addressed in future work in the area.

1 INTRODUCTION

1.1 Introduction to EI

In recent years there has been an increase in research which considers the role that emotion plays within engineering. Much of this work was included in a scoping review of emotion within engineering education (Lönngren et al., 2021) which identified four themes: academic emotions; emotions and ethics; emotional intelligence (EI) and other socio-emotional competencies; and mental health. Of these, EI was one of the most researched something which was proposed to be because the quantitative methods used to study EI appeal to engineering researchers (Lönngren et al., 2023).

EI is used to conceptualise the relationship between cognition and emotion and can be considered as an attempt to counter views of emotion as associated with lower intelligence, and as a possible source of bias (Solomon, 2008). This is of particular interest within engineering, a profession associated with rationality (Lönngren, Adawi, & Berge, 2021). It became influential through popular work such as that of Goleman (1995; 1998; 2013), with the EI model (Mayer, Salovey, and Caruso, 2000), defining EI as “the subset of social intelligence that involves the ability to monitor one’s own and others’ feelings and emotions, to discriminate among them and to use this information to guide one’s thinking and actions” (Salovey and Mayer, 1990, p. 189), and as involving the ability to: perceive and express emotions; understand emotions and emotional change processes; use emotions to facilitate particular types of cognition; and regulate emotions in oneself and others. Whilst this (ability) model considers EI as a group of cognitive abilities, other work frames it as a personality trait involving dispositions (Petrides, Frederickson, and Furnham, 2004).

EI is typically studied using quantitative instruments developed within psychology, with the two EI models introduced being differentiated with respect to the measurement method used to operationalize them (Petrides, 2011). Trait EI involves self-perception measured via self-report, whilst ability EI measures cognitive abilities related to emotion measured via maximum performance tests. The model used has significant implications for the development of EI within education, with the ability model focusing on possessing certain cognitive competencies, and trait EI focusing on consistent, cross-situational traits such as self-esteem and happiness, which form part of personality. Although the distinction between the types is well documented, in some cases the distinction is not acknowledged, this having implications for the ability to organize development and accumulation of knowledge in the field (Petrides, 2011). Examples of the commonly used measures are shown below.

Ability based measures:

- The Mayer Salovey Caruso Emotional Intelligence Test (Mayer & Caruso, 2002; Mayer, Salovey and Caruso, 2004).) considers EI as four abilities.

Trait based measures:

- Schutte Emotional Intelligence Scale (Schutte et al., 1998) a self-report tool which focuses on users’ perceptions of their abilities.
- Bar-On Emotional Quotient Inventory (Bar-on, 1997a; 1977b; Bar-On, Brown, Kirkcaldy, and Thomé’s (2000) EQ-i) which considers emotional-social intelligence as a mixture of skills, competencies and facilitators.

- Trait Emotional Intelligence Questionnaire/ TEIQue-SF (Petrides, Pita, and Kokkinaki., 2007) which considers EI as a subset of personality.

A significant amount of the work published in the area focuses on the gendered nature of results which have been shown to depend on the way in which the test is presented (Horgan & Smith, 2006; Ickes, Gesn, & Graham, 2000; Koenig & Eagly, 2005). In the case of self-report measures, the focus is on “abilities and the potential for performance” rather than performance itself (Bar-On., Brown, Kirkcaldy, & Thomé, 2000, p.1110) and results are often skewed by desire for positive self-presentation (Dawda & Hart, 2000; Mandell & Pherwani, 2003). Any gender differences tend to be associated with particular aspects of EI.

1.2 EI and participation and access in STEM

Findings pertaining to gender differences are particularly relevant within engineering. Several papers have focused on benefits of EI in terms of gender representation within STEM. For example, Tripon (2022) claims the ‘superior’ EI of girls could be key to motivating girls to study STEM. Besser et al. (2020) investigate how the inclusion of empathy needed for EI may act as a mechanism for cultural change and result in a critical mass of women in engineering. Van Oosten, Buse and Bilimoria (2017) describe a leadership course aimed at advancing and retaining women within STEM which featured “skill development in the areas of leadership and emotional intelligence” (p.3). Melbourne (2016) suggests that STEM educators trained in EI emphasize how emotion regulation skills can help someone succeed, something they say is essential for women and other underrepresented groups, saying that those not trained in EI may “internalize their failures” (p. 9). Similarly, Musa (2020) claims EI “can lead her to success in any engineering disciplines” (p. 3917).

1.3 Criticism of use of EI

There is a limited amount of literature within EER that highlights the need to be cautious with respect to EI. For example, in talking about experiential learning, McDermott, Göl, and Nafalski (2001) question “is it ethically defensible to seek to modify students’ intuitive or emotional behaviour?” (p. 74). Chan et al. (2020) draw upon the work of Blackmore (2011) to critique the way EI focuses on individualised competencies rather than context, as well as the power relations which define how expressions of emotion are controlled and understood. Lönngren et al. (2023) highlight the emphasis on individual self-improvement and expectations to conform to norms and encourage research to draw upon sociological perspectives. They highlight the work of Zembylas (2007) who compares EI to ‘emotional capital’, a concept based on the work of Bourdieu (e.g. Bourdieau, 1997).

More broadly with respect to equality, diversity, and inclusion (EDI), critical work in the area has highlighted the role of power and status in determining the components of EI considered of higher social value, and the way beliefs regarding ‘good’ and ‘bad’ emotion are tied to beliefs about characteristics such as social class and race (Shields, MacArthur, and McCormick, 2018). Shields and Warner (2007) argue that EI “favor(s) those who are in the position to recognize privileged knowledge and deploy it”, pointing out that “recognizing knowledge is distinct from the ability or privilege to use it. (p.172)”. They comment on the way types of EI that women are ‘supposedly’ not good at are framed to ignore structural issues, and how those emotions which are considered as ‘undesirable’ are often the ones experienced by those who undergo gender discrimination (Gibson, Schweitzer, Callister, & Gray, 2009; Vescio et al., 2005). Drawing upon expectation states theory (Ridgeway and Bourg, 2004), Shields and Warner (2007) describe political dimensions of emotions, claiming that judgments pertaining to how and when emotion should be felt and displayed serve interests of regulating organization and functioning of social groups.

In the context of education, Boler (1999) questions "how emotions are disciplined to maintain social control" (p. 22), this linked to the idea of 'feeling rules' which define who can feel which emotions, how they should feel them, and in which situations (Hochschild, 1979; 1983). In work examining emotional literacy programmes, Boler (1999) failed to observe instances in which emotions were analysed within the wider context and concluded that students were learning to perceive prescriptive rules regarding acceptable emotional behaviour. They raise several concerns around: imposing emotional rules that stem from embedded or arbitrary values; reinforcing the notion of victim blaming and advocating self-control; and contributing towards the maintenance of social hierarchies and capitalist interests.

It can therefore be argued that although the inclusion of EI, may, at first, appear advantageous in terms of diversity, it can act to sustain the status quo within engineering. This review is completed with the aims of understanding the way in which EI has been introduced within engineering education. It is not intended to act as a criticism and there is little doubt that the initiatives included provided a beneficial learning experience to students involved. Analysis is intended to examine underlying assumptions associated with inclusion of EI within engineering, and how educational practices are embedded within larger societal discourses.

2 METHODOLOGY

The research questions (RQs) focus on 1.) the ways in which the concept of EI is utilised within engineering programmes and 2.) the way in which the inclusion of EI within engineering programmes is justified. A systematic literature review (SLR) was chosen as an appropriate methodology to understand this emerging area and serve as a basis for future work. In general, an SLR involves: identifying scope and research questions; defining inclusion and exclusion criteria; appraising and synthesising studies; and reporting findings (Borrego, Foster, and Froyd, 2014).

The following inclusion criteria were used:

- Publications written in English, taking form of peer reviewed journal articles (excluding reviews), conference papers, books, or chapters.
- Work conducted in engineering programmes in higher education (HE).
- EI of engineering students is addressed (for examples as part of an intervention) or measured as part of the study.

Three of the databases recommended for SLRs in engineering education by Borrego, Foster, and Froyd (2014) were chosen, these being ERIC (ProQuest), Web of Science and SCOPUS. The search was completed in February 2024 and the keywords used were "engineering education" AND "emotional intelligence"'. The search resulted in 173 records. 28 duplicates were removed because they appeared in multiple databases, 9 could not be accessed, 3 had been redacted. One literature review and one workshop were excluded. The remaining records were partly screened by abstract and partly by full paper to examine whether they met inclusion criteria. Most records removed were done so for: describing workplace-based studies; focusing on use of technology to develop EI more widely; mentioning EI briefly as something required in engineering, along with other skills and competencies; focusing on skills surveys or employer needs; being theoretical or conceptual in nature; focusing on staff within engineering education. The remaining 34 papers were read and further analysed in a spreadsheet using the following categories: author, title, publication year, journal/conference name, reason for focusing on EI/purpose (RQ2), context, measurement tool used (if any) and justification of choice (RQ1), findings, teaching approaches (RQ1).

3 RESULTS

Of the 34 papers, 14 were journal articles and 20 conference proceedings. Table 1 shows the locations in which studies took place. Perhaps unsurprisingly, over a quarter of papers describe studies situated in the USA. Although the number of articles per year are relatively similar, there are some peaks, primarily more recently in 2023, but also in 2017.Although the number of articles considered limits the extent to which trends can be identified, the increase in recent years may be linked to increasing focus on professional skills and competencies such as cultural awareness, within accreditation criteria and engineering education more broadly.

Table 1. A summary of EI papers by year published and context of study

Location of study	Number of papers	Year of Publication	Number of Papers
Abu Dhabi	2	2001	1
Brazil	1	2007	1
Canada	2	2009	3
China	1	2010	2
Colombia	1	2012	2
Hungary	1	2013	1
India	1	2014	1
Malaysia	4	2015	1
Morocco	1	2016	2
Peru	2	2017	4
Portugal	3	2018	1
Saudi Arabia	1	2019	2
Spain	3	2020	3
Turkey	1	2021	3
Ukraine	1	2022	1
USA	9	2023	6

In answering RQ1, papers were broadly split into three categories: those describing just the use of measurement tools (21); those focused on EI based interventions (6); and those including both (7).

3.1 EI measurement tools

28 of the 34 papers described studies that employed the use of EI measurement tools, 7 of which being used in combination with teaching based interventions. A summary of the 21 papers that made use of tools alone is provided in Table 2.

In three cases the tools were not named. Two studies used both Trait Meta-Mood-Scale (TMMS-24) and the Emotional Quotient Inventory, presumably to provide coverage of both ability and trait-based EI models. The variation in the tools used is of significance when considering transferability of practice within the community, something which was highlighted in one paper (Sushchenko, Borova, and Petrenko, 2023) which suggested a need for instruments that can be used to understand EI associated with activities within the engineering profession. Very few papers discussed differences between ability and trait-based intelligence, this having implications for the development of knowledge (Petrides, 2011). Furthermore, few studies included justification for choice of tool (generally or in the context of EI model used), which impacts on the ability to design curricula or teaching practices based on findings of such work. One study (Kumar, 2019) made use of TEIQue-SF to measure students EI levels claiming it "has been successfully applied in the educational context" and that "traits EI is also able to suggest the right academic or vocational line in the higher education setting" (p. 210). Koontz (2017) made used of the EQI, claiming that the "assessment gives educators a way to measure student's emotional development and offer specific personal-development recommendations" (p. 9268). Lye et al. (2023) said that the TEIQue-Short Form was selected because it measures 'trait' EI, which has a better predictive value compared to the 'ability' EI, in anticipating actual behaviours or outcomes in a range of situations" (p. 481). Although Belanger et al. (2007) do not provide reasons for using Schutte's scale, they do discuss the implications of doing so with respect to findings that suggested no correlation between EI and academic performance, saying that Schutte's scale is trait rather than ability based, meaning that it measures personality traits as opposed to cognitive ability which would be expected to have stronger correlation with academic performance.

6 papers made use variations of tools. One group of authors made use of the EQI adapted for Malaysian traditional culture where individuals may be more prone to appreciate and respect elder people and practice spiritual aspects (Saibani et al., 2012; 2013). Chen, He, and Yang (2020) made use of the Wong and Law Emotional Scale (WLEIS) which was based on 418 undergraduates in Hong Kong. Khefacha, and Sellei (2023) used the Hungarian version of the EQ-I but do not allude differences. Magano et al. (2021) and Nogueira, Castro, and Magano (2023) made use of an EI scale validated by Rego and Fernandes for the Portuguese population. Sushchenko, Borova and Petrenko (2023) used a Ukrainian variant of the Hall EI test which they claimed was short and more accessible for the context. In light of such discussions, it is interesting that some authors discussed potential impacts of socio-cultural factors on test results. For example, Kumar (2019) described a negative perception of emotions which should be avoided to show professionalism in Malaysia. Similarly, when exploring EI in the context of teamwork, Deveci (2015) suggested that higher satisfaction with teamwork, despite low EI, may occur as a

result of the collectivist nature of Arab culture, and discouragement of expressing negative emotions explicitly.

Finally, in some papers there was a noticeable use of deficit-based language when justifying use of EI tools (RQ2). For example, Saibani et al., (2013) claimed that a "test is able to determine the EQ level …which is also beneficial towards consolidating any domain that is deemed flawed" (p.78). Likewise, the same authors (Saibani et al., 2012) justified use of an EI tool "as an effort to examine what domain is lacking amongst the students and what can be done to elevate the low domains." (p. 525).

3.2 EI measurement tools and interventions

Seven papers described the use of EI tools alongside a teaching intervention. One (Casado, Fernández, and Lapuerta, 2016) made use of a pre-post tests to evaluate EI training effectiveness. Deveci and Nunn (2016) used a tool with seminar discussions within a project-based module, claiming results could be used to inform content.

Other studies in this category made use of tools to help guide personal development activities. Stewart, Chisholm, and Harris (2010) used the College Achievement Inventory-Revised (CARI-R) because the "self-report assessment measures

Table 2. A summary of EI papers making use of EI measurement tools

Topic of interest	Tool(s)	Categories of Analysis	Reference
Coping strategies and EI as contributors to -major grade point average (GPA)	Schutte's EIS	GPA, discipline	Belanger et al. (2007)
EI as a moderator of design capability and computational thinking Relationship between EI and innovation	Wong and Law EIS (WLEIS)		Chen, He, and Yang (2020)
Relationship between teamwork satisfaction and EI	Schutte's EIS	Gender and nationality	Deveci (2015)
Levels of EI according to achievement	WLEIS	Gender, year/level of study, discipline	Encinas and Chauca (2020)
Strengths and weaknesses of students' EI to identify areas for development using neurolinguistics programming	EQI (Hungarian version)		Khefacha and Sellei (2023)
Impact of liberal arts on EI as an indicator for general success	Not provided	Gender, discipline, year/level of study	Kissani and Boudihaj (2019)
Relationship between academic performance and EI	Schutte's EIS	Gender	Koppad et al. (2023)
Gender differences in EI/EDI	TEQIue-SF	Gender	Kumar (2019)
EI as an indicator of how much time spent in each of the design activities	EQI-2.0	Year/level of study, gender, major	Koontz et al. (2017)
Determine differences in EI of high academic performance (HAP) students	TMMS-24 and EQi-S	HAP vs non HAP	Pertegal-Felices et al. (2017)

Relationship between team project marks and EI	EQI		Leicht et al. (2009)
Effects of EI and demographic characteristics on Psychological Capital	TEIQue-SF	Gender	Lye et al. (2023)
Impact of EI on students' motivation to learn more about sustainability and whether it plays a role in moderating the relationships between those variables	Rego and Fernandes	Gender, year/level of study, nationality	Nogueira, Castro, and Magano (2023).
Employability/performance in the workplace	EQI-S	Comparison with teaching students and survey results about competencies related to EI needed in workplace	Pertegal-Felices, Castejón-Costa, and Jimeno-Morenilla (2014).
Connection between achievement and EI in women, inclusivity, and diversity	Not provided	Gender, year/level of study, discipline, academic performance	Rizwan et al. (2019)
Cultural differences in EI	Malaysian EQI	major races in Malaysia	Saibani et al. (2012)
Employability/competitive advantage	Malaysian EQI	Year group/level of study	Saibani et al. (2013)
Relationship between EI and personality traits and resilience (needed for project management including teamwork and communication) of GenZ students.	Rego and Fernandes	Gender	Silva et al.(2020) Magano et al. (2021)
Development of (engineering specific) self-evaluation tools, represented by qualimetric instruments to evaluate EI	Hall (Ukrainian version)	Year/level of study	Sushchenko, Borova and Petrenko (2023)
General benefits/employability	Schutte's EIS	Age, gender, hobbies, engineer in family, professional pessimism	Tekerek and Tekerek (2017)

behavioural tendencies and self-perceived abilities" which is suitable when "the intent of EI assessment of students is to provide the student with an awareness of their behavioural tendencies and how to improve their self-perceived abilities." Price, and Cordova-Wentling (2009) claim that EI tests allow for self-assessment and feedback necessary for improvement, and asked students to use their results as the basis of a personal development plan for the semester. Degen et al. (2022) describe teaching students on a programme for first generation students about the EQ-i 2.0 instrument, saying that they made use of their results to produce SMART goals for personal development. In their work into leadership development, Didiano, Simpson, and Reeve (2021) combined the use of a tool with one-on-one debriefs with the instructor which they said allowed students to clearly understand their strengths and areas for growth, this forming the basis of a personal development plan. Crowley et al. (2010) also described the use of EI tools to inform students' development plans.

3.3 EI measurement based interventions

Six papers described EI based teaching interventions. These typically involved an introduction to the concept and discussion. Such content was introduced in leadership (Bayless, Mitchell, and Robe, 2009; Bayless and. Robe, 2010) and management (Burgos-Vera et al., 2021) courses and as a core element of an Innovation, Leadership, and Engineering Entrepreneurship BS Degree Program (Newell, and Varshney, 2017). Catalano, Abdalla, and Delicato (2012) describe introducing EI to help students to differentiate themselves in the labour market. Rojas-Martínez et al. (2021) describes utilising a problem-based learning approach to introduce content addressing three axes within EI: motivation, tolerance, and resilience. The learning outcomes include identifying factors that affect emotional well-being, motivations, identifying situations of stress, setting goals and actions, healthy relationships, support groups, social and academic connections and activities which activate resilience.

4 SUMMARY

The main limitation of this work is the focus on only three databases and the exclusion of non-English publications or non-academic articles or reports. There are also limitations associated with the search terms used. Nevertheless, the findings show that, in the context of EER, EI based studies primarily make use of EI measurement tools. Results were typically analysed by characteristics such as gender, race, year of study and discipline and used to identify constructs of EI which are underdeveloped, to inform course design, or to help inform student personal development plans. In some cases, pre-post EI tests were used to assess the effectiveness of an intervention. In a few cases authors did not report the tool used and there was little consistency in tool used across range of papers. It would be beneficial for researchers to justify reasons for use of tools in the context of trait based or ability-based EI models and research aims. A more consistent approach would help facilitate faster development of knowledge within the field. In some cases, papers took a deficit approach to EI and there was little evidence to suggest that courses included critique of the emphasis on individual self-improvement and the expectation to conform to norms, or analysis of emotions within a wider context. Future interventions within engineering should focus on highlighting such issues. For example, Boler (1999) suggests several ways in which EI can be made explicit, suggesting reflective, collaborative, critical analysis of gendered and cultural differences in emotions and the role emotions play in maintaining power structures, topics which may be considered particularly relevant within engineering, which suffers from a lack of diversity.

Conference Key Areas: Teaching Social and Human Sciences to Engineering and Science Students
Keywords: Arts education; Science and engineering graduate students; Creative personality; Research performance

ABSTRACT

The positive impact of art on science is often mentioned in academic circles, yet there is scarce empirical research and a lack of universal consensus based on evidence. Against the backdrop of numerous new opportunities in arts education, the relationship between the two requires further clarification. Therefore, this study focuses on science and engineering graduate students from top Chinese universities, exploring the potential impact of arts education on graduate research performance and its underlying mechanisms.Therefore, this paper focuses on

[1] Xie, Wengang
wengang.xie@zju.edu.cn

science and engineering graduate students from top Chinese universities, and employs methods such as correlation analysis, independent samples t-test, regression analysis, and structural equation modeling to exploring the relationship between arts education and research performance. The research finds that science and engineering graduate students in top Chinese universities who have received systematic arts education often exhibit more pronounced creative personalities, and such creative personalities can positively influence research performance. Therefore, this paper proposes integrating artistic elements into research guidance and incorporating research elements into arts education, aiming to enhance their creative personalities and thereby improve research capabilities and performance.

1 INTRODUCTION

Due to the influence of the Enlightenment movement in France, science and art have long been perceived as two separate and independent domains by the public. Furthermore, the rapid development of modern technology has fostered an education system that prioritizes tools and scientific rationality, which is not conducive to the comprehensive development of students. This phenomenon is particularly evident among science and engineering graduate students engaged in research. More critically, the absolute centrality of scientific and technological knowledge in science and engineering education has resulted in a neglect of cultivating students' social responsibility awareness. However, throughout history, many great scientists have had strong connections with the arts. Albert Einstein, for example, had a passion for playing the violin alongside his scientific research, Santiago Ramón y Cajal attributed much of his research success to his pursuit of the arts, and Academician Qian Xuesen had repeatedly advocated for researchers and science and engineering students to study literature and art. Currently, both domestically and internationally, the education sector is gradually beginning to integrate arts education into the curriculum, replacing STEM education with STEAM education [1]. Sustainable development, equity, and social justice are at the core of STEAM [2].

This leads us to ponder: as arts education is poised for vibrant growth, can empirical evidence and mechanisms be found to establish the correlation between art and science? Furthermore, can the existing forms of arts education in China enhance the research performance of science and engineering graduate students in top Chinese universities, such as Tsinghua University, Peking University, and Zhejiang University? Unfortunately, to date, although many scholars have focused on the topic of art and science, their efforts have often been limited to speculative or experiential descriptions[3].Even though there are a few relevant empirical studies, they mostly focus on students in the K-12 education stage[4,5], making it difficult to identify and confirm the relationship between the two. By exploring the aforementioned unresolved questions, this study aims to provide new theoretical guidance for the comprehensive development of science and engineering research graduate students.

2 RESEARCH HYPOTHESES

The process of artistic creation shares similarities with the process of scientific discovery, as both require the synthesis of intuition and holistic cognition [6]. Researchers in academia integrate non-vocational experiences and abilities gained from arts education with professional skills and knowledge into interdisciplinary research. This combined approach of learning and practice enables them to perceive problems at the intersection of disciplines, transfer ideas and techniques from one field to another, and even integrate interdisciplinary knowledge [7].

Through a review of related studies, it is found that creative personality is significantly associated with both art education and academic research performance. On the one hand, some scholars argue that the level of artistic literacy among technology talents directly impacts their thinking patterns and creativity [8]. Art education not only advances the brain's visual cognitive system but also promotes the balanced development of cognitive, perceptual, and memory functions. These positive impacts enhance visual-spatial abilities, analytical skills, and mathematical abilities, ultimately fostering changes and shaping creative personality [9–11].

On the other hand, previous studies have shown that innovative personality has an inherent stability and plays a certain predictive role in individual innovative performance [12,13]. When individuals possess higher creative personality traits, they generate more diverse ideas and attempt to transform their ideas into concrete and feasible innovative behaviors, resulting in more innovative performance and creative achievements [14,15].The essence of scientific research in science and engineering disciplines involves creative activities, which are the "rediscovery" and "reproduction" of knowledge, characterized by high accumulation and innovation. Graduate students with creative personalities often possess solid professional foundations, stronger research interests, and more active thinking.

In keeping with this line of reasoning, we propose the following:

Hypothesis 1: Students who have received arts education are more likely to achieve higher research performance compared to those who have not.

Hypothesis 2: Students who have received arts education exhibit more pronounced creative personalities compared to those who have not.

Hypothesis 3: The creative personality of students positively influences research performance.

Hypothesis 4: Arts education play a moderating role in the relationship between creative personality and research performance.

3 RESEARCH DESIGN

3.1 Study Subjects

“Double First-Class” Universities being a group of top Chinese universities and their disciplines that are expected to enter the world's top tier. Most of China's postgraduate education is concentrated in these institutions. Thus, this study selects graduate students from "Double First-Class" universities in science and engineering disciplines as survey subjects to investigate their arts education, creative personalities, research performance levels, and their interrelationships. This study adopts random sampling for the survey. Over a period of four months, a total of 302 questionnaires were distributed through online and offline methods, and 251 questionnaires were collected, resulting in a response rate of 83.1%. Before distributing the questionnaire, participants were informed that completion signifies consent and authorization for data use in research. Subsequently, rigorous screening was conducted on the collected questionnaires, and those with incomplete responses, those with all answers filled as the same option, and those not meeting the requirements were excluded. Finally, 219 valid questionnaires were obtained, with an effective questionnaire recovery rate of 87.3%. The distribution characteristics of the sample are detailed in Table 1.

Table 1 Sample Characteristics (N=219)

Variable	Option	Frequency	Variable	Option	Frequency
Gender	Male	156	Residence	Township	25
	Female	63		Rural	68
Age	≤20 years	2	Discipline	Science	51
	21-23 years	76		Engineering	168
	24-26 years	112	Education Degree	Master	152
	27-29 years	24		Doctoral	67
	≥30 years	5	Arts Education	None	154
	Urban	126		Some	65

3.2 Research Instruments

The variables in this study were established through a rigorous and scientific process. Most of the scales used were adapted from mature scales both domestically and internationally. Additionally, experts in education management were invited to modify items in the initial questionnaire that were conceptually ambiguous, semantically biased, or unclear. Before formally distributing the survey questionnaire, a small-scale and small-sample pre-survey was conducted to delete items with inadequate reliability and validity.

(1) Arts Education: The art categories of discussed in this paper mainly include music (vocal and instrumental), painting, calligraphy, dance, and drama performance. In this study, art education is considered a binary variable with two options: "yes" and "no". Those who select "yes" indicate that they have received systematic art learning and training for at least 1 year (with no interruption of more than half a year). It does not include those who have occasionally received arts education or only received general art literacy education and aesthetic education in school.

(2) Creative Personality: The International widely-used "Williams Creativity Assessment Packet" was employed to measure creative personality. It mainly consists of four dimensions: adventurousness, curiosity, imagination, and challenge[16]. Taking into consideration the characteristics of college students and the context of the art and science fields, 16 items with high reliability and validity were selected. Each dimension consists of 4 self-assessment items, with each item having three options: "fully agree", "partially agree", and "disagree".

(3) Research Performance: In assessing research performance, mainly references were drawn from the research performance scale constructed by Van Scotter and Motowidlo (1996). The research performance of this study includes task performance and relationship performance. Task performance mainly refers to the performance of graduate students in completing research work, while relationship performance mainly refers to graduate students' interpersonal relationship management and their contribution to research work. The scale is rated on a Likert five-point scale, with a total of 10 positively-worded items. Options range from "strongly agree" to "strongly disagree," with scores of 5 to 1, respectively.

(4) Control Variables: Considering the potential influence of individual characteristics on personal research performance, control variables were extracted from individual characteristics. These mainly include gender, age, education level, and discipline.

3.3 Control and Test for Common Method Bias

The questionnaire data were derived from self-reported cross-sectional surveys, which may lead to common method bias. Therefore, two methods, namely pre-procedural control and post-statistical identification, were employed to control and test for the influence of common method bias. Pre-procedural controls included anonymous measurements and random mixing of measurement items corresponding to different variables. Post-statistical identification included using Harman's single-factor test to test for common method bias in the collected data. The results of unrotated exploratory factor analysis extracted 11 factors with characteristic roots greater than 1, and the maximum factor variance explanation rate was 19.834%. Therefore, there is no serious common method bias in the data collected for this paper.

3.4 Reliability and Validity Analysis

This study primarily employs Cronbach's Alpha coefficient to assess the reliability of the scales for creative personality, research performance, and artistic ability. Additionally, the Kaiser-Meyer-Olkin (KMO) measure and Bartlett's test of sphericity, based on orthogonal varimax rotation and principal component analysis, are used to assess the validity of the variables. Table 2 shows that the Cronbach's Alpha coefficients for each variable are generally above 0.8, indicating good reliability for the scales of creative personality and research performance. Thus, the data results are stable and reliable, validating the research hypotheses. Moreover, the KMO values for each variable are generally above 0.7, and Bartlett's test of sphericity yields significant values below 0.01. The cumulative explained variance values are all above 50%, indicating good structural validity for each scale. Therefore, the measurement results to some extent reflect the true levels of creative personality, research performance, and artistic ability among graduate students from top Chinese universities in science and engineering disciplines.

Table 2. Results of Reliability and Validity Analysis for Each Variable

Variable	Cronbach's Alpha	KMO Value	Bartlett's Test of Sphericity	Cumulative Explained Variance (%)
Creative Personality	0.834	0.848	931.357 (P < 0.001)	0.616

Research Performance	0.908	0.911	994.306 (P < 0.001)	0.615

4 Empirical Analysis

4.1 Descriptive Statistics and Correlation Analysis

Table 3 presents the mean, standard deviation, and correlation matrix of each research variable. It can be observed that the mean values of the four dimensions of creative personality among surveyed graduate students from top Chinese universities in science and engineering disciplines are ranked in the following order: curiosity (2.454), challenge (2.448), imagination (2.188), and adventure (2.151). These values are at a moderately lower level (based on a five-point scale, with 3 as the median) indicating that the creative personality level of top Chinese university graduate students in science and engineering disciplines is generally moderate. However, the research performance (3.288) is at a moderately higher level.

In terms of correlation analysis, creative personality (r=0.292, P<0.01) and its dimensions are significantly correlated with research performance. The correlation coefficients are ranked in the following order: curiosity (r=0.335, P<0.01), challenge (r=0.300, P<0.01), adventure (r=0.194, P<0.01), and imagination (r=0.135, P<0.05). Therefore, the creative personality and its dimensions of top Chinese university graduate students in science and engineering disciplines are positively correlated with research performance.

Table 3. Descriptive Statistics and Correlation Analysis Results

	Creative Personality	Challenge	Curiosity	Imagination	Adventurousness	Research Performance
Creative Personality	1.000					
Challenge	0.796**	1.000				
Curiosity	0.842**	0.663**	1.000			
Imagination	0.781**	0.453**	0.487**	1.000		
Adventurousness	0.825**	0.510**	0.614**	0.539**	1.000	
Research Performance	0.292**	0.300**	0.335**	0.135*	0.194**	1.000
M	2.310	2.448	2.454	2.188	2.151	3.288
SD	0.356	0.409	0.417	0.480	0.453	0.721

4.2 Hypothesis Testing

The independent samples t-test was initially employed to examine the differences in arts education across various variables. As shown in Table 4, there was no significant difference in research performance related to experience in arts education

(P > 0.05), thus rejecting Hypothesis 1. Additionally, artistic experience exhibited significant differences in creative personality and its sub-dimensions, including curiosity, imagination and adventurousness (P< 0.05). It was observed that research students from top Chinese universities who have received systematic arts education generally had higher levels of creative personality and its sub-dimensions compared to those who have not. Therefore, Hypothesis 2 was supported.

Table 4. Differential Analysis

Variable	None (N=154)	Some (N=65)	T	P
Creative Personality	2.261±0.359	2.421±0.326	-3.081	0.002
Challenge	2.413±0.400	2.527±0.422	-1.883	0.061
Curiosity	2.413±0.437	2.546±0.353	-2.166	0.031
Imagination	2.125±0.485	2.331±0.438	-2.928	0.004
Adventurousness	2.093±0.454	2.281±0.425	-2.836	0.005
Research Performance	3.326±0.723	3.202±0.715	1.157	0.249

Next, multiple linear regression analysis was conducted using SPSS 26.0 software to examine the influence of creative personality and its dimensions on research performance, with gender, age, and education of top Chinese university graduate students majoring in science and engineering as control variables. The results are presented in Table 5. Creative personality (β=0.268, P<0.001) significantly positively influenced research performance, and its sub-dimensions of challenge (β=0.182, P<0.05) and curiosity (β=0.215, P<0.05) also significantly positively affected research performance. This suggests that as the creative personality of science and engineering graduate students from top Chinese universities, especially in terms of challenge and curiosity, strengthens, their research performance will significantly improve, thus supporting hypothesis 3.

Table 5. Direct Effects Analysis

Predictor Variable	Research Performance			Research Performance			Research Performance		
	β	T	P	β	T	P	β	T	P
Gender	-0.016	-0.234	0.815	-0.024	-0.357	0.721	-0.014	-0.214	0.831
Age	0.022	0.313	0.755	0.019	0.276	0.783	0.011	0.159	0.874
Education	0.147	2.112	0.036	0.145	2.163	0.032	0.149	2.235	0.026
Creative Personality				0.268	4.125	0.000			
Challenge							0.182	2.062	0.040

Curiosity							0.215	2.283	0.023
Imagination							-0.088	-1.119	0.264
Adventurousness							0.015	0.168	0.867
R^2	0.024			0.096			0.135		
F	1.782			5.690^{***}			4.703^{***}		

Furthermore, employing AMOS 24.0 software, a multi-group analysis was conducted, categorizing top Chinese university engineering and science graduate students into groups with "artistic experience" and "no artistic experience" to examine the moderating effect of arts education on the relationship between creative personality and research performance. From Table 6, it can be seen that the comparative analysis of the fit indices for six models, including the unrestricted model and the measurement-weighted model, shows that all models exhibit good fit.

Table 6. Fit Indices for Multi-Group Analysis Models

Model	CMIN/DF	P	CFI	TLI	IFI	RMSEA	AIC	ECVI
Unrestricted	1.674	0.017	0.98	0.965	0.979	0.050	103.513	0.389
Measurement Weighted	1.703	0.009	0.973	0.964	0.974	0.051	102.791	0.386
Structural Weighted	1.725	0.007	0.972	0.963	0.972	0.052	103.197	0.388
Structural Covariance	1.706	0.007	0.971	0.964	0.972	0.052	102.296	0.385
Structural Error	1.667	0.009	0.972	0.966	0.972	0.050	100.671	0.378
Measurement Error	1.655	0.005	0.967	0.966	0.967	0.050	97.838	0.368

However, as shown in Table 7, compared to the unrestricted model, the changes in significance (P) values for all models were greater than 0.05, while changes in CFI, TLI, and IFI were less than 0.05. This indicates structural stability in the models, suggesting no significant differences in multi-group analysis. Consequently, it is evident that the influence of creative personality on research performance among top Chinese university engineering and science graduate students does not significantly differ based on whether they have received systematic arts education. Experience in arts education does not moderate the relationship between creative personality and research performance, thereby rejecting hypothesis 4. For ease of reference, a comprehensive table summarizing the findings is included at the end of this section (Table 8).

Table 7. Test of Differences

Model	ΔCMIN	ΔDF	P	ΔCFI	ΔTLI	ΔIFI
Measurement Weighted	9.278	5	0.098	-0.005	-0.001	-0.005
Structural Weighted	11.684	6	0.069	-0.006	-0.002	-0.007
Structural Covariance	12.783	7	0.078	-0.007	-0.001	-0.007
Structural Error	13.158	8	0.107	-0.006	0.001	-0.007
Measurement Error	24.325	15	0.06	-0.011	0.001	-0.012

Table 8. Hypothesis Testing Results

No	Hypothesis	Status
1	Students who have received arts education are more likely to achieve higher research performance compared to those who have not.	rejected
2	Students who have received arts education exhibit more pronounced creative personalities compared to those who have not.	supported
3	The creative personality of students positively influences research performance.	supported
4	Arts education play a moderating role in the relationship between creative personality and research performance.	rejected

5. Conclusion and Discussion

Although numerous studies have focused on the relationship between art and science, many remain at the level of speculative or anecdotal descriptions, lacking sufficient empirical research and a general consensus based on empirical findings. Through empirical research, this study did not directly prove the enhancement of research performance by art education. However, it found significant differences in creative personality between students who received art education and those who did not, and demonstrated a significant positive impact of creative personality on research performance. These findings indirectly support the potential influence of art on scientific endeavors. The specific discussion is divided into the following two aspects:

Firstly, this study concluded that the creative personality, along with its sub-dimensions of challenge, curiosity, and imagination, are generally higher among science and engineering graduate students from top Chinese universities who have received systematic and continuous art education compared to their peers who have not.These findings align with and provide empirical evidence to support previous research from a neuroscience perspective, which suggests that learning art can promote the development of creative personality[9–11].

Secondly, This study also found that the creative personality and its sub-dimensions of challenge and curiosity significantly positively influence scientific research performance among graduate students in top Chinese universities majoring in science and engineering. Previous research has confirmed that creative personality affects the research output of universities faculty[18], and this study further demonstrates its positive impact on science and engineering graduate students in universities.

Therefore, this paper proposes implementing various measures to encourage and promote arts education aimed at enhancing transferable skills such as creativity among science and engineering graduate students in universities. According to the theory of transfer of learning, the greater the overlap and similarity between the conditions of arts education and scientific research contexts, the better the transfer effects of creativity across different domains. This can be achieved by integrating artistic elements into research guidance and incorporating research elements into arts education, thereby promoting their research capabilities and performance.

This study still has some limitations.

In the future, it is necessary to further explore the substantive factors in arts education that effectively influence science, and to delve into other potential mediators and moderators. Future research could also consider empirical or experimental studies analyzing the relationship between art and science in STEAM education contexts or in scenarios assisted by artificial intelligence.

Conference Key Areas: *Digital tools and AI in engineering education, Building the capacity and strengthening the educational competencies of engineering educators*
Keywords: *Course Evaluations, Automated Feedback, Large Language Models*

ABSTRACT

End of semester student evaluations of teaching are the dominant mechanism for providing feedback to academics on their teaching practice. For large classes, however, the volume of feedback makes these tools impractical for this purpose.

[1] *E D Lindsay,*
edl@plan.aau.dk

This paper explores the use of open-source generative AI to synthesise factual, actionable and appropriate summaries of student feedback from these survey responses. In our setup, we have 742 student responses ranging over 75 courses in a Computer Science department. For each course, we synthesise a summary of the course evaluations and actionable items for the instructor. Our results reveal a promising avenue for enhancing teaching practices in the classroom setting. Our contribution lies in demonstrating the feasibility of using generative AI to produce insightful feedback for teachers, thus providing a cost-effective means to support educators' development. Overall, our work highlights the possibility of using generative AI to produce factual, actionable, and appropriate feedback for teachers in the classroom setting.

1. INTRODUCTION

Feedback is a powerful means of supporting learning (Hattie 2008) to inform the learner about their actual state of performance (Narciss 2008). Academics spend significant energy providing students with quality feedback on their work; but the pathways in which academics themselves receive feedback on their teaching are less supported. There are a range of approaches, such as structured university pedagogy programs and peer reviews from colleagues, but the dominant form of feedback to academics is the end of semester student evaluation.

Student teaching evaluations usually comprise a series of quantitative Likert-scale items as well as open-ended survey questions. The intention is that every student has the opportunity to contribute meaningful feedback about their learning experience, but as class sizes grow larger this feedback becomes less and less workable. For large classes the volume of open-ended feedback becomes unworkable, leading to a reliance upon the averages of the quantitative questions. These in turn become useful only if their values are very high (for the purpose of recognising teaching excellence) or very low (for the purpose of identifying needed interventions).

Recent breakthroughs in natural language processing (NLP), and in particular large language models (LLMs) have shown to have influenced a wide variety of research fields (Wahle et al. 2023), including education (Kasneci et al. 2023). These models show a remarkable ability to synthesise large quantities of text, taking as input long text sequences and generate text depending on the likelihood of the next token in the sequence. One can also tune these models to be able to take instructions and generate text based on these instructions.

There is a wide array of previous work on automated feedback, in the context of student learning, peer-to-peer learning, or peer reviewing. To elaborate, they are focused on comprehensive overviews of peer-to-peer feedback (Bauer et al. 2023), using sentence similarity methodologies for aligning answers to open responses in mathematical questions (Botelho et al. 2023), using language models to assist students improve their critical thinking skills by argumentation (Guerraoui et al. 2023), benchmarking whether GPT-style models (Brown et al. 2020; Achiam et al. 2023) align with feedback on research papers (Liang et al., 2023) and using LLMs in-the-loop during student programming assignments (Pankiewicz and Baker 2023).

In the context of automated feedback tools for teachers, previous studies have extensively explored automated feedback tools, which provide insights into student engagement and progress monitoring (Schwarz et al., 2018; Aslan et al., 2019; Alrajhi et al., 2021). These tools empower educators by offering analytics for intervention when necessary. Recent advancements in NLP enable feedback on educators' classroom discourse, promoting self-reflection and instructional enhancement in real time (Samei et al., 2014; Kelly et al., 2018; Jensen et al., 2020; Suresh et al. 2021; Demszky and Liu, 2023; Demszky et al. 2023). Wang and Demszky (2023) investigate whether ChatGPT can be used for generating feedback that is useful for teacher development. However, to the best of our knowledge, previous work has not looked at using course evaluations as a feedback source. Another line of work is the usage of LLMs for coding student evaluations (Katz et al. 2024), the difference between this and our work is that we use the student evaluations directly as a source of critical information to give feedback on for the instructor of a course.

In this work, we explore whether such models can be used to synthesise meaningful feedback summaries from open-ended student evaluation responses. Therefore our key research question is:

RQ: How can LLMs be applied to automatically synthesise student feedback in a manner that is factual, actionable, appropriate, and generates value for individual lecturers?

In doing so, we must ensure that the output of our models demonstrates three key features, inspired by previous work (Wang and Demszky 2023; Wang et al. 2023; Guo et al. 2023; Chang et al. 2023):

1. **Factuality** – whether the model accurately generates feedback according to the input text, i.e., course evaluation, and does not hallucinate irrelevant information.
2. **Actionability** – that it is feedback that could be actioned by the lecturer, instead of giving a summarisation of the course evaluations.
3. **Appropriateness** – if the feedback that addresses teaching rather than being personal in nature. For example, if a student writes down an unwanted comment, this would not be echoed by the model.

This work was conducted at the Computer Science department of Aalborg University. Our dataset comprises student evaluations of 75 courses ranging across the five different year levels of the degree programs within the Department. Response rates varied from a single response in a course up to a maximum of 44 responses per course, with a total of 742 responses in the dataset. The dataset was drawn from a Covid-19-era teaching semester.

2. OUR MODEL

In this work, we used Llama2 (7B; Touvron et al. 2023) as the core LLM to synthesise the student feedback. Llama2 is an open-source 7-billion-parameter language model based on the Transformer architecture (Vaswani et al. 2017) and it generates text autoregressively.

We used a *zero-shot inference* (direct *prompting*) approach, relying on the ability of the model to make predictions or perform tasks in the absence of explicit training data pertaining to those specific tasks (Romera-Paredes and Torr 2015; Xian et al. 2017) and not showing any examples.

The decision not to fine-tune the model allows for a simpler and faster implementation process. It also allows for a transferable implementation, because it does not rely upon an extensive (and expensive) training or alignment process in order to achieve its results. In doing so, however, we forego the improved performance that tailoring the model to our context would provide.

We adopted a two-stage approach to synthesising the student feedback into an actionable summary. In the first stage we concatenated all of the student feedback for a particular course, and prompted the model to summarise that feedback:

Prompt_1: "Summarise, to a maximum of {X} tokens this text that is based on course evaluations: {INPUT}"

Where "X" number of tokens is determined by a heuristic so that the total input text length does not exceed the working capacity of the model. Having made a summary, we then prompted the model to provide actionable feedback for the lecturer:

Prompt_2: "You are now an actionable feedback bot. Give actionable feedback, based upon these summarised course evaluations, to the instructor of the course. Leave out names that could identify entities. Make sure that the feedback is factual, actionable, and appropriate to the instructor: {SUMMARISATION}"

This process resulted in 75 feedback summaries, one per unique course in our dataset.

3. RESULTS

In this section, we show several excerpts of the output of the LLM and consolidate emergent formatting standards of the LLM. The input of the LLM is a mixture of Danish and English course evaluations. We get the output of the LLM in free text format. We notice there were some issues with the translations between Danish and English, most likely due to our Llama2-based model, being an English-based model.

We observe that there are three key formats the model generates output given our input, without intentionally prompting for these formats. Overall, the majority of the emergent formats blended feedback with comments and listed the feedback points one by one (first format). A second format generated a direct response to the instructor, by listing the strengths, areas for improvement, positive feedback, and recommendations making it more verbose than the first format. In the third format, the model first presents a summary of the key aspects of the feedback (both positive and negative points) and gives the recommended actions in the second paragraph.

Decoupling the issues from the suggestions allows a holistic view of the class to emerge, and ensures that the focus of the feedback is on being actionable, rather than focussing on suggesting actions to the academic. This has similarities to the Chain of Thought reasoning abilities of LLMs (Wei et al. 2022; Zhang et al. 2022), where a series of intermediate reasoning steps improves the LLM on complex reasoning.

In Table 1, we show illustrative examples of the output of the model, specifically of the first and third format.

Table 1. Illustrative Excerpts. We show examples of the generated output of the LLM. To save space, note that these outputs are excerpts of the full output of the LLM.

Generated Output of the Model
(1) Based on the course evaluations, here are actionable feedback points to improve the "flipped classroom" model: 1. Workload Management: Students found the workload excessive, suggesting a reduction in assignments or more breaks. 2. Adjusting Difficulty Levels: Some assignments were too challenging, suggesting a review and adjustment for consistency. 3. Providing Additional Resources: Students suggested additional resources like past assignment reviews and solutions for better understanding. 4. Peer Learning: Encourage interaction through group work or peer-to-peer activities. 5. Exam Structure: Consider revising exams to align better with student needs, possibly integrating a separate programming course. 6. Code Review: Incorporate more code review activities to demonstrate real-world implementation. Overall, while the flipped classroom model was beneficial, addressing these points can enhance the course experience.
(3) Dear Instructor, Here's a concise summary of the key feedback points derived from the course evaluations: 1. Course Materials: The structured nature of the book and exercises received praise for aiding comprehension, with detailed examples enhancing understanding. 2. Exam Preparation: The exam tasks practiced during the course were beneficial, though there's potential for improvement in actively listening to and incorporating student feedback. 3. Communication Style: Some challenges arise from the lecturer's communication style, exacerbated by distance due to COVID restrictions. Utilizing slides for better visibility and adapting communication methods could address this. 4. Instruction Clarity: Unclear or irrelevant instructions during lectures led to student confusion and dissatisfaction.

5. Project Feedback: Students felt project feedback was overly critical, lacking empathy towards project challenges.

Actionable Feedback Suggestions:

1. Enhance Communication Style: Work on improving communication to cater to all students, possibly through slower speech or visual aids.
2. Clarify Instructions: Ensure instructions provided during lectures are clear and concise to prevent confusion.
3. Offer More Feedback: Encourage early project sharing for better understanding of student challenges and tailored feedback.
4. Utilize Online Resources: Integrate engaging online materials to supplement lectures and boost student engagement.
5. Adjust Seating Arrangements: Where possible, consider seating students closer together during COVID restrictions to mitigate visibility issues with slides.

Addressing these suggestions can foster a more inclusive and effective learning environment for students.

4. EVALUATION OF THE OUTPUTS

A team of three human evaluators rated the model outputs on a five-point Likert scale, considering the three dimensions: Factuality, Actionability and Appropriateness. Overall, there was good agreement between the evaluators, with the majority of evaluations receiving the same or similar ratings on the Likert scale. The process of reviewing divergent ratings revealed interpretation differences on the part of the evaluators, and the process of reconciling these differences identified key themes for the feasibility of this NLP approach.

4.1. Observations regarding Factuality.

Overall, the output of the model was largely agreed to be factually correct—it was indeed a synthesis of the input feedback from the students. The model was consistent in the amount of output it would generate, which presented challenges when dealing with the smallest and largest sets of input data.

For the smallest samples (there are seven courses with only one respondent) the output would reflect the input; but it would also include additional feedback not arising from the input. While these were largely benign in nature, they did not actually reflect factual feedback from the students.

These false positives appear to have mostly been introduced in the second step of the model. The first step summarisation of the inputs seems to be an accurate summary; it is the prompt to provide actionable feedback that triggers the model to generate additional comments not based upon the input.

For the largest samples the model suffered from not having pedagogical expertise, and as such being unable to correctly prioritise which input comments most needed to propagate to the output. This challenge was most pronounced where there were contradictory comments in the dataset. The model could identify that students were positive or negative towards an aspect of the teaching, but it struggled to convey the inconsistency among students, instead often only reporting one of the two sentiments.

4.2. Observations regarding Actionability.

The model was prompted to provide actionable feedback to the instructor, and for the most part the output provided suggestions to the academic based on the summaries. Given that the model had not been specifically trained to the operating context of a Computer Science department, it was somewhat surprising how relevant many of the general suggestions were. The model struggled, however, with specific suggestions for domain specific issues. The model also made a number of suggestions that were not feasible or were outside the control of an individual instructor, such as changing ECTS credit points, or the duration of a course.

The model struggled with making suggestions when there were contradictory inputs. For example, if there were two student evaluations and one student mentioned they liked online teaching and one did not, the model selects only one part of the feedback, mentioning that *all* students liked online teaching. On a more general note, there is a common pattern; when the input to the model is *sparse* (i.e., not many evaluations) the model generates non-actionable items, or in other words, hallucinates new problems. When the input is too *dense* (i.e., many evaluations), we notice that the model has a harder time prioritising which feedback to generate.

4.3. Observations regarding Appropriateness.

Overall the model produced output that was appropriate to share with academics, however there were issues with losing some of sentiment from the student feedback. There were multiple instances of names being included, despite the model being explicitly prompted not to include names. In all such cases the mentions had positive sentiment, so this did not negatively affect the appropriateness of the feedback, but it undermines the trust in the model not to convey negative sentiment outputs in the future.

There were instances in which specific comments with strong sentiment, both positive (e.g., “super helpful”) and negative (e.g., “hopeless”), were not incorporated in the synthesised output. A consequence of this was that the resulting output did not convey the strength of that sentiment, instead seeming much like the output for more mild sentiment inputs. While this meets the objective of providing appropriate output, it undermines the factuality and actionability of the outputs by not conveying to the academics how the students are actually responding to their teaching.

5. CONCLUSION

In this work, we present a proof-of-concept leveraging open-source generative AI to automatically synthesise actionable teacher feedback from student course evaluations. We prompted an out-of-the-box open-source LLM to summarise course evaluations and give actionable feedback based on this summary. The model generates output consistently based on three common formats. Despite the simplicity of the model, our findings suggest the feasibility of using open-source models to generate summarised actionable feedback from course evaluations as a cost-effective approach to supporting teachers' development. However, we believe further improvements are necessary to improve the effectiveness and accuracy of the generated feedback. With continued refinement, integrating generative AI into educational settings could significantly contribute to improving teaching practices and supporting educators' professional growth.

ABSTRACT

Authentic engineering learning is an educational model emphasizing the construction of knowledge in practical contexts that closely resemble real-life work situations, which is crucial for fostering students' engineering responsibility. This study aimed to develop a reliable scale for assessing the authenticity of Chinese engineering learning projects. Drawing on existing literature and qualitative interview data, we

[1] *Wang, Shuai*
Wangshuaii2021@163.com

created a 14-item scale encompassing four dimensions: task authenticity, process authenticity, collaboration authenticity, and impact authenticity. The scale was validated through exploratory and confirmatory factor analysis using data from Chinese universities. Furthermore, we explored three implementation contexts for authentic engineering learning: teaching tasks, virtual simulation, and industrial sites, each exhibiting unique characteristics. Multiple linear regression analysis confirmed that these four dimensions enhance students' engineering responsibility, thereby supporting curriculum development and innovative educational models in engineering.

1 INTRODUCTION

Humanity faces increasing pressure to find collaborative solutions to global social and environmental challenges, including climate change, biodiversity conservation, and social inequity (Dobson 2007; Scott 2009). This presents a significant challenge for university-level engineering educators, who must help students form personal connections with these topics rather than perceiving direct involvement in global change as too distant, troublesome, or difficult to understand (Lombardi and Sinatra 2012; Helicke 2014). Recent reforms and transformations in engineering education worldwide, such as the Massachusetts Institute of Technology’s New Engineering Education Transformation program, Aalborg University’s Centre for Problem Based Learning in Engineering Science and Sustainability, and the Emerging Engineering Education Plan implemented in Chinese universities, share a common characteristic: the emphasis on authenticity in engineering learning. The authentic learning sciences offer strategies to address this challenge by fostering curricula where students are motivated to learn in rich, relevant, and real-world contexts (Herrington 2005).

2 LITERATURE REVIEW

2.1 Authentic Engineering Learning and Its Components

Authentic engineering learning is a learner-centered, practice-based model that immerses students in experiences mirroring the "real engineering world" across various contexts, including teaching tasks, virtual simulations, and industrial sites, to facilitate knowledge construction and cultivate a sense of responsibility (Herrington and Kervin 2007; Herrington and Herrington 2007). Most existing studies on authentic engineering learning explore the construction of this model, with few empirical investigations. These studies typically focus on the following elements. **(1) Authentic learning environment.** It is essential to provide contexts that reflect real-life application of knowledge. For instance, students can utilize a variety of professional equipment, tools, information, and real data (Levin et al. 2023; Zualkernan 2006). **(2) Authentic learning tasks**. Students have access to expert performances and process modeling and are required to solve complex, interdisciplinary problems or tasks in the real world (Farrell 2020). **(3) Authentic learning individuals.** The model offers opportunities for students to be effective performers with acquired knowledge, crafting polished performances or products. This stimulates their interest, sense of meaning, uncertainty, frustration, reflection, and other emotional experiences (Renzulli 2004). **(4) Authentic learning outputs.** This includes integrated and process evaluations, participation of enterprise personnel in the evaluation process, and validity and reliability with appropriate criteria for scoring varied products (Lowell and Yang 2023; Renzulli 2004).

2.2 Authentic Engineering Learning in Diverse Contexts

This study synthesizes global practices and related literature on authentic engineering learning, focusing on three primary contexts. **The first context is teaching tasks**, which provide students with contextually rich engineering cases. This approach employs innovative teaching methods such as design-based learning, problem-based learning, maker spaces, and pinnacle design courses to enhance students' understanding of core conceptual knowledge and practical skills (Huang Z et al. 2021; Love T S et al. 2023). **The second context is virtual simulation**, which utilizes modern digital technologies to simulate engineering laboratories or dynamically showcase engineering sites online. This method offers highly realistic, visual, and interactive learning content that reflects real engineering processes and scenarios (Salinas-Navarro D et al. 2024; Yang W et al. 2019). T**he third context is industrial sites**, where engineering practice training platforms are established by enterprises, universities, or joint ventures. These platforms provide real equipment, production lines, and research and development projects. Students engage in on-site engineering practices as apprentices, interns, or student engineers, completing relevant engineering designs or production processes to acquire the skills and experiences necessary for actual work (Tisch M et al. 2016; Mandal N K and Edwards F R 2021). Additionally, we observed that with the advancement of engineering education reforms, some mixed scenarios have emerged, which cannot be easily categorized according to the aforementioned contexts.

2.3 Authentic Engineering Learning and Engineering Responsibility

Engineering responsibility is an ethical theory positing that engineers have an obligation and duty to benefit society, the environment, and the economy, given their unique knowledge and the direct public impact of their work (Garriga and Mele 2004; Frederiksen and Nielsen 2013). The literature review reveals two primary pathways to foster students' engineering responsibility: ethical foundations and civic engagement (Frankel-Goldwater, 2022). (1) Ethical foundations encompass topics of positivity and normativity, anthropocentric and biocentric views, and the notion that "right and wrong" can be subjective. Authentic engineering learning integrates learning moments with students' interests and their sense of morality (Robertson D R 2005). (2) Civic engagement involves taking direct action for societal causes, supporting learning through service. Authentic engineering learning activities foster a sense of agency through in-class reflections, shared site placements, and formative connections with socio-ecological issues (Barth M et al. 2007; Lynch and Boulay 2011).

2.4 Research Purpose

The literature review indicates that accurately measuring authenticity in the field of engineering remains a research gap. Additionally, few scholars have investigated the extent to which and how enhancing authenticity in engineering learning helps students become responsible engineers. Consequently, this paper has two primary purposes. Firstly, it aims to clarify the operational definitions of authentic engineering learning and propose appropriate items to form an instrument for measuring internal dimensions. Moreover, it will analyze whether each characteristic exhibits varying degrees of presence across different contexts of authentic engineering learning. Secondly, this study will assess how the authenticity characteristics within the instrument influence students' sense of engineering responsibility and attempt to analyze the underlying mechanisms.

3 METHODOLOGY

The research hypotheses of this paper include: (1) Different contexts of authentic engineering learning will have differential impacts on the dimensions of authenticity, and (2) the dimensions of authenticity will have a significant positive effect on students' engineering responsibility.

This study employed a mixed research design approach. Initially, 16 items from Zhangwei's (2023) measurement tool and 13 items from established studies (Barab 2000; Herrington and Oliver 2000; Herrington and Kervin 2007) were collected to construct a brief authentic engineering learning framework with four dimensions: task authenticity (TA), process authenticity (PA), collaboration authenticity (CA), and impact authenticity (IA). Semi-structured interviews with 5 engineering students provided 11 additional questions to supplement the items. Three engineering professors and four students from Zhejiang University revised and simplified the questionnaire. In the initial testing phase, 132 completed questionnaires were collected for preliminary model fitting, and unclear or problematic items were modified or removed. The final measurement questionnaire comprised 19 items across four dimensions (TA: 4, PA: 3, CA: 3, IA: 4). Subsequent analyses included exploratory factor analysis (EFA), confirmatory factor analysis (CFA), criterion-related validity (CRV), and descriptive statistical analysis, conducted using IBM SPSS Statistics version 27.

4 FINDINGS

4.1 Qualitative Research Findings

Based on established research and interviews with engineering teachers and students, we defined operational terms for task authenticity, process authenticity, collaboration authenticity, and impact authenticity. Task authenticity refers to learning activities that mirror real-world scenarios and are designed to address complex engineering problems (Farrell 2020). Process authenticity pertains to learning activities that replicate real-world industrial processes and procedures (Callison and Lamb 2004). Collaboration authenticity involves activities completed in teamwork, akin to real-world practices (Ashford-Rowe 2008). Impact authenticity refers to the applicability of learning outcomes, such as products or patents, in contexts beyond the school environment (Barab et al. 2000).

Table 1. Items for Measuring the Authenticity in Engineering Learning

Items
The solutions to the problems I face are usually open-ended. (TA1) The engineering problems that I face are complex and interdisciplinary.(TA2) What I need to solve is the complex engineering problem of poor structure.(TA3) I need to solve engineering problems by investigating, collecting, and interpreting complex data information.(TA4)
My study tasks are similar to the challenges in my daily life.(PA1) I can oversee the entire life cycle of the product, including design, manufacturing, production, and other stages.(PA2) I will contact the project stakeholders, such as suppliers and consumers.(PA3)
I need a clear division of tasks among other students.(CA1) We work together to complete the final problem solution.(CA2) I can discuss with my classmates to come up with a solution to the problem.(CA3)
The engineering products I design or create can be applied to real-world engineering situations.(IA1) I need to design or build a complete and valuable product.(IA2) The engineering products I design or create can have a significant impact on the advancement of technology and industry. (IA3) The engineering products I design or create can be widely utilized in the market after enhancements.(IA4)

We also conducted a qualitative study on engineering responsibility, integrating core competence standards for engineering education graduates as defined by the Accreditation Board for Engineering and Technology (ABET) and related research (Zandvoort 2008). We identified six key questions: (1) Consideration of public health, safety, social security, and global factors; (2) Adherence to professional ethics and engineering practices; (3) Evaluation of the impact of engineering solutions on the global economy, environment, and society; (4) Conservation of natural resources, minimization of waste emissions, and prioritization of ecological protection; (5)

Balancing economic development with environmental preservation; and (6) Addressing social issues such as gender equality and poverty through engineering interventions. These questions were then converted into a Likert five-point scale for data collection.

4.2 Exploratory Factor Analysis(EFA)

In this study, we distributed questionnaires to Chinese engineering students and obtained 159 valid responses. The respondents were enrolled in 29 different schools, including prestigious institutions such as Zhejiang University and Peking University, and represented 35 distinct majors, prominently including Mechanical Engineering. The sample composition consisted of 32.5% undergraduate students, 51.4% graduate students, and 15.7% doctoral students. Statistical analyses revealed a Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy at 0.852, surpassing the recommended threshold of 0.70. Bartlett's test of sphericity yielded a value of 911.512 ($p < 0.001$), indicating the dataset's suitability for factor analysis. We conducted principal component analysis with maximum variance rotation to extract factors, yielding factor loadings ranging from 0.602 to 0.845, with a cumulative variance explained of 66.857%. This demonstrates that the factor structure of authentic engineering learning aligns with theoretical expectations.

Table 2. Summary of Factor Loadings in EFA and Cronbach's alpha (α)

Factors	Items	Factor Loading			
TA（α=0.707）	TA 1	.716			
	TA 2	.700			
	TA 3	.703			
	TA 4	.710			
PA（α=0.697）	PA 1			.818	
	PA 2			.602	
	PA 3			.670	
CA（α=0.808）	CA 1		.802		
	CA 2		.845		
	CA 3		.778		
IA(α=0.792)	IA 1				.805
	IA 2				.747
	IA 3				.804
	IA 4				.810

4.3 Confirmatory Factor Analysis(CFA)

In the CFA study, we utilized a distinct sample by re-collecting 243 questionnaires from Chinese engineering students (Zheng X M et al. 2015). These respondents represented a diverse range of schools, majors, and academic levels. The model fit test results in Table 3 indicate that all indicators reached satisfactory or acceptable levels, demonstrating a good fit for the CFA model. Additionally, we examined the

Average Variance Extracted (AVE) and composite reliability (CR) for each scale dimension. The AVE values were mostly above 0.5, and all CR values exceeded 0.7, affirming strong convergent validity and reliability across all dimensions of the authenticity engineering learning scale in this study.

Table 3. Fit Test of CFA Model for Authenticity Engineering Learning Scale

Index	Reference standard	The measured results
CMIN/DF	1-3:excellent，3-5:good	2.475
RMSEA	＜0.05:excellent，＜0.08:good	0.078
IFI	＞0.9:excellent,＞0.8:good	0.931
TLI	＞0.9:excellent，＞0.8:good	0.911
CFI	＞0.9:excellent，＞0.8:good	0.930

Table 4. Convergent Validity and Composite Reliability Test of Each Dimension

Path relationship			Esti-mate	AVE	CR	Path relationship			Esti-mate	AVE	CR
TA 1	<---	F1	0.721	0.499	0.799	CA 1	<---	F3	0.722	0.663	0.854
TA 2	<---	F1	0.654			CA 2	<---	F3	0.908		
TA 3	<---	F1	0.708			CA 3	<---	F3	0.802		
TA 4	<---	F1	0.740			IA 1	<---	F4	0.755	0.565	0.838
PA 1	<---	F2	0.765	0.655	0.847	IA 2	<---	F4	0.711		
PA 2	<---	F2	0.630			IA 3	<---	F4	0.790		
PA 3	<---	F2	0.992			IA 4	<---	F4	0.748		

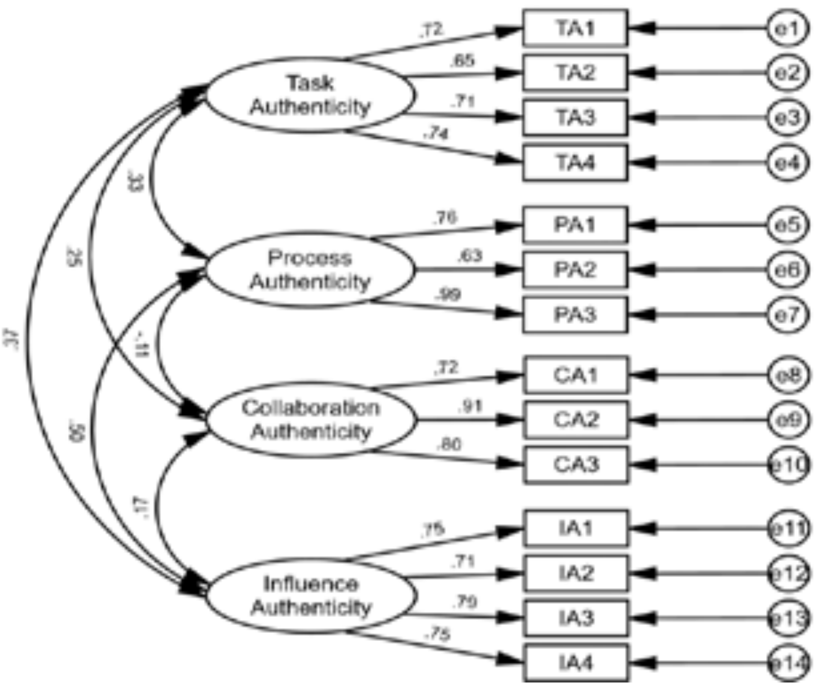

Fig.1. Confirmatory Factor Analysis Model with Standardized Loadings

4.4 Description Statistics and Analysis of Variance

We combined the questionnaires obtained from the EFA and CFA studies, resulting in a total of 402 responses. These respondents were categorized based on their participation in teaching task contexts, virtual simulation contexts, industrial site contexts, and multiple contexts. Descriptive statistical analysis revealed that students experienced the highest CA in the teaching task context, while PA and IA were comparatively low. Students in the virtual simulation context reported low TA and CA but slightly higher PA. Students who participated in the industrial site context or multiple contexts achieved the highest levels of TA and PA.

A one-way analysis of variance (ANOVA) was conducted to investigate the effect of context on the authenticity of each dimension. The results were as follows: TA: F=2.877, p=0.036; PA: F=1.349, p=0.258; CA: F=1.055, p=0.368; IA: F=0.187, p=0.905. A statistically significant difference in TA was found across different contexts (p<0.05).

Table 5. Description of statistics of each dimension of authenticity in different scenarios

Context	TA	PA	CA	IA	Average Authenticity	Average Responsibility
Context1(N1=54)	3.560	2.994	4.049	3.134	3.434	3.941
Context2(N2=26)	3.356	3.090	3.731	3.221	3.349	3.756
Context3(N3=27)	3.852	3.395	3.938	3.278	3.616	3.648
Multiple Context (N4=295)	3.703	3.098	3.950	3.223	3.494	3.869
Total(N=402)	3.671	3.103	3.949	3.215	3.484	3.857

4.5 Multiple Linear Regression Analysis

We calculated the values of engineering responsibility as the dependent variable and conducted a multiple linear regression analysis using the dimensions of authenticity as independent variables. The results indicated that the regression model was significant, without multicollinearity (F=30.268, p<0.001). TA, PA, CA, and IA all positively influenced engineering responsibility and collectively explained 22.60% of the variation in the dependent variable.

Table 6. Results of the Regression Analysis of Responsibility

	B	*β*	*t*	*P*	*VIF*	*F*	Adjusted R^2
TA	0.139	0.152	2.886	0.004	1.430	30.268^{***}	0.226
PA	0.105	0.135	2.290	0.023	1.813		
CA	0.222	0.252	5.226	<0.001	1.203		
IA	0.081	0.113	1.882	0.061	1.863		

5 DISCUSSION

Consistent with previous studies on authentic learning, this study examines variations in perceptions of authenticity across different learning scenarios: teaching tasks, virtual simulations, and industrial sites. ANOVA results indicate significant differences in TA across these contexts, while the other three authenticity dimensions do not show significant differences. This can be attributed to two factors. Firstly, TA refers to activities mirroring real-world scenarios to tackle complex engineering problems. In teaching tasks, students encounter rich engineering cases, perceiving these as solving real-world problems, resulting in moderate TA. In virtual simulations, students use computer-based platforms, perceiving tasks as less connected to reality, thus showing lower TA. In industrial sites, students engage in on-site practices, completing real engineering tasks, leading to the highest TA. Thus, TA varies significantly across contexts. Secondly, with ongoing engineering education reforms, teaching tasks and virtual simulations increasingly integrate industrial site characteristics, creating blended scenarios. Consequently, students perceive similar levels of PA, CA, and IA across these contexts, with no significant differences in these dimensions. Therefore, TA plays a crucial role in crafting authentic engineering learning experiences, especially in teaching tasks and virtual simulations, highlighting the need for its development in these contexts.

Furthermore, this article explores the relationship between authentic engineering learning and engineers' responsibility. The six items of engineering responsibility in the questionnaire encompass aspects such as environmental awareness and social development. Through multiple linear regression analysis, we found that each dimension of authentic engineering learning significantly enhances students' awareness of engineering responsibility, although with relatively low explanatory power. For instance, during the engineering learning process, students feel they are completing real-world tasks, necessitating consideration of public health, safety, social security, and global factors. They perceive their activities as having a genuine impact on the world, prompting them to think about protecting natural resources, minimizing waste emissions, and achieving ecological preservation while promoting economic growth. Experiencing complete and real industrial processes requires them to evaluate the impact of engineering solutions on the global economy, environment, and society. Through collaboration within engineering practice communities, students also recognize the importance of adhering to professional ethics. Therefore, these dimensions of authentic engineering learning contribute to cultivating students' sense of engineering responsibility.

6 CONCLUSION

Pursuing authenticity in engineering education is both a pedagogical and societal imperative, preparing future engineers to address complex global challenges with a strong sense of environmental and social responsibility. This paper introduces a measurement scale for authentic engineering learning, encompassing four dimensions: task authenticity, process authenticity, collaboration authenticity, and impact authenticity. Each dimension contributes to the development of engineers' sense of responsibility. We also identified three primary contexts for authentic engineering learning: teaching tasks, virtual simulations, and industrial sites, while acknowledging the presence of mixed scenarios. And dimensions of authenticity vary across different contexts.

7 LIMITATIONS

As a pilot study, our work had two main limitations. Firstly, in the empirical research section, we collected 402 valid questionnaires. However, the relatively small sample size reduced the robustness of the results. Regression analysis on samples with different authentic learning experiences also yielded unsatisfactory results , likely due to small sample sizes within scenario groups. Therefore, future research should include a broader range of courses and a larger sample size to enhance the generalizability of the findings. Secondly, we did not focus on mixed scenarios, which are common in real life. Future research should scientifically distinguish between different learning scenarios and pay particular attention to mixed scenarios.

ABSTRACT

Engineering students' insufficient work experience, lack of knowledge or misconception about their own abilities to work and communicate efficiently on a complex engineering project, as well as their abilities to manage work efficiently can be a difficult task for lecturers to teach at university. Challenge-based learning (CBL) has been implemented in engineering higher education because it constitutes an active learning pedagogy that provides students with a framework to acquire and develop key transversal disciplinary skills like problem-solving, critical thinking, project leadership or communication skills. The experiential learning that a CBL framework offers allows students to work collaboratively in real-life problems that are challenging to solve. The authors of this paper are involved in integrating the teaching of two important transversal skills, project leadership and management and communication to manage a project and communicate it to different stakeholders for different purposes, into a challenge-based year-long course. In this paper, we report

[1]*M. Aguilar-Perez*
marta.aguilar@upc.edu

on our experience in teaching master engineering students these two transversal skills by means of a pedagogical intervention that is integrated within a course based on challenge-based pedagogy. The pedagogical intervention is described and subsequently students' perceived usefulness of such intervention is explained.

1 Introduction

Innovative teaching practices, such as project-based learning (PrBL) and challenge-based learning (CBL) have become frequent in the context of engineering in Higher Education (Beckett and Slater 2020). Project-based learning is related to action learning and makes students work on real world work assignments on time limited projects (DeFillippi, 2001); it later evolved into CBL. We adhere to Malmqvist et al.'s definition of challenge-based learning (2015) as the identification, analysis, and design of a solution to a sociotechnical problem. The learning experience in CBL usually involves different stakeholder perspectives and aims to find and develop solutions environmentally, socially and economically. Both types share the student-centred and student engagement focus and envision instructors as facilitators, yet CBL differs from PrBL in that students design the problem, and develop and execute the solution, with instructors designing, mentoring and coaching students (see van der Beemt et al., 2023 for a full comparative analysis).

The recent challenge-based pedagogy trend is attributed to the increasingly complex situations that engineers find themselves in, where they are expected to operate efficiently when undertaking actions that require innovative technological and sustainable solutions (Dolougeri et al. 2024). Among transdisciplinary skills that engineers are supposed to develop in their engineering endeavours and projects, we find problem-solving skills, entrepreneurship, collaboration, project management and team building, information gathering skills, critical thinking or communication skills (Tranquillo 2017; Zhao and Watterstone 2021). This brings to the fore the need to take on a holistic stance toward an integral engineering education that includes these transversal skills and disciplinary literacies in the curriculum (Heron et al. 2021; Paretti et al. 2019). In this study, we therefore focus on two such competences, namely, project management and leadership, and communication –missing features in most CBL research, as pointed out by a recent systematic review (Membrillo-Hernández and García-García 2020; Doulougeri et al. 2024).

Both transversal skills are essential for engineers to perform their daily activity effectively, but they stand out as particularly important for engineers working in a project collaboratively with other teams of engineers, sometimes in remote and culturally different countries. It is therefore not surprising to find challenge-based pedagogy implemented in different engineering courses and curricula, as real or quasi-realistic challenges are believed to stimulate self-directed learning by placing students centre stage and pushing them to link new knowledge with prior knowledge (Hadgraft and Kolmos 2020; Dolougeri et al. 2024). Challenge-based pedagogies, however, allow for a wide range of possible designs and implementations, not always equally effective as it comes to student learning (Dolougeri et al. 2022). In this paper, we describe a challenge-based course within a Master's programme that involves external stakeholders and integrates these two transversal skills through multidisciplinary teaching. The educational background, the Master's programme, against which this challenge-based course is taught will be described. In section three the framework and specificities of this course are described in detail as well as students' assessment of the intervention.

1.1 SELECT- Environomical Pathways for Sustainable Energy Systems Master's programme

The emergence of Master's degrees specialised in energy can be traced to the growing global awareness of two interconnected factors. The first is the urgency of the energy transition and refers to the increasing urgency of climate change mitigation and the necessity of shifting from fossil fuel-based energy systems to renewable sources. The second factor relates to the interdisciplinary nature of energy systems, since the complexity of energy production, distribution, and policymaking demands a new generation of graduates equipped with a holistic understanding of technical, economic, social, and environmental aspects of energy.

Among these diverse offerings, the SELECT (Environomical Pathways for Sustainable Energy Systems) Master's program holds a distinct position. SELECT is a collaborative initiative of several European universities. SELECT started as an Erasmus Mundus Program in 2010 and, since 2011 it has been offered within the framework of the European Institute of Innovation & Technology (EIT) InnoEnergy programme. This master's degree originated with the vision of training a workforce capable of accelerating the adoption of sustainable energy technologies and innovations throughout Europe. A core aspect of the SELECT experience is thus its emphasis on international mobility, with students spending semesters at two different partner universities.

Some of the two-year SELECT programme main components are:

- Entrepreneurship and Innovation: SELECT fosters strong entrepreneurial skills and an understanding of how to transform nascent technologies into commercial ventures.
- Global perspective: Through its mobility requirements and diverse student body, SELECT cultivates a nuanced understanding of global energy challenges and opportunities.
- Industry Network: SELECT students build strong connections to the industry through internships, company visits, and EIT InnoEnergy's extensive network.
- Energy Systems Analysis: Besides knowledge in energy engineering, SELECT students acquire deep knowledge about analysis of energy systems, by means of several systems analysis methodologies

The partner universities in SELECT programme are: the Royal Institute of Technology in Sweden (KTH), Politecnico di Torino (PoliTo), Eindhoven University of Technology in the Netherlands (TUE), Technical University of Catalonia in Barcelona, Spain (UPC), Instituto Superior Técnico in Portugal (IST), AGH University of Science and Technology in Poland (AGH), and Aalto University in Finland (Aalto). The first year of the master degree is developed simultaneously in two rooms connected remotely in Barcelona and Stockholm, an approach that can be considered a particular case of blended learning (Valderrama et al. 2018). The three authors work in two of the partner universities.

2 METHODOLOGY

Our primary objective is to present the approach adopted for incorporating Effective Communication and Project Leadership competences into the Project of the Year course, PoY,(12 Ects), a challenge-based course. We draw upon van der Akker's (2003) curricular spider web as a methodological framework. This paper is authored by the course coordinator and the instructors responsible for the two aforementioned competence interventions, so it draws upon the authors' direct experiences.

In March and April 2024 first-year students were asked to give their assessment on the project leadership (PL) and effective communication (EC) seminars that they received at the beginning of the academic year as well as on the guidance, mentorship, and feedback received by the two teachers (Author 1 and Author 3) throughout the Project of the Year (PoY) course.

2.1 Participants

We analysed the engineering students enrolled in the PoY during the second semester of the academic year 2023-24. Although students will submit the final report and deliver the final presentation within a month after the actual writing of the paper (month 5 as per Table 1), students are now at the end of the process and are considered to be entitled to assess and rate the usefulness of the two pedagogic interventions that tackle the transversal skills. The course coordinator (Author 2) sent all students an email asking them to answer the survey on a voluntary basis, specifying it was anonymous, for educational and research purposes only, and that their opinion was to detect and inform possible improvements. A total of 21 students (out of 50) answered the GForm survey.

2.2 Instruments

The GoogleForm survey that was designed and administered to gather information about the students' perceptions consisted of 5 Likert-type quantitative questions, usually complemented with an open-ended question each. Question 5 was excluded from this study because it fell beyond the objective of this study. Below every item, students could choose between 1 (completely disagree) and 5 (fully agree). The open-ended answers in the survey were inductively analysed, arranging the reasons given by students according to broad themes (Saldaña, 2017). The two instructors met to share and discuss the themes they had identified until consensus was found in order to achieve interrater reliability.

1-Project management skills are necessary for a smooth and efficient development of a challenging project like the PoY2- Can you elaborate on your answer and briefly tell us why?

2- Technical Communication skills are necessary for a smooth and efficient development of a challenging project like the PoY - Can you elaborate on your answer and briefly tell us why?

3-Both types of competence are useful not only for the PoY but for our future career as well.

4- Are project management and communication skills necessary for engineers working in multicultural and multilingual engineering projects? What do you think and why?

3 RESULTS

First, we describe the integration of the two transversal skills throughout the year-long project so that the intervention can be, if necessary, replicated. Subsequently, students' perceived usefulness of these competences will be explained.

3.1 Pedagogic intervention to integrate project leadership and communication skills in the challenge-based project

The aims, content, learning activities, teachers' role, materials and resources, grouping, location, time and assessment of the intervention will be described, following van der Aker (Doulougeri et al.2024:6). First, we describe the Project of the Year course, which starts before every group is allocated a company, with its corresponding challenge. Once projects and clients have been assigned, students create teams of 8-10 students to work for one year on a proposed opportunity or need with a significant impact on sustainability. The teams are made of students from different universities, ensuring a diversity of perspectives. One project manager per team is chosen among students in every team to take on the leadership role throughout the project's duration. The challenges always relate to sustainable energy, but the companies freely define the objectives, technologies considered, and scope according to their interests, time, and available resources. The challenge allows for various approaches and solutions, which are negotiated between the students and the company. Each project is supervised by an academic supervisor, a lecturer from one of the partner universities. This provides students with expert guidance and real-world insights. Additionally, students maintain contact with the company that proposed the project, acting as the client. It is important to emphasize that the companies request analyses and proposals that the students develop and complete to meet their specific needs.

The Project of the Year places great emphasis on effective communication and project leadership skills–considered to be key features conducive to success in challenge-based learning (Membrillo-Hernández and García-García 2020). These transversal skills are taught by two instructors, authors 1 and 3 of this paper, who come from different disciplines to avoid disciplinary egocentrism (Doulougeri 2024): management and business administration and English for specific purposes and professional communication. The instructors lead one seminar each at the beginning of the academic year, whose aim is twofold: i) teach students about relevant important factors in project management and professional communication; and ii) allow students to gain practice in a mini project *before* the real PoY starts. Both specialised seminars are given at the beginning of the academic course (months 8-9, see Table 1). The duration is 10 learning hours per seminar, over several days, with the following structure:

- Seminar on project management is based on energy-related mini projects proposed by the students themselves and developed in groups of 3-4 students. This ends in the mini project proposal presentations on the last day. These presentations are recorded.

- Seminar on effective written and oral communication of engineering projects follows. The recorded mini presentations are the starting point of this second seminar by following a teaching strategy that makes the students aware of their weaknesses and improvement needs (Author 1 and Author 3 2023).

When the two seminars finish, the actual PoY starts: students are allocated their company and their challenge starts. Throughout the rest of the year (month 5 to month 10), both instructors become mentors, meeting students at different points throughout the PoY development, to assist students when required and support the actual year-long PoY project. In this way, students put these transversal skills in practice during real-life challenging Project of the Year, receiving feedback and guidance from the instructors and the course coordinator. Examples of the type of guidance given by instructors are:

- The work groups prepare reports on internal group organisation and planning. Possible hurdles and improvement opportunities are addressed in meetings with the coordinator of the whole course and the teacher in charge of the Project Leadership aspects.
- Group and individual assessment and improvement support is provided by the two instructors to streamline their reporting activities, to support students on the difficulties encountered–as voiced by students and identified by the instructors. Every group drafts the report and rehearses its presentation and receives feedback from the EC instructor at least twice during the PoY.

The temporal structure of the Project of the Year and of the activities on effective communication and project leadership skills can be seen below in Table 1.

Table 1. Effective Communication (EC) and Project Leadership (PL) activities within the context of the Project of the Year.

Month	Project phase	EC & PL activities
8	Project allocation	EC + PL instructors give seminars (10 h each). Students practice with a mini-report.
9		
10-11-12	1st Phase: analysis and work plan proposal	PL instructor and PoY coordinator hold meetings with every group separately
1	1st Phase Submission	EC report assessment & feedback during rehearsals. EC instructor meets every group separately before groups submit reports and give oral defence in front of companies
3-4	2nd Phase: project work	PL instructor & PoY Coordinator give assistance on the project and EC instructor meets students when requested.
5	2nd Phase Submission	PL and EC instructors give support before groups submit reports and give oral defence in front of the (client) companies and academic supervisors

3.2 Students' perception

The quantitative results of the survey indicate a high perceived usefulness among students. Around 90.5% of students who answered the survey agreed with the statement that "project leadership and communication are very necessary for the smooth and efficient development of a challenging project like the PoY." Additionally, all respondents (100%) agreed that "both competences are useful not only for the PoY but also for their future careers." To complement this general overview and gain deeper insights into students' thinking, open-ended answers were analyzed. This analysis unveiled that project management skills are perceived as essential because "having so many projects to fulfill, and being the PoY a long run project, it's easy to lose the focus on it. That's why it's mandatory to be organized and good in project management skills to not lose the point on it" (Student 8) and because "project management is needed to be able to effectively choose the needed tasks and properly put them in frameworks that make it easier to work with, track progress, and correctly measure this progress" (Student 6).

As to communication skills, students actually confirm Paretti et al's (2019) findings when they say " it's essential to have good technical communication skills to understand the deliverables requested by the company and put forth our concerns/ requests to the company (...) We are also required to develop a report and give interim and final presentations to explain the work we have done so far. Here, communication skills become important for illustrating our work to a bigger audience" (Student 14) and "as an engineer it is very important not only to have good communication with fellow engineers but also people from different backgrounds and it is very helpful to convey what the challenge is in a broken down manner to make it easier to understand for everyone" (Student 19).

The following excerpt from student 5 summarises the representative answers by students in item 4, when asked about how necessary the skills are for engineers who work in multicultural and multilingual engineering projects:

In multicultural and multilingual engineering projects, engineers must have excellent project management and communication skills. This is because multicultural environments increase the complexity of projects and require engineers to be able to effectively cross cultural and language barriers to ensure that information is accurately communicated and understood. Good communication skills, including sensitivity to cultural differences and mastery of non-verbal communication, are essential to facilitate teamwork and resolve conflicts. Meanwhile, project management skills enable engineers to lead diverse teams, plan and execute projects efficiently, and adapt to the challenges and changes that cultural differences can bring. In addition, these skills help to identify and mitigate risks caused by cultural differences, build trust among team members, and are a key factor in achieving project success. Therefore, for engineers working in diverse contexts, acquiring these skills is not only a necessity, but also a cornerstone to ensure that projects run smoothly and achieve their goals.

Student 21, however, is the only student that, while acknowledging the relevance of the skills, questions their integration into PoY, maybe because of the complexity of the PoY itself: "obviously yes, but I am not sure the current scope of PoY is the best way to assess this".

4 Summary and acknowledgements

Only 21 students replied, maybe due to the fact that students were not given much time to answer the survey. Yet, our case study provides evidence of how two transversal skills were integrated in a year-long challenge-based learning course and how multidisciplinarity was successfully included in the project, as shown by how highly students rate project leadership and communication skills. These preliminary findings also hint that expecting students to acquire transversal skills without any explicit teaching may mean placing too high–and unfair–expectations on them.

Our acknowledgements to César Valderrama, Select Master coordinator.

ABSTRACT

Interpersonal dynamics have a major influence on team processes and outcomes. Psychological safety, in particular, is one of the foundations of effective teamwork. While there has been a recognition of the importance of psychological safety in team settings, in particular in organizational and management literature, there has been an underrepresentation of studies addressing ways by which the concept can be operationalized. Recognizing the primacy of teamwork in higher education settings, this paper aims to raise awareness and provide guidelines for incorporating

[1] *B. Alberink*
beanta.alberink@epfl.ch

interventions centred around psychological safety. We first elaborate on the concept of psychological safety. We then distil and elaborate on three major components of psychological safety: mindful listening, asking questions, and providing and receiving feedback. Next, we review two sample interventions and provide guidelines for developing similar training and learning interventions.

1 Introduction

The collaborative nature of the rapidly changing work environment in the higher education setting is a reality today. From student group projects in a class to research groups led by faculty to work groups in different units, in all those situations, a *supportive learning environment* forms the basis for *individuals working together in groups or teams* to achieve common goals and objectives.

Over time organizational research has shown that three broad factors are essential for organizational learning and adaptability: a supportive learning environment, concrete learning processes and practices and leadership behaviour that provides reinforcement. These factors are considered the building blocks of a learning organization, a concept introduced by Peter M. Senge in the 1990s. “Organizations learn only through individuals who learn. Individual learning does not guarantee organizational learning. But without it, no organizational learning occurs” (Senge, 1990, p. 139). What are the underlying features of a supportive learning environment? Garvin, Edmondson and Gino (2008) describe four distinguishing characteristics: *psychological safety*, appreciation of difference, openness to new ideas and time for reflection. These characteristics are particularly relevant when working in teams.

Individuals working together, whether they are students working on a project or scientists in a research team, share a certain level of interdependence. The higher the level of interdependence in working towards a common goal, the more important it becomes to establish trust and deal with conflicts in a team. Also, Lencioni (2002) stresses the importance of trust as a fundament of successful teams.

Working successfully together in a team is something that people have to learn. It doesn’t come naturally in the competing knowledge economy of today. Edmondson (2012) introduced the word ‘teaming’: “a way of working that brings people together to generate new ideas, find answers and solve problems” (p. 24). Teaming is a verb, an ability, a competence that people can develop.

For teams to function effectively, team members and team leaders have to learn to team and team to learn. This requires interpersonal behaviours. Literature demonstrated different types of competencies that are critical to effective teamwork, including interpersonal skills such as communication and conflict resolution skills (Stevens and Campion, 1994). Developing these interpersonal skills visible in successful teams requires psychological safety. Psychological safety is a collective belief among team members that the team is a safe environment for speaking up, sharing ideas and concerns and taking risks (Edmondson, 1999).

In a recent review of published articles on psychological safety, Edmondson and Bransby (2023) identified the “micro dynamics of conversations” as an important area that has been understudied in the literature. Such an underrepresentation implies that there are no concrete guidelines for designing, developing and facilitating interventions centred around the concept of psychological safety.

The purpose of this paper is to provide practical guidance and ideas on operationalizing the concept of Psychological Safety within teams for different stakeholders in higher education. First, we share the conceptual foundations of psychological safety from leadership, team development and organizational psychology perspectives. Then we translate the concept with a focus on powerful conversations and skills needed and discuss the role of educators and faculty. We share and reflect on our experiences with developing learning interventions for different audiences. To conclude, we provide practical guidelines and insights to invite engineering educators and faculty to design, develop and facilitate activities to promote psychological safety in teams to further develop a learning culture in higher education settings.

2 Conceptual foundations of psychological safety

2.1 Psychological safety as a concept

Prior literature and research discuss the concept of psychological safety within the context of working in teams related to key terms, such as trust, speaking up, sharing ideas and concerns, taking risks and learning from mistakes. While the use of the concept has been growing, in particular in the context of leadership and organizational settings, the accurate meaning has often been misunderstood. Edmondson (2019) addresses some misconceptions related to the concept of psychological safety.

- *Psychological safety is not about being nice*

It is the opposite. It is about frankness, about making it possible for productive disagreement and free exchange of ideas. It is about the willingness to engage in productive conflict for the purpose of learning from different points of view.

- *Psychological safety is not a personality factor*

It is not a synonym for extroversion if people don’t speak up at work. In a psychologically safe environment, people offer ideas and voice their concerns.

- *Psychological safety is not just another word for trust*

Both have much in common though, they are not interchangeable concepts. Psychological safety is experienced at a group level and describes a temporally immediate experience. Trust refers to interactions between two individuals or parties and describes an expectation that someone can be counted on.

- *Psychological safety is not about lowering performance standards*

It is not an ‘anything goes’ environment where people are not expected to adhere to high standards or meet deadlines. This misconception is particularly important in a highly competitive environment, such as higher education institutions.

Psychological safety is connected to another equally important dimension in team and organizational settings, performance standards. Edmondson (2019) illustrates the relation between these dimensions in a 2 by 2 matrix. Only when performance standards and psychological safety are both high, people are in the learning zone. In this zone, people can collaborate, learn from each other, and get complex and innovative work done (Edmondson, 2019).

From another perspective considering foundational aspects of psychological safety, Edmondson (2014) describes the following three pillars for leaders and team members to foster psychological safety in the workplace:

1. Frame the work as a learning problem, not an execution problem

Reframing creates awareness of the uncertainty and interdependency in work. It is helpful to encourage everyone to share ideas and thoughts. It forms the rationale for speaking up and learning.

2. Acknowledge your fallibility

Admitting mistakes and showing areas of uncertainty and vulnerability, invites others to open up. This creates safety for speaking up.

3. Model curiosity and ask lots of questions

Asking questions and seeking to understand stimulates a culture where everyone's input is valued and appreciated. It creates the necessity for speaking up.

By modelling these behaviours, a culture of speaking up and sharing knowledge and ideas freely without fear of failure will be developed.

3 Operationalizing psychological safety

In this section, we share pointers which can help educators and faculty translate and apply the concept of psychological safety into their daily work environment in further developing their pedagogical, leadership and team development competencies. Informed by literature, we explore two main components we identified as the vehicle to operationalize psychological safety: powerful conversations and the critical skills needed for this.

Studies show that the way in which psychological safety affects performance, learning, work experiences and the role of leadership, explicitly or implicitly, is mainly through conversation (Edmondson and Bransby, 2023). Good conversations in interpersonal and team settings share a specific characteristic, a *personalized relationship* between the actors (Schein and Schein, 2018). According to Schein (2013), it is all about building a relationship, a connection to the whole person. This is true for one-on-one and one-to-many conversations in different settings, such as two or more team members talking about a (research) project or a team leader discussing with the team.

A logical question is, how do we build these personalized relationships in conversations as a fundament for psychological safety? One of the answers comes from the Structural Dynamics Theory developed by David Kantor. Structural Dynamics is a theory of how face-to-face communication works and does not work in human systems (Kantor, 2012). It can be seen as a lens on the nature of human discourse. Kantor later refers to this *lens* as the ability to read the room to understand what’s going on when people communicate in small groups or teams, including how the leader him or herself is participating, when the conversation is moving forward, when it may just about to leave the rails, and possibly even how to guide it back on course (Kantor, 2012).

If one masters the skill of *reading the room*, one actively searches for communication patterns and uses conversation cues next to words (verbal communication). Conversation cues, such as tone of voice, facial expressions, and body language, play a significant role in effective communication. They help convey meaning and context that may not be captured by the words alone. Conversation cues give information which allows individuals to *place conscious and targeted interventions* in conversations, in particular on the process of the relations between the speaker and the listener(s) (Kessels & Smit, 2019). Examples of interventions are asking for details, summarizing, providing feedback, creating an atmosphere, reflecting on emotions and confronting.

The ability to read the room and master the art of placing conscious and targeted interventions form the basis of what we call: a powerful conversation. We posit that this ability is critical to the micro dynamics of conversations as mentioned by Edmondson and Bransby (2023).

Which skills are critical in powerful conversations? Moreover, how do these skills contribute to building a psychologically safe environment? In this section, we discuss three skills we see as the most important to further develop in different settings and for different stakeholders involved. We use the terms skills and competencies interchangeably as we would only like to stress the importance and contribution of mastering these interpersonal skills to enhance and facilitate powerful conversations.

3.1 Mindful listening

Giving someone the feeling that they are ‘really’ listened to and to create a personalized relationship, is challenging. In an educational or management setting, educators and team leaders often tell more than they listen, whether that is during a course, working on a project or during a team meeting. Sharmer (2017) illustrates four levels of listening: downloading (habits of judgement), factual listening (noticing differences and perspectives), empathic listening (emotional connection) and generative listening (energetic and with your whole body). For individuals to listen mindfully, they need to reflect on their assumptions, avoid distractions and pay close attention, and understand what has been said from the speaker’s point of view with recognition of thoughts and emotions. Through mindful listening, then, team members can highly contribute to creating a psychologically safe (learning) environment.

3.2 Asking questions

The art of asking genuine and open questions contributes to building a relationship based on curiosity and interest in the other person. Schein (2013) calls this humble inquiry, the fine art of drawing someone out, of asking questions to which you do not already know the answer. Edmondson (2019) talks about proactive inquiry, the purposeful probing to learn more about an issue, situation or person.

What makes a question powerful? Vogt, Brown and Isaacs (2003) identify the following attributes of powerful questions. A powerful question:

- generates curiosity in the listener
- stimulates reflective conversation
- is thought-provoking
- surfaces underlying assumptions
- invites creativity and new possibilities
- generates energy and forward movement
- channels attention and focuses inquiry
- stays with participants
- touches a deep meaning
- evokes more questions.

Using powerful questions in conversations often results in new insights, reflection and learning. When people use open, genuine questions, they demonstrate interest and curiosity about the other person and are intentional to hear and value their perspectives.

3.3 Providing and receiving feedback

Providing constructive feedback stimulates learning, fosters growth and adds to trust and mutual respect. It is an intervention which is key in a higher education setting. Learning from mistakes based on constructive feedback and reflection facilitates taking risks, another element of a psychologically safe (learning) environment. Edmondson (2023) elaborates on *the science of failing well* in her new book which provides practices, skills and mindsets to help us replace shame and blame with curiosity, vulnerability, and personal growth. It is worth noting that mindful listening and asking questions are key skills needed for enhancing feedback literacy.

There are several models for providing constructive feedback used in different settings and contexts. Explaining different models is beyond the scope of this paper.

4 TWO EXAMPLE INTERVENTIONS

Based on the literature and our experiences, engineering educators and scholars can play an important and leading role in building psychological safety. We identify different stakeholders who might have a direct or indirect influence on promoting the concept, for example, student teams (Bachelor and Master students), research teams (PhD students, post-doctoral researchers and scientists), professors and teachers. In the next section, we share two examples of how we used the concept of psychological safety in learning interventions.

4.1 Psychological safety in engineering student teams

One specific example of an intervention centred around psychological safety was a 90-minute module designed for a graduate-level engineering course. For more details about the activity, see Jalali et al. (2024). The goal was to support students in developing conversational skills, more specifically asking questions and listening, to create a safe and open team climate. Incorporating experiential learning and the major constituents of transversal skills development, mainly knowing, experiencing, and learning from experience (Isaac et al. 2023), the session provided several opportunities for practising, reflection, and feedback. Students were first introduced to major features of a skilful conversation, among them showing vulnerability, asking genuine questions, active listening, and reflecting on ways by which they can show genuine interest in others' perspectives (Edmondson, 2019; Senge et al. 1994). Among different components and exercises, an active, experiential element using LEGO bricks was incorporated to practice the skills and reflect on their strengths and weaknesses. Students were asked to create a model of themselves individually as a member of the team they are representing considering the following criteria: i) their background, ii) areas of expertise and skills they bring in connection with the project, iii) skills for improvement, and iv) anything else they could offer to create a better team climate. Then, each team member would share their models and respond to questions from other students in the team. Students were explicitly asked to be mindful of effective listening and asking genuine open questions. Next, to bring the whole team together, students were asked to create one agreed model representing their teams, considering i) team goals, ii) provisional roles, iii) creating a safe and open environment for team learning, and iv) potential risks they would envision. Finally, students reflected specifically on moments, interactions, or comments that increased or decreased their sense of belonging to the team; and how they contributed to creating a safe and open team climate.

Two features of this intervention are worth noting. First, the focus of the intervention was on teams rather than individuals. Prior literature highlighted the importance of delivering team-training interventions on specific knowledge, skills, and attitudes to teams rather than individuals (Mathieu et al. 2008). Second, by incorporating playful elements, learning is intrinsically motivated, immersive, and involves the positive construction of failure (Whitton, 2018). It can specifically facilitate self-expression and discussion of the aspects of the team process that would be more difficult to address outside of such a playful and engaging experience.

4.2 Psychological safety in research teams led by faculty

Leadership behaviour enhances psychological safety, in particular when it comes to leader competency, listening and transparency (Edmondson and Bransby, 2023). This has been one of the insights used for designing the Program 'Building High Performing Research Teams', a leadership journey for Tenure Track Assistant Professors at EPFL.

This blended learning program is designed to provide Tenure Track Assistant Professors with a comprehensive toolbox to address the typical challenges they face in their role as a first-time leader of a research team at EPFL. Always anchored in the daily life in the lab, the program aims to further develop leadership skills by

taking them on an active and explorative journey from self-awareness to sustaining growth in a demanding research environment.

At the end of this learning journey, they can:

- address what is needed to successfully lead and develop a team where all members can reach their full potential
- start building psychological safety as the basis for a high-performing research team

- identify values, motives and drivers within individual team members by asking good questions and by listening effectively in daily conversations
- give feedback to address motivational issues, proficiency gaps or interpersonal tensions, meant to support each team member to grow
- identify obstacles to handling difficult conversations using a method to structure and solve them
- communicate effectively to obtain better results and better relationships in situations where the stakes are high and emotions are involved.

The format of this program is adjusted to their work situation. It includes a blend of short face-to-face sessions, dedicated group coaching, reflection activities and informal round tables to reinforce leadership skills and exchange experiences with experts and peers.

How is psychological safety put into practice in this learning intervention?

The Tenure Track Assistant Professors practice different types of conversations as one of the key elements of the program, whether it concerns one-on-one or group meetings and from mastering daily conversations to handling difficult conversations. The skills covered in these conversations are mindful listening, asking open questions, providing feedback, negotiating and handling conflicts.

By using the key principle *from self-awareness (self-reflection) to growth (fostering fallibility and vulnerability)*, we try to model the behaviour needed for building a psychologically safe learning environment by professors.

So far, the feedback and experiences from everyone involved are promising and motivating to keep working on and promoting psychological safety in research teams.

5 Discussion and conclusion

In this practice paper, we presented how we interpreted and worked on the concept of psychological safety within our institution. While the primacy of psychological safety in enhancing team processes and improving performance has been illustrated for various team settings (e.g., Duhigg, 2016; Gibson and Gibbs, 2006; Nembhard and Edmondson, 2006), there has been an underrepresentation of studies focusing on psychological safety within engineering education literature. Considering the nature of engineering practice and the need for students to develop teamwork competencies, creating contexts where students can function effectively in teams and learn from their experience is critical. A similar argument holds for other team settings in higher education, noticeably research labs, where members of the teams need to feel valued and respected. As noted earlier, a practical challenge is how to operationalize psychological safety and develop meaningful training and learning interventions for different stakeholders. Building on major illustrations of psychological safety, we distilled and elaborated on essential aspects of psychological safety, mainly listening, asking questions, and providing and receiving feedback. Based on our experiences, we share the following guidelines and insights:

- Co-design the learning intervention with the key stakeholders (and future audience if possible). This engages and motivates the audience from the very first start.
- Start simple by using concrete exercises to practice a selected number of skills and explain the reason behind the choice of skills. This makes it manageable and clear.
- Reflect on the experiences with everyone involved. Reflection creates self-awareness, and an open dialogue contributes to creating a supportive learning environment.
- Explore and create an open dialogue around the topic of psychological safety linked to performance standards with key stakeholders. This helps to avoid misconceptions.
- Incorporate major elements of skills development, knowing, experiencing, and learning from experience, when designing activities.

We intentionally focused on three critical skills as we consider these the core skills to build psychological safety in different settings in higher education. We aim to explore further how different stakeholders experience similar learning interventions. We invite all engineering educators and faculty to design, develop and facilitate activities to promote psychological safety in project and research teams to further develop a learning culture within their institutions.

More research on the development, implementation and evaluation of pilot learning interventions is needed to identify and develop an overview of interventions, activities, guidelines and instructions to build psychological safety in different team settings in higher education.

ABSTRACT

This study describes a project in which undergraduate engineering students, from the statistics course, gain practical experience and reinforce their mathematical knowledge by giving lectures on statistics to adult people attending to the University of Experience at the University of Salamanca, Spain. From a group of 53 students from the statistics course, 4 of them selected this project and developed it during the first semester of 2023-2024. The methodologies used by young students are discussed, including the preparation of materials and the effective communication of complex statistical concepts to a non-specialist audience. In addition, the impact of this experience on the development of communication skills, leadership and mathematical understanding of the engineering students is considered. Students feedback underscores the effectiveness and positive impact of the service-learning (SL) concept implemented on campus. Students were highly satisfied with this approach, which integrates academic learning with community service, fostering a sense of social responsibility and civic engagement among participants. Moreover, the feedback highlights the significant growth and development of teamwork and leadership skills throughout the semester. The SErvice LEarning Benefit (SELEB) questionnaire was shared with students that participated in this project and they include the results in a final report. The SELEB scale measures how students view their service-learning experiences covering four areas: practical skills, interpersonal skills, citizenship, and personal responsibility. This allows to get some results from undergraduate degree students participating in a SL activity.

1 INTRODUCTION

The University of Experience, present at several universities with different names, stands as an innovative educational program that offers lifelong learning opportunities to older adults (over 55 or 60 depending on the institution). Through a variety of courses and activities designed specifically for this demographic group, the University of Experience encourages the exchange of knowledge and experiences, thus promoting significant personal and social enrichment. This program enables participants to access quality education, regardless of their age, and provides them with the opportunity to further explore areas of interest and develop skills, thus contributing to a more active and fulfilling life (Cámara and Eguizábal 2008). The University of Experience at the University of Salamanca reflects the institution's commitment to inclusive education and the enrichment of the whole community, regardless of their stage in life.

The activity described in this study took place in a town of 13,000 inhabitants, where the Higher Technical Industrial Engineering School is located.

The integration of methodologies such as service-learning and teamwork in engineering education is essential to prepare students not only in terms of technical knowledge, but also in terms of interpersonal and leadership skills, as well as social awareness and civic responsibility (Pazos et al. 2020). The combination of service-learning and teamwork in the educational methodology provides a comprehensive and enriching experience for engineering students. By participating in community service projects, students not only acquire technical and academic skills, but also develop teamwork, leadership and project management skills. In addition, by working collaboratively with the community, students can better understand real-world needs and challenges, enabling them to more effectively apply their knowledge and skills to make a positive difference in society (Pazos et al. 2020; Queiruga-Dios et al. 2021).

In addition, project-oriented learning develops students' entrepreneurial competence (Crespí et al. 2022; Schmalenbach 2022). Service-learning provides students with the opportunity to apply their knowledge and skills to address real problems in the community, while

fostering a sense of commitment and service to others (Queiruga-Dios et al 2021). Figure 1 shows the diagram of a SL project, which is not a “classical” project, but has some additional phases (Queiruga-Dios et al., 2023): Observation of the social need, preparation of the project that will address that need, action in the community, reflection of the service already done, registration of the development and results, evaluation as part of the course syllabus, and acknowledgement to the persons involved in the tasks.

Fig. 1. Diagram of service-learning with project stages (Queiruga-Dios et al., 2023)

While SL allows students to apply knowledge and skills in meaningful contexts and in service to others,, teamwork enables students to collaborate, communicate and problem solve effectively in a group environment, essential skills for success in the world of work (Ercan and Khan 2017). Teamwork is a fundamental skill that engineering students must develop throughout their academic training and that allows them to apply theoretical knowledge in real-world situations. Recognizing the importance of statistical literacy in today's society, the team set out not only to raise awareness of the prevalence of these errors, but also to provide tools to identify them and critically evaluate statistical information presented in the media. This initiative builds on the growing awareness of the importance of statistical studies today (Pazos et al. 2020; Schmalenbach et al. 2022).

The scientific literature supports the relevance of addressing errors in statistics. Statistical errors in the media can distort public perception of important issues, such as public health or politics. Statistics is not merely a collection of mathematical techniques, but rather a powerful tool for understanding and interpreting data in various real-world contexts. By emphasizing this connection, students are able to appreciate the relevance and applicability of statistics in their everyday lives and in a wide range of fields and disciplines (Gelman and Nolan 2017).

It is important to foster a critical understanding of statistics to counteract the spread of misleading or incorrect information. This research underlines the need for educational programs that enable the population to properly discern and evaluate statistical information presented in the media (Joseph 2011; O'Connor and Wearherall 2019).

Students of statistics acquire several fundamental mathematical competences throughout their education, which go beyond simply manipulating numbers. These competences include mathematical thinking, which involves the ability to approach problems from a logical and analytical perspective. They also develop problem-processing skills, which enable them to break down complex situations into more manageable steps for solving them. Mathematical modelling enables them to represent real-world situations using mathematical concepts and tools, while mathematical reasoning helps them to ground and justify their resolution processes. In addition, students also cultivate skills in mathematical representation, which involves the ability to visualize and present data and concepts clearly and accurately. The use of mathematical symbols and formalisms is essential for expressing mathematical ideas and relationships concisely and accurately. Mathematical communication is another crucial competence they develop, as it enables them to explain, effectively in both written and oral form, their thought processes and the results they obtain (Alpers et al 2013; Niss and Højgaard 2019).

In the context of teamwork, such as giving a talk to older people on statistics, students can apply and strengthen these competencies. Team collaboration allows them to combine their individual skills to plan, prepare and present the talk effectively. In addition, this project encourages the use of mathematical aids and tools, as students can use visual aids, practical examples and technological tools to enhance audience understanding and participation. Finally, this experience not only strengthens the mathematical skills of statistics students, but also enables them to develop interpersonal, teamwork and leadership skills, preparing them to face professional and social challenges in the future (Tishkovskaya and Lancaster 2012).

2 METHODOLOGY

As part of the statistics course, a group of 4 students came together to participate in an innovative project: further exploring service-learning projects and giving a talk to seniors about common statistical misconceptions found in the media, such as television, news and newspapers.

The team was well organized, assigning roles and responsibilities to each member to ensure an effective and cohesive presentation. The engineering students' teamwork involved not only preparing the content of the talk, but also adapting the information to make it accessible and understandable to a non-specialist audience (Anwar and Menekse 2020). As part of the SL project, students observe and prepare for a non-technical audience. Regular meetings were held to discuss the content of the talk, search for concrete examples of statistical errors in the media and devise strategies to make the information accessible and understandable to a non-specialist audience. In addition, visual resources and practical examples were used to illustrate statistical concepts in a clear and concise manner. An interdisciplinary approach combining statistical literacy with effective communication techniques was used to highlight the importance of using innovative pedagogical methods to improve the understanding of statistical concepts in different audiences (Bromage et al. 2022; Kovacs et al. 2021).

In conclusion, the integration of methodologies such as service-learning and teamwork in engineering education is essential to train skilled, ethical and socially committed professionals who can face the challenges of today's world in an effective and responsible way.

The Student LEarning Benefit (SELEB) questionnaire has been designed with the purpose of collecting crucial information about the service-learning (SL) experience and the benefits that participants have gained from this activity. The responses obtained are of vital importance to the ongoing study, as they contribute to a deeper understanding of the impacts of SL on the academic community and society at large (Brown at al 2023; Toncar et al. 2006).

The SELEB questionnaire includes the following 21 topics:

1. Experience personal growth.
2. Ability to work well with others.
3. Enhance my leadership skills.
4. Enhance my communication skills.
5. Gain a greater understanding of cultural and racial differences.
6. Enhance my social responsibility and citizenship skills.
7. Be involved in the community.
8. Ability to make a difference in the community.
9. Apply information learned in the classroom to real-life scenarios.
10. Problem analysis and critical thinking.
11. Apply problem-solving techniques.
12. Build my self-confidence.
13. Conflict resolution.
14. Ability to assume personal responsibility.
15. Learn practical workplace skills.
16. Skills in Learning from Experience.
17. Develop organizational skills.

18. Connecting theory with practice.
19. Establish caring relationships.
20. Empathy and sensitivity to the plight of others.
21. Demonstrate my trustworthiness to others.

To complete the questionnaire, students are asked to indicate how important each of the items in the questionnaire is to them, using a Likert scale ranging from 1, representing “not important at all”, to 7, indicating “very important”. This process allows researchers and educators to accurately assess participants' perceptions and ratings of the different aspects of SL.

By providing this detailed feedback, responses help to identify areas of strength and opportunities for improvement in the implementation of SL, as well as to highlight the tangible and intangible benefits that this experience offers both individually and collectively. In summary, the SELEB questionnaire is a valuable tool for capturing students' perspectives on SL and its impact, providing essential information to inform and enrich future community service initiatives in academia.

Once the service-learning project was finished, students made an oral presentation to their fellows and a written report to the teacher. The qualitative analysis of the responses to the SELEB questionnaire provides a more detailed and enriching insight into the students' experience with older adults. Through these responses, students have been able to express their perceptions and opinions on various aspects related to their participation in this community service activity.

3 Discussion and Results

The resulting speech was a successful event and provided the audience with more practical tools to identify and avoid statistical errors in the media (see Figure 2). The students used concrete examples of poorly designed surveys, misinterpretations of data and statistical manipulation to highlight the importance of being critical and cautious when consuming statistical information in the media. In addition, they provided practical advice on how to identify and avoid these errors, equipping the audience with tools to make more informed and evidence-based decisions in their daily lives.

Fig. 2. Presentation of statistical errors in the media to older adults at the University of Experience

This project not only allowed the students to apply their statistical knowledge in a real-life context, but also strengthened their communication, teamwork and leadership skills. By collaborating to address a relevant and meaningful topic, the team demonstrated the transformative power of statistics education and the positive impact that engineering students can have on the community.

Table 1 shows some results from the SELEB questionnaire. No specific statistical analysis was developed because the qualitative analysis was the main part of the results.

Table 1. Some results from the SELEB questionnaire during the 2022-2023 year

	Question2: Ability to work well with others	
	Question 4: Enhance my communication skills	

Apart from that, students highlighted the personal growth experienced as a result of their participation in the activity, mentioning an increase in self-confidence and a sense of achievement in sharing their knowledge with others. Many students mentioned that the experience helped them develop skills to work effectively in a team, collaborating with others to achieve common goals. They noted that the activity enabled them to improve their leadership and communication skills by having to explain statistical concepts in a way that was clear and understandable to a non-specialist audience.

The activity provided them with a greater understanding of cultural differences, as they interacted with people from different backgrounds. Students expressed a sense of social and civic responsibility while participating in the activity, highlighting the importance of contributing positively to the community and making a difference in the lives of others. Moreover, they valued the opportunity to apply knowledge acquired in the classroom to real situations, allowing them to see the relevance and practical usefulness of statistics in everyday life and of problem-solving and critical thinking skills when faced with new challenges and situations.

The group of students filled a document with the different stages of a SL project see Figure 3).

Fig. 3. Document prepared by students including their feedback in the SL project stages

In summary, the development of a service-learning project reveals a range of benefits and learning gained by students from participating in the activity. The concept of service learning not only provides students with opportunities to apply theoretical knowledge in real-world contexts but also encourages collaboration, communication, and problem-solving within diverse teams. Through engaging in community projects, students are able to enhance their teamwork skills by working closely with peers towards common goals, navigating challenges, and leveraging each other's strengths.

Furthermore, the service-learning experience serves as a platform for the development of leadership skills among students. As they take on roles and responsibilities within their service projects, students have the opportunity to exercise leadership qualities such as decision-making, initiative, and effective communication. Over the course of the semester, students are likely to see noticeable improvements in their ability to lead and motivate others, as well as in their confidence in taking on leadership roles.

Overall, the positive student feedback regarding service-learning reflects its value in promoting holistic student development, fostering meaningful connections with the community, and cultivating essential skills that are applicable in both academic and professional settings.

ABSTRACT

Formative assessment during a course promotes a focus on learning rather than performance. We present ongoing work on the implementation of a formative assessment practice in a large physics course. In this feedback practice, both the students and the teacher have an active role. Two-hour sessions take place in an ordinary lecture hall, where the students in the first part work on exercises and hand in answers on a digital platform. During the second part, the feedback practice occurs. Based on the students' answers, the teacher initiates activities such as

[1] *T. H. Andersen*
Trine.andersen@ntnu.no

discussions and other instructions to target specific issues where the answers show challenges.

During these sessions, the teacher gains insight into the students' learning process, something that forms not only the second part of the session but can form future teaching. The students gain better insight into their learning process and eventually become self-regulated. Our preliminary results show that the students find the exercises difficult, but report the session has a large effect on their learning and understanding.

1 INTRODUCTION

In formative assessment, the aim is to promote students' learning. This approach, to perceive assessment as learning has a different purpose than summative assessment where the aim is to evaluate learning. Due to the learning effect, it is recommended to use formative assessment as a part of the teaching and learning activities (Ashwin, et al. 2020; Dolin et al. 2018). Formative assessment can give students insight into their learning process through a feedback process. For a good feedback practice, Nicol and Macfarlane-Dick (2006) recommend teachers to follow the seven principles: 1. help to clarify what good performance is (goals, criteria, expected standards); 2. facilitate the development of self-assessment (reflection) in learning; 3. deliver high-quality information to students about their learning; 4. encourage teacher and peer dialogue around learning; 5. encourages positive motivational beliefs and self-esteem; 6. provides opportunities to close the gap between current and desired performance; 7. provides information to teachers that can be used to help shape teaching (p. 205). Using these principles, the authors argue that students may become self-regulated learners (Nicol and Macfarlane-Dick, 2006).

OBJECTIVE

This paper presents work in progress from a project on the implementation of formative assessment in a large course. The overall goal of the project is to develop a formative assessment practice that increases learning, and the students find valuable. The paper aims to describe the development process of the formative assessment practice. We present results from this pilot, where the students' multiple-choice answers inform on their performance and questionnaires give insight into the students' experiences. In addition, observations provide information on the development of the practice.

2 BACKGROUND

The introductory physics course for students in physics at the Norwegian University of Science and Technology is a calculus-based mechanics course (NTNU, 2024). Before the pilot, mandatory activities in this course consisted of calculus exercises, numerical exercises, and laboratory work. These activities took place as group work without the direct involvement of the lecturing teacher. Feedback for the approximately 160 enrolled students was provided by student assistants.

To change this, we initiated this project, where the aim is to introduce new formative exercises that give the teacher insight into the students' achievement during the course and thereby form the teaching. At the same time, the students get valuable feedback on their learning process and hopefully, they experience a better connection between the exercises and the lectures.

3 APPROACH

Inspired by the recommendations of Nicol and Macfarlane-Dick (2006), we planned active learning sessions to take place in a lecture setting. Sessions were designed to start off with an individual part, where the students work on exercises individually. By the end, they hand in their answers on a digital platform. The exercises consist of concept questions and calculus-based calculations, which are relevant for the summative exam by the end of the semester. During the break, the teacher goes through the results and decides on the activities for the second part. During this second part, the feedback practice occurs since the teacher initiates activities such as discussions and other instructions to target the specific issues where the answers have shown challenges. These activities are in line with the peer instruction method described by Mazur (2014).

Because the purpose of the pilot was to study the effect of a specific intervention and not a complete redesign of the course, the number of sessions during the autumn semester of 2023 was limited to two. Data was collected during both sessions. In this paper, the focus is on the data produced during the first session as the two data sets show the same trends, and their few differences arise due to a small reduction in the workload in the second session.

4 DATA PRODUCTION AND ANALYSIS

In total 130 students joined the lecture where the first session took place from which 114 of the students replied to the multiple-choice questions. This data informs the students' level of achievement. To explore the students' experiences, a questionnaire with the Likert scale questions listed in Table 1 together with an open text box for comments was distributed afterwards. In total 96 students answered this questionnaire. Participation in all activities and questionnaires was voluntary and anonymous. This was only possible because the activity was not mandatory during this pilot.

Table 1. Likert scale questions and the open question

Questions: How do you find/assess…	Response s
the difficulty of the exercises?	96
the time available in relation to the workload?	96
the effect on your learning and understanding from the activities:	
● Teacher working out problem	95
● Peer discussion	93

• Hint followed by peer discussion	94
• Hint followed by individual work	93
• Follow-up exercises	93
the activities' overall impact on your learning and understanding	95
Comments for development purposes (open text)	19

In addition, both sessions were observed from two perspectives: the teacher in front of the lecture hall as part of the active lecturing, and from the back passively overviewing what the student audience was doing, taking notes of their behaviour and time registration.

The results of the quantitative questions are presented as average and standard deviation. Data from the open question is used to gain a deeper understanding of the students' experience with the session, some of the quotes are presented as part of the discussion.

5 Results

This section is organized into three themes: the difficulty level of the exercises and students' performance (5.1), the flow of information and the overall structure (5.2), and the students' self-reported effect on learning and understanding (5.3).

5.1 The difficulty level of the exercises and students' performance

During the first part of the session there were six problems to work out. Students answered these in a multiple-choice format. Table 2 shows how many correct answers the 114 students had.

Table 2. Students' number of correct answers

Overall score	0	1	2	3	4	5	6
Number of students	6	26	26	24	19	12	1

The average overall score is 43% correct with a standard deviation of 24%. This result indicates that the exercises had a challenging level. Through the questionnaire, distributed after the session, the students were asked about the difficulty of the exercises and their time available in relation to the experienced workload, see Table 3. On a Likert scale from 1 (very easy) to 5 (very difficult), the average of the 96 answers to the question, regarding the difficulty, the average is 3,6 with a standard deviation of 0,7. No one answered that the exercises were very easy. To the question about the time available in relation to the workload, where the Likert scale ranges from 1 (short on time) to 5 (plenty of time) the average is 2,7 with a standard deviation of 1.

Table 3. The average of students' answers on the level of difficulty

Reported answers	Average	St. dev.
The difficulty, Likert scale of 1 (very easy) to 5 (very difficult)	3,6	0,7
Time available, Likert scale of 1 (short on time) to 5 (plenty of time)	2,7	1

The data on the level of difficulty and the students' performance (Tables 2 and 3) show that very few students completed all exercises. Approximately half the students found the exercises difficult with slightly insufficient time for completion. As the aim of the session is for the students to learn and experience challenges, this level of difficulty might be suitable. In order words, most students have had a learning opportunity during the session. If too many students find the exercises easy, the session becomes redundant.

5.2 Flow of information and the overall structure

From the observations, it is clear that all students were well-informed before the session since by entering the lecture hall, the students knew what they were supposed to do. This includes grabbing the worksheet at the entrance and following the rules for the first part by working individually in a classical exam-like atmosphere. Further, the students knew they were supposed to hand in their answers as multiple-choice answers by the end of the first part. As the break was announced by the teacher, the observer experienced silence being disrupted by loud chatter. Students started to discuss, pointing at their calculations, asking "What did you do?", "I managed...", and "I knew things" while they were smiling and looking at each other's notes. During the second part of the session, the students engaged actively in the different activities initiated by the teacher, of which their self-reported effect on learning and understanding is presented in Table 4, next section.

Overall, the students' collective behaviour indicates that the teacher had prepared the students for the session well in advance. His strategy was: to announce the pilot at the beginning of the term; this was repeated in the weeks before each session; a few days ahead of a session students would receive an email message detailing the structure of a session.

5.3 Students' self-reported effects on learning and understanding

The second part of the session is the central part of the feedback practice, here the teacher initiates activities based on the distribution of the answers and the seven principles for a good feedback practice (Nicol and Macfarlane-Dick, 2006). For example, if the multiple-choice answers show an equal distribution of the five possible answers, the teacher will initiate a peer discussion according to Principle 4 encouraging peer dialogue. Since a variety of perspectives exist among the students, there are aspects for them to discuss. On the other hand, if the multiple-choice answers show that very few students answered correctly, it indicates that most students might have problems or misunderstandings. In this case, a better choice for the teacher is to work out the problem and explain the details, thereby showing what a good performance looks like (Principle 1). Another possibility is for the teacher to give a hint and then let the students discuss or finish the calculations themselves, thereby helping the students close the gap between their current and desired performance (Principle 6). These activities were tested out during the first session. Table 4 shows data on the students' self-reported effects on their learning and understanding of the different activities during the second part of the session, along with the overall impact of the session. The Likert scale used ranges from 1 (very little) to 5 (very large).

Table 4. Self-reported effects on students' learning and understanding

Questions regarding the different activities in part two:	Average	St. dev.
• The teacher works out the problem	4,3	0,6
• Peer discussion	3,7	0,9
• Hint followed by peer discussion	3,9	0,9
• Hint followed by individual work	3,8	0,8
• Follow-up exercises	4,0	0,8
The overall impact on learning and understanding	4,1	0,6

The students have reported the follow-up activity where the teacher works out problems to have the highest learning effect, and activities such as peer discussion, hint followed by either individual work or peer discussion with a lower learning effect.

One might speculate whether the students value the teacher's words higher than their peers and the possibility of a discussion due to an authority effect or simply the fact that most students already had discussed the most demanding things during the break. However, the average of answers to the overall impact of the session was 4,1 which corresponds to a 'large' effect. It is noteworthy that no one answered that the learning effect was 'very little'.

6 Discussion

The session described in this paper was the first attempt to implement a formative assessment practice in an introductory physics course for physics students. The results indicate a significant positive impact on the students' self-reported learning and understanding. There are several reasons. First, the students were well informed about the session, the progress, and what they were expected to do. Second, the difficulty of the exercises seemed to be at the right level. All students were engaged throughout the first part, and not too many had everything correct. However, students' comments on the open question suggest that there might have been too little time available during the first part. As one student writes: '*Very informative. This was a good practice in problem-solving. A suggestion is, to have more time, or fewer tasks, so that one can try all the tasks before going through them'.* To have the full learning potential during the second part, it is essential that everyone has had sufficient time to work on all problems. For the subsequent session, which took place later in the semester, we intentionally reduced the workload, and the first exercises were simpler.

The structure of the session with the two distinctive parts is crucial as in the first part the students realise what they need to study more as commented by a student: '*[I] see, what I need to work on'*. Further, it is important to give feedback while the students still remember the exercises and the problems they experienced, as expressed: '*It's nice to have time to do exercises and then go through everything while one still remembers'*. The second part is also where the teacher implements the feedback principles by Nicol and Macfarlane-Dick (2006).

The fact that the students rate the teacher working out the problem as having the most significant impact on their learning and understanding might be similar to the self-reported perception of learning from traditional lecturing compared to an active learning environment reported by Deslauriers et al. (2019). Their study measured the actual learning from two student groups and compared this to the students' perception of learning. Their results show that students in a traditional learning environment think they learn more compared to those in an active learning environment, but the measure of actual learning shows the opposite. We think, our data shows a similar effect, that the students think they learn more when the teacher works out the problem rather than if they discuss it with their peers. A student's comment confirms this: '*The review [by the teacher] was useful to know whether one had thought correctly'.* This perception is something to address in the future. Perhaps, the results from (Deslauriers et al. 2019) could be a part of the information given to the students in advance.

7 CONCLUSION

Our overall goal of creating learning sessions with teacher feedback was achieved. As a student expressed: '*I think it [the session] was very good in terms of learning, I feel like I learned a lot in a short time. At the same time, it was a shock how difficult the tasks were to solve, especially given the very short amount of time'.* The plan is to incorporate this practice into the mandatory activities and further enhance it by researching students' learning experiences during these sessions.

The feedback practice developed and described here is easy to implement in other courses. It represents a cost-effective and relatively simple method to engage large student groups and provide them with relevant feedback.

ABSTRACT

In the field of engineering education, the traditional approach of solely imparting theoretical knowledge has evolved to emphasise the significance of experiential learning. Providing engineering students with opportunities to learn through hands-on experiences, critical thinking, and analysis has become increasingly essential. This shift is not only beneficial for enhancing students' understanding of theoretical concepts but also crucial for fostering practical skills and preparing them for the challenges of the modern workplace.

Theoretical modules such as antennas and propagation in electromagnetics present challenges rooted in advanced mathematics and complex theoretical concepts, leading to a notable gap between theory and practice. We implemented computer simulation classes alongside traditional lectures to address this gap and enrich students' learning experiences. These simulation sessions offer students a virtual prototyping environment, guiding them through the complete design cycle - from model creation to generating Gerber files necessary for real-world antenna fabrication. Additionally, the classes incorporate 3D visualisation tools to facilitate understanding of intricate concepts. To reinforce the connection between simulation and real-world applications, each session begins with demonstrations of antenna prototypes. At the conclusion of the semester, a survey was administered to assess student satisfaction with the approach, yielding positive feedback.

1 INTRODUCTION

Developing engaging and effective approaches to teaching electromagnetics (EM) and antennas has received considerable attention over the last few decades. Among the numerous suggested approaches is software-aided teaching. Initially, basic free space wire antennas simulations were demonstrated using the mini numerical electromagnetics code “MININEC” (Cole et al.1990, Excell 1993). Subsequently, several software tools were developed under the activities funded by the NSF/IEEE Center for Computer Applications in Electromagnetic Education (CAEME) (Iskander 1993, Fabrega, Sanz and Iskander 1998, De Los Santos Vidal et al. 2002). In addition, an EM field simulator with a graphical user interface (GUI) was used to teach introductory EM (Beker, Bailey, and Cokkinides 1998). The concept of multi-media-based teaching of EM and antenna and a virtual antenna laboratory were introduced (Iskander 2002). Furthermore, Mathematica and MATLAB were adopted to teach EM and antennas (Anderson 2003). Computer-aided-design (CAD) tools were proposed to gauge undergraduate students' understanding (Popović and Giannakopoulos 2005). Moreover, a finite element method (FEM) based customised tool was developed for interactive learning of electromagnetics (Trlep et al. 2006). A stronger students’ retention of electromagnetics was observed when adopting technology-enabled active learning (TEAL) compared to traditional teaching formats (Dori, Hult, and Belcher 2007). On the other hand, several virtual tools were developed and used to reach the right balance between EM theory and computer simulations (Sevgi 2008). EM teaching using electromagnetic field visualisation was demonstrated using COMSOL (Talele, 2014).

This study utilised the teaching model that included asynchronous and synchronous activities to support students' learning. The former included the release of recorded videos every week, followed by a synchronous session involving quizzes in conceptual questions and a recap of the recorded material. Furthermore, the CST simulations represent a key element of synchronous teaching. Through these simulations, students acquire practical experience in antenna design, complementing theoretical knowledge with hands-on skills. Using 3D visualisation tools for electromagnetic field analysis simplifies complex concepts and enhances comprehension, particularly for students facing learning difficulties. Moreover, the widespread usage of the CST package in the industry provides students with valuable employability skills, enriching their antenna learning journey with practical applications. By engaging in 3D simulations and virtual antenna design exercises, students develop a tangible connection between theoretical principles and real-world practices. This connection is further reinforced by presenting students with prototypes of the antennas to be designed in each session. A research-led teaching approach was adopted by embedding practical examples based on the instructors' and others' research in the lectures and simulation sessions. For example, explaining the basic antenna theory and design principles in reference to millimeter-wave and terahertz advanced technologies and challenges associated with these frequencies.

The efficacy of this adopted approach is evaluated through an anonymous student survey, detailed in Section 3 that gauges the effectiveness of the teaching methodology and the extent to which it bridges the gap between theory and practice in antenna education. Figure 1 exemplifies a patch antenna design derived from one of the sessions utilising CST Microwave Studio software. The figure displays the proposed antenna structure alongside analysis of relevant parameters post-simulation, encompassing return loss and far-field radiation pattern assessments.

2 METHODOLOGY

The antenna module in question comprised 18 timetabled in-person lectures, with 6 sessions dedicated to simulations. These simulation sessions were strategically integrated into the curriculum, following the delivery of relevant theoretical content. For instance, after a lecture on a specific antenna type, students engaged in a simulation session focused on the same topic to explore modelling and evaluating the antenna performance characteristics as well as think through the design process.

During the hands-on session, students are encouraged to work within a small group. Students are given the time and opportunity to independently think about the antenna design steps and model using the available commercial software (CST). Then, students are shown an actual prototype of the antenna to be designed, which helps to place the learned theory in the practical context. Subsequently, students received guidance on configuring parameters such as frequency, boundary conditions, and mesh type and size as they followed step by step to model the antenna of interest. Under the instructor's supervision, students created the virtual antenna geometry and initiated the simulation process.

Upon completing the simulation, students are encouraged to analyse the radiation characteristics and compare them to the theoretical principles discussed in previous lectures. Following this, students are encouraged to reflect on their antenna modelling experience and the corresponding obtained performance indicator results (return loss, and radiation pattern). Each session concludes with a demonstration of generating a Gerber file, essential for practical antenna fabrication.

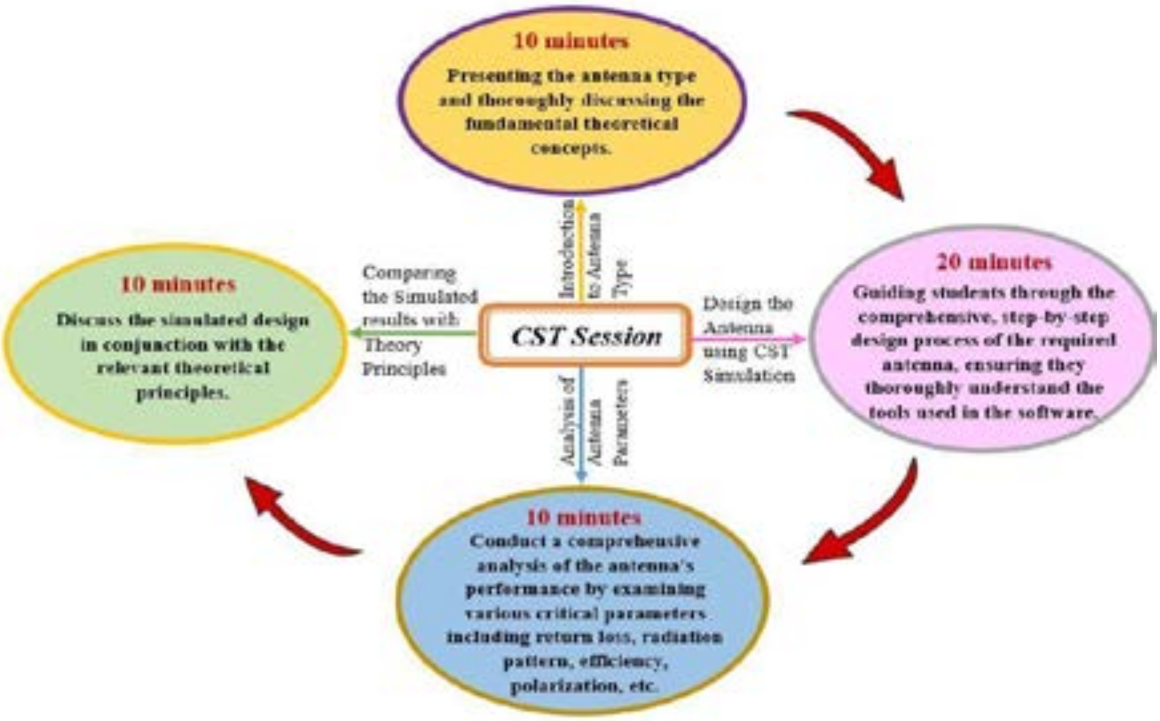

Figure 2. Structure of the CST hands-on session.

Figure 2 illustrates the CST hands-on session structure. The session starts with a 10-minute overview of the antenna type to be analysed and its fundamental theoretical concepts. Next, students spend 20-minute to follow a guided step-by-step approach to apply their knowledge and model an antenna. Then they spend 10 minutes engaging in discussions analysing the design antenna performance with a focus on critically evaluating key design parameters such as return loss and radiation patterns. In the final 10 minutes students engage in making the connection between the resulting simulation performances and the theory discussed earlier.

Historically, the antenna module was taught from a theoretical perspective, taking students through lengthy derivations of Maxwell's equations to derive electric and magnetic fields from first principles, followed by applications to dipole antennas, monopoles and an array of isotropic sources. Students' knowledge of antenna design was limited to understanding the operation of dipoles. Further, students were assessed on remembering and calculating antenna problem-solving problems. Using this blended model of teaching and learning, with a focus on application to electromagnetics and antenna principles, has elevated the scope for students to explore in-depth design and optimisation of various prototypes, dipoles, patch antennas, slot antennas, monopoles, loop antenna, linear arrays, and phased arrays.

We wanted to remove the complexity of theory and focus on real application to support students in developing knowledge and skills favourable to industry.

On reflection, these sessions offer students a holistic view of the antenna design process, mirroring real-world engineering practices and preparing them for future careers. Furthermore, students gain valuable simulation experience, enhancing their employability prospects. Ultimately, the well-structured blended teaching activities embracing the complexity of the theory in a practical setting have increased students' understanding of the subject renowned for its complexity. This is reinforced by the fact that students' attendance increased, and they demonstrated increased interest in the subject by asking creative questions and attempting the quizzes with more than 70% answering the questions correctly.

3 RESULTS

By adopting this technique in teaching, it was observed that students' attendance to the lectures and the subsequent hands-on sessions has increased as compared to other modules taught by the instructor that were delivered using a traditional teaching model. Furthermore, students could make immediate sense of the theory as teaching progressed from discussing simple antennas, such as dipoles, to complex antenna arrays. This instant feedback has given us confidence in the effectiveness of this teaching approach, and we proceeded to design a survey to explore students' opinions and feelings about how they perceived this teaching method. Additionally, students were prepared for their formative assessment through Blackboard asynchronous activities, in-class quizzes, and in-person workshops on CST using antenna design principles to deepen students' understanding. Formal assessment is done in two stages where students sit an online multiple choice and calculation questions text - this aims to examine their basic understanding of the concepts taught in electromagnetics and antennas. This is followed by an in-person invigilated exam where students address problem-solving questions that examine their understanding and engineering skills to design and evaluate antenna performance.

Therefore, an ethically approved survey was administered to a cohort of 102 graduate students, yielding responses from 32 participants. The survey was given to students towards the end of teaching in week 12. It was anonymous, and students were informed that this would not influence their final outcomes in the module. In addition, the survey was sent to students of all abilities, and given it was anonymous, the authors had no influence on who responded or not. When asked whether the hands-on CST simulation session has complemented the traditional lectures, 56.3% of students positively responded that CST simulations significantly enhanced the lectures, attributing their improved understanding of the subject to the 3D visualisation capabilities, as shown in Figure 3. However, 15.6% of the respondents have chosen "To some extent" to answer the same question. This can be improved by mentioning in the lecture how the upcoming simulation activity is relevant to the covered topic.

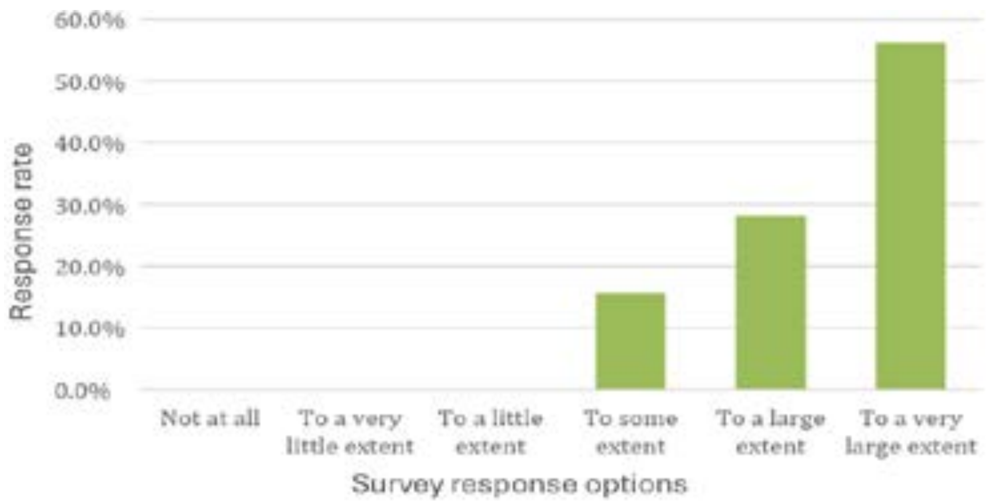

Figure 3 Student's response to the question, "To what extent did you find the CST simulation sessions complement the lectures?"

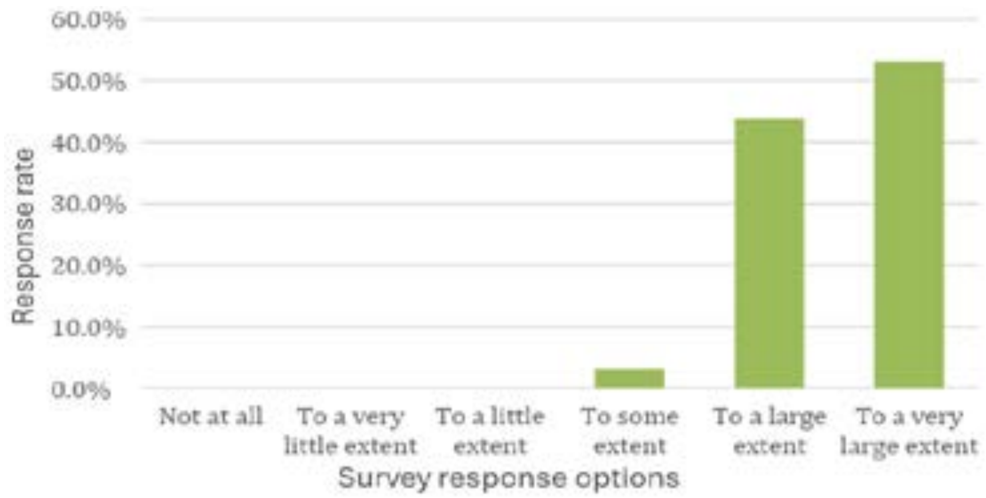

Figure 4. Students' response to the question, "Learning commercial computer simulation skills is a valuable skill for my future career pathway."

Furthermore, exploring students' anticipation on the value of learning a commercial simulation tool within their degree programme, from an employability perspective, a significant majority of respondents, accounting for 97%, affirm the critical importance of the simulation skills acquired during the course to boost their technical and transferable skills and enhance their future professional endeavours, as shown in Figure 4. It was reassuring to ensure that students continue receiving the best teaching and learning value to meet their expectations and career goals.

In the authors' experience, students avoided antenna-based design projects in the past due to the topic's complexity. However, after adopting a research-led teaching approach educating students to design methodologies of antennas in relation to cutting edge technological challenges, in which computer simulations represent a crucial element, students started to take the initiative in requesting antenna design topics for their MSc final year projects, as observed by the authors of the paper. The CST simulation sessions boosted the students' confidence and improved their practical experience with antenna design techniques. A few students took a further step by pursuing PhD studies on antennas. This is confirmed by the responses to a survey question on whether introducing the CST training session within the module has increased students' confidence in pursuing antenna design projects, as demonstrated in Figure 5, where 84.4% of the responses agree to a large, or very large, extent. However, 12.5% agree to some extent, and 3% agree to a very small extent when asked the same question. In the future, additional support will be offered to students who feel less confident with the simulations.

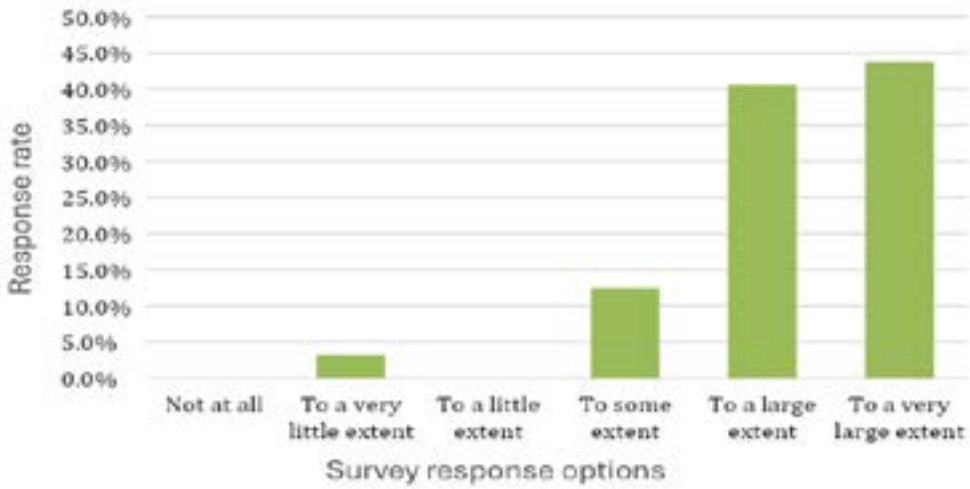

Figure 5 Students' response to the question, "The CST training has made me more confident to conduct antenna related projects."

In addressing the survey question, "Can you provide feedback on the most beneficial or engaging aspect of the CST demonstration sessions?", a prevalent response highlighted the value of the step-by-step guidance provided throughout the sessions. This was frequently cited as instrumental in facilitating comprehension and engagement. Additional comments highlighted the effectiveness of the simulations in clarifying theoretical concepts, fostering interactive learning experiences, and imparting practical skills. As for the question, "What knowledge or skills did you gain from CST antenna visual prototyping?" respondents agreed on acquiring the ability to imagine the radiation from an antenna, deepening their understanding, and linking theory to practice, in addition to offering a different perspective to students with limited 3D imagination capabilities.

4 Summary and acknowledgements

This study demonstrates the efficacy of integrating computer simulation sessions, particularly utilising the CST Microwave Studio, into antenna teaching for postgraduate students. By incorporating these sessions alongside traditional lectures, and immersing students in activities that involve designing, constructing, and analysing antennas, they gain a deeper understanding of complex theoretical principles. Moreover, engaging in hands-on experimentation and problem-solving tasks allows students to bridge the gap between theory and practice, thereby solidifying their comprehension and retention of electromagnetic concepts. The utilisation of 3D visualisation tools aids in simplifying complex concepts, fostering deeper understanding, and enhancing student engagement. The survey results indicate a positive response from students, with the majority acknowledging the value of simulation-based learning in improving their confidence and employability prospects in antenna-related projects. Additionally, feedback from students highlights the importance of step-by-step guidance during simulation sessions and the acquisition of skills in imagining antenna radiation patterns, further underscoring the effectiveness of this teaching approach in bridging the gap between theory and practice.

Furthermore, transforming teaching methodologies to integrate theory with practice yields profound benefits beyond academic realms. By cultivating a learning environment that emphasises application and real-world relevance, students develop technical engineering skills and invaluable transferable skills such as critical thinking, problem-solving, and teamwork. These skills are indispensable for success in the workplace, where engineers are required to navigate complex challenges and innovate solutions effectively.

We sincerely appreciate the graduate students who participated in this study and offered invaluable feedback. Their input played a pivotal role in shaping the development and execution of the computer simulation sessions. Additionally, we gratefully acknowledge the support and guidance provided by Dr. Salam Khamas throughout the entirety of the sessions.

ABSTRACT

Research and innovation thrive on diversity, enhancing collective performance (UKRI, 2023). The All-Party Parliamentary Group (APPG) on Diversity and Inclusion in STEM highlighted that the STEM workforce is less diverse than the broader workforce, leading to underrepresentation of minoritized groups such as Black people, women, disabled individuals, and those from the LGBTQ+ community (British Science Association, 2021). According to Engineering UK's Equality, Diversity, and Inclusion (EDI) strategy, only 12% of the engineering workforce is female, compared to 51% of the working-age population (Engineering UK, 2019). At the University of Warwick, our data analysis revealed that females at the postgraduate research (PGR) level are underrepresented in engineering, though the gender balance is more equitable at the postgraduate taught (PGT) level. To address this disparity, we launched the "Improving Access and Participation in Engineering Research (IAPER)" project. This internship program targeted undergraduate and

PGT female students to enhance their participation in engineering research, aiming to improve gender balance in PhD and postdoctoral populations. We offered research internships to 20 female students, who completed an 8-week program under the mentorship of leading academics (IAPER interns, 2023). Additionally, we hosted three events featuring successful women in industry and academia, who shared their experiences and success stories with the UG and PGT female students (IAPER Lecture Series, 2023). Student feedback was collected through video snippets and project reports, with a reflective section on their internship experiences. The feedback was overwhelmingly positive, with strong recommendations to continue such programs in the future (IAPER overview, 2023).

1 INTRODUCTION

Engineering serves as the cornerstone of innovation and invention. In 2021, women accounted for 16.5% of the engineering workforce in UK, marking a notable increase from 10.5% in 2010 (Engineering UK, 2020). However, when we compare this figure to the overall workforce, where women comprised 48% (Engineering UK, 2022), it becomes evident that substantial efforts are required to attain gender parity within the engineering field. Notably, the highest proportion of women in engineering were observed in the category of 'Associate Professional and Technical Occupations' at 32%, gradually decreasing with seniority to 22% in 'Professional Occupations' and 15% in 'Managers, Directors, and Senior Officials’ (Engineering UK, 2022).

In an Education Development Trust report (EDT, 2023), it was emphasized that while significant progress has been made since the days when explicit social and gender-based barriers limited women's opportunities, there are still prominent gender-related disparities in practical outcomes. For instance, despite more women now participating in higher education (HE), men still constitute 80% of students in technology and engineering fields at this level. It was acknowledged that careers information, advice, and guidance alone cannot be seen as a panacea for rectifying these imbalances. However, this should be integrated into the overall strategy for addressing these disparities. It was also mentioned for the active involvement of career professionals starting from early years education and continuing throughout the education system. This involvement would serve the purpose of ensuring that young individuals are aware of the diverse opportunities available to them and creating more pathways for young women (EDT, 2023).

Female under-representation in engineering is not unique to the UK but it is a global issue. The World Economic Forum's Global Gender Gap Report (Piaget et. al. 2024) indicates that, based on LinkedIn data, women's representation in STEM and non-STEM workforces has grown since 2016. However, women still remain underrepresented in STEM roles, making up only 28.2% of the STEM workforce compared to 47.3% in non-STEM sectors. Overall, women's workforce representation is below men's across almost all industries and economies, with women constituting 42% of the global workforce and 31.7% of senior leaders (Piaget et al, 2024).

A study by (GenderInSITE , 2021) surveyed 120 national science academies and disciplinary associations globally, revealing persistently low female representation in science from 2015 to 2020. In the U.S., although women's representation in the

National Academy of Sciences increased from 13% to 19%, women still make up less than one-fifth of its members.

To address the growing demand for engineers in the future, it is imperative that the engineering workforce becomes more diverse and attracts a greater number of women to the field. A rapid evidence review (RER, 2023) has highlighted various strategies to enhance the aspirations and interest of girls in STEM careers. These strategies range from the presence of relatable role models to fostering a nuanced understanding of the limitations associated with the binary concept of gender. Similarly, the American Association of University Women (AAUW, 2021) has listed some problems indicative of the underrepresentation of women in STEM:

1. Gender Stereotypes: STEM fields are frequently associated with masculinity, leading teachers, and parents to underestimate girls' mathematical abilities from a very young age, often starting in preschool.
2. Male-Dominated Cultures: Reflective of the lack of female representation, patriarchal cultures tend to dominate both STEM education and professions. Such cultures result in an environment that is not conducive to supporting or attracting women and minority individuals.
3. Limited Role Models: Young women have access to fewer role models who can inspire their interest in STEM disciplines. There are few examples of female scientists and engineers to be found within contemporary popular culture, including on social media. Notably, the representation of Black women role models in mathematics and science is particularly scarce.
4. Maths Anxiety: Many teachers struggle with maths anxiety, which they inadvertently transmit to their young female students. This can result in girls receiving harsher grading than boys for equivalent work under the misguided belief that girls must exert more effort to achieve parity with boys.

Considering the literature and the statistics the paper authors proposed an internship programme specifically targeted at female undergraduate (UG) and postgraduate (PG) students. This Programme was entitled “Improving Access and Participation to Engineering Research (IAPER)”. The main aim of IAPER programme was to provide opportunities for young women students to experience first-hand what it is like to take part in ‘real-life’ research projects; the aim was to improve the gender balance across Engineering & Applied Science PhD and Post-Doctoral populations.

The paper is arranged in the following order, Section 2 explains the methodology, Section 3 includes the comments given by IAPER interns followed by the lesson learnt. The summary and acknowledgements are presented in Section 4.

2 METHODOLOGY

The first stage of the project involved completing background research that comprised a statistical analysis of student-data pertaining to the PGT, PGR and UG populations. This initial analysis evidenced the arguments regarding gender imbalances and a lack of female representation amongst our student body. The results of this analysis revealed that the difference in the proportion of male and female PGT students is more balanced than at PGR level (Figure 1) confirming that the Internship Programme was not only timely, but it was also much needed to improve the gender balance in the engineering departments. The percentages in Figure 1 are derived from Figure 2, which details the exact numbers of white and BAME (Black, Asian, and Minority Ethnic) male and female students across WMG and School of Engineering(SoE) departments. Figure 2 highlights that BAME representation in PGT programs is significantly higher than that of white students. However, since this study focuses on gender balance, we combined the male and female populations of UG, PGT, and PGR students (regardless of ethnicity), as shown in Figure 1.

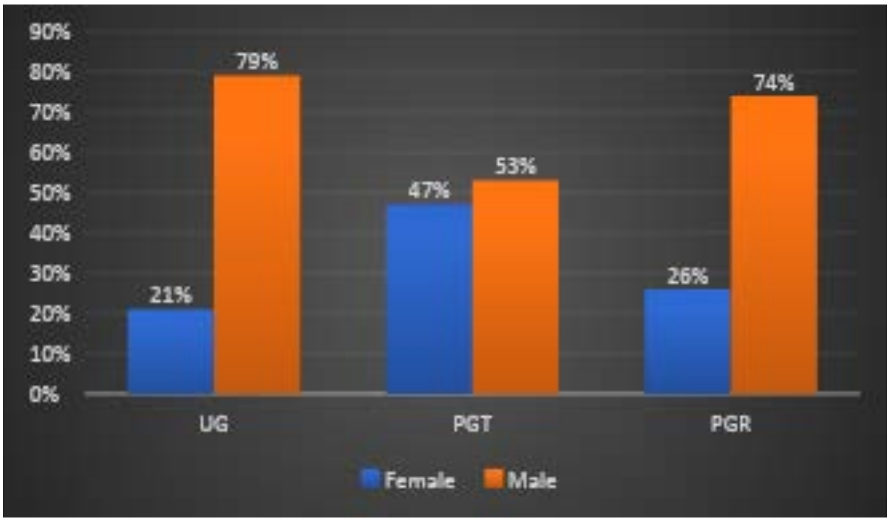

Figure 1: Percentage split by gender for UG, PGT and PGR students enrolled in academic year 21/22, collectively in both WMG and School of Engineering

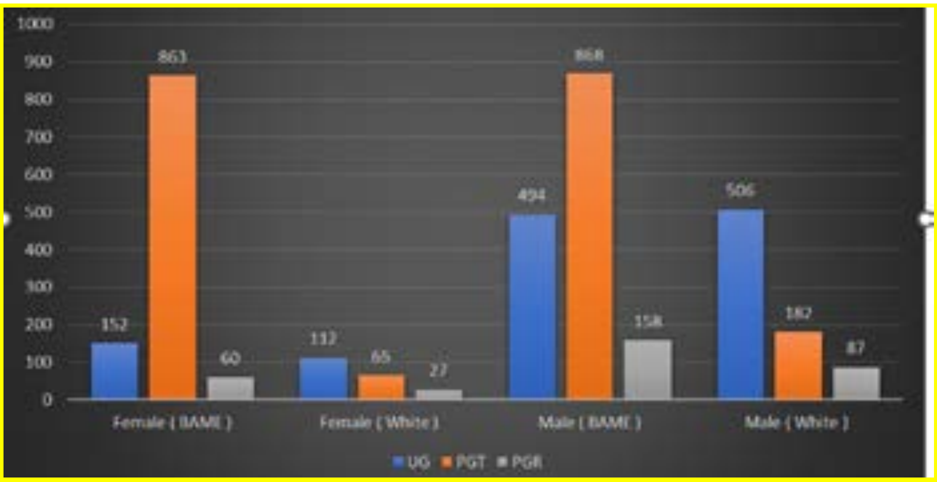

Figure 2: Exact number of male and female students by gender and ethnicity for UG, PGT and PGR students enrolled in academic year 21/22, collectively in both WMG and School of Engineering

In accepting students onto the IAPER Programme precedence was given to female students from low socio- economic backgrounds or who had a learning or physical disability. We gathered this information via the application process of the internship and made this field optional, so that if someone was comfortable to give more information about themselves, they could do.

The IAPER Internship scheme offered 20 research internships of 8 weeks total duration between April-July 2023 to UG and PGT female students from the Faculty of Science, Engineering, and Medicine (SEM). Internship carried a stipend of £1750 per intern. The initial step was to invite project supervisors in both engineering department at the University of Warwick (School of Engineering (SoE, 2024) and Warwick Manufacturing Group (WMG, 2024)) research groups to propose project ideas. The internships were all linked to or relevant to actual research projects being undertaken within these groups and cover broad areas from sustainability to systems engineering and machine learning. Some of the projects include: 1) Role of life cycle assessment in achieving circular economy, 2) Learning to manufacture electric machines- industry workshops development, 3) Systems engineering tools for next generation engineering biology and 4) Implementation and deployment of machine learning algorithm on edge devices (IAPER projects, 2023).

A window of 1.5 months was allocated for prospective interns to apply. The application process involved students uploading their CV, explaining their research interest, and (optionally) providing a statement about why they identify as underrepresented in engineering The Internship Management Team reviewed the applications to ensure the criteria for application were met. Project supervisors made a final choice on who to award the internship for their project, based on those who have selected the project and have met the application criteria.

The recruited interns, who were studying in several different disciplines including Mathematics, Computer Science, Physics and Engineering, were all given an engineering-focused, research-based internship. Completion of the internship was flexible to fit with students' academic workloads (e.g. one day per week during term time, with full time attendance during vacation periods).

2.1. Raising the Profile of Women in STEM

In parallel with the internship scheme, we organized a series of invited guest lectures, with speakers from underrepresented backgrounds who each shared their journey in engineering (and associated) research careers. The lecture series was open to all SEM Faculty students and staff, impacting IAPER's reach beyond the 20 interns. Four events were held over a six-month period concluding in the summer of 2023:

- **Speaker 1**: An award-winning data leader currently working in the Technology and Artificial Intelligence (AI) space. This speaker is the Senior Director of Advanced Analytics at an AI-driven company that fuels intelligent customer engagement in the life sciences industry. She provided excellent examples of how resilience and hard work can help anyone to excel in the career.
- **Speaker 2:** A Chemical Engineer working in the Climate Change and Environment Studio this speaker leads on Circularity and Sustainable Supply Chain ventures: building innovation concepts, pilots and corporate ventures across startups, accelerators, and private sector to decarbonize manufacturing and supply chains. She provided an in-depth account her experience during field work which was dominated by men and how she tackled the obstacles and took actions to make workplace inclusive.

- **Speaker 3:** A Senior Consultant and a Chartered Mathematician working across a major UK Construction Management s Advisory Services Portfolio. Specializing in data in the civil engineering sector and transport-related asset management across 10 years in the engineering sector. Her career journey was inspiring on one end but given she delivered the talk while she was on maternity leave showed audience her commitment towards her field and her continuous effort to help others.
- **Speaker 4:** A Defense Innovation Consultant who previously headed up the industry, technology and innovation team at a public policy think tank. A member of the IET design and manufacturing policy panel, the speaker was a member of the UK manufacturing symbiosis network plus advisory board and Make UK equalities working. She gave interesting perspective as in how one can engage with policy makers by explaining the tips and tricks to ensure voice is heard.

The speakers, all women from ethnic minority backgrounds, have not only navigated workplace politics but also confronted societal stereotypes often attached to women from disadvantaged backgrounds while advancing in their careers. The lecture series attracted not only students but also staff members, all of whom found the insights shared by each speaker valuable.

3 IAPER: LONGTERM OUTCOMES

Following the internship students were asked to reflect upon their internship and their future aspirations, particularly in relation to whether they might consider engaging in research in future. In this section, the views of the interns have been divided into four main themes: soft skills, technical skills, inspirational talks and career aspirations. Each section also includes verbatim quotes from the evaluation.

Soft Skills development:

The majority of the students have said that research internships improved their soft skills. Intern 1 stated that her professional skills and communication skills were improved through completion of set tasks, delivering presentations, and developed understanding of the workplace environment through observation and interaction with those around her. Intern 2 mentioned that internship helped her to understand the operation of real-life projects and how they are managed (workplace dynamics, inspiration and tips), particularly through the opportunity to sit in on Weekly Catch-up Meetings. Intern 2 also found that internship helped her to experience how to document and keep up to date on different aspects of the project through using a tracker and the importance of bringing people who may not be directly involved but are knowledgeable on the subjects and have additional expertise to aid in the project's development. Intern 3 stated that the internship has helped her to improve herself confidence in terms of her ability to produce work and that she can excel in STEM research. Majority of students mentioned that imposter syndrome and self-doubt are some of the feelings they have been combatting during their time in the university and this internship has shown them that they can indeed excel in the workplace and that they had the capabilities to do so. Similarly, Intern 4 stated that she was able to explore those fields using internships which wouldn't have otherwise crossed paths and the internship has made her more inclined to apply to similar opportunities, building both skillset and confidence.

It is important to note that despite the technical nature of the internships, it was clearly observed that all of the interns were able to develop several transferable skills from participating in the programme. .

Technical Skills:

One of the aims of this internship programme was about the exposure to state of art technical labs and facilities so that they can see for themselves what a research career would look and felt like. By working in such facilities, students were able to develop technical skills.

The student interns on variety of projects and developed technical capabilities in their interest. Intern 1 stated that although her degree is in physics, she was able to learn about electric machines and how they work. This has increased her knowledge about the electrical and electronic side of research and science. This student also noted that whilst completing the internship, the intricacies of delving into data, identifying trends, and drawing meaningful conclusions piqued her curiosity and passion.

Intern 2 described how she has managed to learn a new 3D printing technique in some depth. She also talked about how gaining hands-on experience, whereby she had the opportunity to dive into the exciting field of computer graphics and digital twins, she learned much.

Intern 3 had the opportunity to delve into the realm of sustainability and environmental impact assessment as part of the internship. As a computer sciences student, sustainability was initially unfamiliar to this intern, but she quickly realized its significance and relevance in today's world. She gained a comprehensive understanding of the challenges faced by these countries in collecting, managing, and utilizing data for sustainable decision-making. The literature review broadened her horizons and introduced her to various concepts, methodologies, and strategies employed in LCA research.

Inspirational talks:

Guest lectures played a key role in enabling students to make connections to the successful women in academia and industry. The majority of the students enjoyed the inspirational guest lecture series and described how they took away many positive points. Intern 1 shared that hearing the inspirational talks of incredible women from different stages in their career journey was enlightening. Intern 2 told how she was really encouraged by how each guest speaker overcame their challenges and worked towards finding opportunities to further develop their capabilities and skills. Similarly, Intern 3 mentioned that beyond her individual research project, the remarkable impact of the IAPER scheme was that is fostered an inclusive and empowering environment through its guest lectures and emphasis on community.

Career aspirations:

Most of the students mentioned that they have decided to pursue research as a career as an outcome of the internship programme. Intern 1 recalled how the internship provided her with a great insight to the running of a real-life project; she continued to discuss how the programme made her aware of what a career related to research may be like giving her better knowledge of the potential pathways she can take in the future. Likewise, intern 2 stated that after the internship, she is considering further study and career options related to research. This is something she has never previously considered it as she thought it was something one could only do after a few years in industry. She found the environment of learning and intellectual growth to be enjoyable as the focus was to improve oneself rather than just deadlines and results.

Intern 3 also described how she has learned that industrial research is more interesting and that it's practical nature means it can be applied in the next few years.

Intern 4 discussed how she learnt a lot about prioritisation and flexibility whilst working on a research project. She started research internship during the final term of her first year at the University, a time when she had exams and coursework to attend to. In this scenario, a research project like this provided her with the opportunity to adapt to the coming pressures and priorities, but also taught her that work cannot be left for a few weeks before the deadline to be completed.

Intern 5 shared the following: *"This internship was unlike anything else I have done before. I applied for this because I was intrigued to learn a different side to my scientific degree, I would like to continue to explore a future in research. I think there are many exciting projects and opportunities that research presents that other jobs do not, and the ability to create something really appeals to me. I plan to look for further internship posts, focusing on more mechanical engineering-based roles, so I can explore how my degree can connect to research.*"

Lessons Learnt and Conclusion

If this project were to be undertaken again, it would be advisable for students to showcase their project through either a poster presentation or a video summarizing the project outcomes and their reflections. Utilizing a poster or video format could enable them to effectively communicate their findings and experiences to a broader audience compared to a traditional written report.

The project team also intends to assess the viewpoints of the supervision and research groups in the future to determine if this project has influenced any stereotypes, biases, or attitudes within those groups. Additionally, the team observed that 25% of the interns were postgraduate (PG) students, while 75% were undergraduate (UG) students. Consequently, efforts will be made to devise strategies to attract more postgraduate students in future endeavours.

For the wider engineering education sector, the project team recommend that developing curriculum materials which are inclusive and highlight the contributions of women in engineering throughout history can help make engineering more relatable and accessible to young women. Also providing opportunities for young girls to engage with engineering concepts from an early age can help spark interest and confidence. This could include activities like coding classes, robotics clubs, or STEM-focused extracurricular programs. Providing scholarships and financial support specifically for female engineering students can help offset the cost of education and make engineering programs more accessible. By implementing these strategies and fostering a culture of inclusivity and equity, the engineering community can work towards improving access to engineering for female from all backgrounds, including those from working-class or poorer backgrounds.

4 Conclusion and Acknowledgements

This paper summarized the methodology and results of a project that was aligned to gender equality, diversity, and inclusion agenda at the University of Warwick. As a result of this project, 20 students identifying as female in the Faculty of Science, Engineering and Medicine at Warwick University were able to participate in research internships and got exposure to state of art engineering facilities present in both departments. As a long-term result of this initiative, we aim to achieve an increased number and diversity of students choosing to pursue engineering research at the University of Warwick. Also, we hope this scheme may be extended across the institution and potentially increase the diversity of those entering research.
We would like to acknowledge and thank Research England for supporting the University of Warwick Enhancing Research Culture Funding. With this funding, we were able to offer internships to female students and arrange guest lecture series for the Faculty of Science, Engineering, and medicine.

ABSTRACT

Engineers are not only problem solvers but also individuals with social responsibilities and ethical considerations. Incorporating empathy into engineering education goes beyond imparting technical skills; it involves fostering the holistic development of individuals. In this practice paper, three courses tailored to their unique institutional and subject contexts yet unified by a shared objective of fostering empathy through design education are described: two courses offered at one higher education institution in North America and one course offered in Europe. The courses are centred on the principles of design thinking and project-based learning, providing students with a structured framework to tackle complex societal challenges. Taken together, the courses demonstrate the wide adaptability of this pedagogical approach across educational levels, institutions, countries, themes, and disciplines.

1. Background and rationale

1.1 Empathy

Empathy is the ability to understand and share the feelings of others. It involves putting oneself in someone else's shoes, seeing the world from their perspective, and experiencing their emotions as if they were one's own (Davis 1994), “the ability to understand people by perceiving or experiencing their life situations” (Segal 2011, 267). This capacity for empathy is fundamental to human connection and lies at the heart of meaningful relationships, communication, and understanding. It allows individuals to recognize and respond to the needs of others, fostering compassion, kindness, and cooperation in both personal and social contexts.

In the realm of education, empathy plays a crucial role in creating a supportive and inclusive learning environment. When educators cultivate empathy within themselves and encourage its development among students, they promote a sense of belonging and mutual respect within the classroom (Borba 2018). By understanding students' diverse backgrounds, experiences, and emotions, teachers can tailor their instruction to meet individual needs and provide appropriate support. Moreover, empathy helps educators to address conflicts and behavioural issues with patience and understanding, rather than resorting to punitive measures (Kohn 1996). In this way, empathy fosters a positive and nurturing educational atmosphere where students feel valued, understood, and empowered to learn and grow. Additionally, by modelling empathetic behaviour, educators instil in students the importance of empathy in their interactions with peers and in their future endeavours, preparing them to become compassionate and socially responsible members of society (Noddings 2013). Thus, empathy serves as a cornerstone of effective teaching and learning, nurturing not only academic success but also the holistic development of individuals as empathetic and empathic beings (Hoffman 2000).

1.2 Empathy in Engineering Education

Empathy is an essential skill in engineering education that goes beyond technical expertise. Moreover, it is a learnable skill, a practice orientation, and a professional way of being (Walther, Miller and Sochacka 2017). As engineers design solutions to address real-world problems, they must understand the needs, perspectives, and experiences of the individuals and communities they serve (Rasoal, Danielsson and Jungert 2012). Empathy enables engineers to approach challenges with a human-centred mindset, considering not only the technical feasibility of their solutions but also their impact on people's lives (Dym and Agogino 2005). By empathizing with end-users, engineers can design products, systems, and technologies that are more inclusive, accessible, and responsive to diverse needs and contexts (Cross, 2011).

In engineering education, fostering empathy involves integrating interdisciplinary perspectives, social awareness, and ethical considerations into the curriculum. Through project-based learning, collaborative activities, and engagement with stakeholders, students can develop a deeper understanding of the societal implications of engineering solutions and the importance of empathy in the design process (Hess and Fila 2016; Crespí, García-Ramos and Queiruga-Dios 2022). Additionally, incorporating case studies, role-playing exercises, and experiential learning opportunities can help students cultivate empathy by immersing themselves in the lived experiences of others. By emphasizing empathy alongside technical skills, engineering education prepares future engineers to tackle complex challenges with compassion, empathy, and a commitment to creating a positive social impact.

1.3 Empathy and educating the whole engineer

Teaching empathy to engineering students is not merely about instilling a technical skill; it is about nurturing the development of the ‘whole person’. By incorporating empathy into engineering education, we recognize that engineers are not just problem solvers but also individuals with social responsibilities and ethical considerations (Noddings 2013). Empathy education encourages students to engage with the world around them in a holistic manner, fostering qualities such as compassion, humility, and cultural sensitivity. As engineering projects increasingly intersect with diverse communities and global challenges, empathy equips students to navigate complex socio-technical landscapes with a deeper understanding of human needs and values. By educating the ‘whole person’ through empathy, we empower engineers to create innovative solutions that are not only technologically sound but also ethically grounded and socially impactful (Bairaktarova, 2022). Moreover, empathy skills are transferable skills that students can apply across various domains, enriching their personal and professional endeavours beyond the realm of engineering.

2. Education contexts

In this paper we present three contexts in which empathy education was integrated into existing courses offered during the academic year 23-24 at two higher education institutions in North America and Europe: 1) Foundations of Engineering, 2) Create! Ideation and Innovation, and 3) Biomedical Engineering. Each of the three courses is tailored to its unique institutional and subject context yet unified by a shared objective of fostering empathy through design education and educating the ‘whole engineer’. Embracing a project-based approach, all courses centre on the principles of design thinking (Brown 2009; Elmansy 2021), providing students with a structured framework to tackle complex challenges. Central to this methodology is the recognition of stakeholders' perspectives, which are integrated into the design process to ensure solutions are both inclusive and responsive. This approach encourages students to actively reflect on the impact of engineering design on the community (Ropers-huilman, Crwile, and Lima 2005) and has been widely promoted in service learning in engineering education (Hess and Fila 2016). Activities aimed at fostering empathy are woven throughout the curriculum, emphasizing perspective-taking exercises to encourage students to empathize with diverse user experiences and needs.

Moreover, the courses adopt a solution-oriented approach, guiding students towards the creation of tangible outcomes that address identified challenges while also considering the broader societal context. Through this practice paper, we aim to illuminate commonalities and differences in the implementation of empathy-focused design education across diverse institutional and subject contexts, shedding light on effective pedagogical strategies for nurturing empathetic, whole engineer practitioners.

3. Design projects – courses curricula

3.1 Foundations of Engineering – First-year engineering course (USA)

Foundations of Engineering is a project-based course in which students explore different parts of the design process and different software tools used in engineering work. The project is tailored to help students develop various engineering skills and utilize tools to solve design problems. Through working on the semester-long project students build on their proficiency in implementing the engineering design process (Dym et al., 2005) and communicating engineering decisions to technical managers, along with contributing effectively to an engineering team and evaluating the ethical implications of engineering solutions. Working in a team of four to deliver a tangible solution on a “choose your own adventure project” students are enabled to apply the design process practically and innovatively, setting the stage for the kind of real-world challenges they will encounter in their engineering career. While the challenges provided through the open-ended project are designed to ignite students’ creativity, the main challenge students face lies in conceptualizing something profoundly personal or globally impactful. For this, building on the skill of empathizing in the design process becomes a medium in this course. Students engage with empathy during the semester in structured activities, such as 1) Empathy Walks: Students spend time in public spaces, such as the campus or their local community. Observing everyday challenges faced by various individuals can lead to enlightening design opportunities; 2) Talk to Others: Students engage with potential users or peers, understanding their daily struggles or unmet needs. Direct conversations can often highlight pain points overlooked in everyday life; 3) Gap Analysis: Students investigate existing solutions in the team’s area of interest. What is lacking? What could be improved or streamlined? Finding these gaps can lead to significant innovation; 4) Cross-industry inspiration: Students realize how a method or technology from one domain might be ground-breaking in another. Can the team repurpose a strategy or tool from an entirely different field to create something novel?; 5) Current Events & Global Goals: Students explore contemporary issues, news, or the United Nations' Sustainable Development Goals. Designing solutions to address these urgent challenges can be both impactful and fulfilling. At the end of the semester, students present their project deliverables to a variety of the projects' stakeholders.

3.2 Ideation and Innovation – Undergraduate multidisciplinary course (USA)

This course is part of an Innovation Minor and is designed to lead students through the process of creative inquiry, design, and collaboration to explore the intersection of art, science, and design. To identify these ties, students engage in activities that build participation and questioning strategies for workshops and lectures, problem finding, analogical and metaphorical thinking, and collaboration in multiple formats. The students work in teams of four on a semester-long project where the instructor chose to challenge the teams with the intricacies of addressing global issues without the allure of tangible (physical) outcomes. As the purpose of the course is to improve quality of life through collaborative, integrative, innovative design, the instructor deliberately designed the course to challenge traditional boundaries, urging students to delve deeper into interdisciplinary collaboration and navigate the complexities of global issues (e.g., earthquakes, floods, geopolitical conflicts, inequality employment issues). Empathy in this course is a core value and students engage in empathy activities through a structured curriculum. For example, every class time, there is an activity focused on fostering empathy towards the user (e.g., Human-Face activity, empathy map, data gathering, etc.) and students are tasked weekly to reflect on these activities and how their learning of empathy techniques applies to their project and their daily life. With this structured curriculum, the instructor aims to equip students with skills that transcend disciplines and empower students to tackle challenges with empathy, creativity, and collaboration – the essence of the course. Representatives of the local town community and the general education faculty and administration attend the final presentations at the end of the project and act as judges to select the top three project solutions.

3.3 Biomedical Engineering – Master course (Belgium)

Biomedical Engineering is a project-based course which focuses on design thinking in the field of biomedical engineering. The students work in teams of three to five during seven full-day sessions spread out over a semester. This setup allows the students to build up a strong team bond and allows for sufficient incubation time between the sessions for the topic to mature. The project revolves around a real-world problem chosen from a bank of research questions that were submitted to the university by civil society stakeholders. For instance, in '23-'24 the manager of a horse owners' association raised their grave concerns about an equine chronic liver disease that is assumedly caused by ragwort poisoning and asked the students to come up with solutions. Students first familiarize themselves with diverse perspectives on these authentic issues through various learning activities. After identifying, analysing, mapping and prioritizing all stakeholders involved (Taylor and Bancilhon 2019), the students develop personas ('avatars') for each stakeholder group. In this way it is no longer sufficient to consider stakeholders in the abstract; instead, students get into a character, and they gain an insider ('emic') understanding of how the issue at hand can impact individual members. They also engage directly with various representatives from the work field and conduct an in-depth study of the scientific state-of-the-art. This phase of the course encourages teams to look at the challenge from various perspectives before converging on their specific problem statement. This initiates a new ideation phase in which each team thinks up multiple approaches for addressing the problem by putting themselves in the stakeholders' shoes, using perspective dialogue techniques (Hermsen, van Dommelen, and Hueso Espinosa 2023), such as figure storming, in which students brainstorm from the perspective of a stakeholder persona, and lateral thinking, for instance through the 'six thinking hats' activity (de Bono 1986). After selecting their specific design objectives, students create and recreate low-fidelity prototypes of their tangible solutions. Through user feedback, stakeholder interactions and cross-team discussions, students are given the opportunity to assess their initial prototype and (re-)create a modified version. In the final session of the course, students are invited to present their solutions to invited stakeholder representatives and engage once more in dialogue with them.

A comparison of the three courses' curricula, their shared similarities, and differences, is presented in Table 1.

Table 1. Comparison of the three courses' curricula

Features	Foundations of Engineering	Create!	Biomedical Engineering
Similarities	▫ Project-based course structured along design thinking process. ▫ Project outcomes are tangible. ▫ Instructors integrate empathizing activities in a scaffolded and purposeful way throughout the course. ▫ Culturally diverse student body. ▫ English is the medium of instruction.		
Differences	Compulsory course for all engineering majors. Bachelor level (first year). Class size: +/- 75. Dominantly male. Empathy is not an explicit theme.	Elective course taken by some engineering majors. Bachelor level (all years). Class size: +/- 30. Evenly distributed. Empathy is an explicit theme.	Compulsory course for biomedical engineering option. Master level. Class size: +/- 20. Evenly distributed. Empathy is an implicit theme ('professional competences').

	Physical Prototype.	Tangible outcome but not physical outcome.	Both – prototype and tangible outcome.

4 Discussion on the alignment of the three courses geared towards nurturing empathy

The alignment of the three courses towards nurturing empathy is evident through the inclusion of empathy-related activities and practical guidance on promoting empathy within the learning environment. Each course, catering to first-year, undergraduate, and graduate students, demonstrates a commitment to fostering empathy as an essential skill for engineering professionals. The courses provide practical guidance on how to cultivate empathy through various explicit and implicit means, such as role-playing exercises, case studies, and reflective discussions on real-world issues. This approach ensures that students not only understand the concept of empathy but also learn how to apply it effectively in their personal and professional lives.

Moreover, the adaptability of the work to diverse contexts is apparent since the activities can be easily tailored to the background and educational stage of the students, making it readily applicable in classrooms, universities, and other learning environments throughout the curriculum. The courses' emphasis on empathy also transcends disciplinary boundaries, making them suitable for international and interdisciplinary contexts. Whether students are studying engineering, social sciences, or humanities, the principles of empathy remain universally relevant and applicable.

Furthermore, the impact of incorporating empathy into engineering education is profound and far-reaching. By intentionally integrating empathy into project-based learning and design thinking courses, students develop a deeper understanding of human needs and perspectives. This not only enhances their ability to collaborate effectively but also equips them with the transversal skills needed to address complex societal challenges with empathy and compassion. Additionally, by fostering a culture of empathy within the engineering education community, these courses contribute to creating more inclusive and socially responsible engineering professionals, ultimately enriching the field of engineering.

5 Summary

In integrating empathy into the curriculum of engineering students, we transcend the mere imparting of technical skills to educate the whole person. By emphasizing empathy alongside technical expertise, we acknowledge the importance of emotional intelligence, ethical decision-making, and interpersonal skills in engineering practice. Engineering education becomes more holistic, nurturing students' abilities to understand and empathize with the diverse needs and perspectives of end-users, communities, and stakeholders. This approach fosters well-rounded professionals who are not only proficient in their technical field but also compassionate, culturally competent, and socially aware. The fact that we as an authoring team ourselves embody a multiplicity of disciplinary, professional, linguistic, and other sociocultural backgrounds has reaffirmed our belief in what can be gained as professionals from purposefully considering a diversity of perspectives in what we undertake.

Moreover, in the three courses, students engage in hands-on learning experiences where they work on real cases with real stakeholders and individuals directly affected by their solutions. By immersing students in real-life contexts, they are exposed to authentic challenges and gain a deeper understanding of the impact their work has on real people and communities. Through interactions with stakeholders and individuals affected by their solutions, students not only apply technical knowledge but also develop empathy by listening to real stories and understanding diverse perspectives. This experiential approach not only enhances students' problem-solving skills but also cultivates empathy by fostering connections with the human aspects of engineering challenges. As a result, students graduate with a heightened sense of responsibility and a deeper appreciation for the ethical and societal implications of their work, better preparing them to address complex problems in the real world with empathy and compassion.

ACKNOWLEDGEMENTS

The authors would like to express their gratitude to all students and stakeholder representatives involved in the three courses. They made us realise once again that behind every statistic, behind every headline there is a human or other sentient being with their story.

ABSTRACT

Recent advances in Artificial Intelligence (AI) coupled with public access to related tools have influenced every aspect of human life and society. Engineering education

[1] *N. Barakat*
nbarakat@uttyler.edu

has already experienced numerous related effects raising many questions regarding the appropriateness and effectiveness of integrating AI. The purpose of this project is to examine introducing AI tools into the Mechanical Engineering curriculum and use the results to guide a wider integration of AI into the curriculum. During this project, students in different courses and stages in the curriculum experienced utilizing AI tools available to the public, such as Chat-GPT, to assist in their educational tasks. Students were allowed, or requested, to utilize AI tools while performing different educational active-learning tasks such as report writing, homework assignment solving, and tasks within comprehensive design projects. In parallel, students were requested to provide information explaining how they used these AI tools to complete the different educational tasks as well as their feedback regarding these experiences. Meanwhile, assessment and reflections from the instructors were taken into consideration. Multiple methods were implemented to carry out the project, collect data, and analyse results to draw conclusions that will inform plans to implement AI in entire curriculum. Results show that students and instructors experienced and reported learning both the potential benefits, limitations, and requirements of using AI tools, as well as how it can be handled reasonably in assisting education while avoiding potential flaws. Meanwhile, instructors gained insight into the requirements, limitations, and expectations related to integrating AI in the curriculum.

1 INTRODUCTION AND BACKGROUND

Countless changes to engineering education and practice have recently taken place due to the integration of Artificial Intelligence (AI) in numerous aspect of the profession. The explosive expansion of AI can be felt by indicators such as the number of related publications in English and Chinese surveyed by Stanford University and reported to have reached half a million by 2021 (Stanford, 2023). It is no surprise that engineering and STEM fields were the most engaged areas in AI because they represent both the developers and the first implementers of AI into technology that will benefit humanity. Engineering led in benefiting from AI with the advancement of computational power and the digital world in parallel with direct application to research and education. An example of such engagement came as a response to the COVID pandemic, where utilization of digital tools for almost everything related to education and communication, including engineering education and practice, expanded exponentially, resulting in more opportunities to utilize AI for many reasons, starting with improving efficiency (Barakat et al, 2021). These were additions to the continuous changes in engineering education and practice stemming from the dynamic nature of interdisciplinarity and diversity which is a vital part of engineering. Any engineering endeavour would not even start without the integration of many expertise and dimensions. These changes in the nature of engineering, particularly the parts related to the integration of software or AI, continue to confront engineering, and STEM, academics and practitioners with an evolving set of questions on the best utilization of AI and associated potential risks, especially the parts focusing on the preparedness of both engineering researchers and practitioners to effectively integrate and use AI in their profession.

Meanwhile, academia has already been implementing AI in a multitude of ways related to almost all aspects of education and research. To set the tone for AI implementation in education, a report by UNESCO (UNESCO, 2023) stated that using AI in higher education should target improving human capabilities and protect human rights through effective human-machine collaboration in different life needs such as learning, work, and sustainable development. These goals are perfectly aligned with the general goals of engineering endeavours. As a result, many literature reports discussed implementing AI in engineering education, and some have presented results of early testing of AI in supporting learning, teaching, and assessment (Zawacki-Richter et al, 2019) and (Bates et al, 2020). Salim et al. reported utilizing AI to monitor students' learning and provide rapid feedback for potential intervention at different levels to improve their academic progress (Salim et al, 2022). Furthermore, many students and instructors are currently using Chat-GPT to help with assignments and grading, with the aim of time saving, improved accuracy, and timely feedback (Dempere et al, 2023). Learning management systems (LMSs) such as Canvas and Blackboard are now starting to integrate AI based functions assisting in assessment and data analytics (Aldahwan and AlSaeed, 2020). Meanwhile, multiple issues have already emerged in parallel with these developments such as upholding academic integrity and the need for continuous professional development of instructors to be able to handle and integrate appropriate parts of AI in the curriculum. This in addition to issues related to better planning of AI integration to optimize its effect on the educational process. These issues present an opportunity and a need for higher education entities to establish policies and regulations allowing the expanded utilization of AI in the most effective, fair, and ethical manner, especially when this process is still in its infancy across higher education around the globe, and before sporadic skewed results generate unbalanced resistance at the decision-making levels to the entire idea of improving engineers' competency by educating them on utilizing AI tools.

This paper includes a description of a project that constitutes the initial stage in a larger plan aiming to introduce AI-based tools into the Mechanical Engineering (ME) curriculum at UNIVERISTY. To achieve the goal of gaining insight and learning from the experience, from both students and instructors, active learning tasks were selected to implement AI tools. Moreover, AI-based tools were utilized in different courses to examine supporting multiple aspects of interactive learning at different levels in the curriculum. Results were collected from the different courses while implementing various assessment methods to measure the effects of these changes. Findings were evaluated to draw conclusions that will help guide the next stage of the plan to integrate AI into the Mechanical Engineering curriculum.

2 RESEARCH PURPOSE AND QUESTION

The purpose of this study was to investigate the effects of introducing AI-based tools into an Engineering curriculum and evaluate the results for the ultimate goal of informing future plans for to widely integrate AI tools across an entire Mechanical Engineering curriculum. The research questions were:

1. What would be the effect (advantages and disadvantages) of introducing AI tools to selected parts of the curriculum on the education process?
2. What would be needed to integrate AI into the curriculum for an improved educational experience?

3 METHODOLOGY

Different aspects of the curriculum could be selected to introduce AI tools and study their effect on the educational process. However, areas where the impact of change would be widely felt are those where students take an active role. Active learning engages both students and educators. During active learning, students tend to look for tools to help them accomplish the required task while carefully monitoring time savings and effort, especially time needed to learn a new tool. Meanwhile, educators can assess students' experiences and provide feedback that includes their own observations. Therefore, three major areas of active learning were targeted within a Mechanical Engineering curriculum at University of Texas at Tyler (UT Tyler) to introduce AI. These areas are:

1. Technical Report Writing.
2. Technical problem solving assigned outside the classroom (Homework).
3. A technical problem in a project such as a senior capstone design project.

Four different required courses were selected to include the targeted areas with student populations from the sophomore, junior, and senior levels. Direct and indirect assessment methods were implemented to provide feedback from both students and the instructors. Table 1 presents details of the selected courses and related learning outcomes that were targeted to examine introducing AI tools.

Table 1: Details of courses and student groups in curriculum areas targeted for AI inclusion.

Curricular area / Selected Course	**Student Population composition**	**Targeted Course Learning Outcome**
Technical Writing: **Material Science and Manufacturing (MSM)– Sophomore level**	Sophomore = 8 Junior = 14 Senior = 14 Total = 36	CLO: Perform mechanical testing and metallographic procedures to report material properties and microstructures of various metal alloys in laboratory reports.
Homework assignments: Mechanics of Materials (MoM) – Junior level	Junior = 13	CLO: Use various external loads to determine internal forces and related stress and deformation for a variety of structures.
Homework assignments: Thermodynamics (Thermo) – Junior level	Junior = 33	CLO: Perform analysis of thermodynamic cycles.
Senior Capstone Design Project (SCD) – Senior level	Senior = 5 (One group among 52 seniors in the course)	CLO: Apply knowledge and skills acquired in the undergraduate engineering curriculum in an integrated culminating design project experience to articulate and solve a complex engineering problem.

4 PROCEDURE AND INSTRUMENTS

4.2 Technical writing (Material Science and Manufacturing Course - MSM):

Technical writing is learned along a thread in the Mechanical Engineering curriculum. It usually takes place in the lab part, guided by a dedicated learning outcome. MSM lab included individual short reports and group full reports. In the group full reports, the instructor provides specific guidelines on components of each section of the report and each student in a group contributes their section to the final assembled report of the group. At the beginning of the course, AI was allowed in technical report writing without any prior training. The only requirements were to include a statement declaring that AI was used to assist with writing this report, information about the AI tool used, and the intended purpose of using AI.

Towards the last quarter of the semester, students were formally introduced to AI-assisted technical report writing with instructions and a goal to reduce human effort in the writing process. At this stage, a pre-report survey was distributed to students to capture their expectations and perspectives. After submitting the reports, direct assessment data was collected in addition to results from a post-report survey of the same ten attributes in the Pre-report survey. The survey questions were:

Using Chat-GPT or similar AI programs will help me achieve the following:

1. Start a report that later requires my input to make it an excellent report.
2. Improve a report if I started it and gave it to the software.
3. Produce an excellent report without errors.
4. Produce an excellent report without the need for multiple iterations.
5. Produce a report without committing plagiarism just by stating that I have used Chat- GPT.
6. Improve my own report writing skills.
7. Improve my own report writing skills and slowly not needing to use the software.
8. Improve my report writing grade but not my related skills.
9. Save time on writing my report.
10. Learn how to write a report properly.

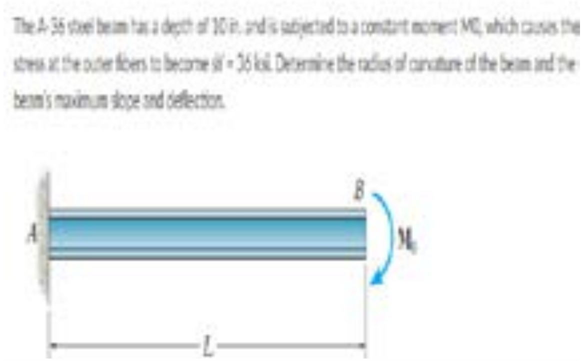

Figure 1: Technical problem assigned as homework within the Mechanics of Materials Course (MoM) and used for AI testing.

Indirect assessment results from all surveys were based on a 5-point Likert scale as follows: 1 = strongly disagree, 2 = disagree, 3 = n3utral, 4 = agree, 5 = strongly agree.

4.1 Solving Technical Problems - Mechanics of Materials (MoM) and Thermodynamics (Thermo)

In these two foundational courses, students learn and practice applying concepts by solve specific technical problems, per course learning outcomes. One of the assigned problems was selected for this experiment in each course. In MoM students were asked to determine changes in the dimensions of a cantilever beam under load, as shown in Figure 1. In Thermo, students were asked to determine the absolute value for exergy with different conditions, as shown in Figure 2. Answers were requested manually, then again using AI tools. In addition to direct assessment of the submitted work, students' reactions were surveyed after completing all tasks using the following seven questions:

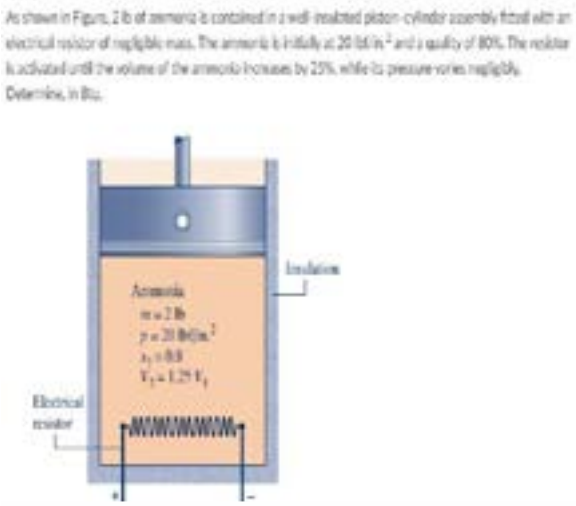

Figure 2: Technical problem assigned as homework within the Thermodynamics Course (Thermo) and used for AI testing.

1. I found AI results to be accurate.
2. Using AI to solve this problem was difficult.
3. AI helped me save time in solving this problem.
4. AI could help me learn topics related to this problem.
5. I will use AI again to solve engineering problems.
6. I recommend AI as a learning tool for MoM / Thermo.
7. I recommend using AI as a tool to assist in engineering design.

4.2 Senior Capstone Design Projects (SCD)

In these two consecutive courses, teams of students solve a complex engineering problem within a real-world industrial project. A team of five students was assigned a project to automate a pick-and-place process of multiple parts that could be presented in random orientation and position. The team designed and built a system based on using a camera with a classic vision software to assist a robotic in the process. A rough industrial environment of operation augmented the challenge of random parts' placement and orientation. The vision system required extensive training time and effort to enable an acceptable rate of accuracy. The team of students explored an AI tool that is based in MATLAB to solve this issue and employed it as part of the project. Training to accomplish a very high rate of accuracy was completed in few minutes.

5 RESULTS AND OBSERVATIONS

Table 2 presents direct assessment results of students' products with and without inclusion of AI tools, in all courses involved except for SCD project due to its unique nature and treatment.

Table 2: Direct assessment results of students' products with and without the inclusion of AI tools from curriculum areas.

Conditions	Grade (%)	Technical Writing (MSM)		Technical Problem Solving	
		Individual short reports	Group full reports	MoM – HW	Thermo - HW
Without AI	Average	82.60	83.90	94.50	92.59
	St. div.	7.90	7.90	1.44	3.92
With AI	Average	82.60	80.80	82.50	26.21
	St. div.	5.20	5.30	6.08	3.45

Results from the technical writing area (MSM) included 125 submissions without AI and 13 submissions with AI, as individual short reports for multiple lab activities. Meanwhile, there were 14 submissions of group full reports without AI and 2 submissions with AI. The self-reported purpose for using AI by students was mainly to improve the language aspects and presentation aspects of the report, compared to very low use for assistance with technical content. Instructors in both MoM and Thermo observed that most solutions with AI included correct formulae and solution steps but did not lead to a complete or correct final solution. In fact, the majority of AI-based solutions using Chat-GPT stopped short of providing a numerical answer.

In the SCD project, a process that would have taken weeks, and frequent calibration, based on data from previous use of the selected vision software, was reduced to minutes using an AI tool, with increased adaptability to accommodate new parts with high efficiency. Input from the SCD student team was collected and summarized in the following anecdotes:

1. At first, students were worried of the possibility to fail when using AI tools because their lack of familiarity of it.

2. AI tool helped students address intricate programming tasks such as object detection, resolving a common challenge among students with low to medium programming skills.

3. AI tools are instrumental in saving students time, enabling them to dedicate their efforts towards enhancing the project.

Comments from the instructor of the SCD project were along the same lines, with the addition of emphasizing that AI tools should be used carefully to empower students and improve their learning and time management while ensuring that AI does not hinder students' development of critical thinking, creativity, and problem-solving skills.

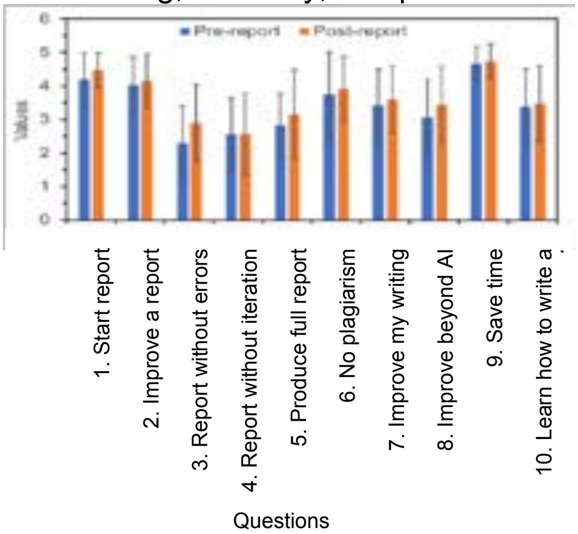

Figure 3: Survey results from students conducting technical writing regarding AI implementation.

6 DISCUSSION

Introducing AI within active learning areas in the ME curriculum to improve the educational process allowed expanded opportunities for students' engagement using commercially available tools.

In technical writing, it was insightful that very few students chose to use AI tools to improve their reports (13 of 125 and 2 of 14). The instructor observed that even the small number of 13 diminished quickly from nine to three, to two, and to zero consecutively. Additionally, those using AI were mainly aiming to improve the language and writing aspects of the report, not the technical content of the report. This helps in understanding the direct assessment results in Table 2 showing almost no change between reports with or without AI. However, these results do not provide sufficient information about the effectiveness of AI implementation in the technical writing area. Checking indirect assessment results of students' perspective on the usefulness in technical writing, as summarized by Figure 3, it can be noticed that receiving instructions on how to use AI tools resulted in increased agreement that AI could improve learning. The highest agreement was on AI helping to start a technical report, which later required input from the author for improvement, and on time saving during writing. The lowest agreement was on AI's ability to produce excellent reports without errors and without multiple iterations. Collectively, this points out issues related to knowledge of, and training on using, AI tools, as well as trust that AI will produce what is desired quickly and efficiently. After providing instruction on using AI tools the biggest change in agreement was seen in students' perspectives regarding trusting AI to help produce an excellent report without errors. These results and the diminishing use of AI tools by students were influenced by the fact that Chat-GPT was mostly used to help with this task. This software is limited by training data and performs as a natural language processor which reduces its ability to handle technical tasks. Students realized that as requirements and expectations of the written reports became more specific, using a general AI tool would be disadvantageous, especially with unchanged grades received for their shorter reports while taking extra time to write the report.

Table 2 shows lower scores in direct assessment of solutions to technical problems in MoM and Thermo using AI tools, compared to solutions without AI. The instructor noticed that in most AI-based solutions students arrived at the correct formulae but ended with the wrong final answer. Figure 4 shows related indirect assessment where students agreed mostly that AI saved them time and could help them learn related topics, as well as recommended using AI in engineering design. The lowest level of agreement was on AI providing accurate solutions and on using AI to learn the specific topic in question. Figure 4 also shows almost similar results of high agreement that AI helps to save time and could help to learn related topics. However, this population was almost neutral regarding the accuracy of AI results. The least agreement was on AI being a candidate for use in engineering design. Notice that indirect assessment results MoM did not provide strong agreement or disagreement but rather a band of answers between some disagreement and some agreement. The band was even narrower around the neutral line in the Thermo course. Direct results were more helpful in showing contrasts. These results confirm the existence of issues related to students' knowledge of AI capabilities and best utilization. When AI tools provided the correct formulae to solve the problem at hand, it was perceived as very helpful and time saving, but when the final answers needed refinement which required time and effort from the student, this perception was retracted due to lower expectations and trust. In addition to confirming the findings from the technical writing area, these results pose questions of suitability of the selected AI tool for the task.

Using AI tools to solve an industrial problem in SCD provided the most positive reactions. A dedicated suitable tool was implemented which enabled students to overcome barriers and embrace a new technology. As a result, students have gained confidence in utilizing AI tools which they could implement across various subjects.

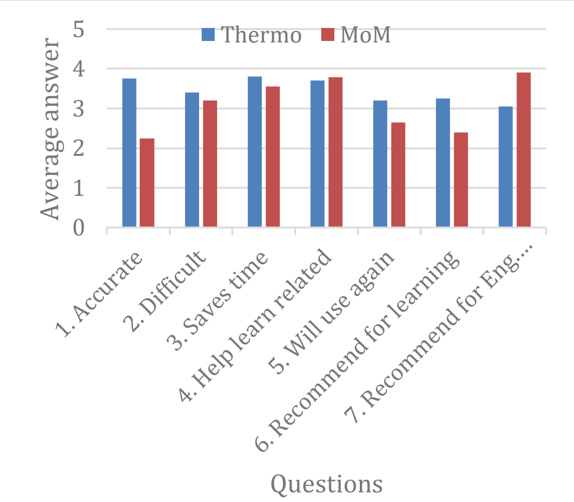

Figure 4: Survey results from students attempting technical problem-solving using AI tools within MoM and Thermo.

7 Conclusion

This project aimed to examine the integration of AI tools into a Mechanical Engineering curriculum to enhance student learning. AI-based tools available to students were utilized in active learning tasks such as technical writing and technical problem solving as well as a senior project within required courses. Various assessment methods were implemented for feedback. Evaluation of the results emphasized the importance of training of both instructors and students on AI tools and their limitations to allow proper integration of this new technology in the curriculum as part of continuous improvement. Understanding AI and proper training on its tools is critical to curriculum innovation without compromising the foundations as well as ensuring engineers are properly equipped to address societal needs.

ABSTRACT

The Artefacts Project presents a unique, self-guided, 12-week practical where second-year materials students analyse the materials of everyday objects (e.g., razor blades, irons etc.) to unravel their properties, processing, and applications.

This project fosters a dynamic learning environment where students take ownership of their research. Guided by discussions with an interdisciplinary teaching team, they develop their own hypotheses, aims, and objectives. The students actively consider each member's strengths and interests throughout the project, ensuring an inclusive and effective research experience and building strong team-working skills. Literacy is also integrated seamlessly. Dedicated workshops equip students with essential skills for crafting impactful presentations, posters, and communicating science effectively.

The presentation will delve into the successful Artefacts Project, outlining the steps that guide students towards formulating their own research questions. We'll outline the stages and the project methodology. In the first five weeks the students concentrate on the fundamental soft skill development (crafting talks, creating posters, and fostering successful teamwork). During the last six weeks student teams disassemble their assigned artefacts and analyse the materials' properties putting into practice the technical skills they have acquired throughout their two years of practical studies. Finally, the presentation will showcase how the project brings materials science to life, demonstrating its application in the everyday objects that surround us.

This project offers an innovative educational approach for engaging students in real-world materials science, fostering essential practical and soft skills, and igniting their curiosity and passion for research.

1. INTRODUCTION

The Artefacts Project presents a unique, self-guided, 12-week practical where the second-year Materials Engineering students analyse everyday commercial objects (bike brakes, phones, toasters, etc.) from a point of view of materials development, processing, and properties. The student groups are given two objects (old/new or expensive/cheap) and are guided to use their creativity and knowledge to decide upon an action plan, the experimental process, and set their own research questions they want answered at the end of their project.

This project is adopted as a core learning approach that allows better alignment of course learning and assessment activities with the two-year undergraduate program's learning outcomes, including active learning, technical analysis skills, research methods and teamwork.

This project is designed to challenge students' implicit notions of learning and to develop their self-efficacy by giving them creative freedom to work in a supported, collaborative, practical process. We want the students to foster professional skills alongside technical skills, supporting innovative, student-led learning in the applied materials engineering curriculum, which can improve students soft and technical skills in ways that teacher-led, lecture-style learning does not (Tell and Hoveskog 2022).

There are different studies on how to address in practice a more student led learning in the curriculum (Rodriguez et al. 2021). Various learning models have been developed in recent decades such as, for example, problem-based learning (PBL)

(De Graaf and Kolmos 2003), Experiential Learning (ExL) (Kolb 1984) and the Conceiving, Designing, Implementing and Operating (CDIO) approach that focuses on all phases of a product, process, or system lifecycle. They all have their own emphasis with the general purpose of engineering education is to provide the learning required by students to become successful engineers – technical expertise, social awareness, and a bias towards innovation.
The Artefacts Project leans more towards the CDIO model and incorporates multiple technical learning outcomes. The 'Conceive-Design-Implement-Operate' (CDIO) movement of engineering education reform emphasises project-based, experiential learning and the development of professional skills such as teamwork, collaboration, and design (Crawley et al. 2007). It addresses the gap between classic engineering education programs and industry needs. Researchers have strongly supported this approach in their call for a change in the traditional, teacher-led engineering curriculum.

1.1. Professional skills

The term 'professional skills' (also called 'soft', 'transferable', 'transversal' or even '21st Century' skills), has come as a requirement for accreditation engineering programs for years (Picard et al. 2021). There is an overall agreement that engineering education should not only address science and engineering but also social, ethical, and organisational aspects of engineers' practices and responsibilities (Winberg et al., 2020). Furthermore, they should also have the abilities needed to solve "complex technical challenges along with being able to work in interdisciplinary teams and dealing with social and cultural issues" (Rodriguez et al. 2021).

A lot of engineering programs today focus narrowly on the technical skills (i.e., the hard skills). Assessments can be seen as puzzles that have one pre-determined correct answer requiring analytical skill but no integrative or creative capability (Edström 2018).

The aim of the Artefacts Project is to address aspects of the 'soft' skills looking at teamwork, communication, and project management. As a possible organizing scheme, Table 1 presents our framework of four categories of soft skills that we have addressed with the Artefact Project as derived from three papers in the soft skills engineering literature (Tell and Hoveskog 2022).

Table 1. Soft skills addressed by the Artefact Project as described in previous research.

Soft skills	Shakir (2009)	Chamorro-Premuzic et al. (2010)	Rodriguez et al. (2021)
Creativity	Critical thinking and problem-solving skills	Critical thinking; attention to detail, planning and organizing skills	Problem solving skills – time and project creativity and management
Cooperation	Teamwork, leadership skills communication skills	Interpersonal and emotional intelligence	Interpersonal skills – social interaction, and leadership

Self confidence	Life-long learning and information management skills	Self-management; insight maturity	Intrapersonal skills: self-direction and the ability to prioritize
Commitment	Entrepreneurship skills	The ability to work under pressure; willingness to learn; imagination/ creativity and initiative	Meta-cognitive skills – willingness to learn, critical/ analytical and innovative thinking

1.2. The Importance of Teamwork and Instructional Support

Several studies highlight the importance of teamwork as an engineering ‘soft’ skill (Costa et al. 2019). To foster this skill, we designed the Artefact project where student teams have freedom to explore their own questions related to materials of their artefact. It is crucial to differentiate between teamwork and group work. While often used interchangeably, these terms have distinct purposes. **Group work** is a pedagogical approach where students collaborate to achieve specific learning objectives. It's a common teaching method. **Teamwork** is formed for a long-term, common goal requiring a high level of interdependence and collaboration, such as a project-based report. Teams exhibit a stronger sense of shared responsibility compared to groups, which often work towards separate goals with a related interest (Davies W.M. 2009).

One of the main challenges we have faced was integrating diverse students into successful teams. Different motivations, expectations, task and role ambiguity and academic disparity can become unpleasant experiences if not managed effectively. Previous studies (Oakley et al. 2004) emphasize the importance of instructor interaction and feedback, alongside collaborative learning, in fostering professional competencies like group skills and problem-solving.

Our strategy for effective teamwork is building on the importance of guidance (Isaac and Tormey 2015) and implementation of specific strategies to ensure a positive learning experience. We divided students into small groups, provided coaching sessions, and incorporated self and peer assessment throughout the 12-week project. We provided feedback on the project’s progression, support on issues or conflicts arising from teamwork, and communication regarding the project due dates. Recognizing the challenges of varying skill and presentation levels, we allowed students to choose presentation roles that maximized their strengths. Confident presenters could handle the main presentation, while others could focus on the poster or support preparation. Our observations suggest that students with lower initial motivation benefit more from working alongside high-achieving peers compared to working independently implying that using individual heterogeneity is an advantage (Torres et al. 2017). This was achieved by providing constant supervision and guidance across the Project indicating that training students in teamwork was crucial (Aranzabal et al. 2022).

1.3 Technical Skills

The aim of the Artefact project is to combine professional and technical skills. The engineering students should not only work in interdisciplinary teams and deal with social and cultural issues but also have the abilities needed to solve “complex technical challenges” (Cukierman and Palmieri 2014).

Project-based learning provides a platform to practice valuable technical skills, the students can put into practice operation procedures, data collection techniques, and analysis methods. Analysing materials on everyday objects may lead to unexpected data, requiring students to troubleshoot, analyse their approach, and potentially adjust their methods or test parameters. This process encourages critical thinking and problem-solving skills that are essential in any field of work, not just Engineering.

A strong foundation in technical skills, also known as hard skills, is the bedrock of engineering education and can be achieved using a joint learning method, example-based learning (EBL) and problem-based learning (PBL) (Sanchez-Gomez 2022). Through coursework, labs, and projects, the 2nd year Materials students gain the ability to utilize relevant software and technologies for the Artefact project at the end of their second year of study. We believe that this technical proficiency is essential for applying engineering principles to real-world challenges and fostering innovation across various engineering fields.

2. METHODOLOGY

The 12 weeks Artefact project is divided into two parts. In the first five weeks, students in their assigned groups study the fundamentals of crafting and delivering talks, creating effective posters, and fostering successful teamwork. The following six weeks focus on applying technical skills honed throughout the past two years of study as students analyse their artefacts and prepare for the final presentation and poster in week 12. A crucial aspect of the project's launch (week one) involves familiarizing students with the course's learning outcomes:

1. To examine real life application of materials design, selection, and application to product design
2. To develop and apply practical laboratory skills.
3. To examine the potential health and safety issues surrounding a practical investigation and manage them accordingly.
4. To develop scientific presentations skills and use them in presenting the project work.
5. To understand what makes a good poster and apply this to design of research poster.
6. To develop team working skills and project planning abilities.

2.1. Weeks 1 to 5 – Skills Development

The first five weeks focus on honing presentation and poster creation skills. Students work collaboratively in groups, utilizing a blend of group discussions, lectures, and workshops.

2.1.1 Developing Presentation Skills:

- *Identifying a Key Paper:* Students select a research paper from the prestigious journal Nature to analyse and present.
- *Crafting a Compelling Presentation (7 minutes):* Presentations should follow a clear structure, including:
    - Introduction: Highlighting the paper's significance
    - Results: Summarizing key findings and discussing potential limitations
    - Conclusion: Exploring potential future applications

To equip students for impactful presentations, an introductory lecture delves into key concepts:

- *Pre-Planning Considerations:* Defining the topic, choosing a captivating title, and conducting relevant research.
- *Structuring the Presentation:* Establishing a clear flow with a beginning, middle, and end, incorporating visuals, and identifying key points
- *Storytelling Techniques:* Structuring a compelling narrative for optimal audience engagement.

Presenting before the project's experimental phase offers several advantages:

- *Practice Makes Perfect:* Students gain valuable presentation experience.
- *Identifying Areas for Improvement:* Self-reflection allows students to pinpoint areas for further development.
- *Skill Sharpening:* Students refine their presentation skills before the final project showcase.

2.1.2 Crafting Effective Posters:

Moving on from presentations, students turn their focus to creating impactful posters. Through group discussions, they analyse a poster from a previous year's report, identifying strengths and areas for improvement. This exercise helps them grasp the key elements of a successful academic poster, including:

- *Tailored Communication*: Considering the unique needs of the target audience.
- *Accessibility and Clarity:* Ensuring the poster is clear and easy to understand.
- *Concise Messaging:* Delivering key information using minimal text and effective visuals.

Following this interactive session, a lecture unpacks the core principles of poster design, incorporating elements like discussions and workshops.

- *Visual Storytelling:* Students learn to strategically select diagrams that enhance their narrative and support key points.
- *Engaging Titles and Keywords:* Choosing clear, concise titles and keywords to grab attention.
- *Effective Use of Images:* Understanding how to present images that inform and guide the audience's interpretation.

Mirroring the structure of a research article, the final portion of the session focuses on organizing poster content, where students learn to:

- *Divide Text by Topic:* Break down the information into clear sections.
- *Essential Elements:* Include an introduction, methodology, results, analysis, discussion, and conclusion.

2.1.3 Team Performance:

To enhance the team performance, the students are asked to divide the activities into these stages:

1. *Familiarisation*. This is the stage when the individual members of the group get to know each other and begin to understand the task they need to undertake.
2. *Planning and preparation*. This is the stage when the group should plan exactly what needs to be done, how it needs to be done, and who should do what. The students should divide the different tasks and the responsibilities among the group. They should make the most of the individual expertise and finally make an action plan.
3. *Implementatio*n. The students should work on an effective communication by establishing regular meetings and sharing contact details to facilitate contact between everyone in the group.
4. *Completion*. As the final stage of the project, it may require a different approach. The students may need to regroup at this stage to agree a new action plan to tie up loose ends and review the whole project rather than discrete part of it.

2.2 Weeks 6 to 11- Artefact Analysis

The Artefact project has two key objectives. First to develop teamwork skills where students collaborate in groups to create oral presentations and impactful posters, fostering teamwork and communication skills. Second to apply knowledge in practice: Students can apply the theoretical and practical knowledge acquired throughout their two years of Materials Science and Engineering studies.

During this phase, student teams disassemble their assigned artefacts and analyse the materials' properties. This analysis focuses on understanding, but it is not limited to, Mechanical Properties, how strong and ductile the material is; thermal properties, within which temperatures a material works at its best; chemical and microstructure compositions, which the students can use to explain materials properties and applications.

The project encourages exploration beyond conventional testing methods. Past students have analysed bicycle brakes using UV-Vis light and moisture to study degradation. They have investigated corrosion in iron plates by ironing lab coats with hard water. Also, they have studied bacterial growth on razor blades under varying conditions.

Students have the freedom to choose specific components of their artefacts to analyse and determine the most suitable analytical techniques. However, this freedom comes with the responsibility to conduct thorough risk assessments and obtain Control of Substances Hazardous to Health (COSHH) approval for any proposed activities. This fosters resilience, creativity, and the responsible application of their knowledge, while focusing on their poster and presentation delivery.

3. RESULTS

The Artefact project fostered a deep sense of discovery in students. The independence granted during the research and experimentation phase was highly valued. Unsupervised access to lab equipment boosted their confidence and proficiency in utilizing a variety of techniques. This is exemplified by their independent use techniques such as X-ray diffraction and infra-red spectroscopy to analyse the chemical composition, crystalline and molecular structure of the components of their chosen artefacts. Crucially, students interpreted the data themselves, leading them to explore limitations of the techniques and delve into robust analytical methods.

The project actively encouraged students to consider techniques beyond the confines of the main laboratory and seek collaboration with staff from other labs. For instance, in the "Razors" project (2023), they investigated bacterial growth on razor handles in simulated bathroom environments. While the metal handles of the "cheap" razors showed minimal bacterial growth, the plastic handles of the "expensive" razors, with their intricate designs and crevices, demonstrated the potential for harbouring bacteria. Similarly, the "Brakes" project (2021) saw groups utilize the chemical and biological processing laboratories to design and test their own corrosive solutions. These projects highlight the ingenuity and real-world applications fostered by the students during the Artefact Project.

The project culminates with a student-led presentation and poster showcasing their work to peers, department members, and an industry panel. This open-ended approach ignited students' imaginations, leading to a broad spectrum of research questions and results. In the "Irons" project (2022), groups explored themes such as material selection and sustainability. One particularly creative group investigated chemical corrosion by hard water by ironing lab coats for five weeks! (Figure 2) Another group encountered health and safety limitations that prevented direct skin shaving, so they found alternative approach using a surrogate material (kiwi) with similar properties to employ (figure 2).

This diverse range of projects encompassed chemistry, sustainability, and materials engineering, fostering student enthusiasm while simultaneously developing their soft skills and understanding of industrial applications and expectations.

Fig. 1. 2022 poster – Effect of hard water on irons

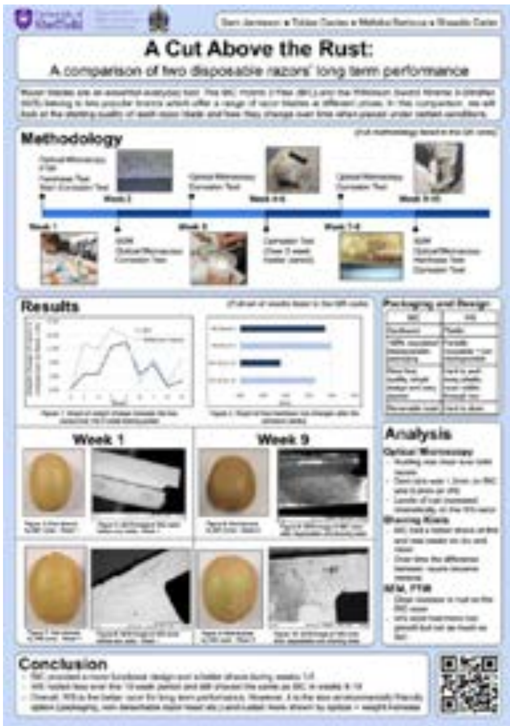

Fig. 2. 2023 poster – Innovative way of shaving

4. CONCLUSION

We have demonstrated that the Artefact project empowers second-year materials students by granting them the freedom to explore the materials within a commercial artefact using technical and literacy skills. This approach fosters a sense of discovery, as students relished the independence during the research and experimentation phase.

The project's two-pronged approach of presentation and poster development proves successful. While collaboration remained crucial to maintain thematic cohesion between the deliverables, dividing the tasks ensures a more equitable workload distribution. This approach built upon the initial emphasis on effective teamwork, equipping students with valuable organizational and collaboration skills. Evidence of this was their proactive scheduling of meetings, task documentation, and fostering open communication within their groups.

Overall, the Artefact project achieves its primary goal of fostering student technical and soft skills using independence and exploration. However, the discussion of student self-reflection highlights an opportunity to further emphasize the broader applicability of the acquired technical skills within various career paths. In today's competitive environment, success is not solely defined by technical ability. The teams that thrived during the Artefacts project were those who could effectively combine their technical expertise with the power of soft skills. By fostering a strong correlation between these two essential skill sets, the students empowered themselves to navigate the complexities of modern work and achieve remarkable results.

ABSTRACT

In today's landscape of global challenges, the role of the engineer is experiencing a significant transformation. The expectations of engineers are no longer confined to traditional technical expertise; they are increasingly acknowledged as key players in driving sustainable development agendas on a global scale. As nations endeavour to achieve the ambitious targets outlined in the United Nations Sustainable Development Goals (SDGs), it becomes imperative to equip engineers with a diverse skillset capable of addressing increasingly intricate and multifaceted projects, often characterised as "wicked" problems. The PROFESS 12 research project was conceived to address the gap between traditional and required skills by piloting a summer school which sought to expose students to opportunities where they can develop some of the required skills. This paper describes the design of the summer school and provides evidence from student feedback of its value and effectiveness in addressing learning outcomes. The resources from the design of this summer school can be used by educators who wish to contribute to activities to enhance skills in engineering students.

1 INTRODUCTION

The context in which the engineering profession operates has undergone significant transformation since its inception, now necessitating collaboration within diverse, multidisciplinary international teams. The requisite skills for success now extend well beyond technical prowess (Byrne and Mullally 2014; Craps et al. 2017; Kolmos and Holgaard 2019). Seminal studies on skill requirements for sustainable development in particular (Wiek et al. 2011; de Haan 2010; Rieckmann 2012) have presented a spectrum of competencies that engineers must possess. Recent investigations, such as those conducted under the Erasmus+ project, ASTEP-2030, particularly in the context of achieving the SDGs, have further identified a multitude of skills (53 in total) including Sustainability Awareness and Intercultural Skills (Beagon et al. 2022). The UNESCO (2017) report "Education for Sustainable Development Goals – Learning Objectives" also provides educators with a framework to enrich their curricula, thereby equipping students with the skills essential for the future. Whilst the lists of skills requirements are a useful starting point, many educators encounter challenges in implementing what is termed Engineering Education for Sustainable Development (EESD) initiatives in the classroom. Successful implementation of EESD necessitates a holistic and transformative approach, entailing the integration of novel strategies and appropriate pedagogical methods into engineering curricula (de Haan 2010). Kolmos et al. (2016) summarise three response strategies to EESD: (1) the add-on strategy, involving the inclusion of sustainability subjects into the curriculum at the micro-level, (2) the integration strategy, encompassing content and values at the meso-level, necessitating program modification, and (3) the re-building strategy, entailing a paradigm shift in education by accentuating values, identity, and commitment at the macro-level. The add-on strategy predominates in EESD however, typically entailing the introduction of new courses or topics (Thürer et al. 2018). The use of situated learning and the importance of self directed learning is espoused as critical to provide motivation for students to learn about sustainable development (de Haan 2010). One extracurricular, add on strategy which has been implemented is the use of summer schools, to enhance innovation and entrepreneurship (Qosaj et al. 2023) and multidisciplinary skills (Larsen et al. 2009).

1.1 Background

The project was a joint initiative between Ulster University in Northern Ireland, which is part of the UK and TU Dublin in Ireland. Funded by the Higher Education Authority, its aim was to improve cultural relationships and build connections between researchers, academics and students in each jurisdiction. Hence the summer school was designed with ten student participants from each university and was hosted in each location with travel and accommodation fully funded by the project.

2 METHODOLOGY

2.1 Cocreation exercises (Jan/Feb 2023) and Launch Day (March 2023)

Two co-creation exercises were undertaken with engineering students to test ideas and gather information as to what they would expect or hope to achieve from the summer school. The outcome of the co-creation exercises determined the learning outcomes for the summer school (shown in Table 1) and the types of teaching pedagogies to be utilised. Applications and interviews enabled the team to select ten engineering students from each university, being mindful of diversity in gender, age, university course and year of study. There were concerns that students may not commit to a five-day summer school and so the team organised a Launch Day to engage students in the project at an early stage and to allow them to meet each other before committing to the main five-day event. The Launch Day was organised to coincide with the World Engineering Day for Sustainable Development. Staff and students met at an Area of Outstanding Natural Beauty (AONB) halfway between the two Universities where we had arranged a mountain walk in the morning to remind us of the importance of maintaining our natural environment. The afternoon session included a guest speaker on sustainable manufacturing and a rousing call for action from a climate action activist with the National Youth Council of Ireland.

2.2 Five Day Summer School (May 2023)

The design of the summer school was carefully planned to ensure that students had the opportunity to meet the learning outcomes as well as enjoy the experience itself. A Summer School Toolkit is available on the project website with full details of the itinerary, detailed descriptions of each activity and workshop and a student handbook which was circulated one week before the summer school began PROFESS 12 website. A simplified schedule is included in Figure 1 outlining the main activities and workshops. In line with the literature on the most appropriate methods for EESD, many of the activities were formed around the concepts of active learning, self directed learning, situated learning, future thinking and role playing (de Haan 2010; Thürer et al. 2018; Chernyshova and Tokmylenko 2020). The activities were student centred, with lecturers acting as facilitators.

2.3 Feedback on Summer School

The research team wanted to better understand if the summer school was effective in reaching the aims of the PROFESS 12 project and also to gather information and feedback which would help refine the design of a future iteration of the summer school. Therefore, research questions included:

- How effective was the Summer School from the students' perspective?
- What can we learn from the experience to provide feed forward advice for the next iteration of the project at an international scale?

The data was collected from students in three strands; two reflective exercises which included a voice/text submission from each student interrogating their reflections on the site visits and summer school in general and an online survey which was circulated a week after the summer school ended. The students were asked to either provide responses as voice notes or text-based responses (typed or handwritten) – any of these formats were acceptable in line with Universal Design Principles (Novak & Bracken, 2019). For the purposes of considering the effectiveness of the summer school, responses to the student survey are presented. The team are also proposing to thematically analyse the reflective responses to better understand the overall student experiences, but due to length limitations, these will not be included in this paper.

3 FINDINGS

Students were invited to answer questions relating to their overall experience of the summer school and how it was organized, their views on whether they had met the learning outcomes and also on which skills they have developed during the school. Responses to these questions used a 5-point Likert scale with possible responses which ranged from "Strongly Disagree" to "Strongly Agree". Figures 2 to 3 indicate the overall responses from nineteen students involved in the programme who responded.

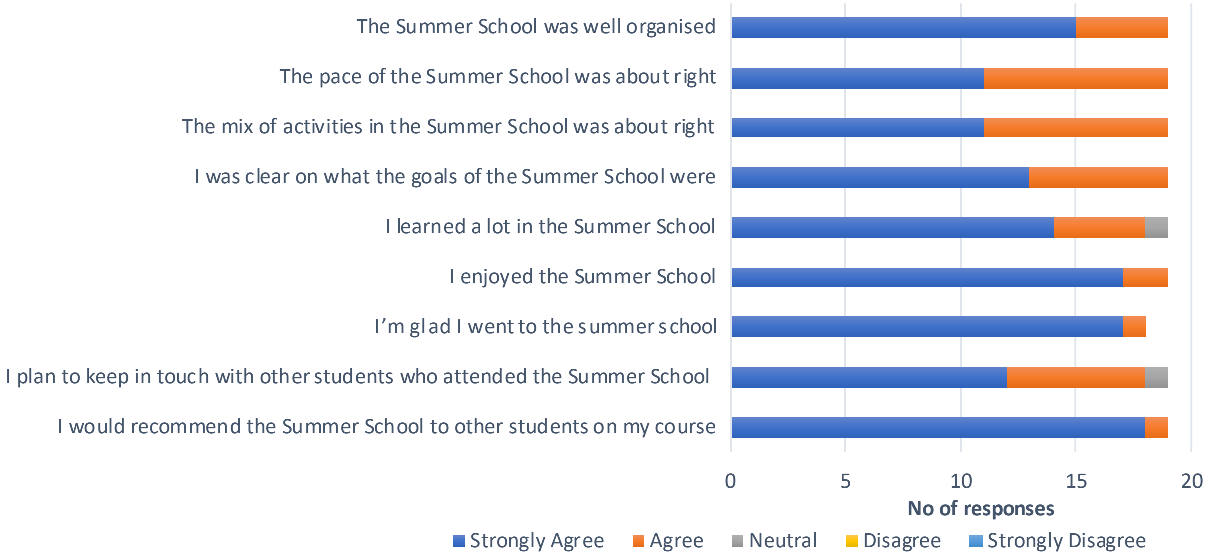

Fig. 2. Responses to survey questions on organisation of summer school and overall experience. (Note one student did not answer one question)

It is clear that the overall feedback from the summer school is positive, with students mainly strongly agreeing or agreeing that the summer school was well organised. There were some indications that the pace and the mix of activities were not ideal for all students, however, nineteen (eighteen ("strongly agree") and one ("agree")) students would recommend the summer school to others. Overall students enjoyed the summer school and were clear on what its goals were. Eighteen out of the nineteen students who responded indicated that they had learned a lot in the summer school with one student remaining neutral on this response.

For the most part, students felt they had achieved the nine learning outcomes associated with the summer school, with a "strongly agree" or "agree" rating for five of the learning outcomes as shown in Table 1. It is worth noting that across all learning outcomes, the majority of students broadly "agree" or "strongly agree" that they achieved them. Further, no student indicated "disagree" or "strongly disagree" for any of the learning outcomes. Two learning outcomes had the highest number of "strongly agree" responses: the appreciation of similarities and differences of different cultures and the learning outcome relating to collaborating with students from diverse backgrounds.

Table 1. Student response scores on achievement of learning outcomes

Learning Outcome	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
Explain the SDGs and the principles of sustainable development	11	8	0	0	0
Describe SDG 12 and the concepts of sustainable consumption and production	13	6	0	0	0

Appreciate the importance of R&D in developing solutions for carbon-neutral transport technologies	11	5	3	0	0
Apply the concept of the circular economy to an engineering problem	13	6	0	0	0
Calculate my carbon footprint.	11	5	2	0	0
Better communicate and present	13	4	2	0	0
Collaborate with students from diverse backgrounds	15	4	0	0	0
Appreciate the similarities & respect differences in how people from diverse cultures perceive things	15	4	0	0	0
Be more aware of my reactions in conflict and communication style	11	7	1	0	0

Only four learning outcomes received any neutral response as to whether the students felt they had achieved the learning outcome. These related to: appreciating the importance of R&D, calculating a carbon footprint and better communicating and presenting and being aware of reactions in conflict and communication. The research team discussed the findings seeking to unpack why these few neutral responses were provided. Two site visits were organized to companies which are working on research design and manufacture of carbon neutral technologies (real world experiences). One of the site visits included a long tour around a large manufacturing facility and it was difficult to hear the tour guide discuss the technologies at certain times. It may have been better to organize a short presentation from the company prior to the tour, in order to emphasise the company approach to research and development of technologies. A presentation was provided in the second tour, which was appreciated by students and noted in their reflections. The exercise to calculate one's own carbon footprint (thinking and acting for the future) was undertaken on Friday morning at the end of the week and was only allocated 1 hour. The research team considered that perhaps the students were tired at this point and going forward, it is recommended that either this activity is moved to a different time in the week or removed completely.

The final survey question related to student perceptions of being able to develop their skills. Overall, there is a positive indication from students that the summer school was effective in developing all five of the skills noted, particularly an increased awareness of intercultural skills and developing skills to work in a team as shown in Figure 3.

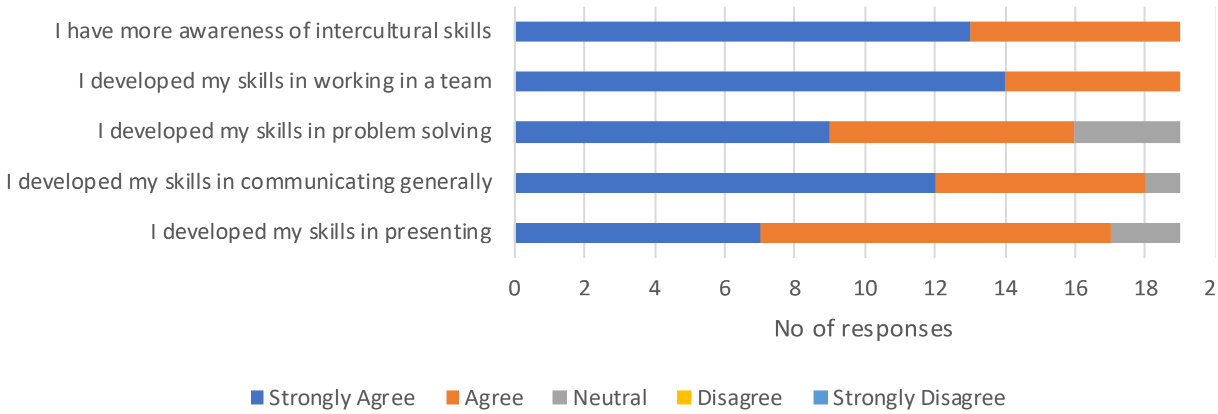

Fig. 3. Responses to survey questions on "What was your experience of being able to develop your skills during the summer school?"

The majority of responses were very positive (either "Strongly Agree" or "Agree"). A small number of neutral responses were received for the skills: problem solving, presenting and communicating generally. This may be explained by the fact that students were permitted to volunteer for presentation opportunities so perhaps not everyone availed of that opportunity through the duration of the summer school. There were no negative responses ("Disagree" or "Strongly Disagree").

4 DISCUSSION AND CONCLUSIONS

In response to the overall research question, "how effective was the Summer School from the students' perspective?", we can draw several conclusions. Students thoroughly enjoyed the summer school, felt it was well organised and would recommend it to their fellow students. They felt the pace and mix of activities on the programme was about right. There is evidence that the majority of students felt that all of the learning outcomes had been met, but particularly noteworthy were the learning outcomes related to understanding the SDGs, SDG 12, the circular economy and aspects of working with students from diverse backgrounds and appreciating intercultural differences. Learning outcomes which were slightly more difficult to achieve for all students related to "Appreciate the importance of R&D in developing solutions for carbon-neutral transport technologies", "Calculate my carbon footprint" and "Better communicate and present". Detailed instructions on how the summer school was designed and facilitated are included on the PROFESS 12 website and are freely available for use.

The evaluation exercise also provided feed forward advice for the next iteration of the summer school. Whilst the overall outcome of the summer school was successful, there are some areas for consideration in designing summer schools in general.

- Energy levels were low at the end of the week and students were not as receptive to learning due to tiredness or overstimulation. The recommendation for the next iteration is to allow some down time for students to rest or explore the local areas in their own time to enhance their cultural understanding.
- An introductory presentation on the nature of site visits and the work of the company, outlining what students are likely to see during the visit is invaluable.

- We identified some barriers to engagement for women who were restricted from attending due to childcare responsibilities or work commitments. In future, considerations should be given to providing some funding towards childcare arrangements or to explore the possibility to attend on a part time basis or participate in some elements remotely (i.e. daytime only or non-residential options). This may necessitate that some aspects of the school are designed as core and mandatory.

The research questions sought to examine the effectiveness of the summer school and provide feed forward advice for the next iteration, however it is also interesting to reflect on how a summer school initiative such as this can influence further change within a University. It is clear that systemic change at the organisational level is required in order to fully address the gaps in our engineering educational system (Kolmos et al. 2016), however, it is acknowledged that systemic changes encounter challenges. The three curriculum response strategies, “add on strategy”, the “integration” strategy” and the “rebuilding strategy”, all require different levels of engagement with university management, external companies and society (Kolmos et al 2016). This pilot project is an example of the “add on strategy” as it was an elective for interested students without academic credit. Further, it was initiated by interested academics, early adopters hoping to lead change within the department. However, it is recognised that systemic change requires support from a top down and bottom up approach. Recent strategic plans in both Universities recognise the importance of Education for Sustainable Development (top down influences) and it is intended that piloting of the summer school will give confidence to the lecturers involved to become change agents and to incorporating these activities more widely in the curriculum (bottom up influences). The challenge lies in transforming the learning opportunities from this summer school into reimagining the entire curriculum within each University.

It is also interesting to reflect on the effectiveness of the different pedagogies used in the school. Students appreciated the site visits where they were able to engage with real world experiences and the workshops where they had the opportunity to investigate aspects of sustainability themselves (self directed learning). Of particular note in student reflections, were two activities: the circular economy workshop and the Majoria Minoria activity. In the circular economy, students were introduced to the topic and asked to reimagine and design a product (food packaging, makeup container, desk chair) using circular economy principles. This was an example of situated learning which is oriented towards behavioural change as a result of reflecting on the experience of activity (Chernyshova and Tokmylenko 2020). Several students reflected on how this exercise made them think about and take note of how everyday things are manufactured (future thinking).The Majoria Minoria exercise was a role play in which members from a rich country and a developing country needed to negotiate. This activity was also identified by students as being very effective in developing an awareness and better understanding of different perspectives. Thürer et al. (2018) highlight in their systematic review that lecturers should develop approaches to learning and teaching that consider the role of values and assumptions in decision making and this role play is a good way to engage students in that type of activity.

Finally, Thürer’s et al. (2018) systematic review raised a further research question: How can faculty be motivated to integrate sustainability into the curricula? Our intention in the design and roll out of this summer school was to pilot this initiative on a small scale to build confidence in our design and delivery and to ignite a wider integration of EESD into the overall curriculum. We hope that the resources provided on our website can be used by other educators to ignite similar reform strategies in order to move from small to large scale implementation, or rather from an add on strategy to an integration, or full-scale rebuilding strategy to enhance engineering curricula to prepare our students to solve the sustainable development challenges we currently face.

ACKNOWLEDGEMENTS

We would like to acknowledge the HEA, DFHERIS and the Shared Island Fund for support of this project under the North South Research Programme. We would also like to thank all students who were involved in the summer school for their engagement and open and honest feedback and the companies who hosted the site visits.

ABSTRACT

Science and technology have the potential to profoundly transform societies. Employed within a logic of innovation, they disrupt the reference points and values needed to judge and act. This raises several ethical risks, notably the inability to know clearly whether a specific process or technical invention will raise moral issues. Because of their involvement in the design of new technologies, engineers of all specialties are the first to be exposed to this disturbing and unpleasant situation. It therefore seems essential to develop ethics training programs for this specific audience. The Prometheus Challenge is one such proposal. Inspired by the methods of active and creative pedagogy, this two-days training aims to develop awareness of ethical issues, reflexivity, and autonomy in judgment. It also fosters the ability to formulate appropriate ethical assessments of science and technology problems through collective debate. It has already been tested with four groups of students from

T. Ménissier
thierry.menissier@univ-grenoble-alpes.fr

several engineering schools in Grenoble (October 2022 and February 2024). The feedback from students and facilitators is mostly positive. They praise the interdisciplinarity made possible by the mix of students from different backgrounds and the presence of various facilitators trained in ethics. They also appreciate the alternation between theoretical content and debate time, that raises awareness about ethical issues and allows them to reflect on their future engineering profession.

1 INTRODUCTION

Ethics is recognized both as a graduate attribute and a professional competence in the ENAEE (European Network for Accreditation of Engineering Education) and IEA (International Engineering Alliance) guidelines, which represent engineers in 35 countries globally. Indeed, teaching engineers about ethics is crucial for several reasons. First, choices relating to sciences, technologies, and public policies must be ethically justified, i.e. by considering socially accepted and defensible values in the context of public debate. Second, the favorable image of positivist rationalism, which has prevailed since the nineteenth century, is now in decline. Trust in science and technology is being challenged due to past industrial disasters and reactions to the current environmental crisis. This public distrust is also reinforced by the fact that engineering is often subject to a logic of productivity and profitability, relegating ethics to the background. Finally, the continuous technological innovation disrupts uses and ethical points of reference that are needed to judge and act. This raises questions about the practical application of ethics by scientists and engineers. Hence, it seems essential to propose ethics training specifically adapted to these professions and integrated into their training curriculum. This is the goal of the Prometheus Challenge, a teaching method invented by Prof. Thierry Ménissier (philosophy, Université Grenoble Alpes) (Ménissier 2022).

Based on an active and creative pedagogical approach, the Prometheus Challenge aims to develop awareness of ethical issues, reflection, autonomy of judgement, and the ability to formulate appropriate ethical evaluations for the problems posed by the design and use of technologies through collective debate. It also aims to provide philosophical knowledges adapted to current ethical issues and moral dilemmas encountered in the different fields of science and engineering.

By invoking the name Prometheus, we wish to express that today’s engineering students potentially find themselves in the situation experienced by the titan of Greek mythology. This legend is related by Hesiod in his Theogony: Prometheus gave fire to humans after stealing it from the Olympian gods. This present, fire, the symbol of technical intelligence, turns out to be ambivalent. While it is an effective means of transforming matter, it is also potentially destructive and dangerous if left unchecked. Moreover, the myth tells us that the possession of fire carries the risk of fostering what the ancient Greeks called hubris: a propensity for excess and violence, which can lead to uncontrolled and potentially destructive behavior for the individual and society. The myth of Prometheus therefore seems to contain a warning about the dangers associated with the use of technology and the risks inherent in its advances. The exploitation of technical tools, the acquisition and domination of technical knowledge, as well as the development of technological and scientific power, represent major challenges for humans. Some psychoanalysts even go so far as to speak of a deep and insurmountable guilt, described as "Promethean guilt" (Azar

2015). This myth has resurfaced in popular culture with remarkable force, recurrence and fecundity, whether through novels since Mary Shelley's "Modern Prometheus" (Shelley 1818), or more recently in mainstream films, such as the Prometheus of Ridley Scott in 2012. These numerous revivals reflect the importance of the myth of Prometheus for our time. Today's scientists and engineers are faced with the challenge of mastering powerful science and technology, with effects that are often ambiguous and potentially disturbing for society and nature.

In this article, we wish to present the context and method of this training. Then, we will analyze the sessions organized up to now to reflect on how best to promote ethics training in the scientific and engineering community.

2 BACKGROUND

The Grenoble area is a major center for research and innovation, sometimes referred to as "Europe's Silicon Valley". It boasts numerous cutting-edge infrastructures, including the European Synchrotron Radiation Facility. Grenoble Alpes University is also a major center for technical and scientific training. In particular, it is home to the Grenoble Polytechnic Institute (Grenoble INP), which groups together 7 engineering schools and 1 management school. Including the integrated preparatory cycles, Grenoble INP welcomes over 8,000 students and awards around 1,500 engineering diplomas per year.

In 2022 et 2024, Grenoble INP organized the Kaleidoscope week: an event meant to bring together students from different schools during several educational workshops. Each student had the opportunity to choose from about fifty different activities, including the Prometheus Challenge. This challenge was proposed and supervised by members of the Ethics & AI chair of the MIAI Institute (Multidisciplinary Institute in Artificial Intelligence), one of the 3 French research institutes in artificial intelligence. We also relied on the tools and methods developed by Promising, the pedagogy and creative thinking department of the university.

3 THEORETICAL AND METHODOLOGICAL FRAMEWORK

3.1 Theories at the service of practice

The Prometheus Challenge is scheduled to last 2 days. It is divided into a series of nine modules, listed in Table 1. Its purpose is to make students practice ethics. It is based on an active problem-solving pedagogy where theory is necessarily linked to practice.

The training begins with workshops to raise student’s awareness of the ethical issues associated with engineering professions (modules 1 to 4). During module 5, we present four distinct forms of reasoning used to address moral problems[2] : Kantian deontologism, Bentham’s utilitarianism, Aristotelian virtue ethics and axiology. After a short presentation of these forms of reasoning, students are invited to implement them on a topic of their choice to test their differences and limitations.

---

[2] Deontologism, Utilitarianism and Virtue ethics are the normative ethics theories more commonly studied, see (Billier 2014) or (Downs 2012). Axiology (theory of values) was added, since it is particularly well suited to tackling ethical challenges.

The choice of these theoretical currents responds to a methodological concern: since ethics is not an absolute value and ethical judgments may vary, we choose to appeal to different schools to account for the different possibilities of reasoning. The Prometheus Challenge thus demonstrates an assumed eclecticism.

In addition to the four forms of reasoning mentioned, two theoretical elements that are particularly important for ethical reflection are also mentioned: the notion of responsibility and that of value. The notion of responsibility is introduced through the figures of Prometheus, then that of Frankenstein (introduction to the challenge and module 3), to raise the consequences of actions undertaken in the name of technology and science. Indeed, these two literary figures open the door to a reflection on the anticipation of rebound effects and the long-term perspective of the practice. Then, the work on values (modules 6 and 7) allows us to return to the foundations of philosophical reflection on morality and its norms. Values, which are strongly rooted in culture, are intuitively mobilized to address morally problematic situations. A work of reflection on values, justification, and hierarchy allows us to take a step back from this intuitive level, to register on a critical level (according to Richard Hare's distinction (Hare 2017)) and thus refine the ability to make ethical judgments.

Table 1. Modules' descriptions

Modules	**Description of the activities carried out by the students**	**Duration**
Identify ethical situations and make recommendations		
1) Ethical risks	Choose a technology that raises risks. Identify those that fall under ethics. Formulate recommendations to mitigate these risks.	30 min
2) Cases of conscience	Imagine an example of an ethical dilemma that an engineer may face. Describe possible solutions.	30 min
3) Frankenstein's responsibility	Identify examples in history or current events of rebound effects that are harmful or dangerous for humanity. Formulate recommendations to frame/regulate these effects.	30 min
Imagining desirable futures		
4) Utopia or dystopia	Using a recent (or future) technology, imagine an ideal society. Represent it graphically.	1h-1h30
Enriching Ethical Reasoning		
5) Ethics beyond utilitarianism	Analyze the dilemmas identified above from the perspective of different forms of ethical reasoning (utilitarianism, deontologism, aretaism, axiologism)	1h30-2h
Reflect on the ethics of your profession		
6) Engineer's values	Identify a list of values that can be claimed by engineers.	45 min
7) Value cards	Depict the most important value(s).	45 min

8) Engineer's oath	Prepare a solemn declaration committing to respect the above values.	1h-2h
9) What's next?	Imagine what actions can be implemented at the end of the training.	30 min

3.2 An active and creative pedagogy

The pedagogical challenge of this training is to transmit knowledge in ethics that can be used to address complex situations. To achieve this, we rely on an active pedagogy based on creativity and emotion. We take into account the three strategies proposed by (Vanpee, Godin, et Lebrun 2008) for implementing active teaching in large group: 1) placing the student in an active situation based on global and complex tasks; 2) splitting up the groups; 3) encouraging the transfer of learning by implementing contextualized teaching. Each theoretical content is followed by group application exercises, based on concrete cases proposed by the facilitators and by the students. The modules on ethical risks and cases of conscience (modules 1 and 2) allow a step back on the social dimension of the engineering profession, particularly concerning technological innovation. Then, the participants are engaged in a reflection on the potential unforeseen rebound effects related to scientific development (module 3), and next to formulate ethical assessment, based on the work on values (modules 6 and 7).

This teaching strategy aims to include the three main factors that encourage student commitment, acording to (Viau 2009). First, a sense of value of the activity is created by contextualising it to the students' future profession. The second factor is controllability, which refers to the potential control that students have over the course of the activities proposed to them. Since the students themselves choose the subjects on which they work, the sense of controllability is very high in the Prometheus Challenge. The final factor is the sense of competence to complete a task, which is facilitated by providing them with the key elements (theoretical content, support) so that they can carry out the activities required.

In this way, students are led to develop reasoned points of view that are subject to a rational, collective and supervised discussion. Here, the role of facilitators is essential. They are responsible for guiding discussions during the group reflection process and then in plenary. This follow-up makes it possible to clarify the theoretical elements covered and to highlight the students' mode of reasoning. Facilitators must then be able to adapt their knowledge of ethics to the problems proposed by the participants during the workshops.

In addition, the Prometheus Challenge calls for creativity, assessment, and emotion to promote ethical sensitivity and the appropriation of theoretical concepts. Creativity and assessment are at the top of Bloom's taxonomy of educational objectives, because they foster learning that lasts (Anderson et Krathwohl 2001). Emotion is also an important variable in the learning process (Puozzo 2013) since there is a "close relationship between the content of an idea and the affective dimension to which it is attached" (*Ibid.*). In the case of the Prometheus Challenge, a real work on emotion is required from all the participants. From the very beginning of the training, the facilitators have to create an atmosphere that makes students willing to work collectively, to listen and to be open to each other. Since the participants don't know each other, each half-day starts with a few minutes of warm-up and ice-breaker activities. The body is engaged by vocal exercises or by movements where the awareness of others is important (for example: walk in a defined area and follow changes of pace).

Regarding the content, the modules are introduced with mythical narratives, literary and historical references with strong symbolism, to question the engineering profession, its potentials, and its risks. Group exercises seek to deepen this emotional work, engaging the creativity of the students. It is also an opportunity for them to engage in activities that are rarely present in their usual curriculum, such as drawing or theatrical performance. In particular, the modules on utopia (module 4), values (module 6-7) and engineer's oath (module 8) lead students to imagine the potential of their profession, as well as the possible contributions they can make, by giving free rein to their imagination. Examples of their creations are showed in Figure 1.

Fig. 1 Examples of student creative productions.
On the left, module 4 (utopia). On the right, module 7 (value cards).

4 RESULTS

For its first edition at Kaleidoscope Week (October 2022), the Prometheus Challenge took place over two sessions, with a total of 175 participants. In February 2024, the second edition took place, with 53 participants also spread over two sessions[3]. We collected the participants' feedback over the two years through an online survey filled at the end of the training (module 9). The first part of the survey contains several closed-ended questions regarding the session of the challenge, school of the student and overall assessment. The second part of the survey consists of three open-ended questions: strengths of the training, weaknesses, and suggestions for improvement.

We received 107 responses in 2022 and 46 responses in 2024. There are no substantial differences between the first and second editions, nor according to the schools from which the participants come from.

The overall assessment of the activity is positive, with an average of 4.4/6, on a scale where 4 corresponds to "satisfactory" and 5 corresponds to "very satisfactory"

[3] This year we see a lower number of students, partly because in 2022 several schools have asked their students to choose an activity on ethics. This year it was no longer the case.

(see Figure 2). Among the strengths identified by the respondents in both parts of the survey, we can mention the plurality of the discussions (favorized by the instruction to create groups between students from different backgrounds), as well as the balance between theory and practical work.

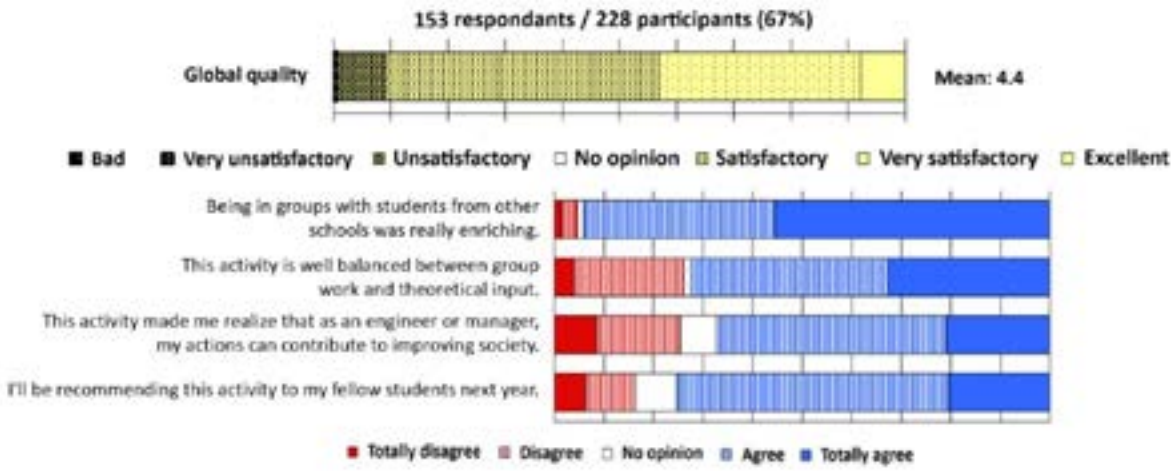

Fig 2. Student survey results (2022 and 2024)

While answering the open-ended questions, the students mentioned four other positive aspects: the theoretical contributions in philosophy (9 mentions for the year 2024, out of 46 responses); the role played by the facilitators (7 mentions in 2024), whose relevance of their interventions and varied backgrounds are appreciated ("supervisors who get out of the habit", "Interventions by philosophy professors"), as well as reflexivity on the engineering profession ("open-mindedness and reflection on our future actions") and the pedagogical approach integrating collective debates.

These elements seem significant, since they are then found in the participants' proposals. For the 2024 session, 7 people expressed that they would have appreciated more theoretical or philosophical elements. In addition, the role of the speakers is also mentioned 7 times in 2024, but this time concerning their support for the groups and their feedback on the activities carried out, as a point to improve or a weak point ("Make more visits to the groups"). These remarks seem to us to underline the involvement of the students in the exercises. In 2024, 4 students proposed to increase debate times.

Overall, the pedagogical objectives seem to have been achieved. We interpret the requests of some participants for more philosophical content and time for debates as a proof of success in raising awareness of ethical issues. Exchanges within each group and plenary discussions allowed us to see an appropriation of the theoretical content. Among the points for improvement, we recognize the importance of strengthening exchanges between student groups, an important moment for clarifying the ethical concepts.

5 CONCLUSION

Active pedagogy is the key to success for the Prometheus Challenge. By alternating the transmission of theoretical knowledge with practical collective work, in a creative and welcoming atmosphere, it allows an open-mindedness that is conducive to ethical reflexivity. The challenge is experienced by the participants as an enrichment and a valuable opportunity to reflect on their future engineering practices. The post-challenge survey analysis shows their engagement and satisfaction. It must be underlined that the role of facilitators is crucial. While transmitting philosophical theories, they must continuously adapt to the participants by clarifying the concepts to their understanding and integrating their topics of concerns, thus strengthening their involvement and interest in the challenge.

The Prometheus Challenge places animation at the heart of its innovative pedagogy by offering a continuous and complete training process to participants. After completing the training, each participant has the possibility to become a facilitator. To obtain the facilitator certification, a candidate needs to participate in a 6-hour preparation seminar and to accompany a complete cycle of the challenge as a co-facilitator. They can then join the team of facilitators, a think tank that contributes to improve the challenge, exchange best practices, and develop their skills in ethics. This ongoing training process ensures respect for the values of democratic inclusion defended by the first creator of the challenge. It also promotes the renewal of the team of facilitators, whose expansion and diversification allow to reach an increasingly wider public.

Although originally proposed for engineers, the Prometheus Challenge has been designed to be easily adapted to other audiences. A double transformation can be carried out: the modification of the initial myth and the choice of suitable examples, without upsetting the order of the modules. A version for management students could be based on the myth of Midas, which describes the curse that befalls the ruler of Phrygia, punished by Dionysus for wanting to accumulate too much money. A version oriented towards environmental ethics has been tested and named by the students from the myth of Persephone, which evokes the regular return of the seasons. In these modifications, the initial myth plays the same role as that of Prometheus: to provide an imaginative and emotional basis that engages the participants in ethical reflection.

ABSTRACT

In this paper, we present the development and evaluation of an online quiz system designed to enhance learning outcomes in multivariable calculus (MC) for engineering students. MC is crucial for understanding various engineering disciplines but often poses challenges due to its abstract nature. The quizzing system integrates formative and summative assessments, drawing on cognitive psychology research, and aligns with educational principles emphasizing active learning. Results indicate a positive correlation between engagement in practice quizzes and graded quizzes scores, supporting the system's effectiveness in improving student performance. However, student feedback suggests areas for improvement, particularly in quiz randomization and feedback adaptiveness. The study underscores the importance of integrating technology-enhanced learning tools into mathematics education, offering insights for future refinement and implementation in engineering curricula.

1 INTRODUCTION

Multivariable calculus (MC) is a core course in the mathematical curriculum of engineering programs, offering a crucial mathematical framework for the analysis and resolution of complex problems across a spectrum of engineering disciplines. This course builds upon the foundational knowledge acquired in introductory Calculus, extending mathematical concepts to multiple variables and enabling engineering students to model problems more accurately. MC is essential for the mastery of fundamental subjects such as thermodynamics, kinematics, and fluid mechanics, which are integral to the engineering discipline.

However, despite its critical importance, MC poses significant challenges to engineering students as concepts are built up sequentially, requiring sufficient proficiency at each step. MC is frequently experienced by students as a challenging and abstract course, which can lead to frustration and disengagement. In response to these challenges, we developed a structured online quizzing system, incorporating both formative and summative elements, based on research insights from cognitive psychology and in alignment with the institution’s vision on education and assessment. The aim of the study presented in this paper was to evaluate the impact of the Quiz System on student performance and their subjective learning experience.

1.1 Theoretical and Practical Underpinning for the Quiz System

The act of (repeatedly) recalling previously learned information from memory has been proven as a robust effect to enhance learning and long-term retention (Agarwal et al., 2021; Rowland, 2014). This phenomenon is also referred to as the *testing effect* or *test-enhanced learning* (Roediger & Karpicke, 2006). Studies exploring this effect in the classroom showed that weekly quizzes improve end-of-course test performance (e.g. McDaniel et al., 2007). In the context of calculus courses specifically, research suggests that practice testing benefits within-semester retention (Lyle et al., 2020; 2022). Researchers attribute the impact of this phenomenon to the fact that (repetitive) practice testing requires active, recurring engagement with the material and promotes deeper processing (Dunlosky et al., 2013). Though, studies so far often take place in a laboratory or controlled setting. Therefore, it has been stressed that further investigation is required on how to establish the power of practice testing in authentic educational settings (Dunlosky et al., 2013).

Corresponding with these research insights, the education institution's vision on education focuses on a student-centred teaching method that promotes active learning, emphasizing four learning principles: constructive, contextual, collaborative, and self-directed learning (CCCS). Within this framework, the quiz system plays a crucial role in fostering self-directed learning. It encourages students to plan, monitor, and evaluate their own learning process by engaging with the practice questions (PQs), possibly improving student learning (Gaspar Martins, 2018). Regarding assessment, the institution highlights a balance between assessment for formative evaluation and summative decisions.

In this line of reasoning, the PQs allow students to check their understanding of the subject matter at any time and as many times as they want. Moreover, the answer-dependent feedback is necessary and timely, allowing students to update their learning trajectory. The final question of each quiz asks the student to estimate how many questions they got right, providing a reflective moment in each quiz. In addition, the weekly graded quizzes (GQs) spread out the summative decision over multiple and frequent insights into student learning, obtained in a low-stakes environment. All in all, the quiz system as investigated in this study is built on a robust framework from both a theoretical as well as a practical perspective on student learning.

1.2 Research Context: Multivariate Calculus

Multivariable Calculus is an intermediate-level mathematics course of 5 ECTS in the BSc Circular Engineering at the institution where the research was conducted. The course had 59 students and was taught in period 5 (April-May) of the first bachelor year, alongside Thermodynamics, building on the prerequisite courses Calculus and Linear Algebra, which are taught in Period 1 and 2, respectively. The course was divided in seven modules focusing on: 1) vectors and the geometry of space, 2) infinite sequences and series, 3) partial derivatives, 4) vector-valued functions and motion in space, 5) optimization, 6) multiple integrals, and 7) integrals and vector fields. Each module featured one lecture and one or two tutorials, in which 12-15 students come together for interactive group sessions. While tutorial attendance was mandatory, lectures were not. Pre-lecture and pre-tutorial tasks helped the students to prepare for the content of the lectures and tutorials.

The course featured assessment components for formative evaluation and summative decisions. The assessment for formative evaluation included two voluntary ungraded components: a prerequisite quiz at the start of the period and PQs, which were aligned with the GQs. The assessment for summative decisions includes three mandatory graded components: a closed-book written exam (70%), a team assignment (15%), and weekly GQs (15%). The components were weighted into a numerical grade on a scale from 1 to 10, with 10 being the highest possible score and 1 the lowest. A bonus point could be earned by making the pre-requisite quiz and the pre-lecture and pre-tutorial tasks. The course is developed and hosted on the Learning Management System CANVAS.

2 METHODOLOGY

2.1 Mixing Formative and Summative Assessment: Repeated Practice and Graded Quizzes

For each module, we introduced topic-aligned PQs and GQs where students had the flexibility to attempt the PQs multiple times and receive fast automatic grading and instant feedback, in line with existing systems (Greenhow, 2015; Lowe, 2015; Marjoram 2013). The feedback mechanism is tailored based on the accuracy of the response: incorrect or partially correct answers prompt the delivery of hints or partial solutions to guide the student, while correct answers are met with a "validation" response, providing a detailed, worked-out solution. Questions can also feature neutral information that is provided regardless. Our strategy aims to enhance the formative and feedback-driven aspect of the PQs. Similarly, the GQs follow this feedback-centric approach, with the key distinction that they can only be attempted a single time. Students decide themselves when to move on from PQ to GQ, in line with self-directed learning principles, see Fig 1.

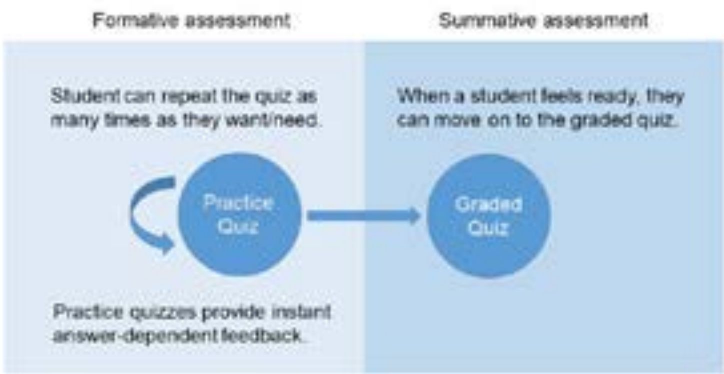

Fig. 1. Successive, topic-aligned practice and graded online quizzes fit the UM vision on assessment, combining formative and summative components, and encouraging students to take ownership of their learning by letting them decide on when they feel ready.

This PQ-GQ combination is repeated weekly for the whole period, creating multiple “low”-stake assessments that feature both a formative and summative component. This approach aims to nudge the students to “stay on track,” see Fig 2.

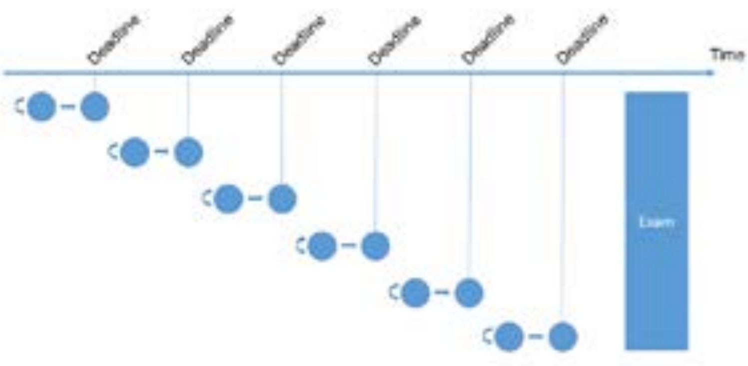

Fig. 2. Multiple, frequent, “low”-stakes practice quizzes and “mid”-stakes graded quizzes with instant answer-dependent feedback build up to the final exam in this course. Multiple, clearly communicated deadlines nudge students to stay on track throughout the period.

2.2 Meaningful Retries: Randomization, Parametrization, and Diversification

PQs with unlimited retries requires each retry (or at least the first few retries) to be meaningful for the learning experience. If the quiz is static, i.e., it remains the same after every retry, then students will not be incentivized to retry multiple times. If the quiz, on the other hand, is *dynamic*, i.e., it changes after every retry (in a reasonable way), then students are nudged towards multiple retries, which can positively affect their learning experience. In order to make multiple retries meaningful, we use three guiding principles: 1) randomization, 2) parametrization, and 3) diversification.

2.2.1 Randomization

The teacher constructs a quiz in Canvas by choosing questions from item banks. Questions banks are tied to a specific Intended Learning Outcome (ILO) allowing teachers to choose which ILOs can be assessed in a particular quiz, see Fig 3. Instead of choosing a particular question in an item bank, we randomly pull a question from each item bank, making each quiz unique. It is crucial to have sufficient questions per item bank to make the quizzes sufficiently randomized. Given time constraints, we aimed to implement five questions per item bank. (The number of questions in an item bank can range between 1 and 10, but, *on average*, we have about five questions per item bank.) As an example, a quiz consisting of ten questions, drawing from item banks with five questions each, would have 5^{10} (i.e., about 10 million) possibilities.

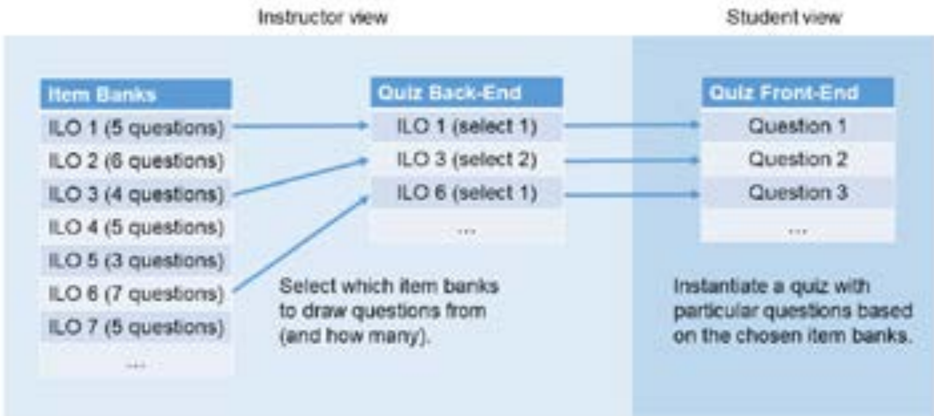

Fig. 3. Randomizing the quiz questions makes the quizzes more meaningful for the students. This is possible by using the item bank system in Canvas, drawing random questions in the back-end and generating unique instantiations for the student.

Randomization can make multiple retries more meaningful. In addition, PQs and GQs are constructed in the same way, hence, students are rewarded for attempting the PQs multiple times because it will allow them to maximize their score on the GQ. This of course has the downside that students can retry many times, pushing the limits of the system, to obtain more answers, thus the importance of parametrization.

2.2.2 Parametrization

Parametrization allows the construction of apparently unique quizzes. We achieve this by using the Canvas-supported formula question, which is a numeric-answer question that involves one or more parameters. One can set bounds on each of the parameters and number of decimals used. Based on these settings, a desired number of possible problems and corresponding solutions (with a margin of error) can be generated. In our question repository 110 out of 510 questions are parametrized, i.e., 21.6% of the repository. For example, consider the integral:

$$I = \int_a^b \int_0^{\sqrt{x}} \frac{y}{cx}\, dy\, dx \tag{1}$$

Where a, b, c are integers and bounded as $1 \le a \le 4$, $5 \le b \le 10$, and $1 \le c \le 10$. The solution of the integral is given by $I = \frac{b-a}{2c}$.

2.2.3 Diversification

We used a variety of Canvas question types to vary the experience of each quiz. Table 1 shows the question types used and their distribution. Multiple choice, multiple answers, formula, and numerical answer questions were mainly used because they are the most straightforward for mathematics-related topics.

Table 1. Distribution of question types in our item banks.

Question Type	**Amount**	**Percentage**
Multiple choice	210	41.2
Formula	110	21.6
Numerical answer	60	11.8
Fill-in-the-blank	41	8.0
True/False	31	6.1
Multiple answers	23	4.5
Matching	17	3.3
Categorization	12	2.3
Hotspot	5	1.0
Ordering	1	0.2
Total	**510**	**100**

2.3 Implementation

The quiz system consists of 510 quiz questions across 109 item banks with one to ten questions per item bank and on average five questions per item bank, where 110 out 510 are parametrized. The quiz system is implemented a separate course in the Canvas LMS system using item banks and quizzes. The course features information on the system so that other teachers can easily join, update, change, and expand the item banks and quizzes as they see fit.

We created item banks aligned with specific ILOs using a simple naming convention: topic – subtopic – concept, where the latter is optional, with a list of tags for ease of sorting. Sub-concepts are used to differentiate further if necessary. The topics correspond to the seven modules mentioned above. For example, the multiple integral module was structured in three topics: double, triple, and multiple integrals, and further refined as illustrated in Table 2.

Table 2. Example of the naming convention used for organizing the item banks in Canvas.

Double integrals	Rectangular coordinates	Computation
		Construction
		Order of integration
		Splitting
	Polar coordinates	Computation
		Construction
		Order of integration
	Substitution	
	Transform	Rectangular to/from polar

2.4 Data Collection

We collected course grades, a pre- and post- survey, and the default end-of-period course evaluations. The grades consist of multiple components: weekly quizzes, assignments, exam, and resit, and anonymized by the course coordinator. We also extracted metadata such as number of attempts, difficulty indices, etc. The pre- and post- survey took place in a tutorial at the start/end of the period, resp., but before the final exam. The surveys were administered anonymously via Qualtrics. The end-of-period course evaluations are also anonymous.

All students in the course (N = 59) were considered possible participants in the study. They were informed at the start of the course about the data collection. The assessment is an integral part of the course. Participation in the pre-survey (N = 46), post-survey (N = 45), and course evaluations (N = 11) are voluntary. No remuneration was provided. We received ethical approval by the institution’s ethical review committee to conduct the research. We omit the course evaluations because the number of submissions were very low.

3 RESULTS

3.1 Grade Analysis

Grade analysis indicates that students that engage more in the PQs tend to have higher GQ scores, see Fig. 4 (left). This makes sense as the PQs and GQs draw from the same item banks. The effect on the final exam score is less clear, see Fig. 4 (right), which can be due to the (closed-book) exam having different question styles.

Rounded mean number of attempts on practice quizzes

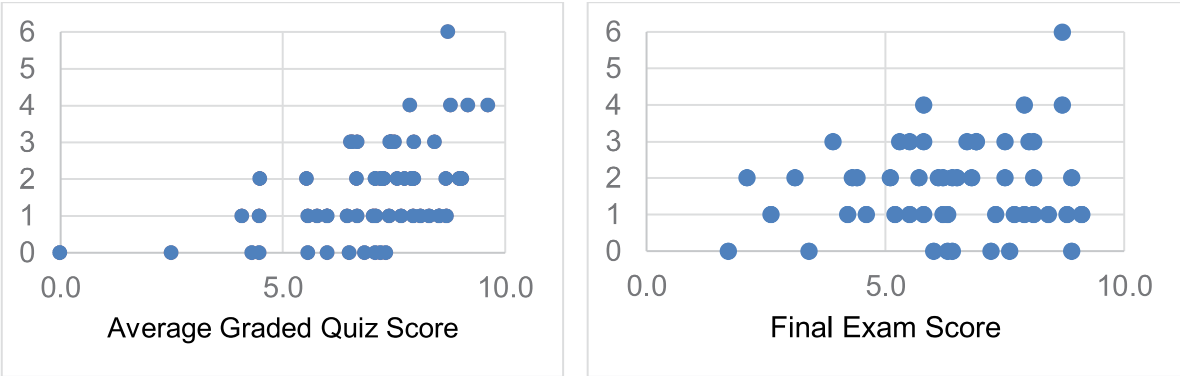

Fig. 4. Students that engage more in the practice quizzes tend to have higher average quiz scores, while the effect on the exam score less pronounced.

3.2 Survey Analysis

3.2.1 Practice Quizzes

The survey seems to support that students reported positively about the weekly PQs as a learning experience, Fig. 5, especially as a preparation for the GQs.

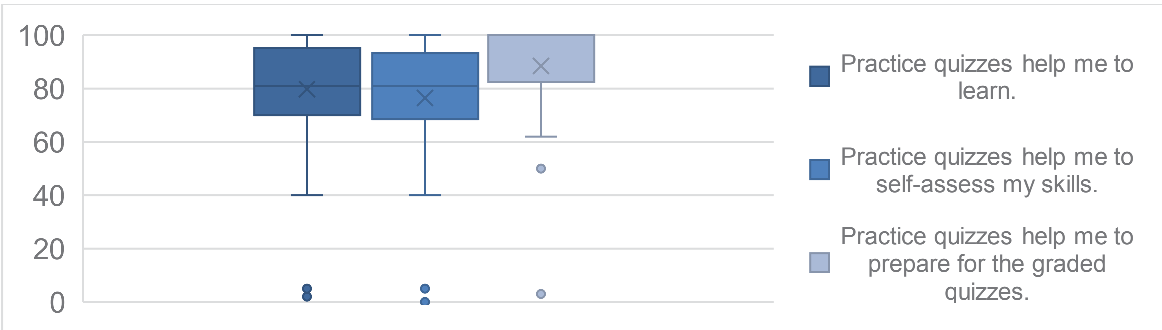

Fig. 5. Students experienced the graded quizzes as a helpful learning experience overall, especially as a preparation for the graded quizzes. Students indicated how much they agree with the statements on a scale of 0 (no agreement) to 100 (full agreement).

The responses to the open-ended question "*Why do you think the practice quizzes helped you to prepare (or not) for the weekly graded quizzes?*" indicated two main advantages of PQs. First, students reported that PQs can give a good impression of what to expect for the GQs: "They give us ideas on the types of questions that will be there and provide us with technique about how to approach the questions." Some students indicated that this could also have a perverse negative effect "…because most of the time they're very similar and so I do the practice quizzes so often until I understand them and then the graded ones are pretty easy." On the other hand, this can also be seen as a positive because at least they engaged a lot with the PQs. Second, students indicated that the PQs are a great revision tool: "I think the practice quizzes enable me to see what topics I need to review to take the graded quiz, and overall which topics I need to review for the exam." Another student mentioned: "It trains you on the kind of problems you need to prepare for in the graded quiz, it particularly helps with time management and acts as a reality check for acquired knowledge. It also incentivises you to revise questions that took longer to answer." Finally, students suggested possible improvements to the PQs: "It might be nice to have a randomized question (or two) from a previous section to help with interleaved learning. I would not necessarily suggest this for the graded quizzes though."

3.2.2 Graded Quizzes

The survey seems to support that students reported positively about the weekly GQs as a learning experience, see Fig. 6, but less so as a preparation for the final exam.

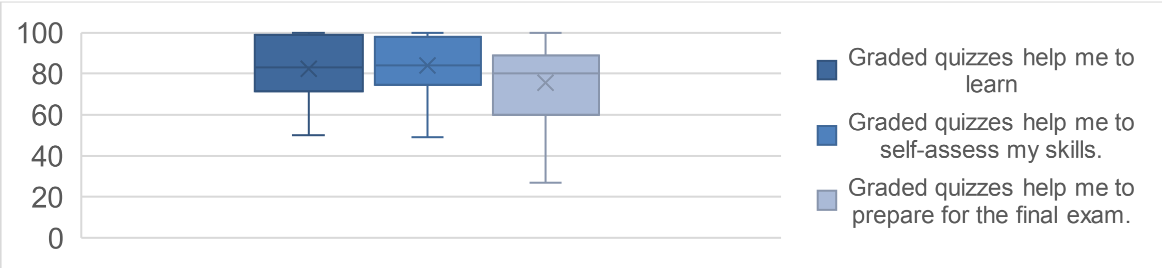

Fig. 6. Students experienced the graded quizzes as a helpful learning experience, but less so for the final exam. Students indicated how much they agree with the statements on a scale of 0 (no agreement) to 100 (full agreement).

The responses to the open-ended question "*Why do you think the graded quizzes helped you to prepare (or not) for the final (exam)?*" were mixed. On the positive side, students indicated that GQs helped them to stay on track ("They allow me to assess my progress throughout the period rather than having only the exam at the end as a final assessment. This means that throughout the period I can see how well I am doing and if there are any gaps in my knowledge.") and that they lowered the stakes of the exam ("They were helpful and since they count for credit they also take a little bit of pressure off."). On the other hand, students reported their concern about a possible difficulty gap between the GQs and the final exam: "I think the graded quizzes allow me to see where I am at in understanding the material, and where I need to review. I am concerned the exam will be a lot more difficult than the graded quizzes, as I imagine the questions will cover multiple topics." and "I feel like only some questions from graded quizzes can reach exam level difficulty. However, they are good to get a decent base on the subject to be able to tackle difficult questions."

3.2.3 Randomization and Parametrization

The survey indicates that randomization and parametrization can be improved, see Fig 7. Students' responses to the question "*Were the quizzes sufficiently randomized and parametrized?*" were mixed. While some students found the quizzes sufficiently randomized, others argued the contrary: "They weren't very randomized, you had to do the quiz more than five times to get the full range of questions, doing it twice often just gave you the same questions. Also, the answer dependent feedback was not very helpful. It would be better just to explain the correct worked out solution." This is because item banks have between 1 and 10 questions; some banks need more questions to improve the randomization. Interestingly, students were also critical about the *need* for randomization in the GQs: "I don't believe they should be randomised because I think it is unfair that all students are given a different quiz that contributes to their final grade, when some questions could be 'easier' to different students and that means that it doesn't feel good."

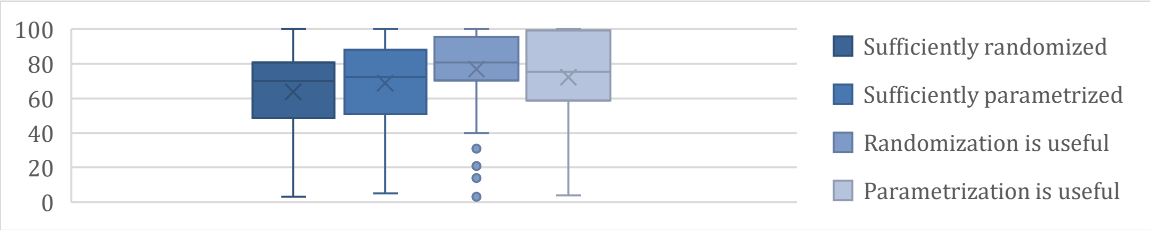

Fig. 7. Students' experience regarding randomization and parametrization was mixed. Students indicated how much they agree with the statements on a scale of 0 (no agreement) to 100 (full agreement).

3.2.4 Answer-Dependent Feedback

The survey indicated some dissatisfaction with the strategy for answer-dependent feedback, e.g., "Please give the worked out solutions to the questions regardless of if we get the answer right or not." Some students seemed frustrated when they got the answer wrong, and the feedback only gave a hint on how to continue instead of a fully worked-out solution: "I would prefer if the practice quizzes on the answers you got wrong give you more details for what you got wrong." Indeed, feedback should be more adaptive and personalized, but we are limited by the LMS' functionality.

4 SUMMARY AND ACKNOWLEDGEMENTS

The aim of this project was to develop a repository of questions that are aligned with ILOs of MC. Our approach featured weekly PQs and GQs with answer-dependent feedback. Randomization, parametrization, and diversification creates a unique student experience per quiz attempt. The quiz system is constructed so that it can easily be used and expanded by other teaching staff. Weekly GQs provide multiple "low"-stakes tests with instant-answer dependent feedback, nudging students to stay on track (Dunlosky et al., 2013). The PQs lowers the stakes of the GQs, providing additional scaffolding and increasing self-directedness. The approach is aligned with the institution's vision on assessment, providing multiple, frequent, and "low" stakes formative and summative assessments. Future work involves further randomization and diversification, the introduction of interleaving and improved feedback.

This project was funded by the Learning & Innovation Grant on "Testing is Learning: Using Randomized, Parametrized, and Diversified Online Quizzes with Answer-Dependent Feedback in Multi-Variable Calculus for Engineering Students."

ABSTRACT

We present the design, development, and evaluation of an automatic grading system that integrates Moodle with a Kubernetes cluster, aiming to be sufficiently general for use across a variety of courses. Experimentation in two large courses demonstrated the system's capability to support diverse programming assignments, handle substantial concurrent user loads, and enhance the educational experience. Future work will focus on system refinements, exploring additional integrations, and open-sourcing the project to benefit the wider educational community.

1. INTRODUCTION

Automatic testing of programming assignments, recognized for its effectiveness in providing prompt feedback to students and enhancing the scalability of grading processes, is increasingly adopted globally. Within our institution, this trend is reflected across numerous large courses, where we observed similarities in grading processes. We discussed with instructors collectively teaching over fifteen courses across various faculties, each using their own distinct infrastructures, although performing similar functions: students submit their source code for evaluation, feedback is generated on a remote machine and communicated back to them. Developing and maintaining these infrastructures represents a significant investment. Additionally, the presence of multiple systems requires students to adapt to a wide range of user interfaces, workflows, and reporting systems.

This situation highlighted the necessity for a unified system that could be adopted across multiple courses to reduce operational costs and enhance the overall student experience. We identified that an appropriate system would need to be:

- **General:** Not tied to a programming language or assignment format.
- **Simple:** Easy to operate by the students, teachers and system administrators.
- **Automatic:** No human intervention should be necessary for grading.
- **Scalable:** It must be possible to handle thousands of concurrent users, which is crucial to be used during exams and peak submission times.
- **Local:** Students' data must remain within the private network of our institution.

Many existing open-source and commercial solutions (discussed in section 7) do not meet all of these requirements, often being either too specialised, challenging for first-year or non-CS students (e.g., solutions based on Git), or necessitating the outsourcing of data handling.

This inadequacy has prompted us to design and build our own system tailored to these needs, which we present in this practice paper. We evaluated our system over a semester within two significant courses:

- **CS-107: Introduction to Programming (503 students):** The first programming course in the computer science curriculum at our institution. It was important for students to have a simple user interface (UI) since most of them are not yet familiar with tools such as git. Our system was used to automatically grade a self-assessment project and to verify the integrity and proper structure of a larger project.

- **CS-214: Software Construction (383 students):** A second-year course that introduces functional programming, software engineering principles, and formal verification concepts. Here, students completed weekly programming assignments, which were graded using our system. Additionally, our system has also been used to grade its final exam.

In Section 2, we begin by providing a high-level description of the system, followed by details on its implementation in Section 3. We then describe some applications tested in pilot courses in Section 4. The performance and usability of the system are evaluated in Section 5. Finally, future improvements are outlined in Section 6, and we compare our system with alternative solutions in section 7.

2. SYSTEM OVERVIEW

Our system integrates *Moodle* with a *Kubernetes* cluster and our key contribution is establishing a bridge between the two.

Moodle Plugin: Our system extends Moodle through a custom plugin.
Moodle (Dougiamas and Taylor, 2003) is an open-source Learning Management System (LMS) and the officially supported tool for collecting submissions and distributing online material in many universities. It enables educators to create different content types through *Activities*, including static content as well as dynamic content such as quizzes, polls, and assignments. Comparative studies by Kumar, Gankotiya, and Dutta (2011), along with a systematic review by Gamage, Ayres, and Behrend (2022), have underlined Moodle's efficacy and its evolving role in e-learning. Its widespread adoption among faculty and student body and built-in support for useful settings (e.g., the number of allowed attempts and the submission time window) make it a good foundation to build upon.

Kubernetes Cluster: When students submit their work, our Moodle plugin creates a job within a Kubernetes cluster to run a *Docker image* provided by the teacher. Docker (Merkel, Dirk. 2014) is a virtualization technology that has seen widespread adoption over the past decade. Docker allows for the definition of computing environments, known as images, specified in text files. Kubernetes (Hightower, Burns, and Beda 2017) facilitates the creation of clusters where these images can be efficiently deployed and managed. Basing our interface on Docker images gives teachers complete freedom to run arbitrary programs or workflows for grading student submissions, allowing for a diverse range of assessments possibly beyond programming assignments.

Web Service: The Moodle plugin communicates with the Kubernetes cluster through a small web service. This additional component enables more fine-grained access policies than a direct connection between Moodle and Kubernetes would allow, and also enhances system modularity.

3. IMPLEMENTATION

We extend Moodle's capabilities; and specifically the *Assignments* activity, with a plugin. This plugin allows us to hook into certain events such as submissions by students and assignments creation or deletion by teachers. In particular, the plugin performs an HTTP request to our web service, notifying it of a new submission ❶. In addition to defining webhooks, our plugin extends the Moodle API by providing an additional HTTP endpoints that allows downloading the submission ❺ and uploading grades and feedback to submissions being graded ❾. This endpoint is secured using Moodle's *web services authentication* mechanism.

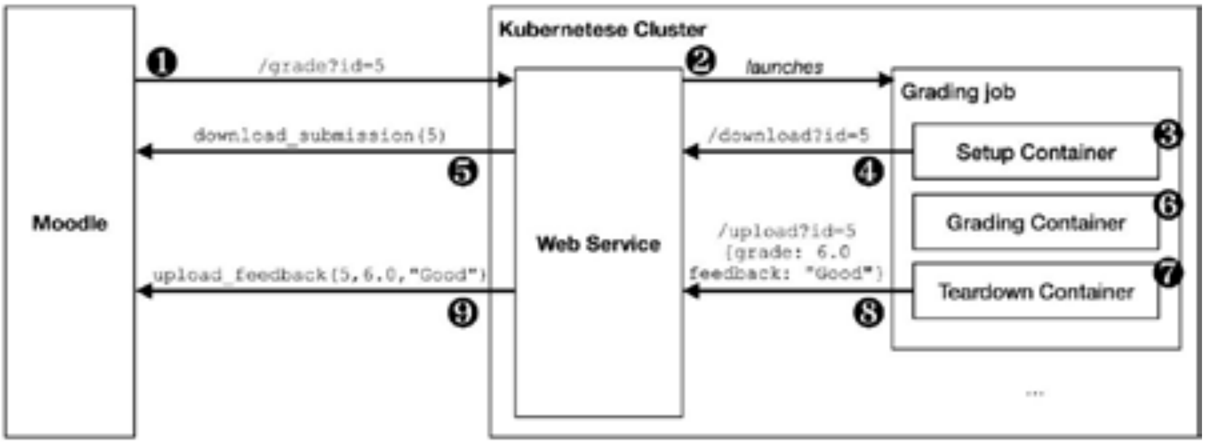

Figure 1: Step-by-step workflow: from the submission to the feedback

As the receiving end of the requests, our service defines a minimal API. On grading requests ❶, the service proceeds by creating a Kubernetes Job ❷; a scheduled task, that will safely download the submission ❹, execute the grading environment ❻ and upload the feedback to Moodle ❽. To enable the possibility to replicate the service, our system avoids storing the state. As such, we currently do not use any database. Authentication is performed by comparing the provided token by a token initialised during the startup of the service. To provide *high-availability* and increase the throughput, the webservice is replicated over multiple nodes of the cluster. On the Kubernetes side, the scheduled job is an aggregate of three *containers* running sequentially. While each container is isolated from the others, they are linked by a shared folder mounted into their file systems, allowing them to share data. The first container ❸ is responsible for downloading the submission ❹ and preparing the grading by putting the files in a dedicated folder in the shared space. The second container ❻; an instance of the provided Docker image, is responsible for running and generating the feedback. It is under the full control of teachers, and it can execute arbitrary code. We require from this executed image to store the feedback in a specific folder of the shared resource. This small contract, with the ability to fully define the grading environment, makes this system *general*. The last container ❼ will upload the feedback and grade to Moodle by calling a specific endpoint of the webservice ❽.

To secure the system, we make sure that all the endpoints of the webservice are protected. As such, we require for each request an authentication token to be stored in the header. Alongside it, and for internally used endpoints ❹❽ –which are not meant to be used by users– an additional parameter consisting of a digest of both the context and an internal secret is required. Requests to internal endpoints are generated by the service itself when building the job; specifically in the definition of the setup ❸ and teardown ❼ containers.

4. APPLICATIONS

Our system is agnostic on the format of submissions—files submitted via Moodle are directly forwarded to the grading jobs, which can perform arbitrary operations before generating feedback. This approach opens the room to a variety of applications. In this section, we outline a few of them that were tried during the test phase of our system.

Both CS-107 and CS-214 make extensive use of unit testing. For these cases, we employ a wrapper script on top of the testing framework—JGrade[1] for CS-107 and MUnit for CS-214—to count points and extract feedback. For first-year students in CS-107, we enhance the feedback by displaying test results in an HTML document, which makes navigation easier. In contrast, second-year students in CS-214 are presented with direct text outputs.

Feedback solely based on input-output tests has limitations, especially for solutions that are unusual, whether in a good or in a bad way. For instance, different implementations of the greatest common divisor function for two natural numbers, despite having identical input-output behaviours, might embody distinct algorithmic approaches (e.g., subtraction-based vs. modulo-based Euclid's algorithm). Milovancevic et al. (2024) conducted a trial in the CS-214 course to address this problem, employing our system with a custom image that integrates formal verification of students' code. Specifically, they extended the Stainless verifier (Hamza, Voirol, and Kunčak 2019) to compute equivalences between student submissions and reference solutions. This system not only verifies the correctness of solutions but also analyses and clusters submissions.

In CS-214, students learn the concept of equational reasoning with programs. This primarily consists in transforming simple code expressions using a given set of axioms, emphasising the mathematical foundations of programming. Checking these proofs is also an opportunity for automatic grading. To do so, the teaching staff developed a small surface syntax on top of the LISA interactive theorem prover

[1] JGrade is an in-house library built for grading on top of JUnit 5. Authors are planning to make it open-source in the future.

(Guilloud, Gambhir, and Kunčak 2023), enabling students to write their proofs similarly as they do in traditional paper exercises.

Beyond grading code, another application example is the teaching of *git*. CS-214 teaches students to generate and manipulate *git* patches—text files containing the differences between two project versions. Adapting the grading image for this course to automatically test and apply these patches was straightforward.

5. EVALUATION

Our system allowed course teams to focus on developing the grading logic rather than on infrastructure management. Moodle instance and the Kubernetes cluster were maintained by system administrators, and the maintenance required for the plugin and web service after this initial development phase was low. Early feedback from the teaching teams suggests that routine maintenance tasks, such as updating tokens or adjusting to Moodle updates, should require roughly one to two days of work per semester for a student.

We estimate the development cost of our system at around $16,000[2]. The running costs of the Kubernetes cluster is not known in our case because it was part of the shared resources of our institution, but we estimate that a similar setup running on Amazon EC2 would cost approximately $9,000 per semester[3].

One of the goals of our system is to efficiently manage the load and to be secure enough to be used during exams. We had the opportunity to validate these aspects during the final exam of the CS-214 course. There, we successfully handled 1715 submissions from 383 students across two batches, including about 600 submissions in the final 15 minutes of each batch with no failures and no delays. A potential drawback of our direct use of Kubernetes jobs worth noting is that it does not use first-in-first-out scheduling, but this was not an issue for us as we provisioned enough resources to avoid queuing delays. If needed, there exists systems that implement this on top of Kubernetes[4]. Additional logistics aspects of organising this exam can be found in (Chiplunkar and Pit-Claudel 2024) .

[2] The bulk of the expense was attributed to the development work, which was undertaken by students for a total of 450 hours at a rate of $25 per hour. Additionally, domain specialists installed and configured the Moodle plugin, and created and administered the Kubernetes cluster, amounting to about 20 hours of work at $80 per hour. Project supervision involved around 80 hours from a PhD student at $25 per hour and 20 hours from a staff member at $80 per hour.

[3] Our Kubernetes setup comprised 3 admin nodes, each with 4 cores and 8 GB of RAM, and 5 worker nodes, each with 8 cores and 8GB of RAM, for the semester's duration. For the CS-214 exam, we increased the number of worker nodes to 13 for 20 days. Running on Amazon EC2 instances would incur approximately the following costs for 6 months: 3 c6g.xlarge instances for admin nodes at $1660 and 5 c6g.2xlarge instances at $5540 for six months, assuming a 1-year reservation paid upfront. For the exam period, an additional 8 c6g.2xlarge instances for one month would cost $1600. The total cost per semester would therefore be $8800.

[4] For example, kueue is a Kubernetes queuing system.

While we lack comprehensive quantitative data on student usability, informal feedback indicates that a large majority of students found the tool user-friendly. On a more concrete note, an analysis of the CS-214 final exam data revealed that out of 1367 submissions (counting only the latest attempts), 31 had missing files, 10 were left in draft mode, and 18 were complete yet unsubmitted, indicating that approximately 4% of students encountered difficulties. These challenges, especially under the stress of exam conditions, highlight areas for potential improvements in the interface's simplicity that we plan to address (see Section 6.).

6. FUTURE WORK

In this section, we describe a few directions in which our work can be improved.

We are actively documenting the system; from the development, installation by system administrators to the usage by students and teachers, including the development of grading images. We also plan to test the system in more classes and to open-source for other schools to use.

In addition to the informal feedback we already got, the natural next step will be to collect more qualitative data and conduct surveys among the students and the teaching staff, which we plan to do during the second trial phase of our tool.

We are also implementing new features and usability improvements, both for students and teachers. Notably, we plan to add the possibility to check the current status of a submission—for example whenever it is queued or has timed out—from Moodle's interface. Additionally, we plan to integrate more monitoring and management features for teachers, for example allowing them to access raw logs of the containers. To facilitate this, we might switch to a custom Moodle activity in the future, instead of extending the *Assignments* activity.

As it is, the integration with Moodle only allows us to fully grade the project. One use case would be to allow the system to partially grade the submission; by validating the submitted code and delay the grading process for later; e.g. to be graded manually.

We will also investigate the possibility of extending the frontend to support additional LMS. Advanced classes might also benefit by allowing their students to integrate the system with their workflows. For example, by providing students with specific submission tokens and a dedicated API, they would be able write their own submission script or even define custom workflows using *GitHub Actions* or GitLab's equivalent.

7. ALTERNATIVES AND RELATED WORK

Prior to the widespread adoption of Docker and Kubernetes, Danutama and Liem (2013) developed a system using custom sandboxes for isolation. Peveler, Maicus, and Cutler (2019) analysed Docker-based isolation versus jailed sandboxes for automatic grading, implementing both and concluding that Docker offers stronger isolation guarantees with minimal performance overhead. Calderón, Petersen, and Rodas (2020) introduced SALP, a project aligning with our goals of modularity and generality, albeit as a standalone system rather than integrating with an LMS. Rao (2019) discussed a system similar to ours but tailored for the Canvas LMS. Tafani-Dereeper (2017) designed a system integrating Moodle with RabbitMQ and a set of workers using LTI, which we avoided due to its unsuitability for asynchronous grading and our preference for direct Moodle integration to leverage existing assignment activity features. A+ represents a comprehensive, albeit complex, solution with extensive functionality, including a Moodle plugin last updated in 2021. Unlike these systems, which involve states, databases, separate authentication systems, or UIs, our solution is more minimalistic and has less components to administer and maintain.

For the predecessors of the CS-214 course, we initially adopted GitLab, creating individual repositories for each student and leveraging custom runners for continuous integration. This method, however, presented challenges, particularly during exams, with performance issues leading to outages on both the frontend and Git servers. The recommended GitLab setup for handling 1 push per second with up to 3000 users—a 27-node system—proves both costly and overly complex for our needs. Alternatively, GitHub Classrooms, a system designed to streamline the use of GitHub for educational purposes, was considered. It simplifies repository management and student submissions but lacks the capacity for detailed points allocation. While direct usage of GitHub Actions could potentially address some of these limitations, using it requires additional effort and lacks the user-friendly interface advantages. Tu et al. (2022) highlighted similar constraints.

Commercial platforms like Ed Lessons and Gradescope offer web-based interfaces for coding, and manual or automated grading of programming assignments, with Gradescope additionally featuring a GitHub plugin and plagiarism detection capabilities. However, these are separate systems that educators must familiarise themselves with, and they raise concerns regarding sensitive data ownership.

8. CONCLUSION

We described the architecture of an automatic grading system in Sections 2 and 3. By leveraging standard tools such as Moodle and Kubernetes, we developed the system with minimal effort. We evaluated its effectiveness through pilot tests in two courses totalling about a thousand students, including one where it was used for the final exam. The system demonstrated its versatility by supporting several programming languages and assignment types, as evidenced in Section 4. Furthermore, we confirmed its scalability and practical usability in real-world scenarios in Section 5. Looking ahead, we aim to refine our system based on user feedback, pursue further integrations, and make our solution open-source, as discussed in Section 6.

ACKNOWLEDGMENTS

We would like to thank Dimi Racordon, Barbara Jobstmann, Jamila Sam, Samuel Chassot, and Marwan Azuz for their useful reviews and advice. We are also grateful to the entire teaching teams of CS-107, CS-214, and CS-320 at EPFL, in particular to Clément Pit-Claudel for valuable discussions and guidance, to Sankalp Gambhir for the developing the equational reasoning grader, and to Yichen Xu and Yawen Guan, who organised the CS-214 final exam and provided insightful feedback. Additionally, we appreciate the efforts of everyone else who contributed to developing and refining the tool, including Didier Berguerand, Carlos Perez, Fabien Salvi, Dixit Sabharwal, Benoît Morawiec, Patrick Jermann, Cécile Hardebolle, and Pierre-Olivier Vallès. This project was funded by the DRIL funds from EPFL.

ABSTRACT

This paper presents the design and implementation of a novel Augmented Reality (AR) experience for teaching engineering students the principles of elastic beam theory. Traditionally, this concept has been conveyed through physical laboratory experiments. However, at Sheffield University's Department of Multidisciplinary Engineering Education, such setups require extensive preparation by technical staff

---

[1] *E Browncross*
e.browncross@sheffield.ac.uk

to accommodate large student cohorts. This translates to lengthy turnaround times between activities and hinders efficient laboratory scheduling.

Furthermore, the existing equipment similarity with previous sessions earlier in the semester contributes to lower student engagement and participation compared to other experiments utilizing different sets of apparatus. The proposed AR solution addresses these shortcomings by eliminating the need for a complex physical setup within the lab. Students only require an AR headset and a designated 2x2 meter flat space. Initial data suggests a significant increase in student participation and satisfaction with this AR approach.

Beyond its logistical advantages, the AR simulation holds immense potential for enriching learning experiences. It allows for the rapid manipulation of material properties, beam cross-sections, and data overlays in innovative ways, exceeding the capabilities of traditional equipment. This enhanced flexibility paves the way for a more dynamic and engaging learning environment for engineering students.

1 INTRODUCTION

The landscape of Higher Education (HE) is undergoing a transformation fueled by the burgeoning adoption of Extended Reality (XR) technologies. Encompassing a spectrum of immersive experiences, XR incorporates Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality (MR). VR creates interactive, computer-generated environments, while AR overlays digital information onto the physical world. MR, meanwhile, seamlessly blends elements of both. Recent advancements and investments in hardware and software have propelled XR technology into a period of significant resurgence, with its applications extending far beyond commercial and domestic use. Meta reviews have indicated a year-on-year increase in published papers on this topic within the field of education, often with a large focus on teaching practical-procedural skills in engineering (Radianti et al. 2020) and this trend has continued up to the year of writing (Lin et al. 2024).

Meta-reviews of recent studies of XR technologies in HE have shown encouraging patterns, with VR increasing student engagement across a number of measures (Lin et al. 2024) with one meta-review focusing on Engineering showing impact on student satisfaction in 96% of cases (Vicente dos Anjos et al 2022)

In previous work, the authors have highlighted many of the perceived benefits and pitfalls of XR technology in the field of engineering pedagogy and explored the effects of fidelity, cost and interactivity on student learning outcomes and virtual laboratory engagement (Bangert et al. 2023) in a flipped learning context. This practice paper aims to highlight ongoing work within the institution to enable better student engagement and efficient use of timetabled resources, whilst maintaining standards of learning attainment. The scope of this work has been based on the total replacement of a physical laboratory activity; the “Deflection of a Beam” lab. This activity is taught to over 150 undergraduate students from the Department of Civil, and General Engineering at the university. The 2020 meta-review previously mentioned (Radianti et al. 2020) suggested there was a lack of publications showing XR activities based on existing experiments, as is offered here.

1.1 Activity and Learning Objectives

The lab activity is based on the elastic beam theory. Students conduct a load test on a flexible elastic beam by hanging weights to it and record the maximum upward and downward deflections at each load increment. At peak load, students also record the cartesian coordinates of seven points along the beam. These data are used to plot the load-deflection curves and the deformed shape of the tested elastic beam. The data processing is assisted with the use of a spreadsheet template that is available to the students on the Blackboard VLE (Virtual Learning Environment).

The students are challenged to create their loading procedure design based on the setup limitations of the experiment, to experimentally interpret the concept of curvature and to justify any discrepancy with the theory.

Students are also expected to gain some laboratory skills, in this case, taking readings from various types of distance measuring devices and dealing with the associated errors and precision. For the students at this point in their studies, it could be the first time they have had to use any form of analogue dial gauge for displacement (see Fig 2).

1.2 The Physical Lab Apparatus

Fig 1 shows the experimental apparatus consisting of a simply supported steel beam, with a cantilever portion where the load is applied. Dial gauges 1 and 2 are used to measure the maximum deflection both within the supported span and in the cantilevered portion of the beam. Dial gauge 1 offers readings between 0-20 mm while dial gauge 2 is between 0-50 mm, both with graduations of 0.01 mm. A caliper and a micrometer are also made available to measure the specimen dimensions and a ruler to estimate the deflected shape of the beam at peak load.

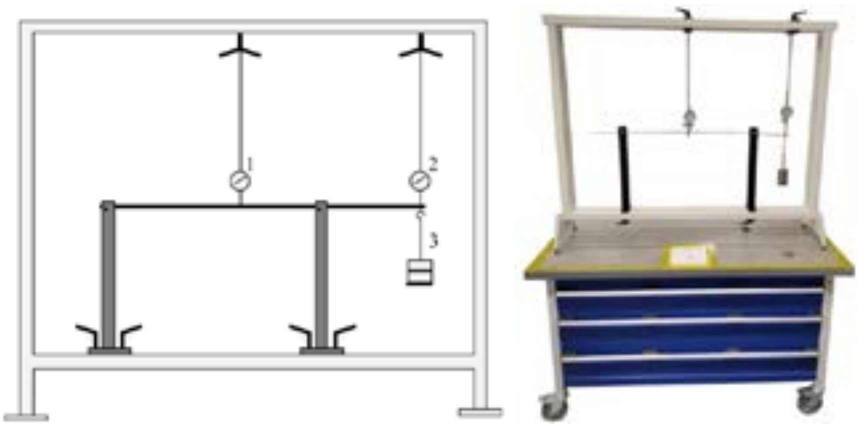

Fig. 1. Diagrammatic representation of experimental apparatus (Left) Photo (right).

1.3 Room for innovation

The existing format and structure of lab sessions have remained largely unchanged for the past decade, with only minor adjustments made over time. However, when compared to similar structural experiments conducted in the same laboratory, this particular session has consistently struggled with low student engagement and attendance rates. There's been speculation that this lack of enthusiasm may stem from student fatigue due to the repetitive nature of the experiments. Despite each experiment having different learning objectives, they all follow a familiar pattern of load-testing, data collection, and analysis, using similar equipment.

Recognizing this challenge, the authors opted to revamp the delivery of the activity while preserving its intended learning outcomes. This involved transitioning from the traditional lab format to a new approach with two distinct stages: 1) Substituting the original activity with a high-fidelity augmented reality/virtual reality (AR/VR) simulation. 2) Directly simulating real-world engineering examples related to the concept, rather than replicating the old experiment. This approach allows for the inclusion of virtual content that may not be feasible, safe, or cost-effective to implement on a large scale in a physical laboratory setting. The following outlines the initial phase (1) of this initiative and its impact on undergraduate engineering students.

2 METHODOLOGY

To realize a bespoke AR learning environment, a game engine was determined to be the optimal platform. This engine would offer the necessary functionalities: immersive visualizations, interactive features, and realistic physics simulations. Following a rigorous evaluation process, the free educational version of Unity 3D (version 2021.3.31f1) was chosen due to its extensive development tools and established compatibility with the selected hardware platform.

The chosen hardware platform consisted of Meta's Quest 3 headsets. These headsets offered a compelling cost-performance trade-off compared to alternative commercial VR systems. Furthermore, their integrated pass-through cameras and depth sensors were critical for facilitating the creation of realistic AR 3D overlays onto the user's physical environment. This technology is crucial for seamlessly blending virtual elements with the real world, a core requirement for an effective AR experience.

The simulation's geometric foundation mirrored the physical equipment's dimensions. These dimensions were meticulously captured and recreated within Solidworks, a 3D parametric CAD software. The resulting high-fidelity model was then exported for further processing in Blender, an open-source 3D modeling program. Within Blender, the 3D mesh underwent a process of optimization. This optimization aimed to minimize the file size while preserving the original geometric details of the model. This balancing act is essential for ensuring smooth performance within the AR experience. To achieve high-resolution measuring scales on the virtual gauges and rulers, a combination of procedural texture mapping and custom UV texture mapping techniques were employed. Procedural mapping allows for the efficient generation of textures based on mathematical algorithms, while custom UV mapping enables precise control over texture placement on the 3D model. Following this meticulous texturing process, the "texture-baked" 3D models were exported as glTF (Graphics Library Transmission Format) files (see Fig 2, right). This format facilitated seamless integration within the Unity game engine, paving the way for the development of the interactive AR learning environment.

Fig. 2. Photo of actual dial gauges (Left), Texture mapped glTF 3D model (Right).

The final component involved the utilization of several plugins within the Unity engine. These plugins, glTFast (4.8.3), Oculus XR Plugin (3.3.0), and XR Plugin Management (4.3.3), played a crucial role in managing file handling and facilitating interactions with the VR hardware. This integration ensured the proper communication between the software and hardware components, enabling the creation of a responsive and immersive AR learning experience.

Custom C# scripts were written to present an accurate deflection of the beam. The differential equations describing beam deflection were solved to give two equations for vertical deflection as a function of horizontal position on the beam for a given applied force: one valid in the region between the supports and one for the region of overhang. The mesh for the beam is divided into 100 sections. The vertices at each section are moved up or down according to the relevant equation, producing the impression of a smooth curve. Specific values at the locations of the dial gauges are similarly calculated for display with rotating hands (with values outside the measurement range of each dial gauge being clamped).

Parameters for beam dimensions and material constants are set within the unity editor (with the mesh automatically reflecting the given dimensions). The parameter for spacing between the pillars is inferred at runtime from the geometry of the scene, and the force parameter is updated as weights are added or removed by the user. A magnifying glass was implemented using a second camera attached to one eye of the XR rig with a narrower field of view than the default. This camera was rendered to the texture of a magnifying glass lens. This allowed a region of the scene to be viewed at a larger size and higher resolution than the natural scale and resolution of the headset without expensive ray tracing (Fig 3).

Fig. 3. In headset image of the magnifying glass effect on a gauge (Left) and ruler (Right).

The user experience of the simulation is as follows; once the program is loaded the user is presented with a scale-correct simplified version of the flexible beam and mounting frame apparatus in the location where the activity is taking place (See Fig 4). Using the Oculus controllers or their hands, users can pick up any of the available weights (1, 5, 10 N) and place them on the weight hanger at the end of the beam to be tested. The users can also pick up the magnifying glass to help them see the measuring scales on the apparatus more clearly. Note, that the weights have physical interactions with the surroundings (gravity and collisions), whilst the magnifying glass interacts without collisions or gravity so that it can be placed in space without being held by the user.

The other interactive elements are the vertical measurement ruler, which can be moved on the x-axis along the length of the horizontal ruler, the rightmost support pillar for the beam, which can also be moved along the x-axis across the frame, and the hangers holding both measuring gauges, which can be similarly moved along the beam. Each of these axis-locked interactions has a restricted range of motion that matches those of the physical equipment itself. The interactive elements in this simulation are considered to be crucial not just for functionally mirroring the physical experiment, but also for increasing the rates of students' knowledge and skill acquisition in a virtual environment (Kyaw et al. 2019).

Fig. 4. 3D Unity scene view with the model of the experimental apparatus (left), In AR headset view of apparatus in the lab (center) and the real unit in the same lab (right).

2.1 Simulation Costings & Setup Estimates

As the physical activity has been run within the department for multiple years it was possible to get accurate figures on the amount of staff time required for setting up the teaching and therefore the costs. In addition, it was also possible to do the same for the development of the AR software and the setup of the VR hardware to facilitate the replacement lab activity. Table 2 shows this data with data based on staff time at ~£25/hr. Figures assume one continuous run of teaching, with classes of 40 students working in pairs. Total equipment cost scales in proportion to class size. Setup time scales in proportion to the number of runs of continuous teaching.

Table 2. Cost data for producing/running each form of the activity

Activity	Preparation of Materials (one-off)	Equipment cost per unit (GBP)	Setup and takedown time	Total
Physical Lab	N/A	Frame with beam deflection kits £3324 (x10 units required)	3.5 hours £87.5	£33,328
XR Lab	CAD/3D modeling: 20 hours. Unity development: 40 hours £1500	Quest 3 Headset with strap and gasket £580 (x20 units required)	4 hours £100	£13,200

2.2 Methods of assessment

Data on student engagement with the activity was recorded using a bespoke piece of attendance software designed and built with the department (Funnell 2020). The "Smiley Faces" application presents the students with a series of faces showing a range of 5 emotions from happy to sad on a touchscreen tablet, approximating a 5-point Likert scale. The students click on one of the faces when exiting the lab session to provide quantitative feedback on their experience. These data are aggregated numerically to produce a "satisfaction rating score", see Table 3. In addition, the attendance rate of students was captured, see Table 4.

Table 3. Student Satisfaction Data

Session	Mean Rating (1-5)	Rating Std Dev	Respondents
Physical Lab 1 (2023)	3.9	1.36	8
Physical Lab 2 (2023)	5	0.00	4
XR Lab 1 (2024)	4.8	0.37	19

XR Lab 2 (2024)	4.9	0.34	23

Table 4. Student Attendance Data

Session	Students Expected	Students Attended	Attendance
Physical Lab 1 (2023)	31	23	74%
Physical Lab 2 (2023)	31	13	42%
XR Lab 1 (2024)	36	30	84%
XR Lab 2 (2024)	32	37	83%

2.3 Analysis of findings

The student satisfaction data (summarized in table 3) was combined into two cohorts: with and without XR. The null hypothesis was no increase in student satisfaction. Applying a Mann-Whitney U Test to the two groups , a z-score of -2.213 was produced. With one tail, this gave a p-value of 0.0134, which is greater than the 0.05 threshold to discard the null hypothesis. Thus we demonstrate a statistically significant increase in student satisfaction when presented with an XR lab experience. To what degree this is due to the quality of their learning experience versus the novelty value of using a VR headset is not known.

The attendance for the XR experience was much higher than in previous runs and is high compared to the average lab attendance (76%) and in particular the average attendance of 2024 CIV1000 students (67%), which was the cohort involved. The two 2023 physical labs, taken by GEE208 students, have an average attendance of 58%, which matches exactly the average lab attendance across the year for that cohort in 2023. To generate test statistics the cohorts were again grouped by presence of XR, and a two-sample proportion z-test was applied. The null hypothesis was no increase in attendance in the XR labs. A z-score of -2.93 was obtained, producing a p-value of 0.0034. This is smaller than the 0.05 threshold to discard the null hypothesis. Thus we show a statistically significant increase in attendance in the XR labs. Students were likely drawn to the lab because they knew it would involve a VR component, further suggesting this method of delivery is exciting to students.

The work by (Huang 2020) has shown that in other iVR studies, the “novelty effect” can be powerful in a science/engineering context. The students' motivation and engagement are initially higher, attenuating after multiple sessions. Novelty was not found to have a consistent impact on learning outcomes. As XR becomes more ubiquitous, it will be interesting to see to what extent our observed increase in engagement holds.

3 SUMMARY

This paper explores Augmented Reality (AR) as a way to revitalize a traditional engineering laboratory focused on elastic beam theory. The original lab suffered from low student engagement due to its repetitive nature. To address this, a high-fidelity AR simulation was developed, mirroring the physical apparatus and offering an immersive learning environment. Initial results show increased student satisfaction and attendance, suggesting AR's potential to enhance engineering education. While the long-term impact on learning outcomes needs further study, AR can prepare students for future careers using these technologies. Notably, for this specific lab setup, AR also presented a more cost-effective solution, although initial development required in-house expertise to create the model. Future work will focus on simulating real-world engineering examples in VR to further enhance learning and introduce scenarios impractical in a physical lab.

ABSTRACT

In this Practice Paper we explore the scope of engineering education academic development and support activities being undertaken by the Teaching and Learning Laboratory in Engineering and IT at University of Melbourne, and the context the Laboratory represents. Activities of the Laboratory include educational design support, inductions to teaching coordination, small-class teacher development, peer review of teaching, scholarship of teaching and learning capability development, and many more. We conclude with the specific challenge of establishing the impact and value of these activities, and how best to communicate this to decision-making individuals and groups within our institution. The literature suggests an approach of proxy rather than direct, establishing the circumstances and processes necessary for engineering education excellence, and involving external experts to conduct and validate assessments against these desirable circumstances and processes. Our recommendation from the literature and our own experience is to create and leverage a network for expert review and we seek to invite potential members to collaborate in developing such a network.

1 INTRODUCTION

Higher education is becoming increasingly professionalised. Educators in universities are expected to hold skills, qualification, and recognition in higher education. Engineering education is an established research field well-supported by associations such as SEFI, and their associated journals and doctoral research programs. To support quality higher education, many universities have central academic development and higher education research units. Similar units have been emerging to support quality engineering education and engineering education research.

In this paper we present the scope of work undertaken by one such engineering education and engineering education research unit, namely the Teaching and Learning Laboratory, Faculty of Engineering and IT, University of Melbourne (TLL), progressing from establishing the Laboratory, and seeking to identify and reflect on impact, value, and refinement. We provide a reference for the types of activities such a unit might engage in, and make a case for an expert review network between multiple such units.

1.1 Engineering Education Units

Engineering education units have developed alongside the emergence of engineering education research and practice as an independent specialisation of higher education research and practice (Borrego and Bernhard 2011). These units vary in nature from schools, such as Purdue’s School of Engineering Education, centres such as University College of London’s Centre for Engineering Education, to substantial research clusters such as KU Leuven’s Research in Engineering Education group.

The different structures of these units generally reflect both focus and scale of the units, with some focused on fundamental research and graduate research training, and others focused on local impacts to engineering education practice in their institutions, and wildly different scales in terms of headcount and funding. A characteristic of many engineering education research and development units is a majority of staff being academic, rather than professional. This is important when considering the nature of these units and how their members interact with wider contexts.

A common lens when examining units with non-traditional tasks in university settings is the ‘3rd space’ (Whitchurch 2012), those university employees “who do not fit conventional binary descriptors such as those enshrined in ‘academic’ or ‘non-academic’ employment categories” (Whitchurch 2015). However, this lens does not capture the nature of an engineering education unit made up of academic staff that conducts activities mostly within academic boundaries. This distinction is the basis for the ‘2.5th space’ description we use in this paper and the perceived need for a fresh look at the contexts of such a unit.

1.2 Glossary

For the purposes of this paper, we use terms as follows:

- **Subject:** A semester long unit of teaching which is atomic/indivisible for the purposes of student enrolment, for which students are given a single holistic grade known elsewhere as unit, course, paper, etc.
- **Faculty:** The highest level of division between disciplinary units of the university
- **School:** The next level of division inside the faculty.
- **Department:** The final relevant level of division inside schools
- **Unit:** A group, team, or other organisational entity, which is tasked with a specific purpose, e.g. an educational development unit.

2 THE TEACHING AND LEARNING LABORATORY

2.1 History, Establishment, and Structure

The TLL was established in 2022 to revitalise the pursuit of quality and innovation in teaching and learning in the Faculty of Engineering and IT. The TLL comprises a core team of the director leading three academics (including the authors) engaged in research in engineering education, and academic development activities. The Faculty has more than 470 academics. We have established relationships with several TLL Affiliates - academics with primary roles in schools and departments within the Faculty, who contribute to TLL research and development initiatives.

The TLL is a research-driven unit with a remit to support enhancements to teaching and learning in engineering and information technology through capability development of and support for academics, celebration of teaching and learning, research, and evaluation. The TLL is a unit at the Faculty-level. In the organizational chart, the Director reports to the Deputy Dean Academic, as does the Associate Dean Academic. The TLL is staff-facing rather than student-facing, influencing students indirectly through academics who teach and through curriculum initiatives.

The University of Melbourne is research-intensive. Academics within the TLL undertake various balances of research, education, and leadership & service. We undertake research in engineering and computing education, and engineering and computing practice. We provide capability development and support activities with peers rather than with students. Our research and the education we provide are intentionally integrated and therefore the demarcation between research and education is complex. For example, the development of innovative teaching is both an education activity and a research activity.

2.2 TLL Activities and Initiatives

The staff in the TLL deliver programs and events to upskill academics, improve the quality of education in the Faculty, promote a culture of teaching excellence, reward and recognise excellence, and conduct education evaluation and research. Below we provide an overview of the breadth of TLL activities, excluding general service and leadership within the institution.

Subject Design Workshops

Subject Design Workshops are one of the more common activities of the TLL, with approximately 20-30 workshops conducted each year. The purpose of the workshops is to improve the quality of teaching and learning within the faculty, and to raise the profile of teaching and learning from an administrative task to a design-oriented task.

The format of each SDW is unique. However typically they are initiated with a series of scoping discussions between the academic and the director of the TLL followed by a workshop of duration within the range 2 hours to several days. The focuses of the workshops range from a single component of a subject to a full subject design or revision. They are motivated by a range of possible triggers from the academic seeking to innovate, to a recommendation by an academic head.

The TLL's primary role in the SDWs is to inform and guide the academics with research-informed approaches and questions, and not to dictate practice. The subject coordinators and subject teams develop material such as lectures, assessments, and tutorial material, with our guidance.

Academic Induction and Support

The TLL facilitates a 2-day induction to teaching and subject coordination, for academics new to teaching in the Faculty. This induction incorporates guest sessions by relevant service providers within the University and with academics from the Faculty. As well as introducing relevant teaching policies and responsibilities, the induction also provides a brief taster of subject design, evaluation, and pedagogic theory. Thirty to fifty academics attend each year. The inductions are heavily interactive, with most sessions modelling experiential learning where participants might for example consider their subject's intended learning outcomes within Bloom's Taxonomy, or conduct live observations of people to learn about classroom observation evaluations. We link the inductions to follow-up support, either through formal programs described below, or through ad hoc relationship building and discussions around teaching and learning practice between the new academic and the TLL.

Small-class Teacher Development

The TLL provides an extensive development program for small-class teachers. To date, these teachers are employed on a largely casual basis. They deliver classes such as tutorials, laboratories, and workshops. The program comprises a mandatory full-day induction workshop, a mandatory inclusive education workshop, and optional workshops on strategies for engaging students and giving effective feedback. Every workshop is offered each semester. Each year more than four hundred new teachers attend the compulsory workshops.

The induction at the beginning of each semester includes some similar mechanical elements to the academic induction, with guest speakers from Human Resources, and from Health, Safety, and Wellbeing, and a tour of relevant policies and procedures. We introduce the small-class teachers, many of whom are new to teaching, to methods for effective teaching, and to management of unexpected situations.

The strategies to engage students and giving effective feedback workshops were developed to expand on topics introduced in the mandatory induction. These additional workshops are later in the semester for two reasons: first, to allow for more time to cover the material in detail and include active participation and feedback, and second, so that new teachers have had an initial experience with teaching to appreciate challenges and identify gaps in their knowledge.

The inclusive education workshops are designed to improve inclusivity in teaching, in response to well-known systemic barriers in engineering and computing education and practice for people with marginalised or non-traditional attributes. These attributes include gender, socio-economic status, and many others. The workshops focus on unconscious biases that small-class educators and/or their students might bring into the classroom, and strategies to recognise these and mitigate their impact.

Communities of Practice

The TLL promotes and supports the development of education-based communities of practice within the Faculty. These communities may be led by any academic from within the Faculty, including TLL staff. There are currently two active communities, the Generative AI in Teaching Community, and the Indigenous Engineering Community, with additional communities emerging on topics including immersive teaching technology, sustainability, and project-based learning.

The Generative AI in Teaching Community of Practice, which has seen explosive growth since its inception in mid-2023, brings together academics and professional staff who are interested in exploring topics including academic integrity, teaching innovations, ethics of AI, use within the profession and many more. The TLL takes a direct hand in leading and facilitating this Community, delivering seminars, discussion groups, and workshops, and managing the online community. The Community has over 400 members and has developed from a Faculty community into a University Community of Practice. By contrast, the Indigenous Engineering Community of Practice has 47 members interested in integrating Indigenous values in curricula. These members engage meaningfully and intensely sometimes over multiples days, aligning with emergent opportunities.

HDR Research Training

The TLL has multiple PhD candidates supervised by TLL academics and affiliate supervisors. Topics under research include sustainability in engineering education and practice, integration of Indigenous values in engineering education, reproductive equity among engineers, Indigenous equity in engineering outcomes, learning analytics, and feedback in computing education. The candidates, academics, and affiliate supervisors form the TLL Research Group, with regular research seminars, invited speaker presentations, and discussions around topics such as methodologies, research design, and research support technologies, and shared project updates.

Innovative Teaching Spaces and Methods

Staff in the TLL collaborate with architects, consultants, and facilities staff to design and pilot new physical spaces for teaching and learning, and work with academics to pilot new and innovative teaching methods and designs in these new spaces. This work accompanies multiple building construction projects and refurbishments underway at significant scale and pace. New teaching methods being piloted focus on breaking down barriers between ‘delivery’ style lectures and tutorials, and ‘experience’ style workshops and laboratories, to promote seamless and integrated flat-floor teaching where appropriate for the intended learning outcomes.

Peer Review of Teaching

The TLL staff designed, developed, and lead a peer review of teaching pilot. The program is a peer-to-peer focused initiative with no oversight from supervisors or managers. Academics have full control over what they have reviewed, who conducts the review, and when the review occurs. The review can take place on any desired aspect of teaching or curricula. To participate in the program, academics complete a workshop facilitated by a TLL lecturer to manage expectations and develop skills in reflection and constructive feedback. Emphasis is on actions academics take following reviews.

Seminars and Workshops

The TLL leads regular professional development and awareness seminars and workshops for academics in the Faculty, around topics such as curriculum innovation, accessibility, education policies and others. The TLL also holds a series for academics to share innovative teaching practices, and shorter bespoke series on a given topic, the first of these being a 3-part series on assessment. These seminars and other TLL activities are informed by a Working Group of academics from across the Faculty, to ensure relevance and support impact.

Industry Practice and Engagement

The TLL actively engages with industry along bi-directional lines: first, the influence of industry on education in the form of accreditation bodies and the promotion of authentic practices in the design of curricula and assessment that the TLL supports, and second the influence of engineering and computing education and practice research on shaping current and future practice in industry. We value our strong connections with peak bodies including Engineers Australia with whom we will host an Engineering Practice Research Summit in 2024.

Scholarship of Teaching and Learning Support: I.D.E.A.S.

The TLL is pioneering a dedicated scholarship of teaching and learning (SoTL) group named IDEAS: Impact from, Development in, Evaluation as, and Application of SoTL. This group is a hybrid of masterclass series, community of practice, and project collaboration space for academics in the Faculty to develop their skills in SoTL as distinct from their existing discipline skills, and to promote the active incorporation of SoTL activities in day-to-day teaching practice in the faculty. This group defines SoTL to be the incorporation of educational research to inform teaching practice in local contexts, and the active evaluation and dissemination of beneficial teaching practice in those contexts.

Broad Engineering Education Research

In addition to the specific activities above which often involve the creation of engineering education research outputs either inherently or indirectly, academics within the TLL and TLL Affiliates are leading engineering education research. Areas of active interest include engineering practice, authentic education and assessment, inclusivity, learning analytics, generative AI in education, Indigenous engineering, and evaluation techniques.

3 THE CHALLENGE

3.1 Evaluation of Impact

A significant challenge (and opportunity) facing the TLL team is how to identify, understand, and communicate the TLL's impact and the value it provides within the Faculty. Good practice for continuous improvement requires meaningful and timely evaluation including lagging and leading indicators of success. There is a need to understand the impact and value of activities, to improve and refine their delivery, identify areas of priority, and align with wider Faculty strategies.

Additionally, while there is currently a significant level of goodwill and space to experiment afforded to the TLL, any well-governed organisation will monitor the value of initiatives. In order to reaffirm resources and ensure we continue to deliver quality and innovation in teaching, the TLL staff must seek and communicate this evidence.

Exploring Existing Evaluation Models

Through review of the literature, the only readily available evaluation model for units with related scope and remit was identified by Kneale et al (2016) and several cited works related to that framework (e.g. by Chalmers and Gardiner (2015)). Although examples exist of evaluations of individual activities, assessing adoption and impact, and identifying findings, outside the above framework, no holistic approach to evaluation and communication of impact was identified.

The key limitation of individual approaches is the lack of a holistic view on impact and value for a given unit, and the way that unit is structured to deliver an overall suite of initiatives both formal and informal. This is critical in an environment where the impact that arises from an integrated teaching and learning unit such as the TLL is anticipated to come not from initiatives in isolation, but rather from widespread cultural and capability change that emerges progressively out of many initiatives, as well as informal collegial interactions between peers. This is a limitation shared by Kneale et al (2016), who provide guidance on the evaluation and communication of individual activities rather than holistically – albeit with consistency between evaluations of different activities that would support aggregation.

Current Evaluation Practices in the TLL

There remains a need to evaluate individual aspects as the necessary components of any wider communication of impact and so these inputs are valuable in determining the best way for the TLL team to evaluate our activities and communicate the Lab's impact and value. However, the consequences of the above limitation mean applying these existing methods on a per-activity basis has shown limited effectiveness.

Evaluation is time-intensive, and good evaluation is more time-intensive. Seeking the maximum value out of the available time and effort for evaluation can only be achieved by considering values across different activities. Academics are already overburdened in terms of workload and available time, and over-surveyed wherever professional development activities occur. This is already an issue we observe for participation in development initiatives in the first instance, but further inhibits the effective gathering of quality data which typically requires more invasive and participant-time-intensive methods.

Evaluation has multiple target audiences, and the communication of value must be in the language of those who are responsible for reacting to and supporting that value. For many audiences, concise stand-alone communication is necessary, such as a single slide in a strategy meeting or executive summary.

One of the active investigations of the TLL is therefore to develop an approach to holistic evaluation and communication of value, an outcome of which is described below.

4 FUTURE DIRECTIONS: IMPACT AND EVALUATION INTER-UNIT REVIEW

4.1 Evaluation by Proxy

In investigating parallel challenges experienced within the higher education sector, in conjunction with the framework presented by Kneale et al (2016), following up on work by Chalmers and Gardiner (2015), our most significant conclusion was that educational quality, and programs to improve the same, were evaluated on a basis of proxy. While it is perhaps a managerial imperative to seek measures that will describe performance, as a discipline we have yet to develop a way of establishing teaching excellence in the form of a number, or at least a number which is valid, useful, and free from blatant inequity (Heffernan 2022).

Two promising methods of proxy were identified: proxy by circumstance and/or process, and proxy by authority. Proxy by circumstance and/or process is the evaluation of teaching excellence via observing that there is fertile ground from which that excellence might spring. In the context of this paper this would require identifying likely contributors to success and using those as a measure.

Proxy by authority is the act of decision-making individuals or bodies deferring to the opinion of acknowledged experts. This is routinely used in higher education for the purposes of audit and review, as well as accreditation (Duarte and Vardasca 2023; King 2012). In this case this proxy would also be necessary to identify and validate the selection of desirable circumstances and processes to measure against.

4.2 Operationalising Reviews

We conclude that the ideal solution for the TLL lies in establishing a culture of external review by experts in the field of engineering education practice, development, and research. This will serve both to provide valuable insight and direction for the TLL internally, and the credible communication of successes, opportunities, and contextual inhibitors to decision-makers. Rather than a complex document showing the multi-faceted interacting elements in any educational context, these can be abstracted away behind a simple but powerful statement, e.g. "the review by entity XYZ has drawn conclusions 1, 2, and 3, and made recommendations 4, 5, and 6". This is already a language these decision-makers are fluent in through audit, review, and accreditation processes.

Willing, relevant experts would be critical, to identify the desirable circumstances and processes, conduct a review against those, and present findings in the necessary forms for internal and external use. We anticipate a review network across engineering education units, expert engineering education practitioners, and researchers. Members of the network would establish common expectations about the desirable circumstances and processes which underpin such reviews. Work is ongoing in the TLL to establish such a network, and we invite interested groups and individuals to connect with us to join in its development.

5 ACKNOWLEDGEMENTS

Critical to the establishment of the TLL and gratefully acknowledged are Melinda Sung, Senior Administrator, affiliates, graduate researchers, and Ashlee Pearson, former Lecturer in the Laboratory.

ABSTRACT

The Initiative for Innovation in Engineering Education, IDEE, is a university-wide activity at Delft University of Technology (TU Delft), aiming to strengthen the capacity for evidence-based innovation in engineering education. The goal is to create a more systematic and evidence-informed approach to educational innovation at TU Delft, and to ensure that the knowledge gained is documented and shared with the wider education community. This paper describes the first steps in establishing the structures for the initiative, identifying the educational themes to be addressed, mobilising teams of faculty members and recruiting junior researchers, creating support for these teams, and building a productive community. Through this setup, IDEE has high ambitions for creating both educational innovation and associated

[1] *Annoesjka Cabo*
A.J.Cabo@tudelft.nl

scientific gains. It is also intended to create role models for novel kinds of academic careers with an emphasis on teaching.

1 INTRODUCTION

1.1 Engineering Education Innovation and Research as Strategic Goals

Delft University of Technology (TU Delft) is committed to innovation and research in engineering education, as evident in its Strategic Framework (TU Delft Strategic Framework, 2020-2024; Strategic Agenda 2024-2030). The strategic goals are to further strengthen the connection between research and education by supporting research into education and learning, and fostering a culture of evidence-based innovation and experimentation in teaching and learning. To reach these goals, the university needs a structured way of driving innovation in education to address challenges in education, in a scientific and timely manner. It is important that the knowledge gained can be preserved and implemented by the wider education community, in the education at TU Delft as well as globally.

For this purpose, the university has launched the *Initiative on Innovation in Delft Engineering Education*, IDEE. The term innovation is consciously chosen as it does not just refer to producing novel ideas per se, but to making a meaningful impact through the implementation of new practices in education. Within this initiative, scientific staff members from across the faculties work in teams, with each team addressing an educational challenge, called a *theme*. Themes should represent issues of broad relevance to the university and to engineering education in general.

1.2 Comparable initiative as inspiration

Comparable initiatives can be found at EPFL in Switzerland and Utrecht University in the Netherlands. At EPFL, the Center for Learning Sciences, LEARN, is a collaboration between researchers, practitioners and policy-makers in the field of education. It aims to continuously improve education by designing solutions informed by the state-of-the-art, and empirically evaluating the impact of their implementation (EPFL, n.d.). The 'Senior Fellow Programme' at Utrecht University (Utrecht University, n.d.) aims to strengthen educational leadership within the university and to increase the number of professors with a special focus on education. The programme contributes to the visible appreciation for education and teaching and demonstrates that also a full professor career in education is possible. The programme also aims to promote innovation in teaching and learning and to increase the overall quality of education. Senior Fellows are intended to play a key role in improvements of the education at the university and be an inspiration to their colleagues (Crone et al., 2023).

When creating IDEE, these role models were adapted for the context of TU Delft. This concerned the way the educational challenges were prioritised by many stakeholders, operating in teams to tackle the challenges (as opposed to single scientists innovating or addressing research questions from a specific course), the expectations of the career path (enabling advancement in careers on all levels rather than a specific track to full professorship), adding junior researchers to the teams, and focusing on Engineering Education Research and Innovation for TU Delft and the wider community.

1.3 Combining research and innovation to create institutional change

The design of IDEE was guided by some principles to ensure that the teams can create impact. Firstly, the teams should work on a coherent set of university-wide educational challenges, or themes. This is based on the recognition that in a complex environment like higher education an organization requires simultaneous and sustained interventions to gain momentum for changing practices (see for instance Luisiani & Langley, 2019, cited by Schophuizen et al., 2022). By choosing coherent challenges that are widely supported by both upper management and the education community at TU Delft, IDEE ensures a collective sense of responsibility to create educational change on an institutional level.

Secondly, the challenges are tackled by teams. When individual educators innovate in their courses and programs, impact is often limited to a single faculty, or even department. The IDEE teams are interdisciplinary in nature as they consist of scientific members from different faculties, mostly with an engineering background. To strengthen the capacity for educational innovation, each team hires a PhD and two postdocs, with stronger educational background. To include student perspectives, the teams will also involve students in different ways, for instance via surveys, student councils, freelance student project employees, and teaching assistants. This is underpinned by the idea that co-creation between students and faculty staff not only leads to greater value for output, but may also result in greater value to the individuals who are participating (Dollinger & Lodge, 2019).

Thirdly, research shows that when educators make changes in their teaching practices, they can’t always identify if the changes are made based on scientifically sound principles (Kottmann, Schildkamp & van der Meulen, 2023). Therefore, IDEE intends to build bridges between ongoing innovative practices and research, making the underlying scientific principles considered and explicit. A close relationship between educators’ practice and educational research offers opportunities to understand the complex process of educational innovation and consider educators’ and students’ needs. The ideal is to combine the innovations and research in an iterative process. Within the IDEE themes, challenges are discovered, and possible solutions are identified within existing practices or designed based on literature. This process then continues with testing, evaluating, and re-developing. Research shows that a design-based research approach has the potential to promote and facilitate context-sensitive interventions that address issues recognized as relevant by the participants (Tinoca et al., 2022).

Finally, IDEE creates a space for educators to showcase their innovative practices, finding interesting practices of peers and sharing their lessons learned. By bringing their practices into the research being done within IDEE, it creates evidence of faculty teaching competence while also offering a way to strengthen it further.

1.4 Recognition and Rewards in the Dutch Context

IDEE should also be understood in the light of an important shift on the national level, as the Netherlands is currently going through a renegotiation of the academic career system. In the new system for recognition and rewards, less emphasis is given to quantitative measures of research output, such as number of publications and h-index. To enable more diversity in academic career paths, people can have profiles with different balance between education, research, valorisation and leadership (Recognition and Rewards, 2019).

This new career system is already in place, but it is early days and there is still a need to fully make sense of the implications. In this context, IDEE should be seen as a way for TU Delft to manifest the recognition and appreciation of quality of education. Through their engagement in IDEE, numerous people will have the opportunity to strengthen their educational expertise and build up a merit portfolio of scholarly educational innovation. Especially, because IDEE is funded by the strategic funds of TU Delft, it offers educators a first stepping stone into the field even if they do not have a prior record in educational research. Accordingly, IDEE aims to be a productive breeding ground for role models with an emphasis on education, exemplifying new kinds of legitimate and fully recognised and respected career profiles (Crone et al., 2023; Graham, 2018).

2 THE BASIC SETUP OF IDEE

2.1 Teams and Themes

IDEE is designed to offer opportunities for teams of scientific staff members to work on educational challenges. Each team consists of several educators, with a PhD student, two post-docs (one after the other) and an educational developer. While faculty members stay embedded in their respective departments, the teams will also partially work together to inspire each other and share experiences and knowledge. The aim is to have up to five teams working each on a different educational theme at any given time, with each team having five years to research, experiment, evaluate, implement and disseminate their educational innovations.

The themes to be addressed in IDEE are chosen to be relevant and highly interesting for engineering educators, not only strategically important across the faculties of TU Delft but also generally in the engineering education community. To prioritise between potential themes, the following five principles were applied:

I. The theme addresses an educational challenge.
II. The theme relates to TU Delft degree programmes.
III. The theme concerns TU Delft as a whole and is, or is expected to become, relevant to most faculties.
IV. The goal is to improve engineering education at TU Delft.
V. Developed innovations must be applicable to the TU Delft campus and preferably beyond.

The first three themes were formulated in consultation with a group of stakeholders consisting of program directors, representatives of 4TU[*], policymakers, managers within the Department of Education and Student Affairs, and the vice-president of Education. The resulting themes were *Students taking responsibility for their own learning process*; *Retention of knowledge and skills*; and *Future engineering skills*. They are each described in more detail in Section 4 below.

2.2 Mobilising Teams Around the First Themes

During spring 2023, the three themes were announced in an open call to attract educators across the university. The open call ensures an intrinsic motivation of the educator joining the initiative, which is a strong determinant of teachers' commitment

[*] 4TU is the federation of the four technical universities in the Netherlands, see: www.4tu.nl

to education innovation (Kottmann, Schildkamp & van der Meulen, 2023). In total about 60 educators submitted letters of interest, indicating their chosen theme, and elaborating on the roles that they were willing to take. The participation was not limited and the result was three large groups of faculty members mobilising as teams to formulate a project proposal for the work.

The three teams received a go-ahead in September 2023 and started recruiting the PhD candidate and their first post-doc. This required them to identify who, out of their numerous faculty members, would be the supervisors and promotors, and they also had to select a place in the organisation that the student and postdoc would formally belong to. The first three vacancies were advertised in December 2023 and attracted in total 190 applications. At the time of writing, the first few PhD candidates and postdocs have accepted their offers of employment and candidates for additional positions are being interviewed.

2.3 The Next Round of Themes

IDEE is designed to have up to five teams working at any given time. During 2024, two additional themes are being formulated, and new teams will be created around them. The process starts again with formulating themes that are currently relevant in the field, and specifically at TU Delft, involving the same stakeholders as in the previous consultation session. After the open call, the project managers will organize a number of sessions in which the teams collaboratively work towards a project proposal. In the first round in 2023, this part of the process was left unstructured and up to each team to organise themselves. This was difficult for them especially because the teams were very large and the challenge new. This time, therefore, a somewhat more structured approach will be adopted to provide the teams with more guidance. The sessions will support the teams in getting to know each other as teammates, connecting to IDEE as a program, exploring the theme with educators, students, educational experts and policy makers, identifying problems and opportunities within it, choosing a focus for the project, and defining the mode of collaboration as a team.

3 ORGANISATION AND PROCESSES

3.1 Funding and Support Organisation

IDEE is one of the activities of the Teaching Academy (TA), a network for and by educators of TU Delft with the mission to collaboratively enhance engineering education and drive education innovations across the faculties of the university. Through the TA, each IDEE team is funded for five years, covering the cost for a PhD student, two consecutive postdoc positions (of two years each), and a learning designer (on 20%). In addition, the faculty members are expected to spend 20% of their time, as part of their regular research time.

IDEE is also supported by two project managers (one is the third author), in total 1,4 full-time equivalent. The project managers support the teams by overseeing the overall processes, connecting different stakeholders, facilitating collaboration among the teams, organising events and supporting day-to-day activities of the teams. The project managers collaborate with the Academic Director of the TA (the first author), specifically in positioning IDEE within the university context, and with the Scientific Expert to create a supportive work environment for the PhD’s and Postdocs and guide the teams in the educational research field.

A Scientific Expert in Engineering Education (the second author) was recruited in a part-time (20%) position as Professor in Engineering Education Innovation from 2024. The role is to support the IDEE community in their work, with an eye to furthering the quality and impact of the educational innovations, the quality and impact of the scholarly contributions, and the development of all the people involved – not least the PhD students and post-docs.

The IDEE Board is responsible for strategic management. It consists of the Vice President for Education, the Strategic Policy Advisor for Education, the Academic Director of the TA, and the Scientific Expert of IDEE.

3.2 Enhancing Competence

Team members are offered a program to develop themselves in the area of innovation and change. The aim is to strengthen their capacity for combining innovation and research activities that impact engineering education university-wide. The topics addressed are, for example, transdisciplinary team work, engineering education scientific methods, peer consultation, innovation methods, co-creation sessions and valorisation strategies (Crone et al., 2023; Kottmann, Schildkamp & van der Meulen, 2023).

3.3 Forming a Community

IDEE will organize events where the broader TU Delft education community comes together to learn about the projects, new developments, experiments, innovations, to seek inspiration for addressing their own educational challenges. The objective is to work together and find synergy with other educational innovation and research activities at the university, as well as collaborations on the national level such as the 4TU.Center for Engineering Education (4TU.CEE, n.d.). IDEE also aims to become an attractive environment for scholarly exchanges with international partners. International networks such as SEFI is a natural place to find interesting and interested friends, allies, and partners.

To support the community building, IDEE and its teams have a virtual presence. One part of the Teaching Academy’s portfolio is also the Teaching Lab, which is a physical space on campus suitable for hosting large and small meetings, events, and incoming visits. Such activities are intended to strengthen the relationships across the community. Some would be led by internal participants and focus on the work in the teams. Others will feature external experts to discuss subjects of joint interest to the themes. Some events will be more widely open, to enhance the visibility of IDEE, internally, nationally and internationally.

The PhD candidates and post-docs are a key group within IDEE. In addition to the wider aiming workshops and seminars mentioned above, there will be an ongoing seminar to directly support the junior researchers as a group, also with activities such as study trips and joint conference participation.

4 Introducing The First Three Themes

Based on the proposals as written by each team, the first three themes are here introduced, starting with a brief description, some possible questions to be addressed and mentioning some of the planned output. For full descriptions, see the website where each theme has a section (IDEE, n.d.).

4.1 Theme: "Students taking responsibility for their own learning process"

"Taking responsibility and acting autonomously are key competencies for professional engineers and their future contribution to society. They also play an important role in stimulating intrinsic motivation. In this theme, the main question is how to create the conditions to have students take the responsibility for their own learning process. These conditions apply to students, lecturers, the curriculum as well as the learning environment in which they operate."

- What do students need to be able to take responsibility?
- How to design a curriculum which allows students to take responsibility?
- What should lecturers do to stimulate and enable students to take responsibility?"

Some of the outputs that are expected in this theme is a *Glossary of Common Ground* that includes the shared approaches, concepts, and mindsets on the theme, and resources for addressing the issues through a *Pedagogical Pattern Language* (Laurillard, 2012) for pedagogies that foster student responsibility.

4.2 Theme: "Engineering students' progression and retention of knowledge and skills"

"The design and implementation of a seamless continuum of education should take place at all levels: as a learning activity in a single course, as a connection between multiple courses in a single program, with teachers and learners being part of a local teaching and learning culture."

- How to design a consistent curriculum to stimulate progression, retention and transfer of knowledge and skills?
- How to teach new concepts to foster students' understandings of this knowledge with a view on progression ("forward teaching")?
- How to support students in transfer of their knowledge and skills to new settings and applications?

This theme will be addressed through design-based research. Some of the expected result will be principles for curriculum and course design to promote progression, retention and transfer.

4.3 Theme: "Future engineering skills"

"Courses on engineering skills are part of many engineering education programmes. In a rapidly developing society, required engineering skills change quickly. One of the challenges is to better anticipate engineering skills needed in the future and to stay updated on the state-of-the-art engineering skills needed in society."

- How to design agile degree programmes in which future engineering skills are effectively acquired and seamlessly integrated?
- How to make sure that the skills addressed in the programmes are in line with the skills needed?
- How to stimulate critical reflection among students on the application of new engineering skills in professional practice and society?

Some output that is expected in this theme is an *Inventory of transdisciplinary teaching and learning* that is already practised at the university, a *List of desirable skills* with a *Stakeholder analysis*. Later stages, the team formulates and pilots *Design principles for future course development and for program development*.

5 DISCUSSION

5.1 Combining Innovation and Research

The aim of IDEE is to further meaningful *combinations* of innovation and research. The intention is to support a scholarly approach to innovation, meaning systematic rather than ad hoc interventions. The experiences of educational experimentation are intended to contribute to the engineering education research field. In other words, the work should be evidence-informed as well as evidence-producing. One potential research approach is to use a design-based cycle to test, evaluate, redesign and adapt solutions. Documentation and scholarly communication of the experiences plays an important role not only for spreading the innovations within the university, where the work should be made tangible and visible, but also beyond in the wider community of engineering educators. Submitting work to conferences and journals makes it subject for qualified international peer review, while it also provides forms of archiving and dissemination. Together with establishing local recognition and legitimacy for the educational innovation at TU Delft, such traditional research outputs also serve as recognised merits in an academic career. This is of particular importance since the Dutch academic career system is currently open for reconsideration, and there is a need for role models with regards to careers in which education is emphasised.

Combining innovation and research is not trivial, however. For those who base their scholarship on educational innovation, as the IDEE educators are expected to do, the challenge is to make direct impact within their own environment, *and* to design and publish their work in a way that is both scholarly and useful to others.

5.2 Worthy Ambitions

IDEE sets the ambitions high, but the aims are worth striving for and the conditions have arguably never been better.

The legitimacy of IDEE will rest on its ability to create positive impacts on education, to enable addressing the challenges in education and driving innovation. Therefore, the work needs to be locally embedded in contexts where the real, practical problems exist, and where experimentation can take place under realistic conditions involving students and staff. This is where the ideas must prove their usefulness. Impact is likely to be created through the process (rather than just by the research output on its own), especially through collaboration with colleagues and students in the different educational contexts.

Research output plays a key role for creating a strong presence and recognition in the research community. This is important for IDEE as a whole, and for the involved individuals. Since the themes that will be addressed in IDEE have emerged as strategically important within TU Delft, they are likely to be relevant and timely also for others in the research field.

A key legacy of IDEE is the involved people. This initiative should strengthen a significant number of long-term strong supporters of educational innovation and research. The people involved should develop attractive expertise, capacity to handle educational challenges, and ability to lead future endeavours. Their long-term career is a showcase for the model and an important indicator of success; it will also be seen as an indicator for the importance of education at TU Delft.

6 ACKNOWLEDGEMENTS

The authors want to acknowledge the enthusiasm and engagement of everyone involved in the teams, including the junior scholars – the PhD students and post-docs who are just starting their career within the initiative. IDEE is all about their ambitions and effort for educational innovation and research. We also acknowledge the strong support for IDEE from university leaders and administrators.

ABSTRACT

To enable engineering students to design effectively for manufacturing, hands-on practical experience is of paramount importance. Although students who are planning to progress into professional engineering careers do not necessarily need hands-on proficiency in all techniques, a basic understanding of the capabilities and limitations of different manufacturing processes is required. Students should be aware of how issues can arise by considering key aspects of manufacturing processes. Providing access to this, however, is a complex undertaking. Large engineering cohorts and limited resources and teaching spaces mean it can be difficult to provide every student with these opportunities. This paper reports on the redevelopment of an undergraduate manufacturing module for second year engineering students. The course was developed based on input from several stakeholders (lecturer, student co-design and workshop personnel) with feedback gathered at regular points before, during and after module implementation.

The new module allows students to produce an artefact which requires CNC machining, drilling, turning, metal folding, 3D printing and laser cutting. Student surveys, attendance analysis and detailed interviews were used to ascertain the effectiveness of the module. Analysis has shown that average attendance has increased by 6% and feedback from students was very positive, with 96% rating the practical elements as either good or very good.

The benefits of developing the module with stakeholder involvement has ensured that students are introduced to processes by experienced technicians, that logistically the workshop schedules have run efficiently and that the Student Voice has been considered throughout, resulting in a high-quality experience for the students.

1 INTRODUCTION

1.1 Background

According to (Graham 2018), the style of educating engineers is rapidly changing, increasing the amount of project/problem-based content within modules and moving away from the traditional lecture-based approach. Additionally, accrediting bodies require that students are given these experiences to meet mandatory learning outcomes, such as the UK Engineering Council's AHEP4 standards ("The Accreditation of Higher Education Programmes (AHEP) Fourth Edition" 2020). However, in parallel, Mechanical Engineering undergraduate programmes have increasingly large class sizes, particularly in Stages 1 and 2, which presents the risk that, as the student numbers rise, engagement will fall (Kinsella, Mahon, and Ullis 2017).

A significant body of pedagogical literature has focussed on the challenges of large class sizes and student engagement (Cole and Spence 2012; Shekhar and Borrego 2018). Finn et al. (Finn, Pannozzo, and Achilles 2003) reviewed the existing literature on class size effects and concluded that; "students in small classes are more engaged in learning behaviours," and that, "teachers' interpersonal styles benefit from class-size reduction." Svinicki and McKeachie (McKeachie and Svinicki 2011) also noted that, "students in a large class are usually more anonymous and feel less personal responsibility, reducing motivation for learning."

It has been reported that the most effective teaching involves active student participation and meaningful activities for learners (Freeman et al. 2014). Increased educational engineering practice including project/problem-based activities is a resource intensive endeavour, particularly, with increasing class sizes (McCartan et al. 2008; Servant-Miklos and Kolmos 2022). However, it can be an effective method to reduce the staff-student ratio and can allow students to learn from experienced technical staff beyond the traditional 'teaching by telling' methods and help link theory and practice (Prince 2004; Kamp 2023; Alhawiti 2023).

It is unrealistic to expect a single lecturer or delivery technique to facilitate all types of learning for a large class in a practical environment. Therefore, to enable engineering practice in education, a number of stakeholders are typically required.

1.2 Stakeholder involvement in curriculum development

Stakeholder involvement in course development has been widely studied (Lu, Nguyen, and Ersin 2015; Ringler 2022). The biggest stakeholders are the students, since they have the largest stake in the final outcome (Mulay, Tandon Khanna, and Somaiya 2017). Lu et al. (Lu, Nguyen, and Ersin 2015) note that, "having students take part in curriculum development cultivates a sense of shared responsibility among faculty members and students." Indeed, Kay et al. (Kay 2010) suggest students should be considered as, "evaluators, participants, partners, cocreators, experts and as change agents." However, other key stakeholders such as technicians and postgraduate demonstrators are important in the development and delivery of a course, particularly with practical elements.

Student input is normally incorporated based on feedback from the previous academic year. End of term evaluations (module and teaching evaluation questionaries (MEQ/TEQ)) are a standard part of course evaluations (Ringler 2022). However, the virtue of relying on end of term surveys has been questioned. Literature has shown that, "factors other than teaching quality, including the size of the class, course grade distributions, and whether it was being taken as an elective or a requirement can influence students' responses on such evaluations" (Villanueva et al. 2017).

1.3 Module Case-Study – Manufacturing Technology

This paper will focus on Manufacturing Technology (MEE2034), a second-year undergraduate module for all students from Mechanical, Aerospace and Product Design Engineering pathways within the School of Mechanical and Aerospace Engineering (SMAE) at Queen's University Belfast ("School of Mechanical and Aerospace Engineering | Queen's University Belfast," n.d.).The purpose of the module is to instil fundamental understanding of different manufacturing technologies and facilitate some workshop practice. In accordance with Engineering Council requirements, students must utilise practical skills in laboratory and workshop environments and experience solving "broadly-defined problems" ("The Accreditation of Higher Education Programmes (AHEP) Fourth Edition" 2020). Additionally, the module is vitally important to the CDIO (Conceive, Design, Implement and Operate) educational framework implementation in SMAE, as it directly links to CDIO standards 4 (introduction to engineering), 5 (design-implement experiences) and 7 (integrated learning experiences) and is also relevant to standards 6 (engineering learning workspaces) & 8 (active learning) (Berggren et al. 2003).

For over 20 years the workshop elements of this module were delivered at a local technical college, experienced in training technicians and operators via skilled workshop staff and multiple machines, external to the university. Due to external factors, in March 2023, the module could no longer be facilitated externally and would be brought to SMAE. This necessitated the rapid development of a new module to ensure that students were still provided with a good hands-on workshop experience, starting in September 2023. The rest of the paper will focus on the collaborative work to complete the module redesign.

1.4 Rationale

The aim of this study is to document the process of incorporating stakeholder input, specifically lecturer, technician, and student voice into the development of a new manufacturing module for engineering students. In this exercise a number of requirements needed to be met; the module should be able to cater for a large cohort (150+ students) but also react to variation in student numbers year on year and it should include dependence-based tasks to replicate real-world manufacturing processes. The research question was answered through a series of stakeholder engagement and feedback exercises before, during and after module implementation. Various levels of feedback, surveys and interviews, were used to ascertain the effectiveness of the module (i.e. both practical and lecture components).

2 METHODOLOGY

2.1 Module Design

There are a wide range of manufacturing processes and technologies used both in industry and within the School Workshops. The SMAE technical team encompasses workshop and technician staff, who are highly experienced, time served machinists, toolmakers or fabricators, with a combined 286 years of experience in both industry and academia. The SMAE boasts a wide variety of capabilities, such as: Laser Cutting, Hot Wire Foam Cutting, 3D Printing, CNC machining, a robot platform and various Polymer & Composite Processes. Clearly, there are too many to be covered in one twelve-week module. Therefore, the approach here was to focus lectures on the underlying theory of different manufacturing methods while facilitating some workshop-based practice on the available equipment and resources. These sessions would consolidate fundamental principles rather than teaching students how to use the latest piece of manufacturing equipment (Smith et al. 1995).

Stakeholder input was key to the module development, particularly since the practical aspects would be delivered by the technical team, rather than the lecturer. The primary development challenge was creating a structure encompassing a variety of manufacturing processes and scheduling the sessions. There were 172 students enrolled in Manufacturing Technology in 2023/24 (110 Mechanical, 62 Aerospace and 10 Product Design) and students were divided into 29 groups (five or six students per group) to allow for scheduling at each session.

Module design centred around the manufacture of an artefact, and associated programme of workshop practice, shown in Figure 1, to expose the students to different manufacturing technologies around the school. Five technician-led workshops and demonstrations, shown in Figure 2, including CNC milling, lathe turning, water jet and laser cutting and 3D printing were devised. In addition, three sessions of hand tool-based tasks, including sheet metal work, measuring, drilling, tapping and final assembly were included. Complimentary lecture material to supplement the learning from hands-on experience, along with both formative and summative assessments, were also created.

Fig. 1. Artefact

Fig. 2. Students taking part in practical tasks

Practical sessions would promote specific skills, demonstrate fundamental principles, and support manufacturing theory presented in the lectures. The practical tasks could also be linked to the different learning stages in Bloom's Taxonomy. Table 1 compares the tasks with the learning stages and shows that the practical programme can cover four of the six levels of the revised Bloom's Taxonomy (Krathwohl 2002).

Table 1 - Link between workshop tasks and Bloom's Taxonomy

Workshop Topic	Workshop Task(s)	Bloom's Taxonomy Level
3D Printing (including assignment)	Design a new component, Observe and learn about concepts, Operate the 3D printer and relevant software.	Create, Remember, Apply
Laser cutting (including assignment)	Design a new component, Observe and learn about concepts.	Create, Remember
CNC Machining/Waterjet	Observe and learn about concepts.	Remember
Sheet Metal Work / Drilling and Tapping	Operate workshop equipment, Interpret engineering drawings.	Analyse, Create, Apply
Final Assembly	Assemble various components according to engineering drawings	Analyse, Create, Apply

A period of iterative module design was completed where the learning was standardised across practical classes ensuring all students receive identical teaching and hands-on experiences. The member of the technical team with a particular specialism reviewed and commented on the proposed lecture content for that part of the module. Similarly, the module coordinator reviewed the scope of each practical. This ensured a synergy between lecture and practical content. Some students would complete practical sessions before the lecture or vice-versa.

The assessment structure for the module remained unchanged from 2022/23 with 70% coursework and 30% class test. However, the contributing elements of coursework were different. 40% was associated with workshop participation, two small SolidWorks design and make tasks, and final assembly of the artefact. A further 30% came from a group assignment, beyond the scope of this paper.

2.2 Learning environment

The workshop and practical sessions were facilitated by the SMAE Technical Team. Sessions were delivered across four primary locations; The Engineering Workshop (Figure 3), two student groupwork rooms and the Student Design Centre (Figure 4).

Fig. 3. Ashby Engineering Workshop

Fig. 4. Ashby Student Design Centre

2.3 Student Co-Design

Once a baseline lecture and practical programme had been designed a period of student co-design and evaluation was completed. Four third-year students were recruited, who had completed the previous version of the module. These students were asked to complete a dry-run of the practical sessions, review the assignment documents and other information before providing feedback from a student perspective. This student feedback was collected through a review meeting and incorporated into the module design.

2.4 Surveys and Data Collection

The effectiveness of the new module in encouraging active engagement with subject content (Taylor 2016), was evaluated using both quantitative data (attendance, student surveys and assessment marks) and qualitative data (student interviews).

Two short Vevox surveys were taken during the week two and week eight lectures to get both an early indication of student perceptions when modifications could still be made, and an overview of student satisfaction when the course content was complete. One-to-one interviews with students were completed in weeks 11 and 12 of the semester. Students were selected from the class list, both male and female, both BEng/MEng and from the three degree pathways. All students were asked the same questions from a predefined list (Krueger and Casey 2009).

3 RESULTS

3.1 Survey Data

During the development of the module, a focus group of students who had completed the module in the original format at the external college was gathered, and the practical elements of the module in its new form were delivered to them. Feedback on the content, clarity and timing was collected. The feedback received on the new format was very positive, with students commenting on how interesting the sessions were, particularly with equipment they have never seen before. Some comments were made surrounding timing, a lack of hands-on experience and about the content of the sessions. Before the module was delivered to students, changes to the timing of each session and to some of the content were made in line with these comments. During the semester, a total of 112 (65%) and 67 (40%) students, respectively, completed the two Vevox surveys, with 93% and 96% rating the practical classes as good or very good. In week eight, 95% of respondents rated the support provided by technicians, demonstrators or lecturers at the practical sessions as good or very good (Figure 5).

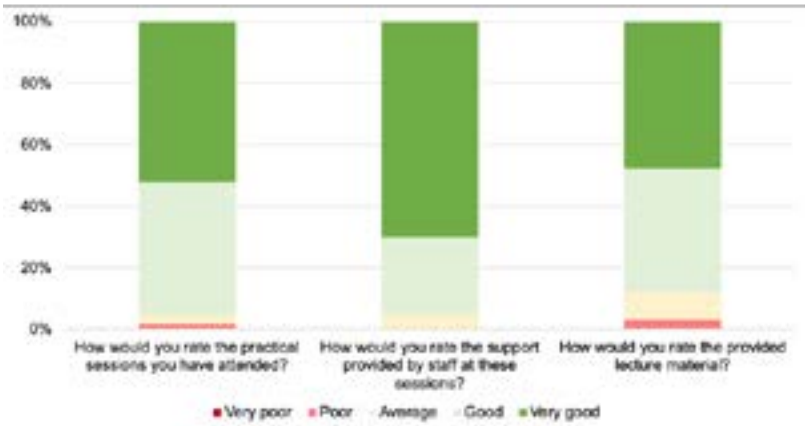

Fig. 5. Selected student survey responses from week eight lecture.

3.2 Student Comments

Table 2 presents selected comments on module content and perception from interviewed students. All students stated they felt they were learning when completing the practical classes. The collaborative effort to create synergy between the lecture and practical content was appreciated and reflected in student feedback, as there were, “good links between the lecture content and the practical classes.”

Table 2: Selected comments on module content and perception

How did you find the practical classes?	*“[It was] good to see all practical elements in person. The CNC practical was a lot of standing - too much information for the time spent. Technician support throughout was great.”* *“I very much enjoyed the practical sessions – I did Technology and Design at school and missed the practical side in first year Aerospace. Seeing the workshop was great.”*
How did you find the lecture material?	*“Very good lecture content with good links to our Design and Manufacturing module. Despite a couple of repeated lectures, I took different things from each.”* *“[The] lecture content was interesting – clear layout and diagrams,* *One mechanical and one aero example would have been good.”*
Did you feel you were learning when	*“Yes – more so when actually doing and when practicals complimented each other”*

completing the practical classes?	*"Yes – in some more than others. I don't feel I learned as much when only observing."*
How did you find the module overall?	*"Manufacturing Technology has been my favourite subject this year. I really enjoyed making the artefact and enjoyed [the] lectures. I appreciated how the subject could be applied to industry."* *"Happy overall with module - a good break from the theory heavy modules. I really like having the artefact on my desk and play with it when working."*

3.3 Comparison with previous module implementation

Weekly student engagement was high at practical sessions, always above 78%, however, lecture attendance was more variable, plateauing between 40% and 60% from week three. Lecture attendance generally decreased throughout the course of the semester. Student feedback indicated that some felt the lecture was less engaging if they had already attended the corresponding practical session. This could be an example of students' strategic approach to assessment and attendance (Gibbs and Simpson 2004), however, interest in the subject matter also plays a key role in promoting attendance. Further analysis of each practical at the end of the semester showed that only single digit numbers of students missed both opportunities to attend individual practical elements. While the content of the practical sessions was not identical across years, there was an increase in attendance for all sessions. This could be due to the summative assessment strategy allocated to each, however, an additional session outside of this strategy still had overall attendance of 93%.

3.4 Overview of outcomes

The end of module results were compared with previous, non-Covid academic years. The grade average has been rising steadily for the last number of years, 68% in 22/23 and rose again to 76% in 2023/24 (Table 3).

Marks were available for participating in the workshop elements (15% split over five sessions). Assignment 1 (20% of the module) involved the submission of two sets of Computer-Aided Design (CAD) files and the manufacture of laser cut and 3D printed elements with simple marking rubrics. While feedback indicted that students enjoyed these tasks, and the intended goal of promoting student engagement with the workshops was achieved, marks were high on an absolute scale of attainment. The average for the group assignment was 63% and the class test average was 68.9%. The number of fails in 23/24 dropped despite a larger class size.

Table 3: Overview of student outcomes for previous (non-Covid) academic years

Academic Year	No. of students	No. of fails (1st attempt) (%)	Overall average (%)	Std Dev	MEQ Score
2023-24	172	2.33	76.18	9.61	4.3
2022-23	162	6.79	68.46	8.92	4.4
2021-22	155	5.16	65.73	11.33	4.2
2018-19	187	2.67	60.2	9.56	3.9

4 SUMMARY AND ACKNOWLEDGEMENTS

This paper has described the redesign of a manufacturing module for undergraduate engineering students. The course was developed based on input from a number of stakeholders; lecturers, student co-design and workshop personnel. Different forms of quantitative data (attendance figures, student survey data and assessment marks) and qualitative data (interviews with students) were used to gather feedback at regular points before, during and after module implementation.

Technician-led workshops and demonstrations, and hand tool-based tasks were devised which exposed students to different manufacturing technologies including CNC milling, lathe turning, water jet and laser cutting, 3D printing, sheet metal work, measuring, drilling, tapping and assembly. The new module achieved good student feedback and educational outcomes. Analysis has shown that the average attendance has increased by 6% with at least 78% participation in each session, and feedback from students was very positive, with 96% rating the practical elements as four stars or above. Despite it being quite technically and logistically challenging to bring the module into the University in a very a short timescale, the experience for students appears to have been of high quality. Achieving such efficient and effective running of the practical elements of the programme was possible only by working collaboratively with the academic staff, technical staff, including student co-design, and listening to the Student Voice throughout the process. This co-design and collaborative approach will be invaluable to future development of hands-on modules within SMAE but could also be utilised by other institutions.

While engagement with practical classes was high, attendance was comparatively low at lectures. Interaction at lectures has been identified as a key area of focus as has the further development and refinement of the assignments. New Computer Aided Manufacturing (CAM) tasks are planned for 2024/25 which will compliment Computer-Aided Design (CAD), which the same students' study in Stage 1 and 2. The work described herein has been recognised with a teaching award, "Excellence in Teaching or Learning Support by a Team" and by the institutional Continuous Action for Programme Enhancement (CAPE) steering group in their "Institutional Actions for Embedding of Good Practice" report. This demonstrated the impact of the work in influencing the process for curriculum development across an institution, and how this could be adapted to other institutions or settings. This programme will continue to evolve as the School invests in new equipment and infrastructure to further extend onsite manufacturing capacity.

The authors would like to acknowledge the dedication and conscientiousness of the SMAE Technical Team in the support and delivery of this module through the 2023/24 academic year.

ABSTRACT

Practical training is crucial in engineering education as it connects theoretical learning with real-world challenges. By providing laboratory experiences, students develop a comprehensive understanding of engineering principles and their practical applications. This approach ensures that students are well-prepared to meet technical demands throughout their careers, equipping them with skills to operate machinery, conduct experiments, and process and analyse data using software. Additionally, practical training fosters teamwork and communication skills through

[1] *F. J. R. M. Calhindro*
calhindro@isec.pt

group projects and laboratory work, where students learn to share, to collaborate and to communicate their findings.

The present study addresses Pelton Turbine studies in educational institutions; the Pelton turbine testing methodologies used by two different institutions, the Coimbra Institute of Engineering (ISEC), in Portugal, and the Miguel Hernández University of Elche (UMH), in Spain, are compared, as well as the quality and quantity of results that might be obtained. The laboratory practice of engineering education in the field of turbomachinery in both institutions are analysed in terms of how theoretical and real-scale concepts can be applied with the resources available. In the present contribution, special focus will be given to the results obtained at ISEC due to its greater ability to enable and to reproduce different types of tests. When appropriate, reference will be made to the setup and the methodology used at UMH, particularly the challenges in reproducing the same type of tests due to the lack of the ability to control the flow at the turbine inlet, with the injector, limitation that is common in didactic installations.

1 INTRODUCTION

From an educational perspective, conducting turbomachinery experiments, namely with hydraulic turbines, as closely as possible to reality is often challenging, as it is difficult to provide and to sustain the necessary conditions for its operation with the equipment commonly available in educational institutions; this includes all the auxiliary measuring equipment required to perform detailed tests. Thus, the specific conditions available at a given educational institution determine the type of experiments that can be conducted, and consequently, the quality and quantity of data that can be obtained.

In this paper the results obtained at the Laboratory of Hydraulic Machines (LHM) of Department of Mechanical Engineering of ISEC will be discussed. This contribution represents one outcome of the Erasmus+ program that started in April 2023, and since then is being developed and enhanced between UMH and ISEC. The LHM houses a wide range of hydraulic equipment, as well as instrumentation, measurement, and control devices. It serves as a rich laboratory environment for engineering education and practice, unique in Portugal, and perhaps even in Europe, among University and Polytechnique institutions, offering undergraduate and master’s students the chance to test the three most common types of hydraulic turbines, Kaplan, Francis and Pelton, of considerable size for an educational institution.

1.1 Theoretical Background

In real cases, the water is stored in a dam at a given level. However, throughout the year, that level might change significantly. Besides that, the turbine is coupled to an electric generator that must run at synchronous speed, to match grid values. Since load changes from the grid side may occur, the flow rate, Q, must be changed accordingly so that the turbine rotates at constant speed. Therefore, in pedagogical terms, it is important to have a teaching facility capable of simulating those conditions, outside of nominal conditions of the turbine, as frequently occurs in real-life, to understand the associated phenomena and their influence on the performance of the turbine.

At ISEC, the Pelton turbine, main subject of this paper, consists of a horizontal shaft Pelton Spiral Turbine manufactured by B. MAIER, dating back to 1971, with a rotor diameter of 0.3 m and the nominal conditions presented in Table 1.

The turbine is supplied by a pressurized tank through a constant-speed centrifugal pump, model KSB ETA 80-26, manufactured in 1970, with the characteristics presented in Table 2.

Table 1: Nominal conditions of the Pelton turbine at LHM ISEC

Power	Flow rate	Height	Rotation speed
13.97 kW	0.03 m³/s	60 m	1000 rpm
19 CV	108 m³/h	-	104.7 rad/s

Table 2: Nominal conditions of the KSB ETA 80-26 pump at LHM ISEC

Power	Flow rate	Height	Rotation speed
29.4 kW	0.03 m³/s	65 m	2900 rpm
40 CV	110 m³/h	-	303.7 rad/s

This pump is responsible for simulating the gross head, H_g, available in hydroelectric dams, also known as system head, since for experimental reasons it varies with the head losses in the system. The energy balance between the feed tank and the exit of the turbine at ISEC experimental setup leads to (Mendes 2005; Young et al. 2012):

$$H_g = \frac{P_{tank}}{\gamma} + 0.94\ [m.c.water] \quad (1)$$

where P_{tank} corresponds to the feed tank pressure and the value of 0.94 m to the level difference between the pressure measurement level in the feed tank and the turbine outlet. Accordingly, at ISEC, the energy balance between the entrance and the exit of the turbine leads to (Mendes 2005; Young et al. 2012):

$$H_n = \frac{P_{turbine}}{\gamma} + \frac{V^2}{\gamma}\ [m.c.water] \quad (2)$$

where $P_{turbine}$ corresponds to the pressure at the turbine inlet which, for experimental reasons, is kept constant to be in accordance with typical operating conditions of a turbine in a hydroelectric power plant. The shaft power (at ISEC) produced by the turbine can be determined by (Mendes 2005; Young et al. 2012):

$$\dot{W}_{shaft} = T_{shaft} \times w = 0.735 \times \frac{F \times w}{1000} \quad (3)$$

where F corresponds to the force required to brake the turbine at a certain rotational speed. Finally, the efficiency (at ISEC) can be determined by (Mendes 2005; Young et al. 2012):

$$\eta = \frac{\dot{W}_{shaft}}{\rho g H Q} \quad (4)$$

where H can be either H_g or H_n, depending on whether the objective is to calculate the efficiency of the installation or of the turbine, respectively.

1.2 Performance curves

The acquisition and plotting of different performance curves depend on the information to be obtained and the resources available at each educational institution. To understand the influence of a particular parameter on the turbine, the remaining ones must be kept constant while varying the control parameter chosen. If intended to obtain the performance curves as a function of rotational speed, the net head and flow rate must be kept constant while varying the rotational speed. Once the test is conducted for the desired head, it is possible to vary the head (while keeping the flow rate constant) and repeat the test for each selected head, thereby obtaining the same curves as a function of rotational speed for different heads. A simple change in the presentation of the results allows obtaining the performance curves as a function of head, for the different tested rotational speeds, allowing to understand both the influence of head and rotational speed on the power output and efficiency of the turbine. On the other hand, if the aim is to understand the influence of the flow rate on the performance of the turbine, the head and rotational speed must remain constant. For a given head and rotational speed, the position of the nozzle needle is adjusted, thus resulting in a flow rate variation.

A combination of different parameters allows for a wide range of data to be obtained. For a given constant head, different rotational speeds can be tested by spanning all positions of the nozzle needle for each rotational speed. Therefore, for each rotational speed, the process is repeated by re-adjusting the nozzle needle from the beginning. Similarly, the head can also be varied subsequently, further increasing the number of collected data points, since for another head, different rotational speeds can be tested again, which, in turn, enable the testing of different flow rates.

2 METHODOLOGY

2.1 EXPERIMENTAL SETUP

The experimental setup of ISEC is shown in Figure 1, as well as the corresponding flowchart scheme in Figure 2.

Figure 1: Pelton turbine setup at LHM ISEC.

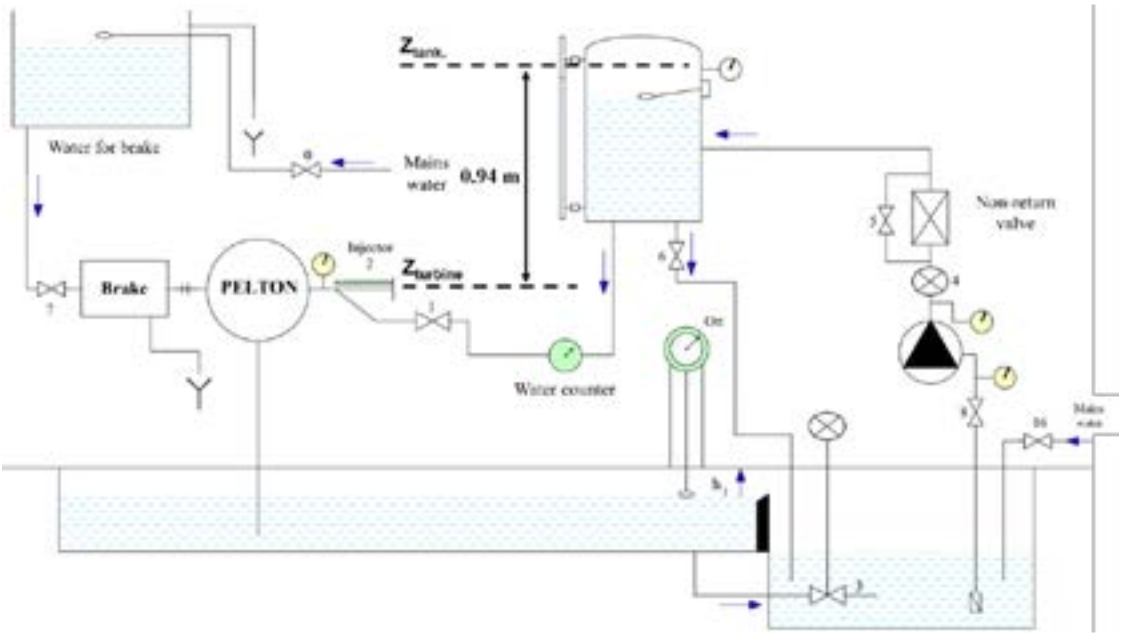

Figure 2: Flowchart scheme of Pelton turbine setup at LHM ISEC.

2.2 Experimental Procedure: Curves as a function of rotational speed or head

To obtain curves as a function of the rotational speed, the net available head and the flow rate must be kept constant throughout each test. The constant flow rate is ensured by maintaining the position of the needle of the nozzle unchanged, while the net head is kept constant by regulating the gate valve (1), shown in Figure 2. The rotational speed is varied by applying a resisting torque on the turbine shaft using a hydraulic brake coupled with a dynamometric balance. The measurement of the rotational speed is accomplished by using different equipment available at LHM such as a tachometer, a stroboscope, or by reading the variation of electrical properties, such as voltage. The braking force applied by the brake is obtained by reading the balance coupled with the brake.

Once the value of head and flow rate is established, the rotational speed is varied within the desired ranges. Upon completed the first test for the specified conditions, the available head measured at point (2) is varied by inducing a pressure drop through valve (1) to the desired head for the subsequent test. However, since this valve simultaneously induces a reduction in the value of the flow rate, the position of the needle valve and valve (1) should be simultaneously adjusted to ensure the desired conditions: the new value of constant head and a constant flow rate, equivalent to the previous test. The results discussed in the following chapter for this type of test were obtained for heads ranging from 40 to 60 meters, a range of rotational speeds from 700 to 1200 rpm, and a constant feed flow rate of 80 m^3/h.

2.3 Experimental Procedure: Curves as a function of the flow rate

To obtain the curves as a function of flow rate, the methodology to follow involves simulating what occurs in a real hydropower plant. For a fixed head, the nozzle opening is varied according to the requirements of the grid, thereby varying the supplied flow rate. After sweeping through all needle positions for a particular rotational speed, the same process can be repeated for another rotational speed. Furthermore, if desired, different heads can also be explored, repeating all the process from the beginning. A sweep of all rotational speeds for all nozzle openings allows demonstrating the influence of the same degree of opening on the value of the useful power for the various rotational speeds. The results discussed in the following chapter for this type of test were obtained for a head of 55 meters, a range of rotational speeds from 700 to 1200 rpm, and a range of injector openings from 20% to 80%.

3 RESULTS

3.1 Energy curves

Figure 3 shows the variation of the system head, the net head and of the velocity head as function of the flow rate, for a net head of 60 m. When the gate valve is fully open, the pressure at the reservoir almost equals the pressure at the injector (since the length of the pipe is small and there are only four components throughout the pipe). Figure 4 shows the variation of the useful (shaft) power, hydraulic power and both the efficiency of the turbine and installation as a function of the flow rate. The test was carried out in order to reproduce the manufacturer's nominal conditions, despite the impossibility of reproducing such high flow rates in the LHM, where the maximum is 80 m^3/h (for the net head of 60 m).

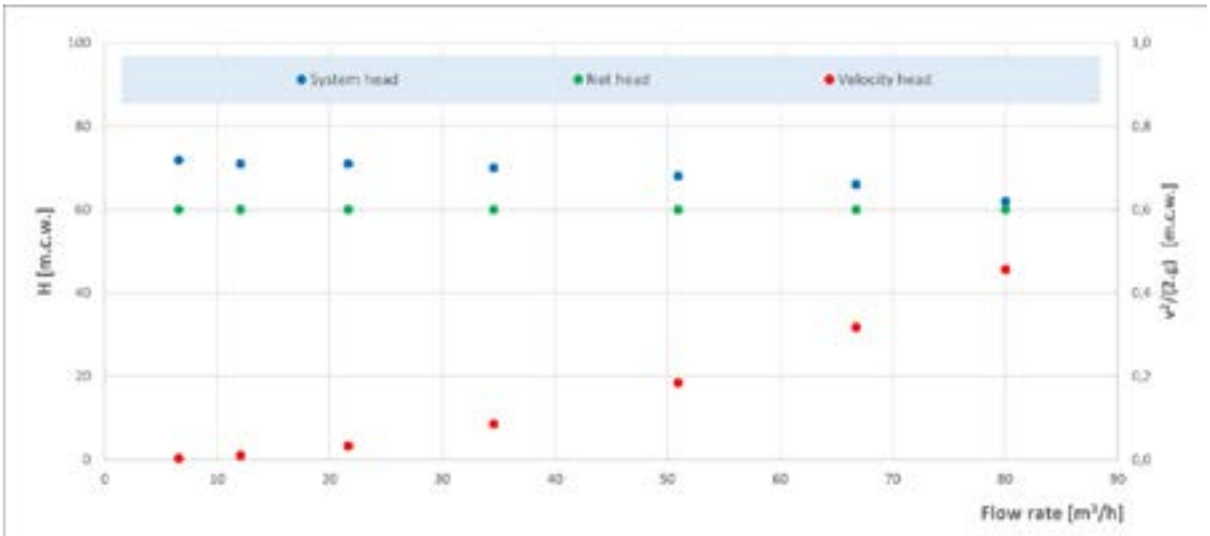

Figure 3: Variation of the system head, the net head and of the velocity head as function of the flow rate, for a net head of 60 m.

Figure 3 and Figure 4, highlight that almost all of the energy available for the turbine is in the form of pressure, with a relative contribution of kinetic energy below 2%, before being fully converted into kinetic energy in the form of a jet in the injector. In this test the maximum values of the useful power and of the efficiency of the turbine were 10.9 kW and 85%, respectively.

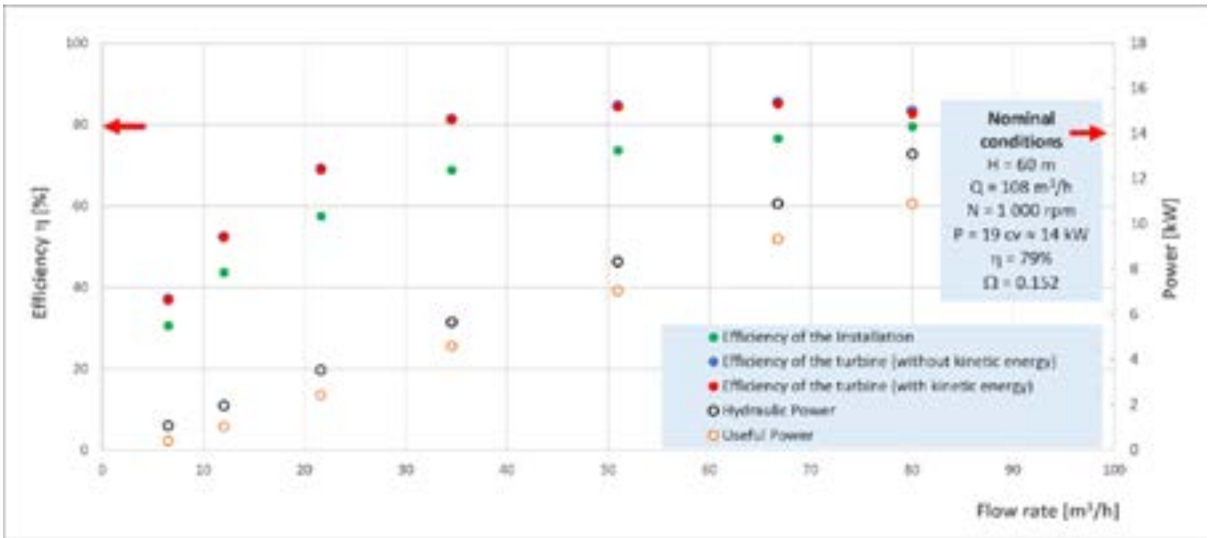

Figure 4: Variation of the useful (shaft) power, hydraulic power and both the efficiency of the turbine and installation as a function of the flow rate.

3.2 Curves as a function of rotational speed or head

Figure 5 and Figure 6 show the variation of useful power and of the turbine efficiency, respectively, as a function of rotational speed for different heads, with a constant feed flow rate of 80 m^3/h. The maximum values of the useful power ranged between 10.9 kW (for a net head of 60 m) and 7.3 kW (for a net head of 40 m) (vd. Figure 5).

Figure 6 shows that, for a net head of 60 m, the efficiency of the turbine ranged between 69.5% and 83.3%.

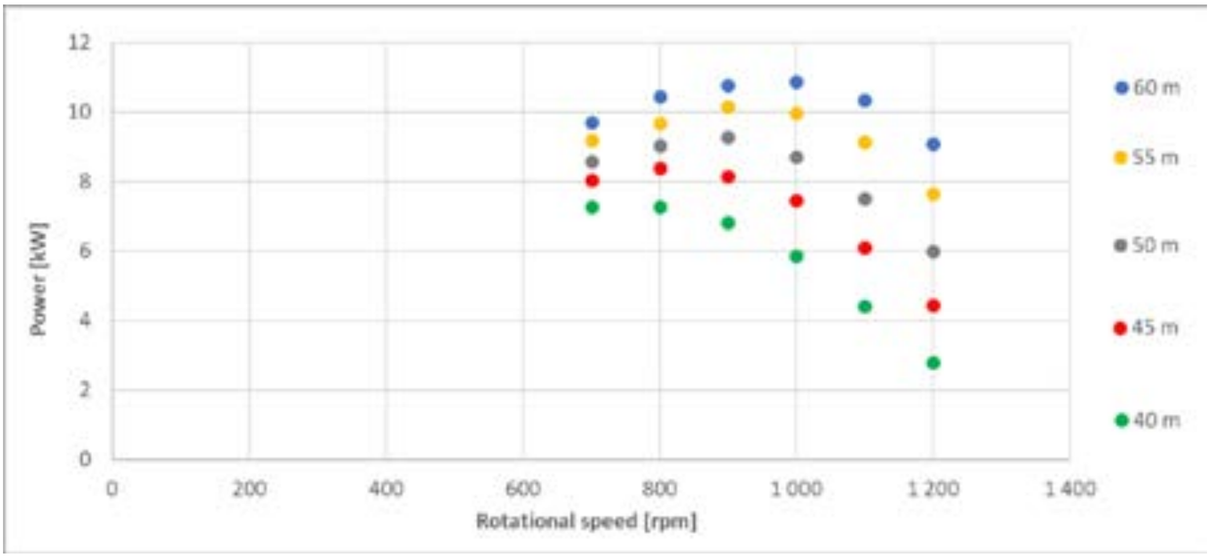

Figure 5: Variation of useful power with rotational speed for different heads, with a constant flow rate of 80 m^3/h

Several didactic facilities, such as UMH, due to the lack of an injector, are unable to fully replicate this type of testing, and while the curves may appear similar, different testing methodologies are used, particularly in maintaining a constant flow between the different curves.

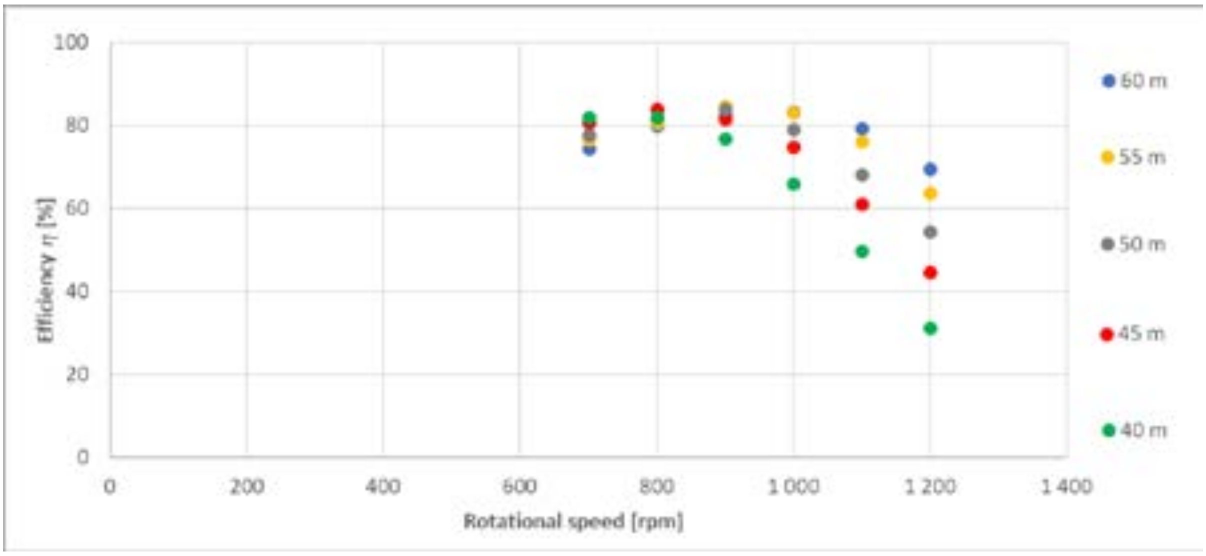

Figure 6: Variation of turbine efficiency with rotational speed for different heads, with a constant flow rate of 80 m^3/h.

3.3 Curves as a function of flow rate

Figure 7 and Figure 8 show the variation of useful power and of the turbine efficiency, respectively, as a function of rotational speed for different nozzle positions, with a constant feed head of 55 m. As previously mentioned, facilities lacking of an injector nozzle are also unable to replicate this type of testing.

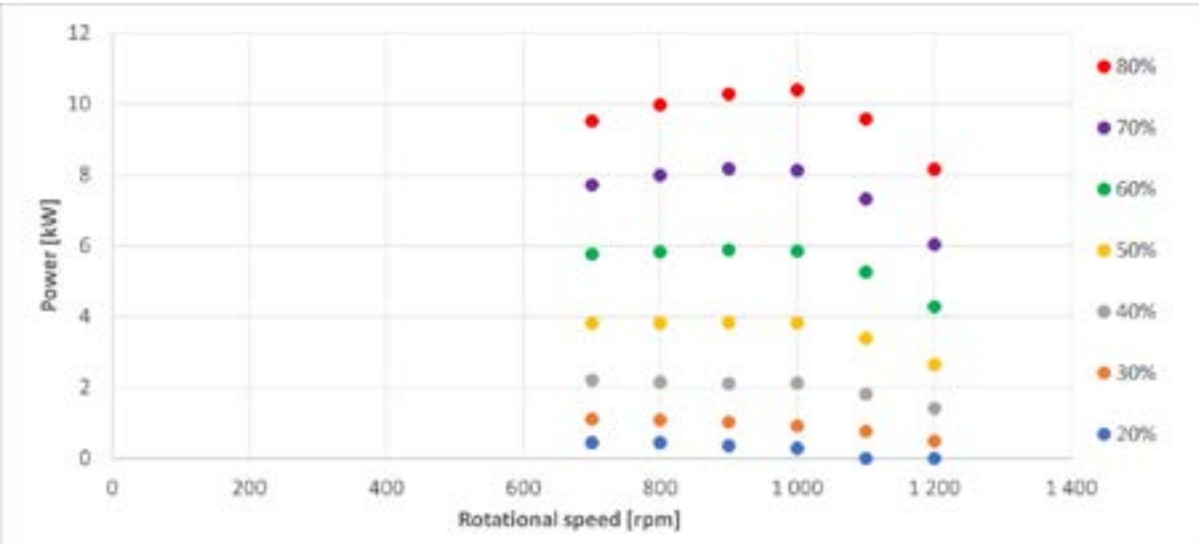

Figure 7: Variation of useful power with rotational speed for different nozzle apertures, for a constant head of 55 m.

Since the head is provided by a pump and the aperture is kept constant between different heads, the flow rate obtained is, barring losses, the maximum flow rate that the pump can provide. In other words, it is always the maximum flow rate available for the reproduced head, not allowing to maintain a fixed head while varying the flow rate. Both figures show that the best performance is achieved at 1000 rpm.

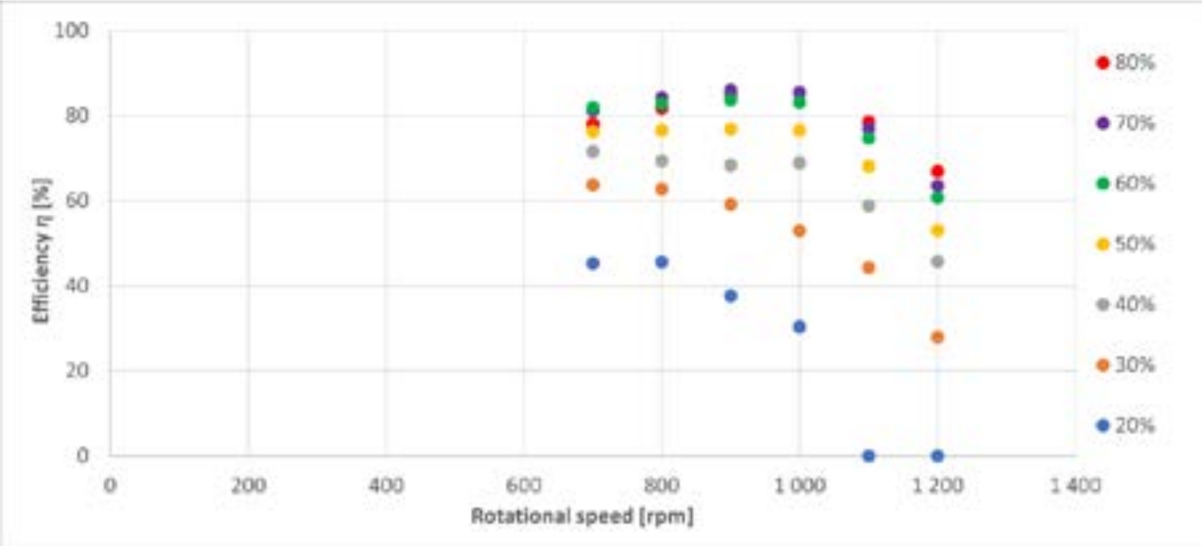

Figure 8: Variation of turbine efficiency with rotational speed for different nozzle apertures, for a constant head of 55 m.

4 SUMMARY AND ACKNOWLEDGEMENTS

The authors would like to acknowledge ISEC and UMH the opportunity to perform all the tests that sustain the present contribution.

ABSTRACT

This paper explores the integration of experiential learning within a curriculum designed to educate students about the importance of accessibility and inclusive design in digital environments. Anchored in Kolb's Experiential Learning Model, the program includes a series of hands-on activities that aim to deepen students' understanding of the difficulties for users with diverse abilities. Initial exercises challenge students to navigate physical spaces in a wheelchair and follow text-based instructions to create an origami cup, simulating the experiences of individuals with physical and cognitive disabilities. These activities are designed to help recognise the challenges inherent in non-inclusive designs and to inspire innovative solutions that enhance accessibility. The course concludes in work placement, where students apply their knowledge in real-world settings. Through this comprehensive approach, the program not only equips students with the skills necessary to create more accessible digital products and services but also instils a lasting appreciation for the principles of inclusive design. This paper discusses the outcomes of these experiential learning

activities, highlighting their effectiveness in students to prioritize accessibility in their work.

1 INTRODUCTION

This practice paper explores the effects of experiential learning activities on User Accessibility students within an Engineering faculty at a University in Ireland, focusing on their comprehension of the challenges faced by individuals with disabilities. Through engaging in these practical exercises, the aim was for students to gain firsthand insight into the obstacles encountered by people with disabilities. The experience also allowed the students to understand the importance of inclusive design and designing for those with diversity in mind. This understanding is anticipated to inspire students to advocate for and contribute to enhancing the accessibility of technical environments.

Accessibility is essential in ensuring an equitable society. According to the World Health Organization (WHO), 15% of the population or 1.3 billion people have some form of a disability (WHO 2023). This includes visual, auditory, physical, speech, cognitive, language, learning, and neurological disabilities. The aging of the global population will further highlight this issue, as it is projected that by 2030, one out of every six people will be 60 years of age or older and common conditions in older age include hearing loss, cataracts and refractive errors, back and neck pain and osteoarthritis (WHO 2022).This increases the need for user accessibility in a range of technological tools and in turn, engineering education needs to respond by providing students with opportunities to learn about accessibility and designing for inclusion. However, impact of accessibility extends beyond individual well-being and touches upon several core pillars of the Sustainable Development Goals (SDGs), underscoring its critical role in engineering education (UN 2015). Accessibility is paramount in advancing SDG 10, which seeks to reduce inequalities within and among countries. It is therefore clear that by removing barriers and creating enabling environments, accessibility ensures that all individuals, including those with disabilities, can fully participate in education, employment, and civic life, thereby contributing to more equitable societies.

There are several design approaches in which accessibility can be incorporated into products and services. These design philosophies include but are not limited to universal design, design for all and inclusive design. While universal design and design for all focus on processes that develop a product or service that can be used by the majority without adaption (Murphy and Goodman 2022, Persson, 2015 #186). Inclusive design is defined as “a methodology that enables and draws on the full range of human diversity. Most importantly, this means including and learning from people with a range of perspectives” (Microsoft n.d.) and so establishes the idea that everyone should be included in the design phase and considers the diversity of the range of human abilities. As Kat Holmes (2018) states in her book mismatch, “it is not designing one product for all people; instead, it’s designing a diversity of ways to participate so that everyone has a sense of belonging”.

In implementing inclusive design, the Inclusive Design Research Centre (IRDC) have developed a guiding framework for designers that consist of the following three dimensions (J. Treviranus 2018a):

1. Recognize, respect, and design with human uniqueness and variability.

2. Use inclusive, open & transparent processes, and co-design with people who have a diversity of perspectives, including people that can't use or have difficulty using the current designs.

3. Realize that you are designing in a complex adaptive system.

The experiential learning activities undertaken by the students in this paper were designed to achieve two primary objectives. These activities aimed to enhance the students' ability to recognize when environments and products do not adhere to inclusive design principles, and to deepen students' appreciation for human uniqueness and variability. This recognition is crucial for identifying opportunities for improvement and innovation in design processes to make them more accessible and accommodating of diverse user needs. ,. By engaging directly with tasks and environments that simulate the experiences of individuals with various disabilities, students were prompted to reflect on the accessibility challenges present in everyday contexts. This hands-on approach not only bolstered their understanding of the theoretical foundations of inclusive design but also equipped them with a practical perspective on how design decisions can impact the usability and accessibility of spaces and products for people with differing abilities. Emphasizing the importance of recognizing, respecting, and designing with human uniqueness in mind, the activities underscored the integral role of inclusive design in creating a more equitable and accessible world, highlighting the need for continued commitment to these principles in future design endeavours.

1.1 Understanding Disabilities

Traditional accessibility content focuses on the details of different disabilities, standards, and policies of ensuring accessibility in technology and suggests that including people with disabilities can give some insights into their needs (LADNER and LUDI). Whereas studies show that the most effective way to impart knowledge about the realities of disabilities is to try to simulate the experience of the disability (Putnam et al. 2016). However, it is important to note, as Jutta Treviranus (Jutta Treviranus 2018b) has pointed out, that simulation exercises do not equate to a genuine understanding of living with a disability. These experiences are unique and deeply personal, beyond the full comprehension of those who do not navigate life with these challenges. Nevertheless, providing students who study accessibility with opportunities to simulate these experiences can significantly increase their awareness. It informs them to the many ways in which poor design can exacerbate the difficulties encountered by individuals with disabilities.

1.2 Experiential Learning

Experiential Learning (B. Kolb 1984) is a learning theory developed on the belief that learning or ideas are not fixed in time but are formed and re-formed through experience. The theory is based on learners been involved in four activities namely Concrete Experience (CE), reflective observation abilities (RO), abstract conceptualisation (AC), and active experimentation (AE).

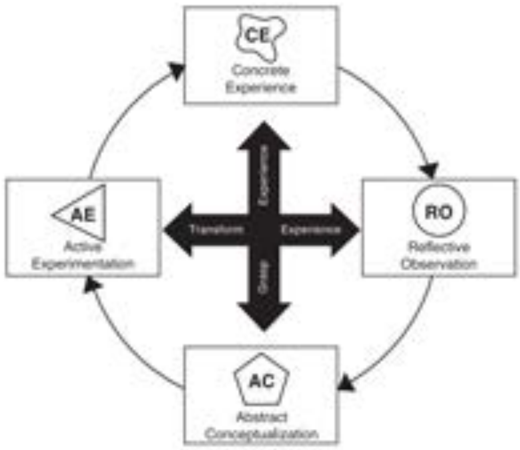

Figure 1: Cycle of experiential learning (A.Y. Kolb and Kolb 2017)

Simulating disabilities through practical experiences stands out as the most impactful method for teaching accessibility concepts (Putnam et al. 2016). As such, experiential learning becomes an essential pedagogical strategy for delivering modules on accessibility. By engaging students in hands-on activities that confront them with the realities of designing for accessibility, experiential learning promotes an understanding of the challenges and opportunities in creating technology that is truly accessible to all.

2 METHODOLOGY

In following the model for experiential learning (Figure 1) as closely as the module allowed the students took part in the activities to simulate disabilities (CE), they then wrote a reflection on their experience (RO), later in the module they developed a report on the accessibility of a website (AC) and then they went on work placement as provided by their course (AE). The qualitative data collected were the reflections and then surveys were distributed after the students returned from placement.

2.1 Concrete Experience

The students took part in two experiences to introduce them to the issues faced by people with disabilities. A wheelchair experience and an experience in which they had to create an origami cup with only written instructions.

2.1.1 Wheelchair Experience

The wheelchair exercise was designed to immerse students in the daily experiences of individuals who navigate university campuses in wheelchairs. Each participant is assigned a realistic task they might encounter in a typical college day. The tasks are varied and specifically chosen to simulate common scenarios a student in a wheelchair might face, such as transitioning between classes located in different rooms or visiting the canteen, A complete list of tasks is included in Appendix 1. Before beginning, students are required to complete a trial run in the wheelchair to ensure familiarity and safety, emphasizing the importance of avoiding reckless behaviour and being prepared for emergencies, with specific instructions to call a designated number if any accidents occur. For example, for tasks involving handling hot beverages in the canteen, students were cautioned to seek assistance if needed, highlighting the challenge of managing such tasks safely while in a wheelchair. Upon completion of their assigned tasks, students are instructed to write a reflective piece. This reflection should cover their experiences, noting any difficulties encountered, tasks they found easier than expected, their emotional response to the experience, and any surprising aspects of navigating the campus in a wheelchair. This exercise is not just about physical navigation; it's an exploration into the accessibility of the campus environment from the perspective of someone using a wheelchair. Through the tasks, students are expected to gain insights into the challenges faced by their peers with physical disabilities and what caused these challenges.

2.1.2 Cognitive Disability Experience

The class were also introduced to an activity in which they created an origami cup using textual instructions (WebAIM 2024).The origami cup activity was designed to highlight the importance of integrating visual content with textual instructions to enhance the user experience, particularly for those with cognitive disabilities. Participants were asked to start with a blank piece of paper, modifying it to a perfect square if necessary. They were then guided through a sequence of precise folding instructions, aimed at transforming the paper into an origami cup. This process involved diagonal folds, aligning corners and edges in specific configurations, and manipulating the paper in a manner that, ideally, resulted in a recognizable cup shape.

2.2 Reflective Observations (RO) - Reflections

After each activity the students were asked to write a reflection on the experience, they were asked a few questions to provoke their own thinking on the challenges of accessibility and the importance of inclusive design, particularly from the perspectives of those with physical and cognitive disabilities.Appendix 1 contains a paragraph of the questions the students were asked to help write their reflection on the wheelchair task and Appendix 2 contains questions on the cognitive disability experience.

2.3 Abstract Conceptualisation (AC) - Accessibility Report

The module's final assignment was to create a report on a website, identifying accessibility issues for users with various abilities and suggest recommendations to improve the accessibility issues. This serves as a key example of the abstract conceptualization phase of the experiential learning cycle. This step moves beyond mere participation in practical activities; it requires the students to critically reflect on their experiences, draw upon the concepts of accessibility and inclusive design, and synthesize this knowledge to identify real-world challenges. By engaging in this comprehensive evaluation, students transition from experiencing and observing accessibility barriers to understanding the underlying principles that guide the creation of more inclusive digital environments. This assignment reinforces the learning gained through direct experience and encourages the development of analytical skills necessary for proposing viable solutions to enhance website accessibility for a broad spectrum of users.

2.4 Active Experiment (AE) - Work placement

The students go on 3 months' work placement in Semester 2, this immerses them in a professional environment where they can actively apply the principles of accessibility and inclusive design they have learned. This stage of the curriculum demonstrates the active experimentation phase of experiential learning by providing students with a platform to test their ideas, strategies, and solutions in authentic settings. A survey was distributed to the students after they finished their work placement to understand if the experiences had helped them in the activities, they took part in on placement.

3 RESULTS

The experiential learning activities undertaken by the students were designed to immerse them in real-world scenarios where the importance of inclusive design becomes evident. Through their reflections and feedback gathered via surveys post-work placement, the impact of these experiences on their understanding and appreciation of diverse users was assessed.

3.1 Reflections on Inclusive Design Principles

The students filled in reflections on their experience based on prompted questions (Appendix 1 and 2).

3.1.1 Wheelchair Navigation Task

Students encountered firsthand the challenges posed by the campus environment to wheelchair users. Their reflections revealed numerous accessibility issues, such as narrow elevators, problematic door designs, and inadequate signage. These observations underscored the necessity for environments and products that adhere to inclusive design principles. For instance, one student noted the difficulty of navigating a standard classroom door, stating, *“Trying to get into the classes was very difficult...the standard classroom door is quite narrow for people in wheelchairs”.* Another reflected on the learning impact due to inaccessible designs: *“It takes a long time to get from class to class, impacting learning.”* These experiences served to enhance the students’ ability to recognize when environments and products do not adhere to inclusive design principles, directly aligning with the first objective of our study.

3.1.2 Origami cup reflections

The origami cup exercise further informed the importance of providing multiple ways to participate and understand instructions, reflecting the second objective of our study: to deepen students' appreciation for human uniqueness and variability. Despite 80% of students successfully completing the task, the exercise revealed critical insights into the necessity of inclusive instruction methods. One student stated, *“I did make a mistake I went the wrong way at the beginning and had to backtrack and read the instructions again”.*Students suggested that pictures or demonstrations could have mitigated their difficulties, highlighting an appreciation for diverse learning needs and approaches.

3.2 Survey Feedback and Increased Awareness

The survey conducted after the students' work placement revealed a significant increase in their awareness of the challenges faced by individuals with disabilities, with the average awareness rating soaring from 2.5 to 8.5 out of 10. This is based on questions 1 and 10 in the survey in Appendix 3. This increase in awareness not only indicates a shift in perspective but also suggests a deeper understanding and respect for human diversity, furthering the second aim of our paper.

As a result of this increased awareness,students expressed a profound change in their approach to design, with one respondent reflecting, “In my future career, I will always consider the challenges faced by all people more closely.” Another noted the impact of these experiences on their design philosophy: “Imagining how differently abled users interact with technology has been a huge consideration in every product or service I have worked on or designed since.”

The activities used in this study are explained in detail within the paper and the attached appendix, making it possible to replicate them. While the survey demonstrated a clear increase in awareness, future research could benefit from a more detailed explanation of the survey methodology and the specific metrics used to measure this awareness. This would provide a clearer assessment of the impact of the experiment and allow for more accurate replication and validation of the findings.

4 CONCLUSIONS AND SUMMARY

This paper has explored the implementation of an experiential learning framework within a module aimed at educating students about accessibility and inclusive design. Through a series of hands-on activities, including a wheelchair navigation task and an origami cup exercise, students were immersed in experiences designed to increase understanding around the difficulties associated with disabilities.

Feedback collected through surveys and reflection pieces provided insights into the students' learning outcomes, highlighting significant growth in their understanding of inclusive design and the importance of accessibility. There was an increased acknowledgement that they had the ability to reduce the challenges for people with disabilities and the students were committed to doing so.

APPENDIX 1: WHEELCHAIR EXPERIENCE

Wheelchair Tasks

This lab will take you through tasks that you will each carry out in a wheelchair on Campus. For health and safety reasons can I ask you to refrain from horseplay. Also, you must complete a trial in the wheelchair before the activity commences. If there are any accidents, we must call 071 9XXXXXX so please keep this number to hand. Also, for the Canteen task please be aware that should you ask for a hot drink and if you cannot handle it with ease you should ask for assistance and reduce the risk of burning yourself.

I will ask at the end of this task that you write a reflective piece about this task.

This reflective piece should discuss how you found the task, what did you find difficult? Were there parts you found easier? How did being in a wheelchair make you feel and was there anything from the experience that surprised you? Overall is there any advice you would offer to either property or timetabling to make the navigation easier following a timetable?

Tasks

1. Its 9am you arrive at registration at 8.50, your first class is in F0014 you must find this class in 10 minutes

2. The lecturer in F0014 lets you finish at 5 to 10, the next class is at 10am in room E0011 time yourself, how long does it take you to get there?

3. You must navigate from F0014 to B1058, we will say that you have 10 minutes to get to the next Class, do you make it?

4.There is an hour break after class in F0014 so you should now make your way to the Canteen and Grab a bottle of water/coffee and navigate to a Table with your item.

5.Make your way from the canteen to room D2037, how much time did you need to get there?

6.After room D2037 you have class in E0011, make your way there and record how long it takes you.

7.From room E0011 you should make your way to D2033 and record how long it takes you.

8.You should make your way from D2033 to A0004 and record how long it takes you.

APPENDIX 2: COGNITIVE DISABILITY EXPERIENCE

The following activity will demonstrate how visual content can supplement text to create a better experience for users, including those with cognitive disabilities.

1. Find a blank piece of paper.
2. If it isn't already perfectly square, cut off one edge of the paper until it is perfectly square.
3. Fold the paper in half diagonally.
4. Lay the paper down in front of you so that the longest edge is facing you.
5. Take the bottom left corner and fold it over the main area of the piece of paper so that the corner touches the opposite edge, and so that the top of the newly folded edge is parallel with the bottom of the piece of paper.
6. Do the same thing to the right corner, folding it across the main area of the piece of paper until it touches the opposite edge. The top edge of this fold should be exactly on top of the top edge of the previous fold.
7. Take the outer layer of the very top corner and fold it down until the corner touches the spot where the bottom of the other two folds meet. You should see a pattern in the shape of an "X."
8. Do the same thing to the other layer, but in the opposite direction.
9. Spread apart the two layers on the top and gently push the sides in.
10. You made an origami cup! (Or did you?)

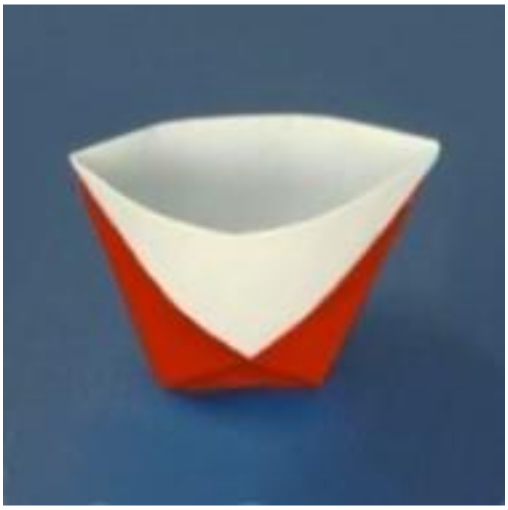
Questions and Discussion – Add answers in red and post to Moodle.

- How successful were you at performing the task?

- Were you able to make anything resembling a cup?

- Are you sure that you performed the task correctly? Perhaps you made a mistake or two, whether you know it or not.

Here's what your origami cup should look like:



How closely does your origami cup match the one pictured above? Is it even close? If not, why not?

Although you may have been able to complete the task by simply reading the instructions, you may have become confused at some point. The instructions may have seemed ambiguous or poorly written. Perhaps you misunderstood an instruction without realizing it.

- Would it have helped to have a picture of the end goal before starting the task?

- Would it have helped to see someone perform the task, or an illustration of how to perform the task?

How This Relates to Cognitive Disabilities

- Visually-oriented readers were at a cognitive disadvantage when trying to fold an origami cup with nothing more than written instructions. Individuals with learning disabilities, reading disorders, or more profound cognitive disabilities often feel similarly disadvantaged when trying to understand concepts that are difficult for them.
- Content needs to be clear and accurate, and sometimes in more than one format, for these individuals to fully understand. In the example of the origami cup, illustrations and animations are particularly useful. With other types of information, audio content may be more appropriate.
- Understanding this principle, making content accessible to people with cognitive disabilities becomes less mysterious, albeit challenging. Designing for people with cognitive disabilities isn't so much an art or a science, but a craft: We are applying creativity to create a tool that widest audience will use to accomplish a task.

APPENDIX 3: SURVEY QUESTIONS

1. On a scale of 1-10, how aware were you of the challenges faced by people with disabilities before participating in these activities?
2. Did you participate in the 'Creating Paper Cup without visual instructions' Activity ? (Please select all that apply)

Questions about the Paper Cup Activity:

3. Describe your initial reaction when you were asked to create a paper cup without visual instructions.
4. How did the absence of images impact your ability to perform the task?
5. In what ways did this activity change your perspective on the importance of visual aids in learning and communication?
6. Did you participate in the 'Navigating Campus in a Wheelchair' Activity ?

Questions about the Wheelchair Navigation Activity:

7. Describe your experience of navigating the campus in a wheelchair. What were the most challenging aspects?
8. How did this activity affect your understanding of the physical barriers faced by people with disabilities on a daily basis?
9. Reflecting on this experience, what changes do you believe could make our campus more accessible?

Impact and Reflection

10. On a scale of 1-10, how aware were you of the challenges faced by people with disabilities after participating in these activities?
11. Has participating in these activities changed your perception of the challenges faced by people with disabilities? Please explain.
12. What is one thing you learned about yourself during these activities?
13. Can you identify any specific moments or tasks that had a particularly strong impact on you? Describe them.
14. In what ways do you think these activities will influence your behaviour or actions towards individuals with disabilities in the future?

Additional Feedback

15. Is there anything else you would like to share about your experience participating in these activities?
16. Do you have any suggestions for how these activities could be improved or expanded in future sessions?

ABSTRACT

Engineering students encounter intricate and abstract concepts that can pose challenges for comprehension and practical application. To enhance learning outcomes in this domain, this study proposes the integration of Design Thinking and Project-Based Learning methodologies, fostering creativity and problem-solving skills among students while exploring fundamental concepts in Components and Circuits and Fundamentals of Physics during the first year of the Telecommunication Engineering program. Students engaged in crafting practical projects centered on constructing electronic circuits and applying physical principles through the design and execution of experiments. The proposed methodology guides the entire project lifecycle, from problem identification to the development of final prototypes.

Necessary materials encompassed literature resources, simulation software, electronic components, and measurement tools. Data were collected from voluntary participants in the Fundamentals of Physics I project and compulsory participants in the Components and Circuits project. Evaluation methods included questionnaires and interviews. Results indicate that students acquired practical competencies in electronic circuit construction and experimental design rooted in physical principles. Practical application and experimentation facilitated a deeper understanding of theoretical concepts, leading to enhanced motivation. However, students in compulsory projects reported greater time commitment. This study underscores the efficacy of Design Thinking and Project Based Learning in enhancing complex subject instruction within Engineering programs. Voluntary participation correlated

[1] *R. Cervigón*
raquel.cervigon@uclm.es

with reduced difficulty and heightened satisfaction and interest, affirming the importance of fostering creativity and problem-solving skills to prepare students for success as telecommunications engineers in the professional sphere.

1. INTRODUCTION

Traditionally, engineering education and practice have been characterized by a linear and analytical approach, emphasizing technical proficiency and adherence to predefined standards and specifications. While this approach has led to remarkable technological advancements, it often overlooks the human element and fails to adequately address complex, multifaceted problems. In today's rapidly evolving world, where societal challenges are becoming increasingly interconnected and ambiguous, there is a growing recognition of the need for engineers who can navigate ambiguity, empathize with end-users, and collaborate across disciplines to develop innovative solutions.

Design thinking (DT), characterized as "human-centered," relies on evidence of how consumers interact with a product or service, rather than assumptions made by organizations. It involves observing user behavior and continually refining products or services to enhance user experience—an iterative process aimed at swift prototyping and refinement rather than extensive research [3, 5, 14].

DT, as an iterative process, facilitates our comprehension of users, challenges, and assumptions. It allows us to redefine problems to identify alternative solutions not initially apparent with our initial understanding. DT encourages students to become critical and empathetic thinkers, seeking innovative methods to address real societal needs [6]. Given its ability to reignite creativity, focus efforts, and articulate objectives clearly, DT holds immense significance in business contexts. Engineering programs are increasingly urged to graduate engineers capable of designing effective solutions for societal challenges [15].

On the other hand, Project-Based Learning (PBL) emphasizes active, inquiry-based learning, where students work collaboratively to identify, analyze, and solve complex problems [10]. Projects are designed to be interdisciplinary in nature, drawing on principles from multiple engineering disciplines and incorporating real-world constraints and considerations [16]. By engaging in authentic, open-ended projects, students develop a deeper understanding of core engineering concepts and principles, while also honing essential skills such as communication, teamwork, and project management.

To examine the principles of Problem-Based Learning (PBL) and Design Thinking (DT) and their application in engineering education and practice, we must consider four key parameters: voluntary/compulsory participation and the distinct features of each methodology. Design Thinking, which is user-focused and iterative, contrasts with Project-Based Learning, which emphasizes teamwork and problem-solving. By analysing real-world examples and case studies, this paper demonstrates how both approaches can enhance problem-solving abilities, foster interdisciplinary collaboration, and drive innovation in various engineering domains. Furthermore, we discuss the challenges and opportunities associated with integrating DT into traditional engineering curricula and propose strategies to overcome barriers to adoption. The positive impact of voluntary and compulsory projects in both PBL and DT contexts underscores the potential benefits of these educational methodologies.

2. METHODOLOGY

2.1 Integration of Design Thinking and Project-Based Learning

The amalgamation of DT and PBL confers several significant benefits within educational contexts, enhancing student learning outcomes and cultivating vital skills essential for success in diverse professional domains:

1. Holistic Problem-Solving Skills: Combining DT and PBL encourages students to approach challenges holistically, fostering a multifaceted problem-solving mindset. By engaging in real-world projects structured around DT principles, students learn to identify complex problems, empathize with end-users, ideate innovative solutions, and iteratively prototype and refine their ideas through hands-on experimentation within a project-based framework [1,2].
2. Creativity and Innovation: The integration of DT and PBL nurtures creativity and innovation among students by providing opportunities for open-ended exploration and experimentation [10]. Students are encouraged to think outside the box, brainstorm diverse solutions, and take creative risks in designing and implementing their projects.
3. User-Centered Design: DT emphasizes empathy-driven design, placing the needs and experiences of end-users at the forefront of the design process. By integrating DT principles into project-based coursework, students learn to empathize with stakeholders, gain a deep understanding of user needs and preferences, and design solutions that are user-centric and tailored to address real-world challenges effectively [12].
4. Iterative Learning and Continuous Improvement: PBL emphasizes iterative learning and continuous improvement through cycles of project planning, execution, and reflection [8]. By integrating DT principles, students engage in iterative design processes, where they prototype, test, and refine their solutions based on feedback and evaluation.
5. Real-World Relevance: Combining DT and PBL enables students to engage in authentic, real-world projects that are relevant to their academic and professional aspirations. By working on projects grounded in real-world contexts, students gain practical experience, apply theoretical concepts to real-world problems, and develop skills that are directly transferable to their future careers [9].

Empirical evidence demonstrates that both PBL and DT significantly enhance educational outcomes, though they impact different areas of learning. PBL has been shown to improve critical thinking, problem-solving skills, self-directed learning, and knowledge retention, as evidenced by studies [4,17]. Conversely, DT fosters creativity, innovation, empathy, and interdisciplinary collaboration, several studies highlighting these benefits [7]. Integrating PBL and DT can yield synergistic effects, enhancing problem-solving and creativity while increasing student engagement and motivation [11]. Overall, combining these approaches provides a comprehensive and dynamic learning experience that leverages the strengths of both methodologies.

In essence, the integration of DT and PBL offers a powerful educational paradigm that not only enhances student learning outcomes but also equips students with the essential skills and competencies needed to thrive in today's dynamic and complex world.

2.2 Methodology based on Design Thinking and Project-Based Learning

At the University of Castilla-La Mancha, this integrative methodology was implemented within the academic domains of Components and Circuits (CC), as well as Fundamentals of Physics I (FF1), targeting first-year students pursuing a Bachelor's Degree in Telecommunication Technologies Engineering. Two important differences were made for both assignments, the CC project was compulsory within the continuous assessment and the FF1 project was optional.

These projects were meticulously curated to align with predetermined curriculum objectives, while concurrently providing an immersive experiential learning environment for students to engage in iterative experimentation and prototyping. Each project was meticulously orchestrated to adhere to the iterative stages of the DT paradigm, commencing with rigorous problem identification, followed by divergent ideation, prototyping, and culminating in systematic testing and validation.

For instance, within the Components and Circuits curriculum, students were tasked with conceptualizing and constructing electronic circuits tailored to address specific engineering challenges or fulfill user-centric requirements. Through this process, students were exhorted to embody empathy towards prospective end-users, fostering a milieu conducive to innovative ideation, and refining their designs iteratively in response to constructive feedback loops.

Likewise, within the Fundamentals of Physics I domain, students were afforded the autonomy to conceptualize and execute bespoke physics laboratory experiments. These experiments were meticulously designed to be both pragmatic and resource-efficient, with an emphasis on pedagogical efficacy and potential applicability within secondary education settings. Employing the principles of Design Thinking, students meticulously crafted experiments that were user-centric, operationally intuitive, and aligned seamlessly with predefined learning objectives.

2.3 Participants

All students enrolled in the first year of engineering, in In the Fundamentals of Physics I, were invited to participate in the study, which was carried out in the first term, but only 18 students, 66% of the total, participated in the project and only 10 students completed the evaluation, representing 55% of the participants. Participants were required to purchase a variety of materials to facilitate their work on the project. These materials included bibliographic resources, simulation software, electronic components and measuring instruments. On the other hand, students of the same course and during the same period, 70% of the students enrolled in the subject Components and Circuits participated in the project, 27 students who chose continuous assessment, of which data were collected from 24 students, 88.8% of the participants, who carried out the assessment process.

In addition, to data collection, various tools such as questionnaires and interviews were utilized throughout the project duration. Following the completion of the projects, a comprehensive 15-item questionnaire was administered to assess the perceived level of difficulty encountered, the degree of interest generated, and the overall satisfaction attained by participants. This evaluation process served to glean insights into the efficacy of the projects and to identify areas for improvement in future iterations.

2.4 Design Thinking-Project-Based Learning (DT-PBL) Methodology Proposal

2.4.1 Understanding User Needs:

Begin by conducting empathetic interviews and observations with students to understand their prior knowledge, interests, and learning preferences for the Fundamentals of Physics I project. For the Components and Circuits project, engage with engineering students to ascertain their understanding of filter design requirements and challenges.

2.4.2 Define the Problem:

Based on insights gathered, define clear project objectives and constraints. For the Physics lab project, the first-year university students have to design an engaging and accessible experiment that aligns to be used and presented in high school physics curriculum objectives. In the Components and Circuits project, define specific requirements for the filter design, considering factors such as frequency range, attenuation, and component limitations.

2.4.3 Ideation and Prototyping:

Brainstorm potential experiment ideas for the Physics lab project, considering hands-on activities, demonstrations, or simulations that cater to diverse learning styles. Prototype experiment setups and gather feedback from high school students.

For the Components and Circuits project, ideate various filter topologies and configurations using simulation software. Prototype designs using electronic circuit simulation tools, considering feasibility and performance parameters.

2.4.4. Testing and Iteration:

Pilot test Physics lab experiments with a small group of high school students, gathering feedback on clarity, engagement, and learning outcomes. Iterate on experiment design based on feedback to enhance effectiveness.

Test filter designs in simulation environments, evaluating performance metrics such as frequency response, gain, and stability. Iterate on designs to optimize performance and meet project requirements.

2.4.5. Implementation and Evaluation:

Implement finalized Physics lab experiments in high school classrooms, providing support and guidance to teachers and students as needed. Collect data on student engagement, comprehension, and interest in physics concepts.

Fabricate and test physical filter prototypes in the Components and Circuits project, documenting the design process and performance results. Evaluate project success based on adherence to specifications and overall learning outcomes.

2.4.6. Reflection and Continuous Improvement:

Reflect on project outcomes and stakeholder feedback to identify successes, challenges, and areas for improvement. Document lessons learned and best practices for future iterations of similar projects.

Encourage ongoing collaboration and knowledge sharing among participants to foster a culture of continuous improvement and innovation in both educational and engineering contexts.

2.5 Planification

The course has a duration of 13 weeks, a planning for the project entitled "Design of Passive Filters for Enhanced Signal Processing", with the following timetable:

Weeks 1-2: Understand

- Define the project scope and objectives, including target frequency range and filter specifications.
- Conduct initial research to understand the application requirements and user preferences.

Weeks 3-4: Define

- Synthesize research findings to define the design requirements.

Weeks 5-6: Ideate

- Facilitate ideation workshops or brainstorming sessions to generate innovative ideas. Prototype selected filter configurations using simulation software or breadboarding techniques.
- Test prototype designs in simulated or real-world environments to assess performance and feasibility.

Weeks 7-8: Prototype

- Develop prototypes based on initial simulation results and testing outcomes.
- Conduct iterative testing and refinement of prototype designs to enhance performance and robustness.

Weeks 9-10: Test

- Evaluate the performance of optimized filter prototypes through testing.
- Measure key performance parameters, including gain, phase shift, and impedance characteristics.
- Analyze test results to identify areas for further improvement and optimization.

Weeks 11-12: Implement

- Develop implementation plans for integrating the optimized filter designs into target electronic systems or applications.
- Collaborate with stakeholders to finalize implementation details and address any technical challenges and execute the implementation plan and deploy the optimized filter designs in real-world scenarios.

We**ek 13: Evaluate and Iterate**

- Evaluate the performance of deployed filter designs against predefined criteria.
- Solicit feedback from end-users and stakeholders.
- Reflect on lessons learned and identify opportunities for further innovation and refinement in future iterations.

3. RESULTS

3.1 Result of the surveys

The survey consisted of three parts. The first part asked for a rating from highest to lowest between 1 and 5 regarding the difficulty encountered, interest and satisfaction in different aspects. Results obtained are shown in figures 1-6, as well the answers have been grouped according to difficulty, interest, and satisfaction in all the questions.

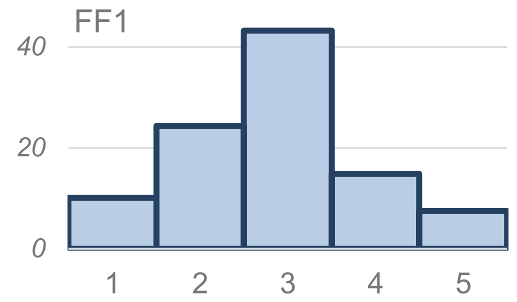

Figure 1. % Difficulty responses in voluntary.

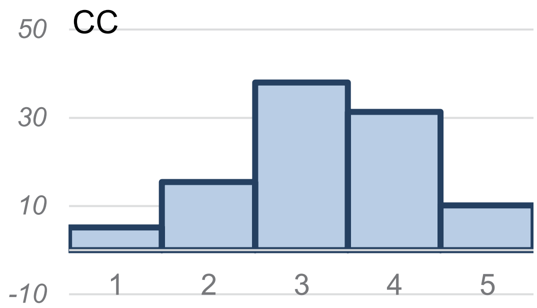

Figure 2- % Difficulty in compulsory

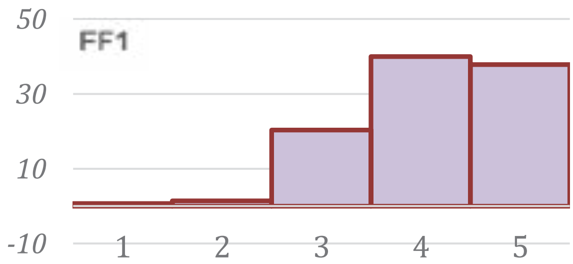

Figure 3. % Interest responses in voluntary

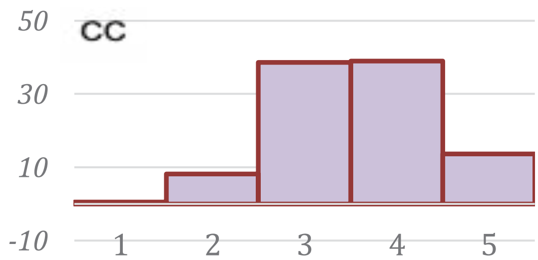

Figure 4. % Interest in compulsory

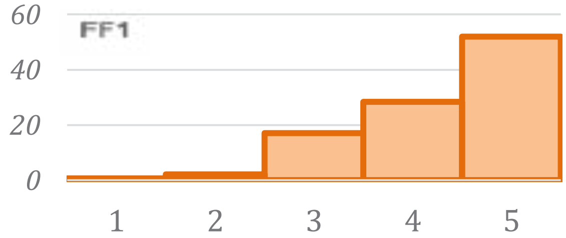

Figure 5. % Satisfaction in voluntary project.

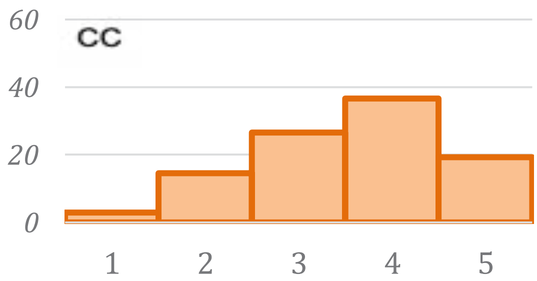

Figure 6. % Satisfaction in compulsory

The fact that the FFI the task was voluntary implies that they show more satisfaction and interest than in the case in which that was compulsory.

A second part of the survey asks students to comment on or seek advantages and disadvantages found in the project-based teaching methodology. Table 1 shows the comments given anonymously by the students.

What advantages do you find in using the project-based learning methodology?
That you feel in your own flesh what it is like to do a laboratory project with practically no reference of how to do it and to do it ourselves from scratch.
You are more self-motivated and it involves you to make memories.
You learn more and have the freedom to choose a topic.
It helps you to understand better what you have studied theoretically.
You learn and become more interested in the subject.
What disadvantages?

Well, some of the technical concepts needed to continue with the creation of the project were beyond our knowledge as students, but with the help of the teacher, they were solved.
it takes up a lot of your time because of a deadline
Lack of time
None
A lot of workload is accumulated due to other more methodical subjects.

Table 1. Advantages and disadvantages presented by students.

The results show that students acquired practical skills in the construction of electronic circuits and experiments based on physical principles. Students expressed their better understanding of the theoretical concepts of the subject through practical application and experimentation, their motivation improved, however, students for whom the project was compulsory expressed their higher time commitment to the subject. The results of the surveys showed that their interest and satisfaction was in all cases above 65%, being much higher in the case where the project was proposed on a voluntary basis (Figure 7)

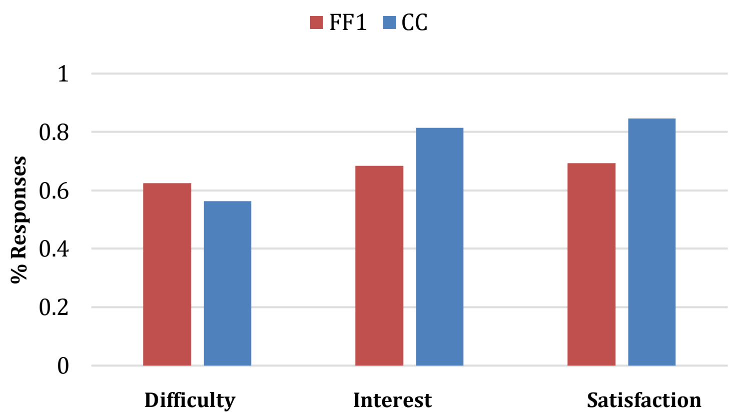

Figure 7. Average values of difficulty, interest and satisfaction in compulsory project carried out on the 24 student participants (CC) vs. voluntary for the 10 student-participants (FF1)

Finally, students are asked to self-evaluate the subject and the project in terms of their involvement and work. Figure 8 shows a graph relating the grade obtained in their self-assessment of the project to that of the subject, showing greater variability in the students who did the project on a compulsory basis (CC vs. FF1).

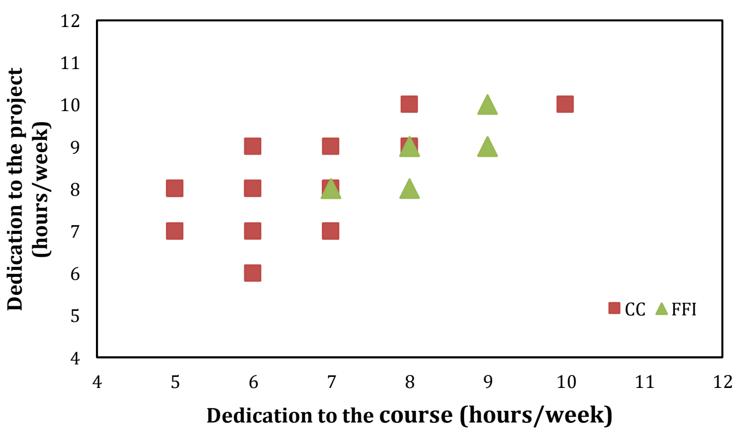

Figure 8. Students' self-assessment of the subject and the project in terms of their involvement and work

To better understand these results, a comparison between the marks obtained by the students in the project and their final marks in the subject. The score for the compulsory project increased the mark for the exam by 1.2 points. Being a voluntary project, non-participation in the project does not limit the final mark obtained by the students in the subject, but as can be seen, there is a highly positive effect between the students who participated in the project and the benefits obtained by the students in the final mark for the subject, with an average of 1.5 additional points. The students who were able to obtain a high mark in the project are those who obtained a good final mark for the subject in general. However, there are cases in which the completion of this project has allowed them to pass this subject. Studies show PBL enhances critical thinking, problem-solving, and knowledge retention [4,17]. Integrating PBL and DT in educational projects positively impacts academic performance, as evidenced by the improved marks among participating students, confirming empirical findings from both approaches.

4. SUMMARY AND ACKNOWLEDGEMENTS

The use of projects as a tool in university teaching and, above all, in technical courses such as this one, requires that the project be oriented towards the future world of work that awaits them. All the practices carried out in this project were oriented towards this end, within the possibilities and considering the limitations found in first semester students of this degree.

The response of the students was very explosive and with a risk of overflowing, here the importance lies in the teacher as project guide being able to guide the students correctly, trying to ensure that the self-imposed objectives of the students are feasible.

As conclusion, DT methodology can be a useful tool to improve the teaching of complex subjects in the Telecommunications Technology Engineering degree. The results show that when the work is done voluntarily, the difficulty is reduced, and the satisfaction and interest are higher. By encouraging creativity and problem solving in students, this project can help prepare them to face the challenges of the working world and succeed as telecommunications engineers.

Conference Key Areas: *Teaching technical knowledge in and across engineering disciplines*
Keywords: *functional programming, software engineering, correctness*

ABSTRACT

This paper lays out a case study of *Software Construction*, a new course in the undergraduate computer and communication sciences curriculum at EPFL. We hope to share some generalizable lessons we learned from running its first edition in Fall 2023. The course targets three core concepts—functional programming, real-world engineering, and correctness—and its design is informed by four principles—students should learn by doing, assignments should be self-motivating, knowledge should be built incrementally, and students should see progress over time. We illustrate how we realized these concepts and principles with practical examples of course materials and teaching methods that we hope will serve as useful inspiration to others teaching similar courses. Lastly, we present some encouraging preliminary data about course outcomes and share our speculations about experiments for its future evolution.

1 Introduction

Fall 2023 saw the first iteration of a new core course in the undergraduate computer and communication sciences curriculum at EPFL: *Software Construction* (CS-214). This practice paper describes the overarching course philosophy and how it was realized in course materials and teaching methods, particularly in their more unconventional and experimental aspects. We hope that others teaching similar courses will find it a useful case study.[2]

We begin with some background about how the course is situated within the curriculum (§ 2). Next, we lay out the three core concepts threaded throughout the course: functional programming, real-world engineering, and correctness (§ 3). We also describe a few informal pedagogical principles we tried to follow (§ 4). These concepts and principles are illustrated by a collection of practical examples, such as the design of an assignment or a lecture (§ 5). We present some preliminary data about course outcomes (§ 6) and conclude by speculating about possible experiments for future iterations (§ 7).

2 Background

Academic year 2023–24 was the first in which a complete redesign of the Computer and Communication Sciences (IC) undergraduate curriculum came into force. Among other objectives, the redesign consolidated some courses in response to complaints about fragmentation and high context-switching burden. *Table 1* summarizes relevant parts of the new curriculum (EPFL 2024). The new *Software Construction* incorporates elements of the three struck-out, discontinued courses. Between the two IC Bachelor's programs, our course is mandatory for Computer Science and optional for Communication Systems; our total enrollment in Fall 2023 was 383.

Table 1: Selected courses from the IC Bachelor's curriculum.

Year	Course
1	*Intro. to Programming* and *Practice of Object-oriented Programming* (Java)
	Advanced Information, Computation, and Communication I, II (discrete mathematics and information theory)
	Fundamentals of Digital Systems (digital design and architecture)
	general education requirements in linear algebra, calculus, physics (mechanics), and the humanities
2	***Software Construction***
	~~*Functional Programming* and *Parallelism and Concurrency* (both Scala)~~
	general education requirements, electrical engineering
	The Software Enterprise – From Ideas To Products (heavyweight project-

[2] Volumes have been written about programming and software engineering education; we do not aim or even attempt to survey the literature, rigorously evaluate its claims, or make novel research contributions. We merely present one possible instantiation of a set of coherent ideas.

3	based software engineering course) *~~Software Engineering~~* algorithms, compilers, parallelism and concurrency, and other computer and communication sciences electives

Note that the broad base of the first year lets us assume basic technical knowledge of all our students and, say, create assignments to implement a physics simulation or a compression algorithm. Further, we aim to prepare students for the courses that follow it—and for computing-related careers in general—by developing their core competencies in functional programming, real-world engineering, and correctness, giving them the confidence to build small but real software. We leave it to *Software Enterprise* to teach project management, collaboration, software architecture, and modern DevOps practices (Pirelli 2024).

3 Core concepts

The three core concepts that *Software Construction* targets are functional programming **λ**, real-world engineering 🛠, and correctness ✔. We will use these symbols to tag the examples in § 5 with the concepts relevant to each.

We teach functional programming **λ**, which we feel especially makes sense at EPFL for two reasons. First, EPFL is the birthplace and home of Scala, a programming language whose central tenet is to unify functional and object-oriented programming (Odersky, et al. 2021). Scala MOOCs and other educational materials have been developed at EPFL for over a decade. As Scala runs on the JVM with a Java-like object model, and as our students come in with two semesters of object-oriented Java programming experience, adding in functional programming with Scala next is a natural choice. The other reason we believe functional programming works well at this point in the EPFL IC curriculum is its conceptual connections to algebra and discrete mathematics. Our undergraduates build a substantial foundation in mathematics in their first year (as outlined in § 2) which lets us explain functional programming in terms of mathematical functions, rewriting, substitution, and so on.

Although our course is about building software in the small, we believe that two aspects of real-world engineering 🛠 are still relevant. One is common software engineering infrastructure, such as command-line interfaces, build tools, networks and filesystems, and version control. For instance, we teach uses of Git that students wouldn't otherwise self-learn online, such as investigating code provenance and collaborating via patches.[3] The other aspect is "external" libraries or frameworks that someone else (often the course staff) wrote, that the student is not expected to read or understand, but only interact with through an API; or students' own past work, that they can build upon with skills from intervening weeks. We hope to build students' confidence as they see themselves improve and encourage them to write code for humans as well as computers, including their collaborators and their future selves.

Correctness ✔ is our third core concept, referring to techniques to specify the absence of, prevent, catch, diagnose, and fix bugs. Diagnosing faults and

[3] These are instances of more general engineering skills in collaboration and version control that powerful tools like Git give us a golden opportunity to teach in the context of software (Wayne 2021).

troubleshooting is essential to any engineering discipline; debugging is the software counterpart, embodying a general scientific skill, viz., the scientific method (Agans 2002, Zeller 2009, Regehr 2010). Yet, it is seldom explicitly taught, and students generally lack competence in reasoning about (possibly faulty) programs (McCauley, et al. 2008, Fitzgerald, et al. 2008, Li, et al. 2019). We train students to systematically make observations about code, determine expected behaviors, make hypotheses for explaining discrepancies, and test them out with controlled experiments. Complementarily, they write automated regression tests to replicate and guard against identified bugs, documentation to record assumptions and expectations, and pre-/post-conditions to monitor them at run time. We later introduce a more formal notion of specifications and program correctness proofs, some checked by computer.

4 PEDAGOGICAL PRINCIPLES

This section describes some principles that inform how we teach the core concepts articulated above. Again, we tag each one with a symbol for later reference in § 5.

First, *students should learn by doing*. Right from the first week of the course until the final exam, students should build real, albeit small, pieces of software. Every topic should have a large collection of ungraded exercises (pencil-and-paper or short programming problems) of varying difficulties and should figure in a graded lab (programming assignment). Students should have plenty of opportunities to receive help as they work on these assignments to maintain confidence. "Active learning" of this form has been shown to improve student performance and reduce disparities in learning outcomes (Freeman, et al. 2014, Theobald, et al. 2020).

A complementary principle is that *assignments should be self-motivating*. A student should never have to wonder why they are being made to do a particular assignment, or whether a concept or skill will ever be relevant outside of class. Rather, each assignment should be fun in its own right, or useful for a realistic application (as opposed to contrived or toy applications), or ideally both. Labs should be self-contained pieces of software with visualizations and UIs whenever possible.

Another main principle is that *knowledge should be built incrementally*. This is in contrast to, say, introducing sets of new concepts in discrete units or modules, whereof the interconnections are addressed only *post hoc*, if at all. An incremental approach lets us build real software from scratch right from the start, with plenty of room to improve that we progressively explore. It also lets us clearly define what we expect students to know prior to the first week and not risk assuming further implicit background when switching between later topics. Anecdotally, this may be more inclusive of students with varied backgrounds—we were happy to find students among the top 5% who only started programming after they came to EPFL.

Lastly, as a corollary to the above, *students should see progress over time*: the progression of incrementally built knowledge should be brought to students' attention. Course materials, including assignments, should make explicit connections to previous ones. Students should have chances to revisit their own past work *in situ* and discover for themselves the improvement in their abilities over time, which we believe bolsters student confidence and reinforces the value of what is being taught.

5 Illustrative Practical Examples

Below, we illustrate the core concepts and pedagogical principles described in the two previous sections with some concrete instantiations from Fall 2023. Each is tagged as follows:

- functional programming λ,
- real-world engineering 🛠,
- correctness ✔;
- learning by doing 👩‍💻,
- self-motivating 💥,
- incremental knowledge 📚,
- visible progress 📈.

	λ	🛠	✔	👩‍💻	💥	📚	📈
`find`	●	●		●	●		
HOFs cards	●			●		●	●
`find` with HOFs				●	●		●
Incrl. abstraction			●				●
Music synthesis		●			●		
Computer proofs			●		●		●
Interview training		●			●		
Weekly debriefs							●

Lab assignment: the Unix `find` utility The first lab assignment 👩‍💻 is to write a highly simplified version of the Unix `find` utility that locates files in a directory tree matching criteria like 'last modified before Jan 1'. The value of such a tool is self-evident 💥, and upon completion, students are able to run their implementations to search their own computers. The key functional programming λ concept exercised is structural recursion. The directory tree is inherently a recursive structure, and even for students who may be scared of or uncomfortable with recursion, a recursive solution is far more natural than an iterative one—as opposed to traditional unary natural number recursion exercises like the factorial function (why not just iterate?), or trickier recursions like the Euclidean GCD algorithm (Krishnamurthi 2024). In addition, right from this first lab, we introduce realistic engineering ideas 🛠 like interacting with the filesystem using a library.

Index cards exercise for higher-order functions (HOFs) An early exercise involves a set of index cards with the definitions of simple recursive functions on integer lists, like `contains` or `product`. Working in small groups, students are first asked to draw similarities between purposefully chosen pairs (e.g. `collectEven` and `removeZeroes`), annotating the cards if they want to, and then to physically group the cards by extending the patterns they find (e.g., adding in `intersection`). Next, they are tasked with generalizing these patterns by writing HOFs λ. In the process, or by comparing with others, they may realize that some patterns are just special cases of others, and we expect them to eventually arrive at some versions of `map`, `filter`, and `foldRight` 👩‍💻 📈. We conclude by hinting that all the functions can actually be written as folds, and foreshadowing polymorphism (allowing for the same functions on strings) and generalized folds (e.g. on trees) 📚.

Lab callback: `find` with higher-order functions (HOFs) Soon after the above, students revisit their lab submission to realize 📈 that large parts of their `find` functions—`findBySizeGe`, `findByName`, etc.—were redundant. They rewrite `find` as a HOF that takes a Boolean predicate argument 👩‍💻. The utility of this refactoring that shrinks code by a factor of five is self-evident 💥. Similar callbacks throughout the semester build on past work with newly learned skills in clear increments.

Incremental abstraction and correctness Abstracting over predicates to turn `find` into a HOF is typical of the incremental progression of ideas in the course. After students define `mapInt` over (monomorphic) lists of integers and `mapString` for strings, we teach them variance and polymorphism to abstract over types; or after noting how functions like `map` and `flatMap` work similarly for lists, option types, and Futures, we introduce the abstraction of monads. Incremental program transformations elegantly lend themselves to incremental reasoning about correctness ✔. For instance, in a single exercise set, we have students (i) observe that some recursive functions perform redundant computation on subproblems; (ii) make careful, encapsulated use of mutable state to fix the issue with memoization; (iii) generalize to an arbitrary function memoizer; and (iv) further observe that it may be sufficient for the memo to record only some subproblems, i.e. convert the function into a *dynamic programming* problem.

Signal processing and music synthesis A compelling real-world application of lazy evaluation in functional style is music synthesis. Starting from just the Java Sound API, an hour-long lecture builds combinators for low-level processing like resampling, higher-level effects like echoing, amplitude envelopes, sequencing based on musical scores, and so on, to synthesize realistic snippets. The lecture is presented in literate style using Alectryon (Pit-Claudel 2020). Using Scala lazy lists bypasses problems with buffer boundary conditions, single-use streams, and variable source-driven sample rates, while letting us build an elegant, compositional library.

Computer-checked proofs In some early exercises, students write inductive proofs of functional properties (e.g. `append` is equivalent to `concat` with a singleton) as a series of rewrite rules ✔. This sets the stage for introducing computer-checked proofs based on the Lisa proof assistant (Guilloud, Gambhir and Kunčak 2023). Students experience first-hand how a computer can make checking proofs less tedious and error-prone and increase confidence in correctness.

Coding interview training In the final week, a lecture about coding interviews includes a mock interview where an instructor is given a programming puzzle and demonstrates how to approach the problem, think out loud, make progress in limited time, and answer questions about generalization and correctness.

Weekly debriefs Every week throughout the semester, we post a debrief on the course website with a summary of student questions that may be of broader interest, tips for exercises and labs, and additional relevant material. The content is informed by periodic class polls and individual student interactions to let students learn from their peers and witness their collective progress.

5.1 Supporting logistics

Below are some logistical details that let us better fulfill our educational objectives.

Computerized final exam The final bears special mention due to the fairness and logistics challenges posed by our large class size and the recent widespread availability of code-generating AI tools. The exam is a set of mini-labs, with no hidden tests, graded at scale with the same homegrown autograder infrastructure as for lab assignments. We conduct the exam on custom virtual machines in thin-client computer labs so that we can test students' abilities in isolation from external help. Students do not have Internet access but do have access to course materials (including any published solutions), their own submitted work, and a standard Scala development setup. They are given opportunities to get comfortable with this environment beforehand but their actions are not persisted.

Student assistant (SA) training workshop We run a workshop to help our SAs better help students during office hours in the spirit of the course's values. We have SAs read and discuss a short handout about professional and respectful conduct, how to enable active learning rather than simply answering questions, Pólya's problem-solving method (Pólya 1945), and other concordant guidelines, encouraging them to reflect on their own teaching and learning experiences. They also watch and respond to mock office-hours interactions of varying helpfulness. Finally, we recommend that they take a complementary SA training offered by CAPE.

6 PRELIMINARY DATA

Fall 2023's *Software Construction* was successful overall, despite being offered for the first time. Some quantitative metrics about the course were very encouraging: in the end-of-semester student course evaluations conducted by CAPE, the EPFL Teaching Support Centre, with a 25% response rate, 96% of respondents agreed or strongly agreed with the statement "Overall, I think this course is good." on a 4-point Likert scale. This was the highest rating among all large courses in IC.

Another set of metrics was designed to evaluate the course's high-level objective of "developing [students'] core competencies […] giving them the confidence to build small but real software" (from § 2). We asked students whether they "feel comfortable", "know how to", or "often" use the techniques and tools we taught, on a 5-point Likert scale. The questions were presented before the first week (alongside other questions about students' background) and after the final exam as part of CAPE's course evaluation survey (alongside their regular questions common to all courses). All data was anonymized and only aggregate, non-identifiable statistics are reported in Figure 1. Students broadly felt more confident along all axes. While our course was not our students' only activity during the semester, none of their concurrent courses addressed our topics[4], and second-years are not yet eligible to participate in research projects.

[4] *Computer Architecture* teaches some hardware programming; *Numerical Methods for Visual Computing and ML* uses Python as a means to use domain-specific libraries, and *Signal Processing* is largely theoretical with some Python assignments.

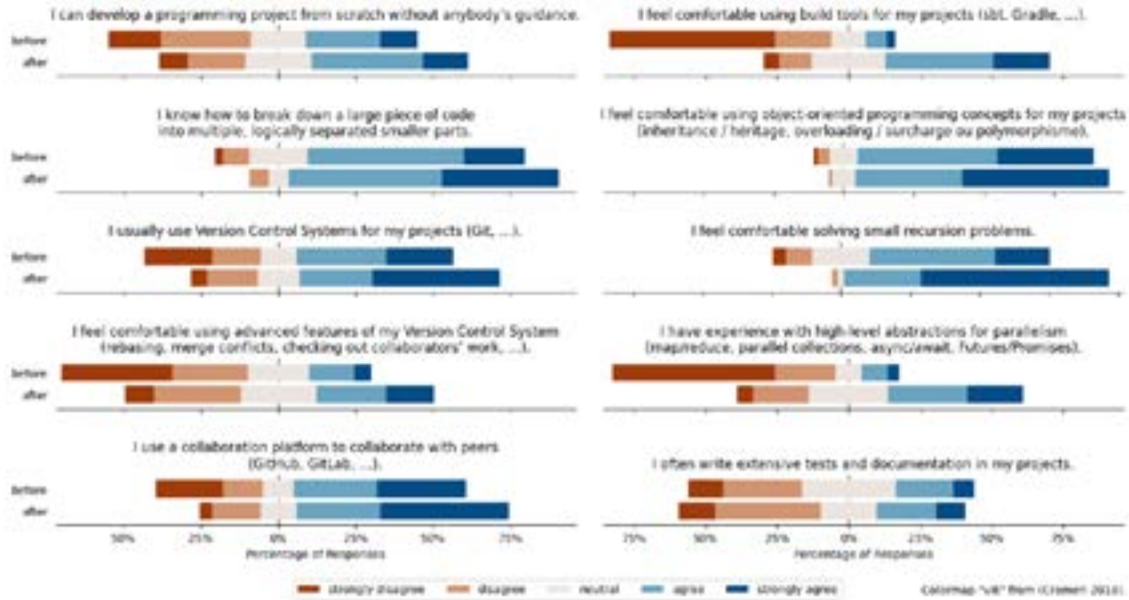

Figure 1: Respondents' answers to Likert-scale questions about skills Software Construction aims to develop, in a questionnaire posted on our LMS before the first week of classes ("before", n = 283), and in a questionnaire administered by CAPE after the final exam ("after", n = 97). Our class size was 383.

7 LOOKING AHEAD

Below, we outline some experiments that we didn't have the time for or hadn't thought of in Fall 2023. Grading is a common theme: our experience indicates that many students don't do assignments if they aren't graded, and don't feel that they learned a topic if it wasn't specifically targeted in grading.

Develop a capstone group project In Fall 2023, we laid the foundations in the form of a lab assignment for what we believe can grow into a fulfilling, open-ended capstone group project for the course: server-client webapps. Following a state-machine–based architecture, the webapp lab has students build two simple games, maintaining a single piece of server-side mutable state of which clients statelessly render projections. The framework is easy to extend to more complex applications, such as a chat room, an authentication meta-application, or classic board and card games. We envision these extensions being developed as group projects that students can showcase on a shared server at the end of the course. We plan to consult prior work on software capstone projects to make ours most effective (Tenhunen, et al. 2023), and in particular, for students not yet ready for full-blown project management techniques (Kuhrmann and Münch 2018, Marques, et al. 2017).

Evaluate code comprehension at scale Software engineering relies as much on understanding and reasoning about code as on writing it, and recent advances in AI will only make the former more relevant. We would like our grading strategies to reflect this. We already know how to automatically grade correctness judgements for small programs (MCQs on a paper exam), pre-/post-condition specifications (run-time monitoring), and some formal proofs of functional properties (Lisa). Beyond that, we could evaluate test writing by running students' tests for a lab assignment on a provided buggy implementation and on other students' submissions, and awarding points based on number of bugs identified, number uniquely identified across peers, code coverage, etc., learning from prior research on peer evaluation of software

(Groeneveld, Vennekens and Aerts 2020). Automated execution visualization tools in the style of PythonTutor (Guo 2013) may also be relevant. However, important skills we don't yet know how to evaluate automatically include debugging, documentation writing, program structure (e.g. types, class hierarchies), and code style.

Provide in-person feedback and evaluation Code comprehension and organization may be better suited to individual, human judgment. We find that one-on-one interactions with staff can be far more effective than other forms of evaluation and feedback—and secondarily, than other forms of detecting cheating. Back-of-the-envelope estimates suggest that such "checkoffs" may be feasible to scale, for, say, 1 out of every 2 weekly labs, if SAs have appropriate training.

Teach the teachers: SA training SAs play a key role in our vision for the course. Ideally, they would be able to judge a student's understanding of code, give design and style feedback, help fix bugs by teaching debugging rather than debugging themselves, answer questions without giving away answers, track and communicate common difficulties with other staff, and participate in developing new materials. (This would also take load off of time-constrained PhD students and let them assume a more supervisory role.) Being an SA is a challenging job—one that we hope to explicitly train them for, and one that we think is a worthwhile outcome of the course in its own right, whether or not they return as staff in subsequent years.

Highlight real-world engineering in labs Despite lab assignments having been the primary training ground for debugging, version control, working with libraries and other people's code, program design, and code evolution, these topics were not tested explicitly. Students consequently felt that labs didn't sufficiently exercise real-world engineering. We aim to address this discrepancy by calling out engineering topics where exercised in each lab and grading them when possible. For instance, for Git exercises, students could submit Git bundles for automatic grading. Other courses situated similarly to ours may have useful lessons, like (McBurney and Murphy 2021).

Reuse classic exercises Learning by doing is a principle shared by our colleagues in mathematics and physics, whose textbooks and course materials include dozens of small cut-and-dried exercises per topic. Students are typically assigned a few key exercises and are free to do more. We believe we can likewise supplement problems we design with others of exceptional quality from classic, highly acclaimed texts like *The Art of Computer Programming* (Knuth 2022) and *Structure and Interpretation of Computer Programs* (Abelson and Sussman 1996).

8 CONCLUSION

Software Construction served—and will continue to serve—as a testing ground for ideas about programming and software engineering education. In this first iteration, we identified a coherent set of ideas that work well together, targeting the three core concepts of functional programming, real-world engineering, and correctness (§ 3), and following some informal pedagogical principles (§ 4). We share some concrete illustrative examples in this paper with the hope that they will be useful for others trying to adapt our approach to their own contexts (§ 5). After presenting some preliminary quantitative data about course outcomes (§ 6), we identify avenues for future experimentation (§ 7). We hope the lessons we learned that we share in this paper will prove helpful to other educators just as they will help us iterate on the course in the future.

9 ACKNOWLEDGMENTS

In Fall 2023, *Software Construction* was co-taught by the second author and Profs. Viktor Kunčak and Martin Odersky. Many materials and ideas were adapted from *Functional Programming* and *Parallelism and Concurrency*, taught in the past at EPFL by Odersky and Kunčak, and MOOCs about Scala and programming, developed by Odersky and others at the Scala Center. *Software Construction* teaching assistants along with the first author were (listed alphabetically) Yann Bouquet, Matthieu Bovel, Samuel Chassot, Sankalp Gambhir, Yawen Guan, Anna Herlihy, Yichen Xu, and Yaoyu Zhao. Lastly, the course would not have been possible without our great team of Bachelor's and Master's student assistants.

We thank Fabien Salvi, our system administrator, for technical support. We also thank Joelyn de Lima and the rest of the CAPE team for productive discussions about the course and this paper.

Keywords: *gender, power dynamics, collaborative learning, phenomenology*

ABSTRACT

Previous research has examined patterns in women's team interactions within collaborative learning environments, highlighting potential barriers that hinder their full participation. This paper explores two analytical frameworks that could be beneficial in investigating power dynamics in such settings. Through a narrative literature review, we establish links between individuals' experiences and broader social or institutional practices, revealing underlying discourses and power relations. We identify a lack of evidence regarding discourses shaping attitudes and behaviours that perpetuate power inequities. Awareness of these dynamics could

facilitate the provision of support and empathy to a more diverse group of students in engineering education.

1 INTRODUCTION

Project-based learning and other group-based pedagogies have proven to be valuable approaches for increasing engagement, self-motivation and performance in engineering courses (Du & Kolmos, 2009; Kolmos & de Graaff, 2014; Wu et al., 2021), factors that may ultimately lead to improved persistence, retention and graduation rates of students in the field. Nonetheless, other research has also indicated that students from underrepresented groups in engineering may encounter challenges or unfavourable outcomes from group work and team-based projects (Fowler & Su, 2018; Henderson, 2023; Hirshfield, 2018; Keough et al., 2021; Meadows & Sekaquaptewa, 2013). For example, Henderson (2023) reported incidents in team interactions related to power dynamics that undermine women's opportunities to participate in learning experiences, including being excluded from team decisions, patterns of interruptions when talking, or inequitable task allocation.

This paper responds to feedback on previously presented work (Cruz Moreno et al., 2023), which reported preliminary findings from a phenomenological analysis of women students' experiences in PBL settings. We aim to comprehensively understand the phenomenon by incorporating an analysis of power relations as intrinsic to examining identity and experience.

Within that context, this paper explores how the phenomenological analysis of collaborative learning environments could include the analysis of power dynamics. The purpose is to examine existing frameworks using an epistemic pluralist approach that combines phenomenology and poststructuralism as a means to improve the qualitative analysis of a dataset of interviews performed to date.

The research questions that guide this piece of the study are:

1. How do phenomenology and poststructuralist philosophies intersect to describe the human experience and knowledge production in collaborative learning environments within engineering education?
2. What existing analytical frameworks could be accurate for researching students' experiences and power dynamics in collaborative learning within the context of engineering education?

The article begins with a literature review summarising research on the lived experiences of women in collaborative learning environments in engineering courses, identifying the benefits and challenges they face regarding such pedagogies. A special focus is given to the literature related to power dynamics within collaborative learning contexts. Then, the theoretical foundations of phenomenology and post-structuralism are briefly described before we explore two analytical frameworks that combine both perspectives. The adaptability and impact of these frameworks aim to analyse power relations embedded in collaborative learning based on engineering education research (EER).

2 LITERATURE REVIEW

2.1 Collaborative pedagogies in engineering education

Within an educational context, collaborative learning is described as a pedagogical approach that entails collective intellectual efforts among students, or between students and their instructor (Stump et al., 2011). The teaching of professional skills through collaborative learning projects has become a common practice in undergraduate engineering programs. Vast research suggests that project-based learning (PBL) positively impacts students' understanding of engineering principles, students' ability to apply such principles to real-world problems, and students' skills with regard to social, ethical and organisational aspects of engineering (Picard et al., 2022). In a collaborative learning culture, students learn with, from and about each other via teamwork (Krishnan et al., 2011). Research on collaborative learning often suggests deeper student engagement than traditional lecture-based transmission methods. Although the effectiveness of the collaboration depends upon the dimension assessed, e.g., social aspects, cognitive aspects or student achievement (Stump et al., 2011), key concepts for successful engineering education teamwork have been identified; they include interdependence, trust and shared mental models (Borrego et al., 2013).

2.2 Women in collaborative learning environments in engineering education

Communication and teamwork are seen as key elements in the training of engineers (Beddoes, 2020), as decision-making in the field is often the result of collaborative contexts (Francis et al., 2022). However, gender dynamics and stereotypes often underpin socialisation processes of women in engineering or other STEM courses (Dancy et al., 2020; Henderson, 2023). This is particularly relevant considering that the cultural characteristics of engineering learning environments often revolve around competitiveness and masculinity (Kamanda et al., 2022). In this context, women students are at risk of underestimating or underreporting their skills during role negotiation in team projects, potentially affecting their academic motivation and performance (Henderson, 2023).

3 THEORETICAL FOUNDATIONS

There is a growing demand to broaden the epistemological perspectives used in engineering educational research. This call aims to promote advancements in both learning outcomes and learning experiences for groups of students who have been marginalized historically (Svihla et al., 2023). In this context, epistemic pluralism acknowledges the importance of exploring diverse theories to elucidate a particular phenomenon across various levels, employing a range of suitable conceptual methods (Wegerhoff et al., 2021).

This section addresses the first research question and aims to understand how phenomenology and poststructuralist methodologies should be integrated to develop a comprehensive theoretical framework for researching collaborative learning environments in engineering education.

3.1 Phenomenology: understanding subjective experiences

Classical phenomenology is concerned with the essential and invariant structures underlying the experience of everyday life from the first-person point of view

(Moustakas, 1994; Sokolowski, 2000). Thinking, reasoning and perception are not confined within the individual's mind but, rather, are related to the world in which the individual is embedded (Sokolowski, 2000), to look at how thoughts and experiences create our understanding of reality, and with it, knowledge (Dodd, 2020).

Furthermore, unveiling the structures of lived experiences requires references to the subjective meaning an action has for the actor (Schutz, 1971). Phenomenology falls short when attempting to interpret the connections between lived experiences of a given phenomenon and power structures that might not be part of the individuals' narratives (and awareness) of everyday life.

3.2 Poststructuralism: understanding power, discourses and knowledge

Poststructuralism, as a critical response to structuralism, challenges the idea of fixed systems of meanings shaped by social structures, in which people have little, if any, control (Savin-Baden & Major, 2012). It also denies that the structures of the experience can be described from a first-person point of view "without attending to the ways in which individuals are positioned in historical contexts that are largely dominated by power relations" (Magri & McQueen, 2023, p. 7). This argument implies the need for a methodological approach that explores beliefs and practices by searching in historical records, avoiding accepting taken-for-granted truths (Wuthnow et al., 1984).

Moreover, Foucault, an influential representative of this school of thought, explored relationships among power, knowledge and discourse and stated that "power and knowledge directly imply one another" (Foucault, 1995, p. 27), meaning that knowledge serves power, but also power produces knowledge. By creating dominant discourses, subjects are shaped with perceived truths (discourses) that emerge from the power-knowledge relationship. Their perception of phenomena (and the meaning they ascribe) varies depending on their standpoint towards power-knowledge.

Within this context, rather than a dichotomous definition of power as the influence or control of powerful entities over powerless ones, a common conceptualisation of power – based on Foucault's work – is defined as a relation to understanding how subjects relate to each other and how institutions are organised (Apple et al., 2010).

3.3 Intersections of phenomenology and poststructuralism

The credibility of phenomenology as a social research paradigm relies on a clear alignment between its philosophical foundations and the practical methods employed (Larsen & Adu, 2022), making it necessary to assess to what extent phenomenological methodologies can be combined with other approaches while maintaining a consistent logic among the theoretical frameworks.

For now, we observe two intersections that demonstrate epistemological coherence between these two theoretical perspectives, namely phenomenology and poststructuralism: (1) language serves as a regulatory system that provides evidence of meaning; (2) constitution of experience and subjectivity are key aspects with which both approaches are concerned. Nevertheless, there are also some methodological disagreements. A central one was mentioned above – related to investigating power structures to inform the understanding of our experiences, ourselves and our world. Critical assessments of classical phenomenology highlight the tacit presuppositions underlying the relationship between power, knowledge, discourse, and social experience (Magri & McQueen, 2023).

4 ANALYTICAL FRAMEWORKS TO RESEARCH GENDER AND POWER DYNAMICS

In this section, we address the second research question by exploring an analytical framework relevant to understanding students' experiences and power dynamics in collaborative learning environments.

Studies investigating the learning experiences of underrepresented minority students in EER have identified relationships between individuals' experiences and a range of structural factors, including social, economic and cultural contexts. These studies have employed diverse theoretical frameworks, methodologies and methods to explore these relationships across the spectrum.

We have chosen these frameworks because they provide conceptual tools to disclose power dynamics from lived experiences while also examining deep structures of inequality.

4.1 Gender at Work Analytical Framework

The Gender at Work Analytical Framework (Rao et al., 2016) explores power relations embedded in institutions and communities. It analyses two dimensions: the individual-systemic spectrum and the informal-formal spectrum. The combination of both dimensions forms four quadrants concurrently: (1) Consciousness and Capabilities; (2) Resources; (3) Rules and Policies; (4) Social Norms and Deep Structures. The framework helps to make explicit power dynamics of each quadrant that maintain barriers to gender equality (see Fig.1).

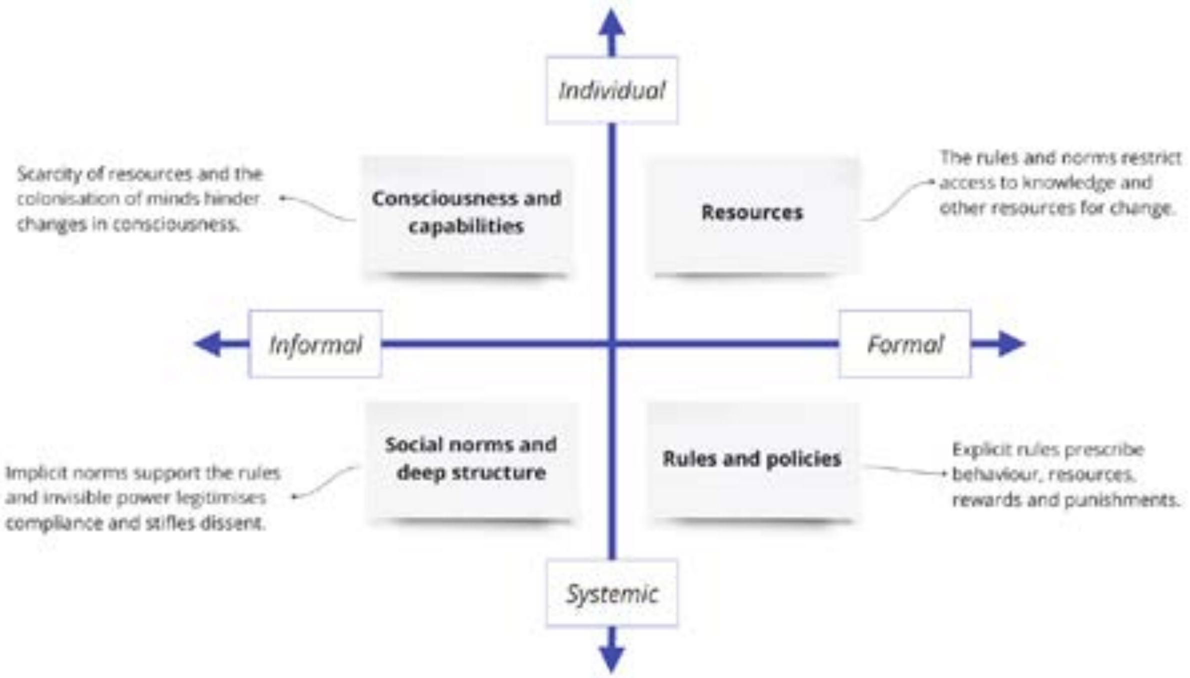

Fig. 1. Gender at Work Analytical Framework, including power dynamics of each quadrant that maintain gender inequality (Rao et al., 2016)

This analytical framework has informed research across various disciplines. For instance, Njuki et al., (2023) used the Gender at Work framework to meta-analyse gender-transformative research in diverse fields such as fisheries, small-scale mining, health, water and sanitation access, gender-based violence, and early marriage, encompassing studies from Africa, Asia, and Latin America. Perhaps the framework could prove useful in engineering education for understanding gender inequality, designing interventions for change, and mapping outcomes.

The relevance of this framework with regard to our research objective (i.e. achieving a comprehensive understanding of collaborative learning by incorporating analysis of power dynamics as intrinsic to the examination of experience) is twofold:

(1) In the context of micro-social interactions such as collaborative learning, the four quadrants of the Gender at Work Framework can be assessed, even at different levels, for instance, group, classroom, campus, university, etc.
(2) We observe that the Gender at Work Framework is compatible with the phenomenological approach, providing conceptual tools to comprehend how power dynamics shape individual experiences and enabling a deeper comprehension of the phenomenon under study.

4.2 Intersectionality

Intersectionality studies how an individual's experiences, constraints, and opportunities are the result of the intersection of multiple systems of power (Carrigan et al., 2023). Social identities (e.g., gender, race, class, etc.) are connected to systems where certain groups can exercise power and privilege and, therefore, are more likely to be heard. A helpful intersectional conceptual tool to make power relations explicit is offered by Collins and Bilge (2020) in the form of four interconnected domains of power concerning:

a. Structural practices. This domain refers to the fundamental structures of social institutions (Collins & Bilge, 2020, p. 7), including policy and policy-like practices (Svihla et al., 2023) .
b. Cultural practices. This domain explores the ideologies that structure power dynamics, creating a narrative about equal opportunities for all (Collins & Bilge, 2020, p. 9).
c. Disciplinary practices. This domain refers to how rules and regulations are differently applied to people based on their identities (Collins & Bilge, 2020, p. 12). This approach delves into how individuals influence and pressure one another to conform to established norms.
d. Interpersonal practices: This approach explores how individual experiences are influenced by social intersecting attributes such as gender, race, class, cultural background, age, etc (Collins & Bilge, 2020, p. 15).

Within those categories, we can distinguish two interconnected factors contributing to those power dynamics: (1) those related to individual identities and (2) those related to institutional structures and educational practices that may either reinforce or mitigate power differentials in students' lived experiences.

This paper's ultimate objective is to identify analytical frameworks beneficial for researching power structures that affect students' experiences in collaborative learning within the realms of engineering education. Such frameworks could prove valuable for researchers and practitioners involved with engineering education.

5 ADAPTABILITY TO THE CONTEXT OF ENGINEERING EDUCATION

Through a narrative literature review (Saunders-Smits & NI, 2024), we have examined 19 references concerning students' experiences within the field of engineering, identifying power dynamics elucidated in these studies and categorising them according to the analytical frameworks outlined in the preceding section. Following that, we attempt to unravel the experience within its context to identify perceived behaviours that account for power relations and the discourse behind those behaviours. This analysis aims to find connections (and contradictions) between individuals' experiences and broader social or institutional practices.

5.1 Social identities and relational habits in collaborative learning

Both analytical frameworks explore the individual's personal mindsets and emotions as well as collective identities and cultures as foundations for analysing the power dynamics. In the realms of engineering education, research indicates that students' feelings of isolation or not fitting into engineering stem from experiences of exclusion or barriers hindering their full participation based on gender and race (Campbell-Montalvo et al., 2022; Dancy et al., 2020; Powell et al., 2009; Stump et al., 2011). The most commonly reported findings in research on collaborative learning, when viewed through the lens of social identity, include examples of discriminatory behaviour, microaggressions and harassment as a response of stereotypical attitudes (Aeby et al., 2019; Hirshfield, 2018; Keough et al., 2021). Such identity politics are often enacted to confine group members by providing them acknowledgement while also serving to further exclude those who do not fit the group identity (Apple et al., 2010, p. 134).

Given this context, frequently students from underrepresented minority groups perform strategies to fit in the dominant group, with one of them involving downplaying the disadvantages associated with being part of the minority group (Powell et al., 2009), a pattern that could be seen as a discrepancy between perception and experiences, for instance witnessing and accepting micro aggressive acts against other students from minority groups (Campbell-Montalvo et al., 2022).

Nevertheless, a prominent discourse masking inequities based on social identities is the claim that engineering is free of sexism and racism (Campbell-Montalvo et al., 2022; Dancy et al., 2020). This asseveration not only reproduces the ideology but also fosters privilege-blind bias.

5.2 Social norms and culture in engineering education

The collective patterns of action and thinking in collaborative learning shed light on a shared understanding of the engineering culture beyond educational settings. These social norms and culture shape the discourses of what is normal and acceptable (Rao et al., 2016). For instance, Kamanda et al., (2022) found that students may imitate behaviours they perceive as indicative of engineering success, such as consistently staying late in the computer lab, to signal such expectations to their peers. Eventually, students collaborating will position and be positioned by others. These patterns of behaviour will often lead to shape role identities, such as "the one who usually knows how to do it", "time organiser", "the one who always needs help", or "the creative thinker" (Holland & Lave, 2001, as cited in Nolen et al., 2024).

Furthermore, given that engineering environments often emphasise competitiveness and masculinity (Kamanda et al., 2022), students may be reluctant to collaborate due to the pressure to outperform their peers (Stump et al., 2011). Regarding masculinity, research also reveals that women students experience offensive behaviours (often veiled as mere jokes), which prompt them to question their choices, capabilities, and aptitudes (Powell et al., 2009). The notions that women engineers are unattractive, insufficiently intelligent, or relegated to the easiest subfields are just a few examples of how the culture within engineering may perpetuate a power dynamic that systematically undermines women in the field. Some implications of it are that women students perform less technical aspects of the project, which might mean restrictive access to equipment and decision-making, and the reproduction of gendered valuation of skills (Aeby et al., 2019; Fowler & Su, 2018; Henderson, 2023).

5.3 Formal structures and policies for equality

Institutional policies and educational practices impact individuals in varying ways depending on their social and role identities. For example, in a study exploring black students' experiences, the research team recognised that negative perceptions toward their race extend beyond the engineering field and are embedded in the broader campus climate (Campbell-Montalvo et al., 2022). In a separate study, researchers discovered that students from privileged backgrounds might view themselves as part of a disadvantaged group. This perception could arise in response to policies and practices, such as affirmative action, designed to address inequality (Stump et al., 2011). Similarly, feelings of rejection or imposter syndrome may arise among women students when they hear messages implying that institutional policies for diversity, equity, and inclusion are the reason for women's participation in engineering fields.

Throughout the analysis, we encountered extensive research elucidating students' emotions and experiences within collaborative learning environments, as well as the social behaviours precipitating these experiences. However, we noted a scarcity of evidence regarding the discourses underpinning attitudes and behaviours perpetuating power inequities. Moreover, evidence of how institutional structures and educational practices may reinforce or mitigate power differentials is much less addressed, a shortage that justifies linking phenomenological and post-structural methodologies for our own research. By labelling these 'truths' in our own terms, we broadened our perspective to explore structural contexts and fostered critical reflection on the challenges of experiencing collaborative learning in engineering.

Finally, a limitation of the Gender at Work Framework consists in the absence of explicit concepts to analyse multiple aspects of identity besides gender.

6 CONCLUSIONS AND IMPLICATIONS FOR RESEARCH AND PRACTICE

Proactively developing collaborative learning environments in engineering is crucial (Beddoes, 2020). Examining students’ experiences and identifying the inherent power dynamics and dominant discourses is essential for addressing the interplay of knowledge, power, and discourse that often perpetuates inequities in engineering education. The assumption that students will work effectively and automatically when placed in teams is incorrect and risky if power dynamics are not acknowledged (Fowler & Su, 2018; Hirshfield, 2018).

Thus far, our research team has faced challenges in finding a method or approach that effectively integrates the emotional depth described in our interview dataset with the broader contextual aspects of learning. An epistemically pluralist approach acknowledges that a single methodology does not promote a comprehensive understanding of the phenomenon and its complexity theoretically and in practice (Wegerhoff et al., 2021). We have thus embarked on an exploration combining phenomenology and poststructuralism to gain a deeper understanding of collaborative learning in engineering education. In this pursuit, we began by exploring analytical frameworks to analyse the power dynamics inherent in students' experiences, constituting this paper's primary contribution to the field.

Based on the research reviewed, further work could address the development of a theoretical framework to support the further analysis of gender and other intersectional inequalities in engineering educational practices. Research on the unseen challenges that engineering students face in collaborative settings due to power dynamics can be instrumental in making these issues visible, fostering support and empathy, and developing a more welcoming learning environment for diverse groups in the field

Keywords: *Engineering design; Problem based learning, Groupwork, Self-learning, Self-determination, Peer support*

ABSTRACT

Large engineering modules containing a diverse array of technical and design content can cause students to both disengage and treat taught content as silos. By not understanding the wider context and inter-linkage between diverse technical content, solving authentic design problems becomes problematic for students and staff. These deficiencies were addressed through repackaging our original engineering problems into smaller but authentic group based 'design shorts'. These smaller problems purposely connect a diverse range of structural engineering topics using formative assessment to facilitate self and peer supported student learning. Constructive feedback and dialogue were key elements to ensure successful student outcomes and attainment of learning outcomes. The impact of these design shorts on student engagement and module results over a six-year period is reviewed. Importantly, these 'design shorts' introduced a strong ethos of 'thinking', self and

[1] *AW Davies*

group peer supported learning and curiosity when addressing structural design problems.

1 INTRODUCTION

1.1 Overview of need

Most teaching practice in engineering revolves around students learning through the acquisition of facts or procedures. Content taught within a module does not usually migrate across that module nor onwards to other modules, let alone across years of study. Students seemingly view taught content and modules as silos, independent of each other and not obviously inter-related. This is contrary to the belief of staff who struggle to understand why students cannot interconnect technical knowledge across diverse content areas.

Our second year BEng/MEng students (FHEQ Level 5; QAA 2014) within the Department of Civil Engineering in the School of Engineering at Cardiff University take a year-long 40-credit module titled ‘Structural Analysis and Design’, equally split between the Autumn and Spring semesters. This large module was formed from separate and smaller courses covering the design of steel and concrete structures, structural analysis, solid mechanics and failure theories content, as well as the detailed design of a multi-storey building in steel and reinforced concrete.

This module was delivered over a 7-hour day every week for both semesters. Traditional lectures were timetabled in the morning and covered fundamental content, with the afternoons being practical workshop sessions held in a large baseroom. The baseroom environment was meant to apply previously taught technical theory to authentic problems initially posed within tutorial sheets. However, students really struggled to connect with the inter-related content, resulting in a decline of engagement and satisfaction.

Pedagogical interventions were introduced over a six-year period with a view to improve student engagement and understanding of structural behaviour. Due to the breadth of taught content and mode of delivery, students struggled to link their learning across these topics and had little intuition on whether solutions to structural problems were viable or not.

The interventions were aimed at moving away from individuals undertaking tutorial sheets and to provide a series of formative group assignments timetabled at regular intervals during the semesters based on previously taught content. These assignments further created a sequence of directed feedback opportunities to enhance students’ understanding of structural behaviour and introduced a self-learning ethos. These assignments became known as “design shorts” which were planned to purposely interlink content across this module and to create a “thinking” culture amongst students.

1.2 Pedagogical reasoning for group ‘design shorts’

Our teaching philosophy within engineering has transformed and evolved over the years, moving away from teacher-focussed approaches to student-centred activities (Trigwell et al 1999). This is important because there is a strong relationship between how teachers teach and how learners learn (Monroy and Gonzalez-Geraldo 2018). The transferable skills involved in creating ‘thinkers’ and for ‘learning to learn’ are vitally important in today's society and engineering practices, as noted by Hacker et al (2009).

Staff began to embrace this 'changing as a person' approach, as highlighted by Marton et al (1993), where learning is about transitioning students to 'think' about their learning and to become self-motivated. Since group work forms a critical aspect of an engineer's life, 'learning-together' would strengthen our existing 'problem-led' teaching practice, which was based on the Universal Design for Learning (UDL) guidance (CAST 2018). This new approach to empowerment also provided opportunities for students to benefit from peer support and provided scaffolding in their early learning journey ie by creating a 'Communities of Practice' environment and a peer-support (Lave and Wenger 1991; Wenger-Trayner 2015) structure. These approaches allowed the introduction of further aspects of cooperative and collaborative learning into group work.

Whilst transforming our own teaching practice and that of others, how students approach studying (van Rossum and Schenk, 1984) can be influenced by their own conceptions of learning. Many students use a surface approach, memorising content for assessment. However, their learning becomes superficial with little appreciation of engineering principles beyond answering specific questions posing as assessment. Whilst trying to promote a deeper approach to study with students, the diverse needs of students focused on understanding the wider learning context and accommodating student circumstances.

After some false starts, our pedagogical approach developed to that best defined as being Andragogy - more independent, learner-directed and self-motivated student learning – with teaching becoming more of a mentoring role (Delahaye et al 1994). The common one-way 'zone of proximal development' (ZPD) model (Vygotsky's 1987) approach modified over time, becoming an authentic two-way collaborative learning environment, which is better known as the 'intermental development zone' (IDZ). Hence, utilising more open-ended and authentic problem-based approaches to promote discursive talk (Fernandez et al 2002) have elicited very favourable student comments. Uncertainty was purposely introduced into the technical "design shorts" to promote discussion and deeper evaluation of solutions.

As noted earlier, a goal of our teaching practice was to create 'self-learning' graduates with the skills for 'asking the right questions'. Is content and subject knowledge more important than 'knowing how to learn'? It is important to facilitate learning, as noted by the various roles ascribed by Bates (2014) and more recently Perryman (2019) to the 21st century educator, such as 'teacher for learning', 'experimenter' and 'educator for everyone'. These metaphors formed the ethos for our teaching practice on this module, promoting 'assessment for learning' and not 'learning for assessment' through our challenging "design shorts".

Feedback is also a crucial aspect of student learning and is one of the most important influences on learning gain (Hattie 1999). However, very few students effectively engage in this process. Feedback is inseparable from assessment, especially when it is relevant, constructive, accessible and timely. To better engage students and develop their curiosity, feedback became a core mechanism for promoting self and peer supported learning within the module. Feedback ideally needs to be done immediately rather than much later and its relevance understood by students as being a key aspect of learning.

2 DESIGN SHORT STRATEGY

2.1 Group work rationale

Group work should be a positive and harmonious experience for students and staff but this often requires careful and detailed planning. Providing clear instructions and guidance on undertaking group work is essential, together with outlining expectations and support on how to assign tasks across group members and how to work as a group, which is not always straightforward. When conflict arises, we defined alternative work for smaller groups and individuals from the onset which we found to be good practice; just knowing there is another route when problems arise can provide reassurance and aid the wellbeing of students (McPherson et al. 2019).

Groups were randomly allocated and normally consisted of six students. To create the team working and self/peer learning environment, the “design shorts” continued to take place in a large open plan baseroom which consists of chairs and tables arranged to allow group members to face each other. This module typically has circa 120 to 140 students, so 20+ groups are formed which require between four and six staff members to purposely interact during the 3-hour long workshops and especially for the feedback sessions.

Our learning pedagogical goals coupled with the diverse structural engineering content directed our thoughts to developing four ‘design shorts’, each being particular to a structural engineering problem that spanned across different taught content and created to enrichen the student learning experience. Each design short takes 3-4 weeks to complete, with findings presented to staff in a design office format within the baseroom. The first week for each design short involves a short introductory talk followed by a baseroom session which then continues over the following 2 weeks. The formative assessment takes place in the fourth week, with each group having 30 minutes to present their solutions to staff via calculation sheets, to discuss arising issues and receive feedback.

The design shorts were also conceived to guide students to explore, compare, validate and verify solutions based on a variety of structural analysis techniques or assumptions made in the behaviour of a structure. Although the individual reasoning behind the design shorts is not the purpose of this paper, an outline of each is provided below for context.

2.2 Design shorts

The first design short investigates load paths in various braced and unbraced 2D and 3D frames using physical K’Nex’ models and utilises quantitative reasoning to provide qualitative answers. Figures 1 to 4 show some typical examples of Design Short 1 tasks. Continuity within the frames and stiffness of components adds to the complexity of calculating values but observation aids students to identify the direction of loads, flexural behaviour and the possible range of support reactions. This is important in appreciating and validating output from computer analysis.

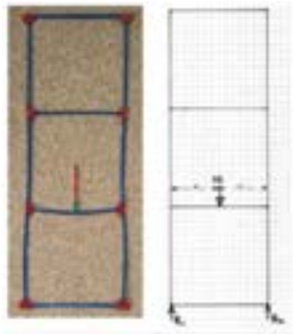

Fig. 1. Design Short 1 - 2D plane frame (R1=R2=5)

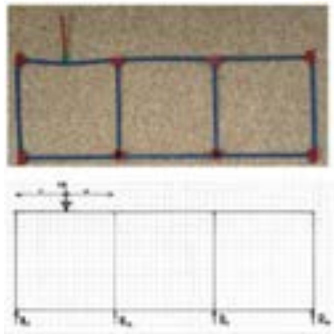

Fig. 2. Design Short 1 - 2D plane frame (R1 ≤ 5;R2 ≥ 5;R3 ≤ 0;R4 ≥ 0)

Fig. 3. Design Short 1 - 3D steel frame equivalent model

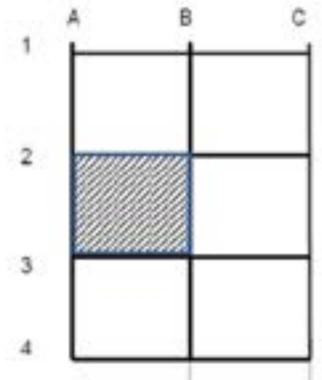

Fig. 4. Design Short 1 – 3D model patch load of 120 units on the first floor

The remaining three design shorts compare and evaluate structural analysis results for indeterminate frame structures. For each task, different analysis techniques such as energy methods and matrix stiffness analysis, as well as linear-elastic structural software (LUSAS) and code of practice design guidance are utilised and compared.

Design Short 2 concerns an indeterminate bridge structure (shown in Figures 5 and 6) and asks students to identify the maximum unfactored variable load (kN/m^2) on the two-span continuous beam bridge, considering the capacity of the beams in bending and shear only. Students were required to use Energy Methods (Castigliano’s Second Theorem) and Design Guidance from the IStructE (2009) to determine the bending moments and shear distribution for the bridge beams. Full calculations were required showing the maximum unfactored variable load determined from the two analysis methods and a brief commentary on any differences in results.

Discussion points to consider included pattern loading, understanding the concept of an ‘envelope’ of results, unequal span lengths, location of span moments and redistribution of moments. Students were also asked to quickly check their results by using fixed end moments (FEMs) or other means.

Design Short 3 builds on Design Short 2, with inclined steel struts being introduced (see Figure 7) to increase the variable load capacity of the bridge. Using LUSAS (structural analysis software) and Design Guidance from the IStructE (2009) the maximum unfactored variable load is again determined based on the resistance of the beams in bending and shear and reactions used for sizing the steel section struts. The struts are partially restrained in direction at both ends.

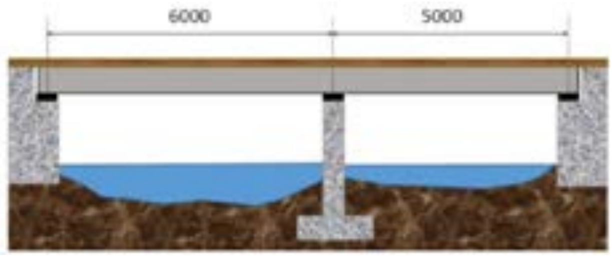

Fig. 5. Design Short 2 – bridge elevation

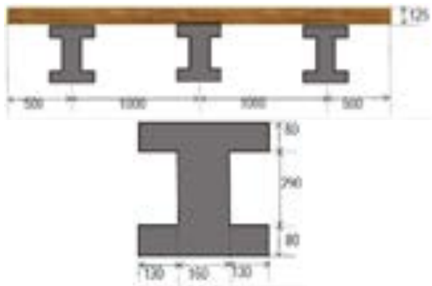

Fig. 6. Design Short 2 – bridge cross-section and beam dimensions

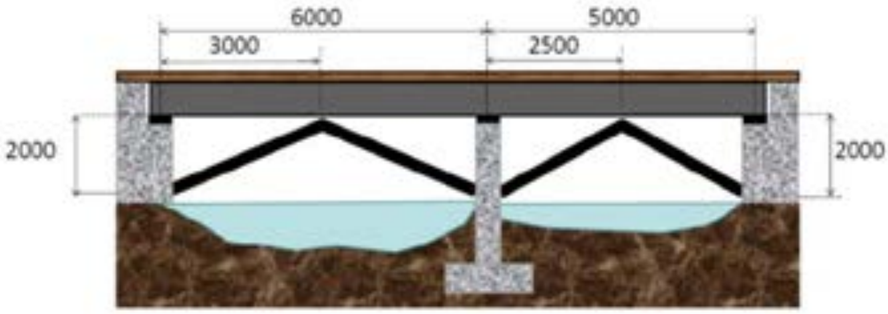

Fig. 7. Design Short 3 – bridge elevation showing inclined struts

LUSAS output had to be quantified against other reliable solutions ie design guidance and utilising FEMs. It is highlighted that results are only as good as the input data and the assumptions made when setting up the analysis model.

Design Short 4 culminates in the detailed design of both a concrete and a steel structural multi-bay single storey frame (see Figures 8 and 9) which is used to infill a space between two existing but adjacent buildings. The frames were spaced at 5m centres and support a pre-cast concrete roof deck.

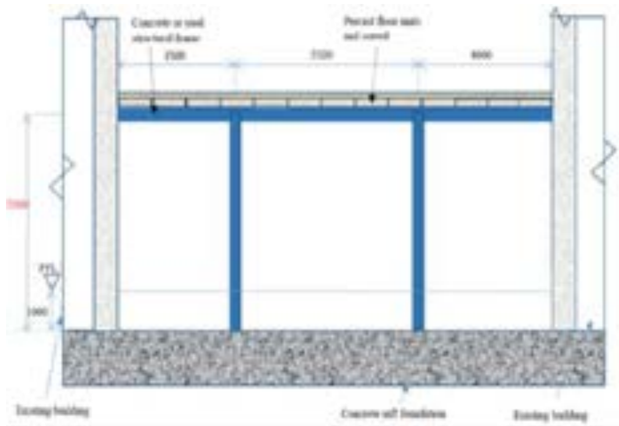

Fig. 8. Design Short 4 – multi bay frame elevation

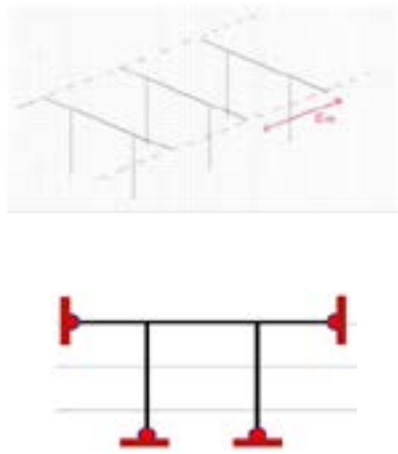

Fig. 9. Design Short 4 – multi bay frame spacing and supports

Students were tasked to use stiffness-based matrix analysis methods to undertake a series of structural analyses. Details provided to students include detailed loading values, support arrangements and foundations. Beam-connections were considered continuous ie moment carrying. Full calculations and sketches were required to support solutions. Commentary on the frame analysis results and verification by other unspecified means was also requested.

2.3 Why formative assessments?

Understanding the ‘assessment for learning’ strategy (CAST 2018) provided staff with student feedback to address any areas where further development or support was needed, while allowing students to determine which areas of their study required additional attention. The importance of discussion and feedback is critical and formative assessments provide a safe environment for student learning while getting rid of the ‘do I get a mark for this’ response. Hence, this module was redesigned to explicitly include formative assessment events aligned with the benefits of a mentoring approach with planned feedback loops. The goal was to have dialogue with students as they tackled problems and how they understood structural behaviour rather than a better-intentioned monologue from staff.

Care is needed in designing these assessments since they can easily become atomised, focussing on the micro-level of what is easy to assess while failing to integrate and assess complex, higher-order learning. Fundamentally, the sum of parts not adding up to making the intended whole. As Lipman (2013) noted, ‘students acquire bits of knowledge that, like ice cubes frozen in their trays, remain inert and incapable of interacting with one another.’

All students were required to attend formative group assessment presentations. Assessments do not carry any marks but are a qualifying element ie they need to achieve a certain standard to pass. Students presented their solutions to a member of staff as part of a round-table discussion; all group members need to present their own work and be prepared to answer questions on any aspect of the design short.

Solutions and all workings have to be presented on calculation sheets and clearly define units, reference to previous calculations and any notes or guidance used. Calculations need to be clear and well presented to allow easy checking, using annotated sketches to quickly explain assumptions, equations, theories or output and to illustrate dimensions, sizes, loads and elements being analysed or designed.

3 OUTCOMES

3.1 Student reaction and results

Students have found these design shorts to be very impactful on their learning. Having to validate and verify different results arising from various analysis techniques applied to the same problem introduced uncertainty and then a deeper appreciation of why solutions differed. Students gradually moved away from asking ‘what is the right answer’ to ‘how do I know that this is correct’ onto ‘Ah, I can see why I got that result’.

Overall, the design shorts bridged content that was evidently inter-connected in the minds of staff but were islands of knowledge for students. This simple change in approach did yield improved module results and student progression by 8% and 5% on average respectively. Individual technical structural engineering examination results over the six-year period showed an increase of up to 8.4%. Covid 19 did disrupt our learning and teaching between 2019-2021, with these examinations changing to being online and split to smaller manageable assessments timetabled over a longer exam period.

Qualitatively, student comments over this period have highly praised our design short approach. Typically, students mentioned that ‘it was a challenge, and the design shorts were good real-life applications of engineering’ and ‘the design shorts engaged you throughout the year and provided constant feedback from the lecturers on results and personally on progressive understanding of the content’ and being applied ‘to a real-life situation’. The workshops and formative assessments also gave ‘a little insight into a design office, (albeit in university) environment’ and ‘improved my teamwork skills’.

Importantly, learner autonomy and empowerment were also observed (Nunn and Nunn 1993; Freire 1998) within the design shorts, where the ‘traditional’ educational model of transmitting knowledge moved towards an environment of dialogue between staff and student but also between students – a two-way learning experience for all.

4 SUMMARY AND ACKNOWLEDGEMENTS

This design short approach has certainly improved student learning and been far more effective in addressing the module learning outcomes than some of our traditional examinations. Development work continues since there is no ‘perfect’ learning model but it is pleasing to note that this pedagogical approach is now being adopted in other large engineering modules within Cardiff University and the wider university.

More satisfaction has been garnered in later years of study where the greatest impact staff found was that students began to show a stronger self-learning ethos and an enthusiasm to ask questions to their previous experiences. The skills involved in undertaking these ‘design shorts’ has created more effective student ‘thinkers’ and fostered ‘learning to learn’ attributes that are vitally important in their engineering career.

ABSTRACT

The Bachelor program in Industrial Design Engineering (IDE) at the University of Twente's Faculty of Engineering Technology is undergoing a transformative journey. Recognizing the need for an update to reflect the evolving landscape of industrial design engineering and its impact on society, the program staff is redesigning the curriculum. Emphasizing the role of design engineers in building a sustainable future,

[1] *W. de Boer*
w.f.deboer@utwente.nl

the reform aims to empower students by offering more choice, enhancing coherence, and integrating more reflection into the learning process.

In collaboration with students and staff, the reform prioritizes ownership of learning, coherence of the program, and relevance to real-world challenges. The curriculum emphasizes hands-on learning through project-based modules, gradually increasing complexity and autonomy for students. Additionally, the program integrates academic and professional skills, encourages continuous reflection and more attention for design and research strategies.

Aligned with the Dutch Ministry of Education's pilot for a smarter academic year, the IDE curriculum reform aims to create a learning environment that fosters student growth and intrinsic motivation, by providing a challenging but feasible program that supports students with formative feedback in the learning process. By embracing these principles, the program prepares students to become responsible design engineers equipped to address the complexities of our changing world.

1. INTRODUCTION

The curriculum of the Bachelor program of Industrial Design Engineering at the University of Twente, within the faculty of Engineering Technology, is currently undergoing a redesign. The staff initiated this process to update the programme, in line with the many developments in the field of Industrial Design Engineering. Such developments relate to technological developments, the ability to focus more on sustainable products, but also the changing role of industrial design engineering in building a socially and environmentally sustainable society. The previous accreditation made recommendations regarding learning outcomes, student guidance and development-oriented feedback and support. These suggestions were reflected in the aims of the reform, which focus on the coherence of the program and providing opportunities for students to take more ownership of their learning. This is achieved through activities that encourage reflection and by offering more electives within the program, with the overarching goal to educate responsible design engineers. Furthermore, the program reform will focus on more explicit attention for design and research approaches, as well as on updating program intended learning outcomes. The aim is to embed the program in a strong learning and teaching community that fosters cohesion and inherently integrates academic and professional skills in the program.

This practice paper provides an overview of the work-in-progress of the curriculum reform. In this context, it is relevant that the IDE program participates in a pilot project of the ministry of education (OCW) that focuses on the problem of high workload for students, teachers, and researchers. The OCW pilot enables a number of universities to organize educational activities in their educational programs in a smarter way, so that more 'rest and space' is created for students and lecturers during the academic year. For the new IDE curriculum, it is imperative that staff and students are able to perform at a high level, for which the feasibility of teaching and studying within the program is an essential prerequisite. In this paper, we will explain how the OCW pilot is contributing to the redesign of the IDE curriculum to make the new academic program smarter, with more feasibility for staff and students. Whereas this approach is described in the context of the IDE programme as a case study, its applicability is not limited to this context. The approach is, for example, is also taken over for the overhaul of the BSc. programme in Mechanical Engineering.

2. THE CURRICULUM REFORM

Industrial Design Engineering at the University of Twente started in 2001 (Van Houten, 2002). It originally initiated from Mechanical Engineering, which is (still) a program at the faculty of Engineering Technology, where IDE is hosted as well. IDE has a bachelor's degree program with an average of 120 students per year. The total number of students is about 450 students. The program also has a master's program with about 250 students. The influx of students is a mix of international and Dutch students, with about 50% of the students coming from outside The Netherlands

The last accreditation was in 2019 (NVAO, 2020), and both the MSc. and the BSc. programs met all NVAO quality standards. Still, the committee did make recommendations to improve the program, suggesting that the learning outcomes should make more explicit reference to the international dimension, that the opportunities for staff to advise and coach students could be expanded, that the relationship between the intended learning outcomes and the thesis assessment could be made more explicit, and that development-oriented feedback to students could be incorporated more systematically.

In 2022, a steering committee of IDE staff was set up, to develop a blueprint for the reform. The mission of IDE's Bachelor's programme was defined: to educate responsible design engineers who integrate societal needs, technological developments, and academic insights. IDE aims to be a top-rated program by fostering a teaching and learning community that prepares graduates for an ever-changing world. Central to the curriculum reform is the proficiency of students to take ownership of their own learning journey. The program aims to cultivate intrinsic motivation, curiosity, and passion for industrial design engineering, enabling students to become the industrial design engineers they aspire to be.

3. A SMARTER ACADEMIC YEAR

The Ministry of Education in The Netherlands initiated a pilot project for a 'smarter academic year' in 2023 (*UToday*, 2023). The rationale behind this pilot is the observation that that the Dutch academic year is relatively long and intensive compared to other countries. This results in a high workload for students, teachers, and researchers, having implications for research and other core scientific tasks.

The aim of the pilot project is to responsibly reduce the number of weeks of education/ examinations and/or to organize existing educational activities in a more resourceful way, so that more 'piece and quiet' is created for students and lecturers during the academic year. This also creates more space for improving and innovating education, conducting research, participating in (scientific) conferences, and attending training and courses. For students this could generate more options in terms of the timing, pace and moments of exams, extracurricular activities, summer schools, internships, visits abroad, and better options to balance study, job and private life.

The pilot is foreseen for four years: 2023 - 2026. The pilots will be evaluated and monitored by the participating institutions and nationally by the leading universities: University of Amsterdam and Erasmus University Rotterdam. Particular attention will be paid to the impact on the workload of students, lecturers, and supporting staff, as well as to the quality of education.

The aims of the pilot are in line with the ongoing IDE curriculum reform. The IDE program, therefore, made a proposal to participate in the Smarter Academic Year pilot, which was granted. The pilot aims to contribute to the program to establish a learning experience in which students can flourish and become the best they can be. For the program it is important that it encourages students to work for their own development and growth - rather than to pass exams. Students pass the regular test at the end of a module, with resits being the exception. The program is also designed to be feasible, which means that students have enough time to study seriously and hard. The program should therefore have well-distributed and sparse deadlines throughout the modules. Next to the summative exams for the courses, formative assessments form an important element what would support learning.

From this list of aspirations relevant for the Smarter Academic Year pilot, several guiding questions emerged that enabled work on the curriculum and program reform:

1. Encourage students to study for their own development: How can students be encouraged to study for their own development, building on intrinsic motivation that leads to curiosity and passion in learning (i.e. Ryan & Deci, 2000)?
2. Sufficient time to study: How can the program be organised in such a way that adequately prepared students (in general) can pass exams/assessments, while having time to study, avoid study overload, and have limited and well-distributed deadlines in the modules (i.e. De Jonge Akademie, 2021)?
3. Include formative practices including formative assessment, giving feedback and build on it: How can formative assessment be incorporated in the modules and the program (e.g., Dirkx, Joosten-ten Brinke & Camp, 2010)?

These questions were used in the operationalisation of the curriculum and program reform, which the next section elaborates on.

4. THE CURRICULUM REFORM JOURNEY

The IDE programs at the UT, at Delft University and Eindhoven University of Technology all make use of the Domain Specific Reference Document for the Academic Industrial Design Engineering Programme (QANU, 2014), which was defined more than 10 years ago. This reference document has its origin in the Academic Criteria for Bachelor and Master Curricula (Meijers, Overveld, & Perrenet, 2003). In the reform, the program intended learning outcomes were updated, while still originating from the original set; they address designing, the disciplines relevant to IDE, as well as research and the scientific approaches to be learned. They also address intellectual skills, the ability to deal with temporal, social and personal contexts, collaboration, and communication. As it is identified as an important new aspect of the programme, a new learning outcome explicitly refers to students becoming responsible professionals who can work in international and intercultural contexts.

At the University of Twente, the TOM-model (Visscher-Voerman & Muller, 20217) is the prevailing educational approach. The core of the approach is that the BSc. curriculum consists of modules of 15EC, each consisting of a project and integrated/related courses. This project orientation aims to give students more control over their learning process. When IDE started (before TOM was introduced), it already was project based (Eger, Lutters, & Van Houten, 2004). The project-based approach implies that the learning environment allows students to work on the knowledge and skills that make them better design engineers. The project-oriented education focuses explicitly on student development by providing realistic engineering environments, which contributes to student motivation and the learning attitudes.

In the reformed curriculum, project work will continue to be a core part of each 15EC module, emphasizing hands-on learning through challenging, relevant projects, balancing real-world complexity with structured support. Initially guided by different design engineering perspectives, students will gradually explore and incorporate additional viewpoints, cultivating a conscious and confident understanding of their role in the field. In the first two years in the BSc. programme, modules increase in complexity, integrating thematic projects with courses that encourage analytical thinking, creativity, technological insight, and affinity with users. In the second year, students have the autonomy to choose specific tracks, roles, and courses in the modules, tailoring their learning experience to their interests and needs. In the third year, students further personalize their path by choosing a minor program that matches their interests. They culminate their studies with an individual final project that showcases their unique skills as an Industrial Design Engineer. The IDE program at UT prepares students for diverse professional contexts, fosters pride in their identity as Industrial Design Engineers, and equips them for their chosen career paths.

In meetings with staff, but also in close collaboration with students and the program committee, a set of curriculum requirements have been formulated to shape the redesign. Within the curriculum the following principles are seen as leading:

A. ***Become the IDE-er you want to be:*** A core element of the curriculum reform is student involvement and ownership of learning. The aim is to create a learning environment and a learning experience that enables students to become the IDE-ers that they want to be, help them to have a clear idea of their own identity and give them (more) responsibility and ownership in their learning journey. The program is challenging, it develops intrinsic motivation, curiosity and passion for industrial design engineering and eagerness to master new and complex content.
B. ***Integration/coherence, being a learning community:*** One of the main targets in the new curriculum is to increase the coherence of the program, based on a strong learning community of lecturers and students. Lecturers in each module develop an explicit vision on how their module fits into the curriculum as a whole. Module teams know what students have learned in previous modules, and (where appropriate) refer to and build on that. They can explain to students what the intended learning outcomes are, how they relate to the programme outcomes and how this relates to previous and subsequent modules.
C. ***Connection with (real) world (issues):*** Another important paradigm in the program reform is that the curriculum will be (and will evolve to stay) up-to-date, with a strong link with the (challenges in the) real world. Hence, currently relevant developments are integrated into the learning activities on an ongoing basis. The integration of academic and professional skills, as well as the relation to practically relevant challenges will make the program more appealing for students, and it will help them to become future problem solvers.
D. ***More explicit attention to research and design approaches:*** In the new curriculum, each module will (more) explicitly introduce specific research and design approaches in relation to the project themes. Students will fill their ‘IDE toolbox’ with expertise and experience, thus they will progressively be able to

formulate what research and design approaches are relevant to the different engineering design challenges they are working on.

E. ***Integrated academic and professional skills/competences:*** Students need academic skills to be successful in their learning. Professional skills prepare students for their futures as professionals. In each module, students work on these skills in the context of the module theme. The importance of the academic and professional skills/competences is reflected by their positioning in the modules, courses, and project learning outcomes and in their assessment.
F. ***Continuous reflection:*** Reflection is an important element of each module. The modules incorporate activities in which students reflect on the research and design approach(es) that have been introduced in this or previous modules. Also, reflection activities are planned for the academic and professional skills. At the beginning and at the end of each module, time is planned for explaining, discussing, and reflecting on how the intended learning outcomes of a module relate to the learning paths of individual students in relation to the programme outcomes, to previous modules, and to subsequent modules. The activities planned in the module result in contributions to the individual student portfolio that captures a student's identity and incites the development of a student throughout the entire bachelor program.

The guiding questions mentioned in section 3 have a clear relation to the principles mentioned here. For example, involvement and ownership of learning (A) and continuous reflection are strongly related to guiding question 1 - study for own development. Simultaneously, reflection (F) requires some distance, and therefore sufficient time to study - question 2. Question 1 also calls for the learning community (B) that is invested in, as students and staff working together strengthens a better understanding and ownership of the program, the activities, the outcomes and the mutual relations between these. In this, formative practices (question 3), are core to prepare students for real world issues (C), while employing academic and professional skills (E)."

The principles were important for the elaboration of the different steps in and levels of the development of the renewed curriculum: from the blueprint level to the design of learning activities, materials, teacher and student roles, resources, time, and assessment (Thijs & Van den Akker, 2009).

The blueprint made in 2022 included topics for each of the 12 modules in the 3-year programme, as well as proposed design and research approaches. Table 1 depicts the themes as well as the research and design approaches of each module.

Table 1. Themes and the research and design approaches of each module

Module	**1. Ideation**	**2. Prototyping**	**3. The human perspective**	**4. Mass-production**
Design approach	Diverging and Converging	Design for functionality	Iterative design, participatory design	Systematic design engineering
Research approach	Desk research	Experimental validation	Usability testing, user evaluation	Market research, text
Module	**5. Data driven design**	**6. Design for value**	**7. Sustainable futures**	**8. Product Service Systems**
Design approach	System thinking	Integrated product development	Tool & techniques	Grounded theory
Research approach	Technology adaption/ acceptance	Decision making	Analysis (LCA) and impact analyses	Desk research, structured interviews
Module	**9. Minor**	**10. Minor**	**11. Design for transitions**	**12. Bachelor Thesis**
Design approach			Futuring, participatory design	
Research approach			Research through design	

For each module, a design team has been established, and regular workshops have been organised in 2023 and 2024. Where the process of the curriculum renewal is very intensive, the module teams, together with the steering team meet in workshops every month, to further develop and detail the new program. In parallel to these content-oriented activities, a lot of more organisational and administrative preparations take place, for example in co-operation with the programme committee, the examination board, study-advisors, and educational support staff. In the spring of 2024, the proposal for the new curriculum is intensively discussed with the (newly installed) work-field committee, the faculty council, and the program committee, so that the first year of the new programme can start in the new academic year (24/25).

5. A TEACHING AND LEARNING COMMUNITY

Projects, courses and other TLAs carry the content of a curriculum, but the physical environment and facilities are also crucial to the success of the reformed programme and its teaching and learning community. Particularly for an academic programme such as IDE that is closely linked to (industrial) practice and constantly seeks to combine research and teaching, it is essential that students and staff can work together in dedicated and inspiring settings. This includes, for example, some kind of community space that challenges all stakeholders to focus on design processes at all stages and with all aspects - while transcending individual projects, courses, and student cohorts. In such a space, a contemporary master-apprentice approach (Lutters and Damgrave, 2023) plays an important role, while strengthening the learning and teaching community. Currently, a community space is being designed and its integration into the academic organisation, infrastructure and budget is being prepared. This master-apprentice approach also is a guiding principle in the development of a so-called learning factory (Abele et al 2024; Lutters and Damgrave, 2023) that is currently being built. This learning factory will include, for example, a metalworking shop floor, model making, woodworking and assembly environments, but also a virtual reality lab, a tinkering lab, and a rapid prototyping facility, as well as an environment for flexible production, assembly, and packaging lines. With its different environments, it integrates many themes, stakeholders, perspectives, and facets that make up a flexible, dynamic, and evolving production facility. As such, it will host a teaching, learning and research community for different disciplines and levels of aggregation - from first year students learning about production processes to PhD students focusing on topics such as factory layout. In this approach, both contribute to the formative practices that are mentioned in the guiding questions, as well as in creating an environment that helps students to study for own development.

6. IMPLEMENTATION

Presently, the programme reform is still in full swing, with the courses/projects in the first year already being detailed, whereas the learning activities for the second and third year are still defined at a more abstract level. An important change in the new planning of the reform is that the coherence of courses within the modules is improved, and as an effect of that, lesser courses per module are foreseen. This has a positive effect on the number of summative assessments and deadlines, which of course contributes to the “study-ability” of the program (see guiding question 2: sufficient time to study).

Working on so many inter-related changes requires strategies to control the quality. From the start of the reform trajectory, quality assurance and educational evaluation are integrated in the work of the steering committee and the module teams. After all, measuring and controlling the effectiveness and efficiency of a significant program overhaul, its facilities and its learning & teaching community is no simple task. For that, a purposeful set of metrics, methods, or approaches is needed. Consequently, in the program reform a pragmatic and straightforward approach, such as PDCA can be of great value to rely on available evaluation techniques from educational sciences, encompassing surveys, focus groups, panel meetings, expert visits, but also more quantitative/statistical tools to compare outcomes and results of the reformed program to the previous program.

One of the innovations that was observed as an essential element within the efforts to support students to study for own development is the implementation of so-called Development Coaches. Starting in September 2024, key staff of the programme will each guide a small group of students in group and individual sessions throughout their Bachelor. The main aim is to interact with the students on explicating their focus and reflection on the learning trajectory and their personalised formulation of their envisaged future learning goals. In this, students are supported and challenged to take (more) ownership in their learning process. This approach is seen as an exiting journey in which we, as a teaching community, also will learn a lot about our students, our programme, and probably: about ourselves.

Interesting in this respect is that all stakeholders in the IDE program, and especially teaching staff and students, have additional evaluation approaches to their avail. After all, IDE is a design program, which means that that the teaching staff and students foremost see the reform as a re-design project, which allows them to employ the entire toolbox of reflections, evaluations, and assessments that product designers habitually use in their design processes and in their interactions with 'the client'. Bringing together such tools from the IDE-field with the educational approaches enables a setup of comprehensive tests and evaluations to measure the success of the reformed program, to adjust the program based on the findings, and to prepare for continuous improvement as well as for staying up-to-date with technological and societal evolvements. Moreover, in the reform process, the amalgamation of design and educational evaluation approaches has already proven to be instrumental, for example, as it has been – and is – a very strong instigator in forming the teaching and learning community that will be the core of the reformed program.

7. CONCLUDING REMARKS

The curriculum reform for the IDE Bachelor Programme aligns with the objectives of the Ministry of Education's pilot for a smarter academic year. The program aims to improve student development, by programming in such a way that students are given sufficient time to study, by integrating formative practices, and by fostering a strong learning community. IDE aims to create a curriculum that prepares students to be responsible design engineers, well- equipped to address real-world challenges.

In the ongoing process of implementing the blueprint and curriculum reform requirements, experiences and educational research/evidence will be used to discuss and decide on how the program evolves in response to issues encountered. It is important to continue to implement the guiding principles in the courses and projects. For the modules of the first year in the programme, this implies that the plans are currently in the detailing phase, as the first module will start in September 2024. For these first modules, this implies that planning and decision-making has moved from tactical to operational level. As the new programme is implemented based on a rolling horizon, the other modules are still at more tactical level. The reasons relate to the available development and teaching capacity, to the time available, but certainly also to the opportunity to still learn from the findings of the commissioning of the modules in the first year. Our journey will provide relevant insights that also will be of interest for engineering programs that have similar ambitions. We are dedicated to systematically keep on learning and sharing our experiences with the engineering community.

ABSTRACT

Debate is a transversal, active, cooperative, and problem-based learning methodology and its use is positively and effectively documented also within the field of engineering education to boost transversal skills. The significant and acknowledged contribution to educational innovation that debate can offer in the current university context and in engineering education in terms of content learning and skill development, however, tends to overshadow its broader potential for Faculty Development. Assuming that Faculty Development can encompass at least broad dimensions such as professional, curricular, and institutional development, this article explores with a case study and qualitative methodology how debate can be fruitfully adopted for supporting Faculty Development in engineering faculties. The experiences conducted at the Faculty of Engineering of the Cattaneo University – LIUC – a systematic adoption of debate in didactics and a national university tournament on Sustainable Development Goals entitled *Debating Agenda 2030*, among others – show how debate can enrich Faculty Development by providing

opportunities for professional and curricular development while fostering learning and collaboration among students, institutions, and communities.

1 INTRODUCTION

In today's work-professional landscape, engineers are increasingly called upon to acquire soft and professional skills in addition to their solid technical knowledge base. These skills include critical thinking and problem-solving, effective communication, and teamwork and collaboration skills, among others (Klaassen, 2019; University College London, 2019; Winberg et al. 2020). However, integrating the development of transversal skills with technical specialization requires an innovative and as comprehensive as possible institutional approach so that the impacts are stable and widespread. This approach is not without challenges. This entails the introduction of innovative teaching and learning methodologies that integrate both technical content and transversal skills development. In this context, debate emerges as a promising approach because debate not only fosters these skills but can also serve as a tool for Faculty Development, helping to enhance teachers' ability to integrate transversal skills into the engineering curriculum as well as institutional development in terms of internal and external community building and relations. Therefore, this paper aims to investigate this relationship, seeking to answer the following research question: how can debate be fruitfully adopted for supporting faculty development in engineering faculties?

2 THE THEORETICAL FRAMEWORK

2.1 Debate methodology between traditional and innovative teaching approaches

Debate is a reasoned and regulated confrontation between two teams on a controversial topic before a panel of judges (Branham, 2013; Anonymous, 2014). It is a transversal teaching methodology, used at all educational levels and across disciplines. As an active method, it engages students in their learning process. It is cooperative, requiring student collaboration despite its competitive nature, and it is centered on problem-based learning, addressing significant, complex problems with no single solution (Freeley & Steinberg, 2013).Debate is promoted as an innovative teaching methodology, yet it has deep roots in Western culture, beginning with ancient Greek dialectical meetings codified by Aristotle in his book *Topics*. In the Middle Ages, debate became a key university teaching method through disputations, including public events like *quodlibetal disputations* (Novikoff, 2013). Since the 18th century, it has spread from Anglo-Saxon universities to global education systems, aimed at developing civic and soft skills (Potter, 1944; Snider and Schnurer, 2002).Currently in Italy, debate is promoted not only by the school government transformation movement *Avanguardie Educative* (INDIRE) but also by the Ministry of Education and Merit through the national competition for excellence, *Campionati Nazionali di Debate* and at university level, by non-governmental organization *Società Nazionale Debate Italia* (SNDI) which promotes the *Italian Youth Debate Championship - University*.

Since the 1980s, debate has shaped academic research by redefining objectives from developing transversal skills (Allen et al., 1999) to enhancing social and civic competencies and academic success (Mezuk et al., 2011; Rogers, Freeman, and Rennels, 2017). Currently, it focuses on assessing competencies in secondary and university education (Refrigeri and Russo, forthcoming), considering the impact of generative AI. But is debate adopted in engineering education, and if so, how?

2.2 Debate in engineering education

The adoption of the debate in engineering is attested in a variety of resources ranging from at least academic papers to international engineering associations or councils. Just as the resources are varied, the educational objectives for which debate is employed are diversified. This aspect demonstrates the versatility of the debate teaching method and offers significant information for reflection regarding its use in universities.

Debate in engineering education is primarily used for acquiring disciplinary and cultural knowledge. It is particularly emphasized in engineering ethics (Takanokura and Hayashi, 2007), as ethical dilemmas help students explore conflicts and apply lecture knowledge (Borgaonkar et al., 2020; Takanokura and Hayashi, 2008). Debate fosters understanding of the technology-society relationship by considering problems from multiple perspectives (Pellicer and López-Mateu, 2021) and encourages active citizenship (Holik, 2023). It is suitable for learning sustainability topics (Rodriguez-Dono and Hernández-Fernández, 2021) and all curricular engineering content (Alford and Surdu, 2002; Chang and Cho, 2010). Debate promotes active knowledge development (Jodłowski and Sztekler, 2017; Scholte, Vasileiadou, and Petersen, 2013) through research, discussion (Hassan, 2014), and increased motivation (Angeli et al., 2020; Hamouda and Tarlochan, 2015). Case studies enhance these processes by providing practical, dilemmatic situations for debate (Gravitt, 2017; Takanokura and Hayashi, 2007).

Debate facilitates the development of various skills, including high-level information research, technical skills, teamwork, time management, critical thinking, and oral and written expression in different languages (Buluev and Fedorov, 2015; Eunice and Pattawan, 2008; Gravitt, 2017; Kirkland et al., 2022; Pellicer and López-Mateu, 2021; Sidorenko and Rybushkina, 2014). It challenges students, including top performers, to step out of their comfort zones (Taly, 2018). By promoting argumentation and persuasive skills, debate enhances logical thinking, scientific understanding, and leadership abilities (Bruschke, 2016; Chang and Cho, 2010; Scholte, Vasileiadou, and Petersen, 2013). It is also an effective assessment method for argumentation, typically presented in written or monological forms (Mackay, Thomas Miller, and Benson, 2022). During the pandemic, debate proved valuable for skill development when online education risked becoming too lecture-based (Borgaonkar, Wang, and Sodhi, 2021; Heesun, 2021; Pellicer and López-Mateu, 2021). These skills, considered transversal competencies, are crucial for engineering education and are effectively promoted through debate (Rodriguez-Dono and Hernández-Fernández, 2021).As the research shows, the educational implications of debate are numerous. However, these studies often present debate as a methodology used by individual teachers or small groups rather than as a faculty-wide strategy. This narrow, compartmentalized approach overlooks many potential benefits, which are only evident in a few rare cases. For example, Crawley et al. (2014) view debate as a tool for cultural change and organizational development within universities, suggesting its use among faculty to address faculty development issues. Similarly, Gabriel et al. (2016) from the University of Aveiro's Department of Mechanical Engineering use debate in an open think-tank on engineering education, fostering face-to-face discussions among stakeholders. Given its limited presence in literature and the potential benefits of linking debate with faculty development, we advocate for a more inclusive Faculty Development framework for integrating and utilizing debate within universities.

2.3 The multiple dimensions of Faculty Development

In literature, «Faculty Development» encompasses many meanings. Not only it is referred to by various interchangeable terms. Fraser, Gosling and Sorcinelli (2010), for example, authors who have conducted research in the field of educational development across continents consider «faculty development» to be a synonym for expressions such as «academic development», «learning and teaching development», «education development» and «educational development» the latter being recognized by them as more suitable than «Faculty Development». But the translation is complex also because the referent itself is not fixed and is culturally and historically conditioned. Mary Deane Sorcinelli (2020) identifies an evolution of the construct from the *age of the academic*, referring mainly to practices improving and advancing academic competence in one's discipline through sabbaticals and scholarships for advanced degrees, to the *age of the network* in faculty, administrators, and institutions face increasingly higher challenges regarding individual learning and institutional development.

William Toombs (1975) elaborated comprehensive dimensions of Faculty Development along three axes: professional, curricular, and institutional. The professional dimension involves the academic role, its professionalization, and the need for continuous development. The curricular dimension focuses on teaching improvement through specific programs, emphasizing teaching effectiveness, student learning outcomes, and curriculum contributions to career objectives. The institutional dimension addresses the functioning of academic institutions, balancing academic, public, and managerial interests. Steinert et al. (2007) revisited Toombs' perspective, highlighting Faculty Development as a multifaceted process involving professional, curricular, and institutional aspects, with faculties being complex systems with multiple stakeholders. Faculty Development includes activities and actions that promote the renewal and development of skills and roles for university professors, aligning with student learning objectives (Lampugnani, 2020). It also entails a continuous process aimed at building internal communities (Eib and Miller, 2006; Morelock, Sochacka, and Walther, 2020) and engaging with the external community. Universities play a societal and economic role through knowledge transfer and transformation within their regions, (Moretti et al., 2021; Pee and Vululleh, 2020; Price et al., 2021).

3 THE EXPERIENCE OF LIUC UNIVERSITÀ CATTANEO

In order to answer to the research question – how debate can be fruitfully adopted for supporting Faculty Development in engineering faculties – the experience of LIUC Università Cattaneo is considered. In particular, assuming the categories hereby detailed and developed, we will illustrate two of the main activities carried out by the Engineering Faculty of the Cattaneo University LIUC related to debate adoption. The adopted methodological approach is the case study, an empirical inquiry that investigates a phenomenon within its real-life context. The case study method is not a method of data collection but a comprehensive research strategy to study in-depth a social unit involving multiple data sources such as questionnaires, surveys, in-depth interviews, participant or non-participant observation, and document analysis (Priya, 2021). The exploratory nature of the present case study, conducted between 2020 and 2023, is intended to tackle the research question introduced at the outset of this study, aiming to arrive at a provisional conclusion that remains contextually grounded and receptive to new, particularly more systematic, avenues for further investigation.

The LIUC - Cattaneo University was founded in 1991 by the initiative of the Industrial Union of the Province of Varese, Italy. Committed to the development and dissemination of knowledge and skills useful to businesses and institutions, LIUC offers courses in Business Economics and Organizational Engineering based on the real needs of companies. Since 2020, Cattaneo University LIUC has significantly invested in the development of debate, based on the potential of this methodology for Faculty Development. There have been various implementations and repercussions of this commitment, but for the sake of brevity, we will focus on the systematic adoption of debate in teaching and the *Debating Agenda 2030* tournament.

3.2 The systematic adoption of debate in curricular activities

In its strategic plan for Faculty Development 2021-2025 (Università Cattaneo LIUC, 2020), the Cattaneo - LIUC University has included debate in its engineering degree courses by heading it under 'didactics' to promote both innovative ways of conducting university teaching and transversal skills. Debate has found widespread use in extra-curricular teaching and in disciplinary teaching since 2021. In disciplinary teaching, debate has found use in the teaching of Ethics for Engineers, Technology and Law, Manufacturing Strategy and Systems Theory. To also demonstrate the versatility of this teaching method, debate has taken on different purposes and applications in each of the aforementioned subjects.

To prepare faculty members to organize and manage debate activities within the university and in their courses, several strategies were adopted. In January 2021, a training course on debate and its use was held, promoted by the University's Learning Teaching Hub and aimed at the entire faculty. Subsequently, the institution published a call for a three-year lecturer position to be assigned to a professor specialized in pedagogy with experience in debate methodology. This professional was tasked with developing debate activities and assisting faculty members in introducing debate into lectures. Faculty members interested in using debate were supported in various ways in the implementation of their activities, ranging from complete management of initiatives to targeted support aimed at fostering autonomy in the teaching methodology.

In Ethics for Engineers, aimed at bachelor's degree students, the debate was used to create a concrete context in which to address ethical dilemmas through argumentation and to apply, in debate preparation, some dilemma-solving procedures such as the ethical cycle (Van de Poel and Royakkers, 2007). The aim was therefore not to assess the acquisition of content but to experientially promote the application of content and skills for better learning. Specifically, the debates were conducted during the final four hours of a 24-hour course. Approximately the first half-hour was used to provide a simple and intuitively understandable overview of the phases, tasks, and roles that the students were expected to undertake. The next hour was dedicated to the students' autonomous preparation, divided into teams, for their respective positions. One and a half hours were allocated to the actual debate, and the remaining class time was used by the teacher to provide feedback on the arguments presented, the exchanges that took place, and the course material utilized or overlooked by the teams so as to promote metacognition and further learning. To make the debate more relevant to real-life situations, traditional motions such as "This house believes that medical doctors should be replaced by AI in disease detection and diagnosis" were replaced with cases providing more detailed contexts, such as "Imagine a rural community with limited access to healthcare services due to a shortage of medical professionals. In this scenario, the local clinic decides to implement AI technology for disease detection and diagnosis to improve healthcare outcomes for the residents [...] Would you support the introduction of AI technology?". In these cases, despite the lack of thorough debate preparation, the outcome was consistently appreciated by both the teacher and the students.

In Technology and Law, a course aimed at master's degree students, debates changed their aims over time. The first two years it was used at the end of each content module to consolidate learning but also to assess the students' learning to date. Last academic year, instead of using it at the end of each content module, the debate was employed before each content module. The rationale was to get the students to debate on topics they did not yet know in depth in order to bring out their naive pre-understandings or stereotypes and then to orient the teaching in such a way as to link it to the content emerged in order to relativise it, redefine it, revise it, and deepen and enrich it. Unlike the approach taken in the Ethics for Engineers course, the Technology and Law course provided an initial four-hour training session on debate. This session aimed to introduce students the pedagogical objectives of the method, the structure to be followed in each debate, principles of argumentation and non-verbal communication, and elements of rhetorical disposition to enhance students' understanding of structuring their discourse. Furthermore, for each edition of the course, three debates were conducted with the same group of students.

In the Manufacturing Strategy course aimed at master's degree students, debates were held in the form of a tournament consisting of 6/8 teams per years, each composed of 4 students, on the topics of Smart Factory or System Engineering. As explicitly stated in the course syllabus, debate was utilized to equip students with the ability to assess the advantages and disadvantages of automation choices, thereby enabling them to propose automation options suitable for both technical and human contexts of application and to defend these theses in front of a jury of experts from the corporate world, including general managers. The evaluation of the debate was carried out according to established practices for this type of competition, with a focus on the clarity of the arguments, persuasiveness and the ability to answer questions from the jury, which in this case could intervene and interact with the students. The activities concluded with high appreciation from the teachers, evaluators, and participating students. Finally, the Systems Theory course for master's degree students implemented debate in a teaching innovation game called *Hard Decisions*. The project led students from the faculty of Economics and Management and the faculty of Industrial Engineering to work together to find solutions to a difficult case study through non-traditional teaching methods and content. One instance of dilemma involved a company managing a social media platform, where significant dependency among younger and more vulnerable users was uncovered, was worded, at the end of the whole case, as following: "The Board of Directors must find a synthesis to submit to the approval of the Shareholders'

Assembly, deciding whether to maintain a successful and profitable business by simply adding a disclaimer to Pistagram's "Terms and conditions," or to temporarily close Pistagram and initiate a study to determine if and how the platform can be modified." Initially, teams, each focused on one of the two decisions, deepened their own position in preparation for debating with the opposing side. The second phase consisted of a debate with a simple structure and reduced intervention times per each student (2 minutes each). Through debate students determined which of the two alternatives, or what integration of the two positions, to develop in order to solve the assigned case. The third phase of developing the identified solution led to a final phase, which involved presenting the solution to the ideal Board of Directors, who could pose questions or objections and evaluate the work done. The *Hard Decisions* project aimed to experiment with inquiry-based learning, with an explicit focus on assisting students in developing critical thinking skills in gathering, analyzing, and synthesizing information on complex and controversial issues and their main positions. In contrast to previous didactic uses, debate assumed the role of a decision-making method extensively documented in the general literature (Cf. Ehninger and Brockriede, 2008; Freeley & Steinberg, 2013).

The questionnaire administered to seven faculty members involved in debate activities revealed both diversity and uniqueness in their usage and perspectives. Some instructors utilized debates exclusively within their courses, while others also employed them in extracurricular activities aimed at high school teachers. Nevertheless, all interviewed faculty members confirmed their intention to continue using debates in their activities, as they facilitate the development of presentation and project justification skills more effectively than other methodologies, help students understand legal concepts outside their engineering studies (as in the case of the Technology and Law course), and serve as a valuable strategy for classroom engagement. An interview with the instructor of the Ethics for Engineering course provided additional insights on this aspect: "Debate has helped restore student interaction, especially in the post-pandemic period, when students tended to apply remote work strategies even in in-person group activities, limiting direct exchanges among them. Moreover, in an elective course like mine, it has encouraged student participation, which often was confined to mere physical presence while they engaged in other activities on their laptops." The questionnaire also highlighted another interesting and counterintuitive aspect: The attempt to use debate as a tool to promote autonomous learning of course topics before exams was disastrous. This observation aligns with findings from the Technology and Law course, where debate, initially used as an assessment tool at the end of each module, was later employed as a method to prompt students to expose and reflect on their naïve conceptions and stereotypes before addressing the module content. Another significant result from the questionnaire is that debate prompted reflection and, in some cases, a change in teaching and learning concepts among the faculty. Debate was considered a coherent and excellent method for achieving situated learning; it made clear that instructors cannot take for granted certain argumentative skills they believed to be acquired, and it facilitated the adaptation of curricula not traditionally designed for engineering students. The faculty also perceived an improvement in teaching quality, as debate made the courses more focused on decision-making process objectives where applicable; increased awareness of the fragility of the argumentative processes often developed by students; and promoted the ambition to reach a higher level of competencies. This last aspect was also observed in anonymous teaching evaluation questionnaires administered by the University to assess the teaching quality, and completed by students before registering for exams, which included appreciative comments for an activity capable of developing useful skills and making students engaged, active, and involved in a course that initially did not attract them.

3.3 The experience of the *Debating Agenda 2030* project at Cattaneo University - LIUC

The *Debating Agenda 2030* project is a periodic event characterized by a course and a debate tournament dedicated to Sustainable Development Goals and aimed at all university students in Italy. The proposal of the tournament to all university students in Italy has allowed for the establishment of relationships between groups, student associations, and debate clubs initiated at other universities, but also to establish exchange relationships on the mutual practical applications of debate. These exchanges have been fundamental for reflecting on the project and for adapting the activity to the learning needs of students from different academic backgrounds. Opening the activity to students from other universities, and the focus on debate methodology mentioned, promoted the establishment of a collaboration with different non-profit organizations. The first organization involved was ASDUNI, the *Italian association for the development of learning and teaching in university*, which allowed for the enhancement of the activity at the university level. Focusing on Sustainable Development Goals has instead favoured cross-disciplinary learning, responding to the University's commitments in terms of raising awareness of sustainable development, involving expert faculty members through teaching interventions on the various Goals of the 2030 Agenda, and obtaining the patronage of ASviS, the *Italian Alliance for Sustainable Development* which contributed to the initiative with in-depth materials and publicizing the event.

The tournament preparation course promoted technological integration as it was conducted on the Moodle platform through materials accessible asynchronously and synchronously. The use of the e-learning platform favoured the creation of a repository of interchangeable and combinable materials with other educational activities of the university related to debate and argumentation as, among other examples, the project *Culture and business: debate experiences*, whose aim is to consolidate and expand the skills involved in the debate methodology through the discussion of a complex topic related to business culture. The *Debating Agenda 2030* course, had a duration of approximately one month for each edition. The course was structured into modules that were made available at regular intervals of one week, consisting of a pedagogical module, a regulatory module, an argumentative module, and a communicative module. Additionally, there was a section dedicated to the evaluation of the Debate as students were required to be familiar with the criteria upon which they would be assessed. All this was aimed at introducing students to the skills necessary for conducting a debate – professionalizing skills such as critical thinking, argumentation, public speaking, and teamwork – also involved introducing students to the British Parliamentary debate format, i.e., the protocol of the World Universities Debating Championships (WUDC). This characteristic allowed for collaboration with the SNDI APS, the national debate society, a non-profit organization that promotes debate from primary school to university and contributed with the intervention of some experts to introduce the rules of international tournaments and the management of the tournament. Regarding the collaboration with the University Cattaneo LIUC, the SNDI APS director stated in an interview that partnering with universities is essential, particularly within the Italian educational context where students require specific tools to cultivate skills such as critical thinking and problem-solving, which are often deficient upon graduating from high school. This is crucial not only for the students but also for society at large, as it benefits individuals and future workers.

The hybrid tournament (online selections and final in-person event), on the other hand, aims to create an authentic and interactive learning context on specific themes of Agenda 2030, environmental sustainability, and social responsibility, as well as to serve as a laboratory for exercising the soft skills promoted in the course. One of the characteristics of this methodology is that it involves a panel of judges, composed also of specially qualified faculty, which provides expert formative evaluation of the interventions and interactions carried out by the students. The *Debating Agenda 2030* tournament also takes place periodically on different Sustainable Development Goals in order to ensure the in-depth exploration, from one edition to another, of the various and heterogeneous topics. The various editions of the tournament phase lasted approximately one and a half months, involving both an elimination phase and a final phase where the top four teams from the eliminations competed directly against each other.

4 DISCUSSION AND CONCLUSION

The provisional conclusion of the case study conducted between 2021 and 2024 among a subset of the overall debating activities carried out at the Cattaneo University - LIUC is that debate methodology can contribute to Faculty Development. Debate is not only properly considered among the methods with high potential to innovate university teaching, still often confined to a transmissive didactic model, but it can also allow the creation of educational and didactic contexts that are integrative or complementary to disciplinary courses. Furthermore, as indicated by the questionnaires administered to the involved teachers, the debate has led them to alter their conception of teaching and learning. This process has facilitated the identification of some of their preconceptions and has also driven them towards a more ambitious pedagogy in terms of the cognitive processes activated in students. As a final point, its confrontational and interpersonal features as well as the various dimensions that the debate method manages to intertwine promote institutional development in terms of internal and external community building and relations.

More in depth, the systematic integration of debate into teaching, aimed at fostering innovative teaching approaches and combine the development of transversal skills with technical specialization, has highlighted how the debate methodology can find consistent application across various technical and social disciplines such as ethics, law, industrial engineering, and statistics. This versatility extends beyond its ability to be adopted for any problematic topic, but also encompasses the multitude of functions it can serve, such as addressing dilemmas and case studies, promoting practical application of content and skills, fostering interaction between students and industry professionals, or serving as a decision-making method. Another aspect explored in our investigation is the *Debating Agenda 2030* activity, a themed tournament focusing on the Sustainable Development domain and its instructional implications. This type of activity has facilitated the establishment of connections among student groups, associations, and debate clubs from other universities, as well as collaborative relationships with national professional and social organizations interested in these issues, their social impact, the methodology employed, or educational innovation in universities. Currently, this particular application of debate is catalyzing the creation of a network among various universities sharing the common goal of supporting a sustainability-oriented approach and integrating transversal and technical skills.

The impacts and implications of these activities and approaches clearly highlight both how the debate methodology can positively contribute to Faculty Development and how this can occur. Specifically, it emerges that debate can not only intervene in the professional and curricular dimension, as one might intuitively imagine, and how this happens, but also operates on the institutional dimension of Faculty Development, which pertains to the balancing among academic interests, public interest, and managerial interests within the institution. This overall, institutional convergence around the debate of the faculty as a whole places a greater emphasis on the development of transversal skills of the engineer. Moreover, the systematic adoption of debate in instruction and the *Debating Agenda 2030* tournament are just some of the ways debate has been institutionalized at the Cattaneo University - LIUC, allowing us to consider that our conclusions can be strengthened and expanded. Nevertheless, they enable the integration and opening of new research perspectives in the study of debate and Faculty Development for engineering faculties, which the literature does not seem to consider except in rare cases (Cfr. Crawley et al., 2014; Gabriel et al., 2016).

The research conducted, however, is subject to significative limitations that stem primarily from its methodological approach. While the case study method can indicate how debate can be used to promote Faculty Development, the response to the logically prioritized assertion that debate is effective for Faculty Development is less solid and would require a different method to be rigorously consolidated and evidence-based. Indeed, not only does this type of intervention appear unprecedented in the literature, which led to an exploratory qualitative design when analyzing the teaching quality evaluation questionnaires, but the types of activities carried out, of which this article only summarizes two, were also diverse (didactic use, debate club, debate tournament, etc.). Moreover, the limited sample size observed is due to significant factors that must be considered and articulated regarding the debate methodology. The first factor concerns the substantial amount of instructional hours that debate exercises take away from traditional teaching, which not all educators are willing to sacrifice. The second factor pertains to the complexity and organizational effort required to arrange meetings or tournaments, which takes time away from the teachers' research activities. Finally, there is a prejudice against this methodology, often viewed as a simple game or as promoting relativistic or superficial personal epistemologies (see Anonymous, 2024). Therefore, the conclusions drawn from this investigation may not be considered as endpoints but rather as starting points for further research and the establishment of new research avenues. Another limitation of this study is its failure to encompass the numerous activities in which debate has been applied within the Cattaneo University - LIUC due to their heterogeneity and multitude. Examples include: the university debate club, which brings together engineering and economics students, interacts with other debate clubs by participating in national and international tournaments, and allows for the attainment of an open badge attesting the acquired transversal skills; the adoption for foreign language learning, which spans both disciplinary and extracurricular activities. Indeed, in its faculty development strategic plan, the University Cattaneo - LIUC has in fact included the debate to promote transversal skills and the placement of graduates in the labour market; to use teaching methodologies to develop critical thinking and integrate ethics with technology; to implement the internationalisation of the institution through student exchanges, building relations with foreign universities and participation in projects beyond the academic sphere; to involve the LIUC in the network of national and international debate networks and the enhancement of associations that collaborate with the LIUC itself. And what is most important is that such flexibility in applications seems to be limited only by the creativity and initiative of teachers or administrators.

ABSTRACT

Being one of the visions of the European University Alliance ENHANCE, the Massive Open Online Course (MOOC) “Responsible Innovators of Tomorrow” was developed by the Chair of Gender and Diversity in Engineering (GDI) at RWTH Aachen University to drive responsible social transformation. The MOOC integrates the expertise of various European experts and contexts to offer students an interdisciplinary and holistic perspective on current topics in Responsible Research and Innovation and Science and Technology Studies. Intended for mandatory integration in all Bachelor curricula of the ten ENHANCE universities, the MOOC is one step towards a broad introduction to Future Skills in technical study programs. This practice paper describes the process of development and implementation as well as our experiences with conceptualizing and implementing the MOOC at the European level to guide future similar projects.

1 INTRODUCTION

Given the global challenges addressed, for example, in the Sustainable Development Goals (SDGs), engineers as drivers of much-needed innovations must be enabled to fulfill their responsibilities towards the environment, economy, and society (Tassone et al. 2018; Owens 2017; Crawley et al. 2007). As the addressed challenges are 'wicked problems' that arise at the intersection of societal, environmental, and economic factors, engineers can only use their innovative potential if they can conceptualize this complexity holistically (United Nations 2017).

Thereby, universities play a central role as drivers of innovation (Owens 2017) by teaching relevant skills such as problem-solving, collaborative work, or critical thinking (Thomas 2009; Puente et al. 2021). Due to the complex and interrelated nature of the addressed challenges, universities can contribute to training responsible innovators of tomorrow by fostering inter- and transdisciplinary education and cooperation, which is cited as a key factor of success when addressing such challenges (United Nations 2017). Engineering education therefore should include technical skills as well as social and ecological future skills (Stifterverband and McKinsey 2021) which are in line with the EU framework “Industry 5.0, a transformative vision for Europe” (Renda et al. 2021) and the “Responsible Research and Innovation” (RRI) framework (Schomberg 2013).

Given the need for inclusive and sustainable research and education, the RRI Hub (RWTH Aachen University 2022), anchored at the Chair of Gender and Diversity in Engineering at RWTH Aachen University, developed the Massive Open Online Course (MOOC) “Responsible Innovators of Tomorrow” (edX 2024b) in the context of the European ENHANCE Alliance (ENHANCE Alliance 2024b) of ten leading technical universities in Europe. The course aims to provide students with the necessary knowledge and skills to act as responsible innovators. The MOOC was published in April 2023 and has since been accessible to students from all ENHANCE universities and the general public –intended to be anchored as a compulsory course in all Bachelor’s degree programs at ENHANCE universities.

In this practice paper, we describe our experiences and learnings from designing and implementing a European MOOC across ten technical universities. We report on conceptual and structural challenges and make recommendations for establishing a European MOOC.

1.1 European Integration within the ENHANCE University Alliance

The European ENHANCE Alliance was founded in 2020 and is co-funded by the European Union (European Commission 2024b) to create an innovative European university where students are empowered to reflect on European values, including democracy, equality, and respect for human rights. With ten leading European Universities of Technology as members, ENHANCE envisions “to drive responsible social transformation” and “turning global challenges into opportunities” (ENHANCE Alliance 2024a). Since November 2022, the following ten universities are part of the alliance: Chalmers Tekniska Högskola AB, Eidgenössische Technische Hochschule Zürich, Politechnika Gdańska, Norges Teknisk-Naturvitenskapelige Universitet, Politecnico di Milano, Rheinisch-Westfälische Technische Hochschule Aachen, Technische Universität Berlin, Technische Universiteit Delft, Universitat Politècnica de València, Politechnika Warszawska (ENHANCE Alliance 2024c).

ENHANCE focuses on three pilot topics: Digitalization and Artificial Intelligence (AI), Sustainable Cities and Communities, and Climate Action, all of which are among society's most pressing challenges. To address these, the alliance seeks to innovate in the domain of higher education by encouraging inter- and transdisciplinary collaboration, engagement, and empowerment of students and academic staff. In particular, it seeks to create mobility, collaboration, and learning opportunities among all university members.

Within the ENHANCE alliance, students shall work with society and industry to understand the complexities of science, technology, society, and environmental interconnections at a European level to “help build a joint European sphere of knowledge” (ENHANCE Alliance 2024a). Our MOOC addresses this in two ways: First, it is supposed to be made eligible for all students from the ten European technical universities: It shall be anchored in all Bachelor curricula from all ten ENHANCE universities as a mandatory course. Second, to map current challenges and different realities of European countries and regions, the MOOC’s contents were designed by experts from the ENHANCE universities. Up to now, 33 videos have been recorded from Rheinisch-Westfälische Technische Hochschule Aachen, Technische Universität Berlin, Chalmers Tekniska Högskola AB, Politecnico di Milano, Universitat Politècnica de València, and Technische Universiteit Delft.

1.2 Holistic Learning Through MOOCs

MOOCs represent a pivotal component in advancing digital education and skill development as they offer accessible, flexible, and (often) interdisciplinary learning opportunities, aligning with the goals of SDG 4, while promoting digital inclusion and fostering lifelong learning (Sosa-Díaz and Fernández-Sánchez 2020; Voudoukis and Pagiatakis 2022; Patru and Balaji 2016). Further, they provide individuals with the chance to acquire digital skills, engage in innovative learning experiences, and adapt to evolving demands in the digital economy (Alraimi, Zo, and Ciganek 2015). Moreover, MOOC platforms contribute to democratizing education by breaking down geographical barriers and offering diverse learning pathways tailored to individual needs (Sosa-Díaz and Fernández-Sánchez 2020; UNESCO 2023). Accordingly, by integrating MOOCs into educational strategies, educators and learners can use these resources to enhance digital competencies, promote collaborative problem-solving, and prepare for the challenges and opportunities of the digital age.

The European Commission's Digital Action Plan 2021-2027 (European Commission 2024a) addresses the learning foundations for navigating this increasingly digital world. By emphasizing digital skills and inclusion, it recognizes the importance of fostering digital literacy and proficiency as essential competencies for student agency and transformational skills. Through initiatives promoting interdisciplinary thinking and developing critical problem-solving skills, the Digital Action Plan contributes to shaping a future-ready workforce capable of thriving in the digital age.

This is particularly in line with the OECD's vision for holistic learning. The OECD Learning Compass 2030 (OECD 2019) guides education systems and stakeholders worldwide to promote holistic and future-oriented education. Its transformative endeavor identifies necessary elements of knowledge, skills, attitudes, and values that students need to actively participate in shaping a positive future as responsible innovators of tomorrow. For this, it names various elements such as student agency, transformation competencies, learning foundations, knowledge, skills, attitudes, and values, as well as the anticipation-action-reflection cycle. This shall enable learners to develop responsible and purposeful personalities who can continuously develop and positively influence their environment by critically analyzing and evaluating alternatives from an ethical point of view (OECD 2019).

2 THE MOOC "RESPONSIBLE INNOVATORS OF TOMORROW"

A holistic learning concept is crucial to recognize the multidimensional nature of education (Mahmoudi et al. 2012; Miller 2000; Miseliunaite, Kliziene, and Cibulskas 2022). It acknowledges that learning goes beyond acquiring facts and figures, encompassing the development of critical thinking skills, emotional intelligence, and a sense of responsibility (Mahmoudi et al. 2012). By integrating various subjects, perspectives, and skills, a holistic approach prepares students to navigate the complexities of the modern world. It fosters interdisciplinary thinking, problem-solving abilities, and empathy – essential qualities for success in both personal and professional spheres. Moreover, a holistic learning approach cultivates lifelong learners who are adaptable, creative, and capable of thriving in diverse environments (OECD 2019). Furthermore, holistic learning can address the diverse needs and aspirations of learners in the digital age and integrate visions of Industry 4.0 to bridge the gap between Industry and Education (Koul and Nayar 2021).

Therefore, the content of our MOOC is structured according to the OECD Learning Compass 2030 (OECD 2019) to offer a didactically future-oriented teaching and learning concept. To achieve the necessary knowledge, skills, and attitudes, the Learning Compass proposes a so-called anticipation, action, and reflection cycle (AAR cycle) to foster the development of transformational competencies that enable learners to adapt to change, think creatively, and actively contribute to shaping the future. The cycle is an iterative learning process in which students continuously improve their thinking, act responsibly, and contribute to collective well-being through anticipation, action, and reflection. In the first phase, *anticipation*, learners consider how their actions today may affect the future. To do so, learners try to anticipate short and long-term consequences of actions, to understand their own and others' intentions, and to broaden their own and others' perspectives. In the *action* phase, learners develop the will and ability to direct their actions towards general well-being. Actions in the action phase can relate to research, taking responsibility, creating new values, or implementing change. These actions can be individual, joint, or collective. In the *reflection* stage, learners improve their thinking, leading to better advocacy for their well-being and the well-being of society and the environment. In this phase, learners train their thinking, which leads to a deeper understanding and better actions in terms of well-being. As a result, learners gain awareness of the possibility of shaping their future actions – and a sense of direction, which in turn promotes agency development.

We designed the MOOC with respect to these three phases in accordance with the three ENHANCE pilot topics: Digitalization and AI, Climate Action, and Sustainable Cities and Communities. The resulting structure is depicted in Figure 1.

Fig. 1. Content of the MOOC structured according to the OECD Learning Compass

To train students to be responsible innovators of tomorrow, they must be enabled to identify wicked problems and develop solutions. For this purpose, they must have fundamental knowledge of topics addressing future skills such as RRI, ethics and gender, and diversity competencies. With this knowledge, students can learn how to respond to the questions and challenges of the second phase in an action-oriented manner based on the ENHANCE pilot topics. Thus, sustainable and social innovation, social responsibility, digitalization, and AI are addressed in the action phase. This is followed by a reflection phase in which the students, guided by the SDGs, reflect on today's challenges and possible action strategies.

Every module comprises video lectures, scientific texts, and additional material like web links or journal articles implemented in a platform-based e-learning environment (edX). The course is designed for a nine-week program with a learning effort of eight hours per week plus an additional 18 hours for final examination preparation. After completing the course, the students should know the Sustainable Development Goals, define different dimensions of sustainability, and understand the relation of their field to sustainable development. Further, they shall understand the relevance of interdisciplinary work and the importance of considering gender and diversity perspectives in research and innovation. They understand the connection between sustainability and their personal and social responsibility as future innovators. In addition, they can explain the concept of RRI, the relationship between technical and social innovation, and their importance in solving global challenges. They can evaluate ethical aspects within their specialization and feel confident dealing with (digital) challenges. A weekly quiz supplements every week's learning by reflecting on the learned content. After completing the whole course, a final exam is aimed at assessing the learning outcomes of the whole course.

3 EXPERIENCES AND RECOMMENDATIONS

This section elaborates on our experiences and lessons learned when planning, designing, and implementing a European MOOC in collaboration with different technical universities to inspire similar future projects.

1) *The MOOC-Concept – Communication and Coordination at European Level*

As part of the conceptualization of our European MOOC, we developed a novel democratic, participatory, and agile teaching concept in line with the ENHANCE network's goal of strengthening European values. Careful planning was required to establish a teaching concept that addresses global challenges related to the SDGs and allows scientists from all universities in the network to participate, supporting the collaborative European education of responsible innovators of tomorrow. Extensive analysis and conversation were required to achieve consistent knowledge without redundancy or alienation of students at any of the member universities. This involved considering different levels of cultural and social influences, too. We have invited academics from all Alliance universities to participate in producing learning content in line with the idea of participatory democratization. This has required efforts in coordination and communication across national and linguistic boundaries. In addition, a uniform design had to be created, implemented, and synchronized with various national or university designs. Despite being a challenge, this allowed for establishing a shared European level of knowledge.

2) *Agile Learning for European Students*

To cater to varying levels of knowledge and promote skill development, we have provided general introductory videos and the option to create additional videos. These videos can cover more specialized topics or showcase scientists' research. This approach opens up a common European horizon, allowing students to learn together at a shared level. The responses of ENHANCE colleagues were positive, and there was great interest in participating in the MOOC. Due to the time constraints of production in the various countries, we decided to finalize the first version and will add more contributions in the second round. Overall, the MOOC already contains videos from almost all alliance universities. Thanks to the agile concept and the possibility of adding additional videos to edX at any time, it is also possible to keep expanding the MOOC.

In terms of the teaching format's agility, one challenge during the course design was to transfer the teaching and learning concept of the OECD Learning Compass into the digital teaching format of a MOOC. In particular, mapping the action phase was a challenge to realize in a solely online format. In future runs, practical supplementations such as project weeks and summer or winter schools are desirable and have been tested in a pilot project at RWTH Aachen University in March 2023.

3) Digital Implementation and Recognition

Further, there were challenges during the implementation. For example, identifying a standardized platform that allows democratic participation for students from all universities has proven to be a central challenge. The primary difficulty stems from the fact that universities use different software applications to implement their digital teaching and learning content. Unfortunately, this has resulted in the absence of a uniform European network in the digital space, which would allow for seamless integration of students without any barriers. Further, the absence of a European software application that is independent of universities, adheres to European data protection regulations, and meets the technical requirements of a MOOC, has made it even more challenging to select a suitable platform. Ultimately, we opted to utilize edX (edX 2024a), an online teaching and learning platform established by Harvard University in 2012. This decision was made due to the absence of European alternatives and the platform's familiarity and accessibility. On the one hand, the MOOC's availability to a worldwide audience is advantageous. On the other hand, its integration into the ENHANCE network is only secondary. Furthermore, there is a conflict or obstacle to the participation of Alliance students due to the anchoring on edX. This is because acquiring a certificate of participation on edX is subject to a fee, which stands in the way of the planned curricular and obligatory embedding in the Alliance universities' bachelor programs and democratized participation in the offer. A voucher system has remedied this, making the certificates virtually free for students. However, the distribution of the vouchers requires a considerable amount of bureaucracy. These difficulties clearly show that establishing and strengthening European software applications must be promoted more strongly if European learning is to be made possible in a contemporary way.

4 SUMMARY

In this practice paper, we presented our concept of the European MOOC "Responsible Innovators of Tomorrow" developed within the ENHANCE Alliance, which aims to educate future responsible innovators in Europe. We reported on conceptual and structural opportunities and challenges and derived recommendations for establishing a MOOC at the European level. We hope to inspire similar projects in the future and guide their practical realization. Although bearing many challenges, the national and international feedback of colleagues shows that it is a promising and future-oriented format that is one step towards raising awareness regarding the social responsibility of engineers on an international level that overcomes disciplinary as well as national barriers and supports the development of a holistic introduction to future skills on the European level.

5 ACKNOWLEDGMENTS

The realization of this project would not have been possible without the support of various people. We thank the numerous contributors to the MOOC within the Enhance Alliance and those who have enriched the development with constructive feedback. The realization would further not have been possible without the EU funding of the Enhance Alliance and the conceptional support of the RRI Hub at RWTH Aachen University. The RRI Hub is funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany's Excellence Strategy.

ABSTRACT

The rapid evolution of artificial intelligence (AI) underscores the critical necessity for engineers to comprehend their responsibilities in AI use and development. This imperative requires equipping engineers with the requisite skills and knowledge to address societal challenges while ensuring that AI technologies are harnessed for societal benefit and mitigating potential risks. To support educators and course developers in identifying relevant competencies, the Responsible AI Competencies for Engineers (RAICE) framework is currently being developed collaboratively among educators, engineers, mathematicians, sociologists, and ethicists. This practice paper reports a work-in-progress based on our first explorations. In particular, we focus on Responsible AI (RAI), connected competencies, and their importance within the engineering domain. This paper answers how competencies of RAI are addressed in current frameworks for AI and ethics in general and for engineers. We report preliminary results from existing Responsible AI and engineering ethics frameworks and outline our research approach toward defining a competence framework that can guide engineering educators in developing novel learning experiences on Responsible AI and integrate these into their programs and courses.

1 MOTIVATION

Engineers today have access to powerful tools such as machine learning systems, data analytics, and advanced computational models that can analyze large datasets and simulate complex systems: For example, these capabilities facilitate the dedicated design of sustainable infrastructure, optimize resource utilization, and develop adaptive solutions for global challenges (Huang, Li, and Fu 2019; Abolhasani and Brown 2023; Tang, Liu, and Pan 2022; Yetilmezsoy, Ozkaya, and Cakmakci 2011)

Besides developing systems with good goals in mind, engineers must also consider the social and ecological effects of their work: With the ability to shape technology and society comes the responsibility to ensure that technologies are developed, deployed, and utilized in ways that benefit society while minimizing potential harms (Lemke et al. 2023). AI has the potential to create new systemic risks, for example, by affecting ecological sustainability (Galaz et al. 2021), reinforcing stereotypes, introducing biases, and having unintended negative effects on marginalized groups (Barocas, Hardt, and Narayanan 2023).

Since risk management is an integral aspect of the work of engineers and in particular when AI is involved, engaging with the field of Responsible AI (RAI) is therefore not just a moral imperative but also a pragmatic necessity for engineers (Blake et al. 2021). As delineated by Drage, McInerney, and Browne (2024), the accountability for artificial intelligence (AI) is primarily attributed to engineers and the stakeholders associated with their endeavors. It is incumbent upon the participating engineers to be incentivized to assume responsibility not only during dynamic assignments but also during routine maintenance activities. Only additional awareness of individual and structural barriers allows for responsibility to be taken (Dignum 2019).

Higher education institutions are imperative for value development among engineers (Yortsos 2021). Thus, engineering educators must understand the underlying competencies engineers must acquire during their study programs to build, deploy, and use AI responsibly. At the same time, engineering educators are often not direct experts in AI systems and ethics, making it challenging to oversee this broad and dynamic field and identify the relevant competencies to teach in their domain-specific courses (Schleiss et al. 2023).

To address this gap and to support educators in (higher) engineering education with related competence development, we are currently developing the Responsible AI Competencies for Engineers (RAICE) framework in a collaborative effort among educators, engineers, mathematicians, sociologists, and ethicists. The framework aims to identify relevant competencies to demonstrate to course developers and educators what aspects are relevant in educating their respective engineering students. This paper reports the preliminary results of categorizing and analyzing foundational work in the literature. In particular, it answers how RAI competencies are addressed in current frameworks for AI and ethics in general and for engineers.

To do so, we mapped out competence frameworks for general AI competencies, AI competencies for engineers, responsible competencies, and responsible AI competencies. A recent systematic review of AI literacy constructs found that almost all frameworks highlight ethical components (Almatrafi, Johri, and Lee 2024). In this work, we propose to add nuances to this construct in the context of AI by applying the differentiation into Ethical sensitivity or awareness; Ethical judgment, decision-making, and imagination; Ethical courage, confidence, or commitment proposed by Hess and Fore (2018). Moreover, our work builds the foundation for further analysis and definition of RAI competencies for engineers.

In the following section, we introduce the background and related work, discuss our research approach and present preliminary results of the explorative literature analysis. We conclude by discussing the results and outlining future work.

2 BACKGROUND AND RELATED WORK

Acknowledging that AI systems are always embedded in socio-technical systems, we refer to the notion of Responsible AI as “the fact that decisions and actions taken by intelligent autonomous systems have consequences that can be seen as being of an ethical nature” (Dignum 2019, 48). This requires ethical reasoning from people involved in developing, deploying, and using AI (Prem 2023). Therefore, the notion of RAI is closely linked to Ethical AI (EAI) – terms that are often discussed within the same vein or used interchangeably (Tahaei et al. 2023; Galaz et al. 2021; Gkontra et al. 2023). To bring these aspects of RAI into practice, guidelines hint at the importance of considering both technical and social perspectives (Prem 2023; Hagendorff 2020). This indicates that understanding both is relevant for both responsible development of and usage of AI.

Many engineering curricula and competence frameworks already consider general foundations of responsible conduct for engineers (Malmqvist, Edström, and Rosén 2020). This includes, for example, the integration of the Sustainable Development Goals (UNESCO 2023) or the emphasis on human-centered approaches in the emerging concept of Industry 5.0 (European Commission. Directorate General for Research and Innovation 2021a, 2021b) as well as the integration of the Responsible Research and Innovation concept (Owen, Schomberg, and Macnaghten 2021) in academia (Berg-Postweiler, Decker, and Leicht-Scholten 2024). At the same time, pedagogical strategies, learning goals, and assessment approaches of societal considerations in engineering education often lack consensus (Hess and Fore 2018).

Next to considering responsible conduct in engineering curricula, proper comprehension of AI-related responsibility issues requires corresponding technical literacy. This requires a shift in engineering education (Bühler, Jelinek, and Nübel 2022) towards integrating more advanced STEM knowledge as well as digital and AI competencies (Guile and Mitchell 2022), including data, technological, and human literacy (McDonald et al. 2022) as well as literacy on ethicality, responsibility, and social aspects (Schleiss et al. 2022; Bosen et al. 2023). While the importance of RAI and EAI is acknowledged in general competence frameworks for AI, it is mostly seen as an external position aside from other principles (Laupichler et al. 2022).

We conclude that there seems to be a shared understanding of the necessity for competencies for engineers to engage responsibly in their field. However, RAI often remains detached from practical implementation, highlighting the need for cohesive frameworks to guide engineering education. Existing accreditations acknowledge the relevance of these skills (Malmqvist, Edström, and Rosén 2020) and pilot studies with engineering students do so as well (Decker et al. forthcoming), but further efforts are required to develop a structured approach for scientifically grounded education in Responsible AI.

3 METHODOLOGY

The RAICE framework is developed in three steps (see Figure 1). First, we undergo a competency mapping of existing frameworks, which we present in detail in this paper. Second, we will derive the initial constructs of RAICE. Third, we will validate the framework in use with educators and translate RAICE constructs into educational offers.

Figure 1. Overall methodological approach in developing the RAICE framework

This study focuses on step 1 and aims to map and categorize existing competence and literacy frameworks as a basis for deriving the RAICE framework and motivating its relevance. Considering the target audience of a learning experience, it is essential to consider the context in which the knowledge has to be applied (Domínguez Figaredo and Stoyanovich 2023). In the long term, the RAICE framework aims to teach engineers to be well-educated users and system owners of AI (Domínguez Figaredo and Stoyanovich 2023). To this end, this paper includes an explorative literature analysis based on four categories of related frameworks: frameworks on 1) AI competencies in general, 2) AI competencies for engineers, 3) responsible competencies for engineers, and 4) responsible AI competencies.

For our analysis, we followed a recent differentiation of AI literacy constructs in aspects of know & understand, use & apply, evaluate, create, and navigate ethically (Almatrafi, Johri, and Lee 2024). This differentiation builds upon the idea of mapping AI literacy constructs to Bloom's taxonomy of learning (Ng et al. 2021b). To add more nuance to the ethical perspective, we followed the differentiation by Hess and Fore (2018) into categories of Ethical sensitivity or awareness, Ethical judgment, decision-making, or imagination, Ethical courage, confidence, or commitment. This categorization allows for better education of responsible understanding and behavior. We employed a qualitative content analysis of frameworks, mapping them to the relevant literacy constructs. Moreover, we described how frameworks address each category.

Overall, the data collection and analysis presented in this paper allow for a first explorative understanding of the landscape of frameworks that can work as a foundation for building and establishing a thorough intersectional framework.

4 PRELIMINARY RESULTS

In the following, we describe the preliminary results of the explorative literature analysis. For each framework, in Table 1, we report the target topic and target group and map the used constructs to the competence constructs of Almatrafi, Johri, and Lee (2024) and Hess and Fore (2018).

Recognize. Recognizing AI refers to the idea of non-professionals knowing which technologies inherit AI and which do not (Almatrafi, Johri, and Lee 2024). This is in line with basic knowledge of defining AI in general (Long and Magerko 2020)In our review, we found that all frameworks that focus on AI literacy include the skills that allow for the recognition of AI. On the contrary, literacy frameworks on responsible and ethical conduct in technical domains did not include the perspective of recognizing the technology behind AI.

Know and Understand. Knowledge and understanding of AI is defined by Almatrafi, Johri, and Lee (2024) as a combination of knowledge of concepts and practices that go from data collection and processing to AI process and output. Similar to the construct of recognition, knowledge and understanding of the technology is recognized in the general and technical competence frameworks but not in the ethical frameworks of our review.

Use and Apply. Based on the knowledge from previous steps, the usage and application of AI refers to the ability to interact with the wide range of applications that fall under the term AI and use them to achieve objectives and goals (Almatrafi, Johri, and Lee 2024; Ng et al. 2021a). Thus, it is generally about the ability to apply knowledge in different scenarios and contexts (Ng et al. 2021a). Moreover, Knoth et al. (2024) add to this that these contexts affect how to assess these skills. Again, general and technical frameworks include this aspect of being able to use and apply, while the ones considered with general responsibility and ethicality mostly do not.

Evaluate. Evaluating AI requires both knowledge of AI and skills with AI, so application contexts, processes, and outcomes can be critically analyzed. Following Wang, Rau, and Yuan (2023) or Almatrafi, Johri, and Lee (2024), this especially requires technical understanding. We found that only a set of frameworks considered these critical evaluation skills. Especially wider critical and technical frameworks (Ng et al. 2021b; Ng et al. 2021a) as well as some ethical frameworks (Bogina et al. 2022) do consider this aspect. Moreover, this construct seems to include classical aspects of professional responsibility (Tenório and Romeike 2023) and is thereby closely related to other more diversified ethical constructs.

Table 1. Mapping frameworks to constructs (R: Recognize, K: Know & Understand, U: Use & Apply, V: Evaluate, C: Create, ES Ethical sensitivity or awareness, EJ: Ethical judgment, decision-making, or imagination, EC: Ethical courage, confidence, or commitment)

Framework	Target Topic	Target Group	Responsible AI Competency Constructs							
			Technical Competencies					Responsibility Competencies		
			R	K	U	V	C	ES	EJ	EC
Knoth et al. (2024)	AI literacy	General Public	X	X	X	X	X	X	X	X
Long and Magerko (2020)	AI Literacy	General Public	X	X		X		X		
Heyder and Posegga (2021)	AI Literacy	Workforce	X	X		X		X		
Ng et al. (2021b)	AI Literacy	General public	X	X	X	X	X	X		
Tenório and Romeike (2023)	Responsible AI literacy	Non-computer Science Students	X	X	X	X		X	X	
Moreno, Decker, and Leicht-Scholten (2024)	Engineering Literacy	Engineering students	X	X	X		X	X		

Lurie and Mark (2016)	Software engineering ethics	Software Engineers				X		X	X	
Barakat (2015)	Engineering ethics	Engineering students						X	X	X
Romero-Yesa et al. (2022)	Engineering ethics	Engineering students						X	X	
Bogina et al. (2022)	AI Ethics	Software and AI Stakeholder				X	X	X		

Create. Almatrafi, Johri, and Lee (2024) recognize the complexity of the construct as not correlating with other AI literacy constructs (Carolus et al. 2023). Still, they see it as relevant so that skills in designing, coding, and releasing AI systems are integrated within the literacy framework. Certain large frameworks (such as Knoth et al. 2024) also include the ability to create AI systems even though the notion of AI literacy often only addresses non-professionals and base competencies (Ng et al. 2021a). Nevertheless, this skill seems relevant to take over decision-making roles in ethical AI contexts (Domínguez Figaredo and Stoyanovich 2023).

We found ethical constructs within AI literacy frameworks to be broad. Thus, when using Almatrafi, Johri, and Lee (2024) as guidance for analysis, we propose that their construct of *Navigate Ethically* can be split into the three following constructs from Hess and Fore (2018).

Ethical sensitivity or awareness. This (sub-)construct aims to increase students' recognition of ethically problematic situations and sensitivity to ethical issues they may face (Hess and Fore 2018). Across our analysis, all frameworks included this awareness of ethical issues. It was by knowledge of the ethical principles of fairness, accountability, and transparency, as in Bogina et al. (2022), or the identification of more general opportunities and risks held by AI (Long and Magerko 2020).

Ethical judgment, decision-making, or imagination. Following Hess and Fore (2018), this construct focuses on acting ethically and reasoning about ethics, e.g. by understanding and discussing ethical theory or codes of ethics or applying technical knowledge responsibly. In the context of the analyzed frameworks, only a subset referred to aspects of ethical judgment or decision-making like "Apply procedures when developing AI tools that can mitigate ethical problems" in Tenório and Romeike (2023).

Ethical courage, confidence, or commitment. According to Hess and Fore (2018), this construct targets the underlying attitudes and values by aiming to develop a commitment to ethical principles or motivation to act ethically. They also identified that this construct is only prevalent in less than 30% of their analyzed articles. As an example, we mention Barakat (2015) who considers this confidence in regard to engineering ethics. For AI ethics, Knoth et al. (2024) shortly mention the construct in their analysis without further elaboration.

5 Discussion and Conclusion

Responsibility is an important aspect of engineering education. With the rapid advancement of AI, it becomes even more important to teach engineers their responsibility in using and developing AI. By empowering educators, we aim to increase awareness of the importance of Responsible AI in the context of engineering and build the foundational educational offerings to ensure that engineers are equipped with the right tools to act responsibly with AI.

Our analysis also demonstrates the ongoing discussion among educators and authors of frameworks along the question of seeing ethical competencies in AI as integrative to all or as a separate construct (Ng et al. 2021b; Knoth et al. 2024). While on one side, the separation of the construct allows individual consideration, it leaves aside the multifaceted nature of responsibility competencies (Hess and Fore 2018).

5.1 Practical Implications

This paper highlights that while most frameworks include ethical components, the notion lacks nuance and detail, making it difficult for educators to address it in course situations. As outlined in the overall research approach, this preliminary analysis builds the foundation for a systematic definition of relevant Responsible AI competencies for engineers.

Hess and Fore (2018) found that only a few educational measures for ethical engineering include ethical courage, confidence, or commitment. In the context of this analysis of RAI frameworks, we can add that frameworks also often do not address the differentiation of ethical judgment, decision-making, imagination, courage, confidence, or commitment. Accordingly, Dutta, Mishra, and Budhwar (2022) find that ethics is considered important but often stays on a broad level or is even ignored in business competence models due to challenges in ideation, conceptualization, and implementation. Additionally, even though a technical understanding is needed (Prem 2023), many ethical frameworks take these skills as prerequisites without putting them into context. This underlines the need and importance for more consideration of educators in terms of what and how to teach about AI, especially with a focus on building practical ethical behavior and a strong ethical disposition in students.

5.2 Limitations and Outlook

In its current stage, the work has certain limitations. First, the work presented in this paper focuses on the foundational work based on an explorative literature analysis. Thus, the framework is not yet in its final version nor validated in practice with educators. For further validation, we will first derive the RAICE constructs and validate them in an interactive workshop for educators and engineering education instructors interested in education for responsibility and teaching about RAI in the context of their domain. Moreover, future work will include different roles engineers take when interacting with AI to add more nuance to the competencies and ethical challenges. We also plan to decrease the depth by considering competencies as a combination of knowledge, skills, and attitudes. Furthermore, future work will include mapping further (accreditation) frameworks such as CDIO 2.0, EUR-ACE, ABET or BCS.

In the long run, the RAICE framework aims to support educators in understanding relevant competence dimensions of Responsible AI and provide them with the tools to develop and integrate teaching about Responsible AI in their courses. In this context, it will be especially interesting to see differences in the disciplinary communities and international perspectives.

ABSTRACT

In Fall 2023, we developed an experiment that would enable two different sectors to participate in a responsible artificial intelligence (RAI) competition for engineering students. MathWorks® and FİGES collaborated with a Science Technology and

[1] *R.A. Downey*
downey.robinann@gmail.com

Society (STS) instructor on this effort. As part of the STS class at Bilkent University, engineering students applied responsible innovation (RI) theory to their case studies on artificial intelligence (AI) innovation sites. As industry players and policy makers have been grappling with the ethical aspects of AI in recent years, this is a key time for engineering students to become aware of the need to innovate for RAI. Through a short questionnaire, we found that students who took part in the Fall 2023 RAI competition are aware of the need for technical solutions to ethical and social aspects, including transparency, discrimination, privacy and the inclusion of stakeholder values. We also found that some engineering students were motivated to learn about RAI through the competition, perhaps partly because the initiative was supported by industry. Although the RAI competition started with STS students, FİGES plans to progressively expand the competition to other engineering courses at Bilkent University and beyond. RAI competitions can help motivate future engineers to begin imagining solutions for responsible AI.

1 INTRODUCTION

1.1 The Emergence of Responsible Artificial Intelligence

Responsible Artificial Intelligence (RAI) is a concept that has been emerging alongside artificial intelligence developments. Recent RAI developments signal a need to pay attention to responsibility practices in AI at an early stage in engineering education. It is also inevitable that engineers will need to prepare for RAI, as funding mechanisms, such as Responsible AI UK, are starting to emerge (UK Research and Innovation, 2024). Through interacting with industry on responsibility practices during their undergraduate training, engineering students can gain an understanding of the need to consider social values at an earlier stage in their development.

In recent years, the Asilomar conference on AI, the Partnership on AI and the Montreal Declaration on Responsible AI all addressed ethical concerns around AI. The Asilomar conference on AI produced a set of principles that were quite broad in nature and advocated that innovators consider transparency, safety, sharing benefits, steering clear of an AI arms race and producing technologies that have been aligned according to human values (Stilgoe and Maynard, 2017; Future of Life, 2017). The Partnership on AI (PAI), began in Berlin and led to similar goals, which look toward safe, transparent, fair and accountable AI (Heer, 2018). In 2018, the Montreal Declaration on Responsible AI held that humans should hold responsibility for critical decisions (Morandín-Ahuerma, 2023).

The debate around AI ethics and the need for regulation certainly deepened after Geoffrey Hinton, who is well known for his contributions to neural networks and deep learning, reacted to the arrival of ChatGPT by sounding the alarm about potential risks (Metz, 2023). In response, policy makers have moved quickly to address the potential problems that may arise. Arguably, the EU is leading these efforts, as European Parliament endorsed the Artificial Intelligence Act on March 13th, 2024. This milestone is set to regulate according to the level of risk and will be regulated according to discrimination, transparency, privacy and explainability (Gibney, 2024). Also, the UK has implemented the AI Safety Institute (AISI) to test AI tools for safety and will collaborate with other countries and several AI companies on this effort (Milmo, 2024). In addition to testing, an international advisory committee on AI will be established to assess emerging AI tools (Milmo and Stacey, 2023). In this context, industry will need to respond to the call to develop RAI solutions (Li et al., 2023). Engineering educators will also need to contribute to this effort.

1.2 The Responsible Artificial Intelligence Competition

In September 2023, MathWorks, FİGES and a Science Technology and Society (STS) instructor at Bilkent University partnered on a competition for responsible artificial intelligence.[2] Over 100 engineering students enrolled in the STS course participated in the RAI competition. The student projects all focused on one specific company or university laboratory involved in AI innovations and asked questions about risks, stakeholder inclusion and solutions that came up in the innovation process. Engineering students from the same class in previous semesters also used responsible innovation approaches to examine innovation sites and discovered that innovators encountered value conflicts, implemented sustainability practices and made responsible adjustments during the innovation process (Downey, 2023). However, for the 2023 RAI competition, the students found innovators that were developing algorithms, machine learning technologies and big data tools. The students asked questions that were intended to help them understand how innovators handled and responded to various risk issues, including discrimination, privacy, inadequate consent practices and explainability. The students also considered how users and other stakeholders were included in the innovation process and assessed how innovators solved relevant social concerns with technical solutions.

The RAI Competition was integrated in the STS course with the goal of inspiring students to challenge themselves within a dynamic and competitive framework. All the students were organized in groups of different sizes and tasked to interview three innovators from one relevant research or innovation site about the role of RI and AI in current industrial workflows. The students were asked to research technical developments, the associated social and ethical values and consider the opportunities for novel technical alternatives. After the instructor identified seven finalists, then the jury for the RAI competition identified two groups that received RAI awards for their work and they presented their work in an online setting. The jury members were not attached to the innovation sites in which the students conducted interviews.

In addition to one of the authors of this paper, the members of the jury were chosen from various companies that are amongst the AI leaders in the local and global market (Science Technology and Society 2024; also see the Acknowledgements section below). To guarantee an equal and neutral grading, the jury used a metric of assessment that was created by the instructor. In addition to assessing writing and creativity (20 marks), these metrics included the following: inclusion of RAI principles (30 marks), attention to key stakeholders (10 marks), focus on relevant risk issues (10 marks) and the identification of RAI solutions (30 marks). The “Outstanding Responsible AI Award” was given to the group with the highest rating and the “Responsible AI Innovation Award” was given to an additional group (Science Technology and Society 2024). The winners of both awards received a personal certification signed by both MathWorks and FİGES. A Responsible AI Competition event was organized at the end of the course and held online. The final event lasted

[2] The RAI competition was conceived during SEFI 2023 conference in Dublin as follow-up from the panel discussion: “Which engineering is needed for AI?.”

for one hour and included a 30-minute presentation on “Responsible AI: Navigating the Importance of Responsible Innovation”, which was given by Akhil Gopinath, an Artificial Intelligence Liaison at MathWorks and presentations from the students (Science Technology and Society, 2024).

2 RESPONSIBLE INNOVATION: THEORY AND PRACTICE

2.1 Engineering Formation, Broadening Problem Definition and RI

STS offers a number of valuable resources for helping engineering students to include social aspects in the innovation process and this can have an impact on the formation of engineers. As Downey notes, engineering students can benefit from going beyond dominant engineering practices, which focus on analytical problem solving, to engaging with “alternative images of engineering work” (Downey, 2009, 67). The alternative approaches go beyond defining problems in narrow quantitative terms, which may emphasize efficiency and economy, through including social aspects at the problem definition stage of the innovation process. Downey suggests that this approach can have an impact on engineering formation: “Key potential benefits from increased attention to problem definition in engineering formation include . . . producing active mobilizers of support for perspectives that take account of other perspectives” (Downey, 2008, 452). Feenberg has also suggested that engineers may prioritize instrumental values during the innovation process, as they are often shaped by the ‘unreflected projections of the engineering culture in which they are socialized” (Feenberg, 2002, 98). These observations both support the idea that students should be introduced to alternative innovation methods and approaches, such as responsible innovation (RI), during their training years. RI theory can help to provide methods and approaches for broadening problem definition at an early stage in the innovation processes.

Alternative innovation paths include social knowledge, which may be included through, for example, consulting stakeholders and making technical adjustments to social concerns. By introducing students to RI, they learn about the importance of identifying social risk issues at an early stage in the innovation process and they also realize that there are implications for tangible technical solutions. RI projects have been used in the STS course for several years at Bilkent University and they provide students with an opportunity to consult companies on their responsibility practices. The projects can help students to notice that social knowledge is routinely considered during the research and innovation context by innovators to varying degrees. Through conducting the RI assessments, students also have the opportunity to realize that social values, which may be aligned with concerns from a range of stakeholders, can lead to technical alternatives. For the 2023 RAI competition project, students used a Value Sensitive Design (VSD) approach. VSD has received attention as an approach for RI practitioners, although it has much earlier roots (Friedman, 1996). The methods include identifying values, addressing mitigation strategies and developing technical measures to respond to various values and risk concerns. van de Poel’s work in the area of values and design helps engineering students to understand how various values, including human well-being, justice, safety, health, and sustainability may be addressed during the course of the innovation process (van de Poel, 2015).

The key goal for our exercise is to demonstrate that collaborative activities, which cross social and technical boundaries, can help all of the participants begin to imagine alternative pathways for the technology. In this case, the key participants are the students, educational technology representatives, the innovators that participated in student interviews and an STS instructor. Boundary-crossing collaborations may be called “critical participations” (Downey, 2009) or “experiments in participation” (Downey and Zuiderent-Jerak, 2016, 239).The very act of engaging with social values may help students and innovators to reflect on emerging technical solutions for the ethical problems associated with AI. For example, MathWorks and FİGES are engaging in the social dimension of innovation through reading and reviewing the student RAI papers. We suggest that students and innovators gain an understanding of relevant AI social values through this experience.

2.2 Building Technical Solutions to RAI Problems

In addition to supporting research and teaching, MathWorks and FİGES have consistently been involved in academic innovation, so they are extremely well positioned to collaborate with universities on RAI projects. Within this context, the university-industry collaboration presented in this paper is designed to prepare Turkish engineering students for what it is an increasingly recognized standard in the world: the responsible development of AI. Elevating their awareness towards AI ethics and equipping them with critical thinking skills are imperative steps for their preparation toward upcoming challenges.

MathWorks, and FİGES are interested in engaging students in proactive learning, including RAI, through interacting with AI industry players. The objective is to motivate next generations to stay informed on latest developments in AI ethics while participating in discussions with their peers and with industries where RAI is already a key priority. This conversation becomes particularly resonant within the ecosystem of the MathWorks platform, where engineers and scientists have the opportunity of using low-code, hence accessible to everyone, AI solutions in connection with their field of expertise.

RAI and responsible innovation approaches in general, align with MathWorks’ technical solutions in terms of safety, security, transparency and explainability. The MathWorks website hosts many public and open access examples and tutorials that promote a responsible use of AI capabilities (see for example, MathWorks Inc., 2021; MathWorks Inc., 2023). Moreover, with ethical values in mind, technical adjustments have been made to enhance explainability and interpretability of deep neural networks. Many other techniques, aligned with current state of the art discussion, will be considered in the software development: compliance with global standards/policies, systematic identification of bias and discrimination, and the integration of ethical decision-making frameworks.

3 CONSULTING STUDENTS ON THEIR EXPERIENCE WITH THE RAI COMPETITION

3.1 RAI Competition Questionnaire for Students

On January 17 2024, 108 students were invited to participate in the RAI competition survey. Unfortunately, we were not able to survey the students directly after the competition, as it was essential to receive ethics approval from Bilkent University and this was not possible until after the STS course had finished and the students were no longer in the class. For this reason, we did not send the follow up questionnaire until a month after the competition had taken place and this may have had an impact on the response rate, which was about 18%. As we only had a limited response rate and many of the students did not respond to the optional open-ended questions, this study does have limitations. However, the findings offer some insight into student views of the RAI competition.

In the questionnaire, we asked students to check a form related to social risks, stakeholder engagements and responsible solutions that they discovered during their interviews with the companies and labs. They were also given an optional opportunity to elaborate on their choice. As some students responded to the open-ended questions, we were able to collect some interesting qualitative data, which we report on in the section below. Just over half of the survey participants reported that their innovation sites were medium to large companies, whereas nearly 40% indicated that they consulted start-ups on the responsibility practices and just over 10% of those surveyed conducted their studies with university labs focused on AI. The survey respondents indicated that they conducted their research interviews at innovation sites that developed AI tools for use in communications, transportation, education, healthcare, aerospace, defense, entertainment, generative AI and object recognition.

3.2 Student Views of Values and Ethical Solutions

The results suggest that students became familiar with responsibility practices in artificial intelligence. The students indicated that they uncovered different types of values through their RAI study. All students checked privacy, three quarters of the students indicated that they found that they uncovered transparency concerns, nearly 70% checked bias, and almost half of the students indicated that they had identified discrimination in their RAI assessments. One student indicated that regulations and ethical values were also a key focus for innovators. The majority of students (84.1%) indicated that innovators included stakeholder feedback in their innovation practices. Although some students suggested that this was an ordinary part of the innovation process, several students clarified that users played a special role in innovation practices and were able to describe how this information was used in innovation practices (see Table 1).

Students were also aware of the different types of technical solutions to social concerns that innovators may apply in artificial intelligence. For example, about three quarters of the respondents indicated that they had identified "privacy by design" solutions that were employed by their innovation sites. For example, the award winning projects included information on how innovators implemented privacy solutions by blurring images and anonymization practices (Science Technology and Society, 2024). Over 60% found that their company considered consent practices in their research. One instance of this is that students found that innovators received consent from parents before using an application for use in a kindergarten environment (Science Technology and Society, 2024). Slightly over 25% discovered that there were some "transparency by design" procedures are in place. Only 2 students suggested that there were not any additional responsibility practices beyond the inclusion of stakeholder values.

Table 1. Student Views on Stakeholder and User Inclusion in the Innovation Process

Role of Users	Student Views
Users identified as key stakeholders	"The company takes feedbacks from pilots, who are the users of the technology" "Users are the largest stakeholders for the company and the company does innovate according to feedback surveys." "Expert opinion is also considered when implementing the design"
Approaches for including users in the innovation process	"They make multiple meetings with the stakeholders and note their feedback to make their product both useful and beneficial." "They gather . . . with customers regularly to get their feedbacks and be responsive to those comments." "They keep doing tests according to users' feedback criteria" "An agile project approach is implemented."

Although most of the survey participants (84%) indicated that they agreed with the innovation site's RAI solutions, two students did not. One student elaborated on how the RAI solutions could be implemented better through the development of appropriate regulation: "Searching for and adapting international RI practices in the defense industry could be a great start." Although some had only a satisfactory experience, others emphasized that the competition helped to motivate them by stating that the competition "was very motivating" or made them "eager to work" on the project. Others noted that they became more familiar with ethical aspects of AI. For example, one student indicated that the experience provided information on "the ethical and stakeholder sides of the engineering process" and another suggested that it helped students to "become more aware of ethical aspects surrounding AI." These views suggest that including RAI activities in engineering education can help to reinforce the importance of attending to social values during the innovation process.

3.3 General Experience with the RAI Competition

Through the questionnaire, we learned about how to improve the competition in the future and we already implemented these aspects in the 2024 RAI competition (Science Technology and Society, 2024). One student indicated that they would like to have a longer competition, which could involve an opportunity to present their work directly to the jury: "I would like to be able to meet with the jury as well in a face to face environment." Other students indicated that they would like to receive more information about how they were assessed: "Maybe we could have learned about the project feedbacks but we only learned about our ranking." We will continue to improve on these aspects in future competitions by having face to face meetings and clarifying the evaluation process.

However, students also indicated that the competition helped to motivate them to learn about RAI practices in industry. For example, one student emphasized that the RAI competition provided new insights into the role of responsibility: "It was a very interesting journey that opened up a whole new world for me . . . this competition showed me that [RI] is . . . necessary." Other students were motivated by industry playing a key role in the event: "It was a great experience . . . this competition opportunity with MathWorks and FİGES was very important for every engineering student." By including industry members in RAI activities, it may help students to see the relevance of responsibility practices in their engineering training.

4 SUMMARY AND ACKNOWLEDGEMENTS

4.1 Improving Awareness of RAI in Engineering Education

Through the "critical participation" experiment described in this paper, the authors learned a great deal about implementing an RAI competition (Downey, 2009). This type of activity has the potential to help students and innovators start to imagine alternative innovation paths. Collaborative efforts that highlight social knowledge are increasingly important to include in engineering training, especially in the area of artificial intelligence. The applied fieldwork project provided an opportunity for students to focus on the role of responsible AI development in their future career. Some students indicated that the RAI competition helped to motivate them to learn about responsibility practices. For example, they discovered that innovators integrate privacy, explainability, discrimination and other key ethical aspects into technical developments. The RAI working group, through this manuscript, hopes to collect feedback and ignite constructive discussions to improve on the RAI competition outcomes. Based on the experience gained from the industry-university RAI collaboration at Bilkent University, the authors are working to create a blueprint for a student competition that can be expanded to other universities, beginning with a national contest in Türkiye. The next steps are to progressively expand the RAI competition to other engineering course of studies at Bilkent University. Afterwards, leveraging the solid partnerships of MathWorks and FİGES with other universities in Türkiye, the basis for a country-wide competition can be established. The RAI competition is not only vital for raising awareness among students about AI ethics but also serves to engage other industries in Türkiye in meaningful discourse on the subject. It has the potential to be a catalyst for establishing a community that bridges industry and academia, with a shared focus on responsible innovation.

4.2 Acknowledgements

We would like to acknowledge the other members of the Responsible Artificial Intelligence competition team. İrem Uncu (Academic Team Manager at FİGES), Sebahattin Babur (AI Team Leader at FİGES) and Talha Korkmaz (Research Engineer at Tübitak Sage) all played an essential role as jury members. We also want to thank Özdeş Çevik (FİGES, Customer Success Specialist), Akhil Gopinath (Artificial Intelligence Liaison at MathWorks), and Zeynep Doğa Dellal (CS Student, Bilkent University) for helping with organizational tasks. The Faculty of Engineering at Bilkent University also provided some support. We sincerely appreciate all of the Bilkent engineering students that participated in the 2023 RAI competition. The award winning projects are available online (Science Technology and Society, 2024). We would also like to thank the SEFI community, as that is where the authors met and started to collaborate on the idea for this competition.

ABSTRACT

Many positive outcomes have been associated with peer transition mentoring at university, there is however limited research on the influence of the mentor-mentee relationship when both sides are mature students. This project investigates how the mentor-mentee relationship influences the development of the mentors' professional skills, such as empathy and interpersonal communication by exploring the experience of engineering peer mentors with mature students in a preparatory engineering programme at a UK university.

[1] *S.B. Economides*

s.economides@ucl.ac.uk

Through semi-structured interviews and thematic analysis, the study aims to deepen insights into mentor-mentee dynamics and learning outcomes, providing guidance for future mentoring initiatives and student support strategies and highlighting the areas where further training of the mentors may be required.

Outcomes indicate that mentors benefited from improvements in their professional skills and some even developed friendships with their mentees. They were surprised by how the experience positively affected them, highlighting the reciprocal nature of mentoring relationships. At the same time, they also reported cases of breakdown of trust and feelings of isolation.

The findings of this inquiry carry implications for the future development of mature student mentoring initiatives, particularly concerning mentor recruitment and preparation. The ongoing project aims to expand our understanding of mentoring in engineering education, especially with traditionally marginalised groups of students and mentors.

1 INTRODUCTION

1.1 Background

The benefits of peer mentoring are well documented, especially for traditionally marginalised student groups (Atkins et al, 2020), (Dennehy & Dasgupta, 2017).

Research on peer mentoring and the mentor–mentee relationship includes qualitative studies exploring the peer mentors' experiences with their mentees. These studies have shown that peer mentors gain significant benefits in their interpersonal skills, such as communication, listening, and assertion (Holt and Lopez, 2014).

This study is looking at a pre-sessional peer mentoring initiative that ran at the authors' institution, a British research-intensive, highly selective, large, multidisciplinary university in 2023-2024. The initiative supported mature students who were admitted to a general engineering preparatory programme that aimed to provide access to a range of engineering degree options to students that do not fulfil the usual entry requirements for engineering, including mature students.

In the UK a mature student is someone who is over 21 years old at the start of their Undergraduate degree. In the 2022-23 academic year only 12 students out of the over 900 newly enrolled in the first year of this institution's Faculty of Engineering programmes were classified as mature students. However, the preparatory programme attracted a high proportion of older applicants and eight of this first cohort of 20 students were mature students. The mature students who participated in this programme ranged in age from 22-49.

According to the Office for Students, the UK's independent regulator for higher education, mature undergraduate students are more likely to come from traditionally marginalised or underserved backgrounds (ethnic minorities, people with disabilities, first generation students etc.), (OfS, 2020). They are also more likely to drop out of their course than younger students (84% as opposed to 94% continuation in 2017-18). Therefore, it is recommended that mature students receive enhanced support during their transition to higher education, in foundation years and the first year of study (OfS, 2020). Several Higher Education providers offer support specifically tailored to mature students (LondonMet, 2022) and the value of prearrival transition schemes is well documented (Lefever and Ahmed, 2015), (Morgan, 2012).

For this reason, and in line with practice at other higher education providers, a mentoring programme was established specifically for mature students, to help them ease into return to study. This was in addition to support offered to the cohort as a whole. The activities planned followed recommendations from other HE institutions (Lefever and Ahmed, 2015), (Exeter, nd), (Morgan, 2012).

The study aims to validate existing research and uncover findings regarding the experiences of mentors of mature students. and especially which aspects of the mentor- mentee relationship require the most support and training.

While university mentorship schemes can provide valuable support to both students and mentors, their successful implementation requires continuous planning and communication (Fishman, 2021). A study conducted in Australia examined the effectiveness of a peer-assisted program specifically for mature Health Science students. Mentors reported positive experiences, expressing personal satisfaction from aiding mentees and simultaneously developing their own leadership skills (Hryciw et al, 2013). Minor (2007) further supports the view that mentors develop leadership skills as they have to solve the problems and challenges that mentees encounter. Mentors also enhance their own study skills, ultimately leading to the improvement of self-esteem and confidence (Drew et al, 2000). Holden (2006) attributed the benefit to mentors to self-reflection and internalisation of their own experiences. Consequently, past literature shows the significant benefits of peer mentoring programs for mentors.

However, mentors also report poor communication with mentees (Gunn et al, 2016) or indicate that mentoring is unexpectedly demanding (Heirdsfield et al, 2008). Numerous studies also highlight issues in peer mentoring programmes, particularly with mature students. These include cultural differences and unclear mentoring information (Chester et al, 2012; Golding and O'Beirne, 2003). Despite these limitation and challenges, mentors' personal capacity may further improve in the process between tackling challenges and self-regulation (Heirdsfield et al, 2008).

2 METHODOLOGY

2.1 Scheme setup

This research is work in progress and builds on an earlier pilot study on transition mentoring (Economides *et al*, 2022). The earlier study examined transition mentors' perceptions of the transition mentoring scheme of the institution. Following the pilot study, a new mentoring scheme was developed specifically for the engineering foundation programme students and was implemented in the 2023-2024 academic year. Here we are presenting the findings of this work in relation to the experience of the mentors who participated in the initiative for mature students. A separate study of the experience of the mature students is under way. A review of the scheme will then be conducted, with a view of implementing changes for the next academic year. A summary of the activities of the project in 2023-2024 are given in Table 1.

Table 1: Timeline of the project activities

Dates	**Activity**

July- August 2023	Recruit student mentors and research assistants
July- August 2023	Invite offer holders to fill in survey/ gather information on expectations and concerns
September 2023	Pre-sessional mentoring sessions (online or face to face) up to three sessions per student
October- December 2023	Mentor meetings
December 2023	End of term survey
January 2024	Collect data on student performance
February-March 2024	Mentor meetings (optional)
April 2024	Individual interviews, qualitative analysis
May 2024	Mentor meetings (optional)
June 2024	New cycle for 2024 offer holders begins
September 2024	Follow up survey/ interviews on expectations for Year 1
December 2024	Interviews and progress check

In August 2023 six students were recruited and trained as mentors. Since the programme of study for which they were recruited was presented for the first time it was not possible to find previous attendees who could act as mentors, so with the help of the Mature Student Society and the Society of First Generation Students, mentors from across the university were recruited, with a preference for students of STEM subjects.

The criteria used for recruitment included knowledge of DEI issues, previous mentoring experience, experience of being an older student and willingness to support other students. The mentors ranged in age from 23-50 and had all studied for an undergraduate qualification as mature students, either at this or another university. Most of them were active in the institution’s Mature Student Society.

The mentors attended paid training, where an emphasis was placed on active listening skills and where they had the opportunity to reflect on their own experiences and expectations. The training also included guidance on how to navigate potential problems and provided a model for topics of discussion. It was explained to mentors that mature students have different concerns than the average 18-year-old student, for example: family obligations, concerns about returning to education, concerns about the future or about having made the right choice by going to university (OfS, 2020).

Mentors were then matched to mentees of a similar age, gender and, wherever possible, similar degree subjects, as it has been shown that such pairings lead to improved rapport and better outcomes (Blake-Beard et al, 2011). The mentees were introduced to their mentors in early September and had three meetings with them before the start of the academic year. The meetings were held online and were followed by a “meet your mentor” session during university induction week. Mentors and mentees were given vouchers that could be used around the university cafeterias, so they could get to know each other in a casual setting.

Mentors were also asked to fill in a form after every mentoring session where they described the activities carried out, topics discussed and any concerns. A member of academic staff with relevant experience acted as a point of contact in case of problems and had meetings with mentors who wanted to discuss their work.

From the start of the academic year the mentors continued working with their mentees on a regular basis for the first term and it was recommended that they have a "catch up meeting" in the second and third term. Mentors and mentees could arrange for more meetings if they wanted to.

2.2 Data collection

The study received ethical approval from the institution. All participants were over 21 years old at the time of the study and provided informed consent. Participants were informed that their names would be pseudonymised and their true identities known only to three researchers. They were also advised that they could retract any information shared, ensuring it would be excluded from the analysis.

The primary method of data collection was semi-structured interviews, which were then transcribed by the interviewers and coded using an inductive thematic analysis. A structured interview protocol was designed to guide the discussions, featuring a range of questions and follow-up prompts to facilitate the conversational flow of each interview (Jacob and Furgerson, 2012).

At the end of the programme, the semi-structured interviews were carried out by student research associates. This intended to narrow the gap between the mentors and the interviewers in the hope that mentors would be reflective, open and critical of their experience. The research questions intended to capture the learning, personal development and thoughts on potential growth of the mentors.

Of the eligible participants two chose not to participate, citing a lack of interest, reducing the number of interviews to four. These four participants were mentoring at the time eight mature students.

Each transcript was subsequently reviewed by the researchers and finalised. All recordings were then deleted.

Thematic analysis was used to help identify common experiences and to help identify best practice. Thematic analysis is used to recognise and interpret patterns or themes, frequently leading to new insights and comprehension (Boyatzis, 1998).

3 RESULTS

Some positive case studies were observed early on in the scheme, especially with students over 25. For example, an older mature student was feeling overwhelmed by the documentation required by the Admissions Office in order to process enrolment. The mentor went above the expectations of the role, to help the student reconsider. The mentor also helped the mentee with organising a language test and offered ongoing support until the start of teaching. Another mentor arranged a tour of a biomedical lab for some mentees and discussed future job opportunities with them.

However, there was also a rift between a mentor and a mentee that led to the mentee no longer participating in the scheme and some other mentors described their relationship as just “professional”.

Most mentors felt that they developed a range of professional skills, with communication being the most common skill developed, followed by empathy and listening. Other benefits of participation included insights into their own education path and personal growth.

Two key themes emerged from the study: the value of the mentor-mentee relationship and the professional skills that mentors developed from their mentoring experience.

3.1 Value of the mentor-mentee relationship

Findings relating to the mentor- mentee relationship are discussed in terms of two subthemes: Role perception and rrewards, respect and friendship

Role Perception and Rewards: All participants believed that the mentoring process can bring personal rewards to mentors, such as satisfaction. One participant noted, *“…mentoring is simply about facilitating the development of your mentees”.* Others expressed similar beliefs:

- *“We are trying to equip them [mentees] with the right tools and strategies that will support their idea of success”*
- *“I hope that my mentees will not have to go through so many iterations of mistakes or struggles [as I had]”*
- *“The reason I participated is that I wanted really to give them help and advice as a mature student myself”*.
- *“The role of a mentor is to provide an outside listening ear, a sounding board, but also access to networks and opportunities […] that might not be available through other routes”*.

One mentor said: *“I'm not seeking out something to put on a CV. I'm not seeking out something to use in my future career”.* This mentor joined the program to support mature students making major life changes. Additionally, they were motivated by a desire to support women entering the field of engineering.

Personal growth was also cited as a reward of the role:

- *“[It gave me] more of an opportunity to support myself with my observation of other people's personal experiences”*
- *“I wasn't expecting it would help me think about how I approach my own studies”*
- *“I will definitely use this during my graduate scheme when I graduate”*
- *“I didn't go into it expecting to learn […] So, the fact that I've got something out of it as well is an absolute plus”*

Respect and friendship: Some mentors felt sharing their personal experience increased openness from mentees, resulting in more fluid interactions and respect.

- "*After one or two meetings, I feel like I and my mentees, developed [a relationship] for us to be comfortable talking to each other about more personal stuff*".
- *"I think there was a lot of mutual respect. There was an openness to share the experience of mentoring. It was very friendly."*
- *"But I feel like the mature mentor relationship was just totally different really. It was more personal".*

However, some mentors described their relationship as a professional exchange, making it inappropriate to form friendships: *"I would say my relationship with my mentees was just professional. We set up a meeting time. We talk about the problems, I give them my advice, and answer any questions they have and it's just formal communication".* One participant wanted the relationship to extend to friendship, but the mentees did not reciprocate: *"I was hoping we could be more of friends […] and kind of possibly hang out or talk more often. But from the way it was at the end of the day, I'm still called a mentor".* In this situation, meetings could become forced *"After a certain number of meetings, the conversation dies […] They don't need you anymore. So, the meeting that you have feels forced and it ends up finishing quite sooner"*.

One mentor described a relationship that broke down, *"There was unfortunately a loss of trust and there was an imbalance in terms of [what] we could achieve."* The dissimilarity of mentor-mentee backgrounds was also noted in this interview, in terms of fulfilling mentee academic needs: *"It would be interesting to know from them, particularly the one that it did not work out whether it mattered to her, that I wasn't from the same department."*

The experiences of the mentors seem to align with Golding and O'Beirne's (2008) findings when mentors and mentees engage in discussions or pass down knowledge, although some mentors described their relationships as formal. The relationships that remained formal appear to align with Heirdfield et al (2008) and will require further investigation in the future.

3.2 Professional skills development

Findings relating to the mentors' skills development are discussed in terms of the following subthemes: Communication, Active Listening, Organisational skills and Empathy.

The findings indicate that most mentors felt that they developed a range of professional skills, with improved communication skills and active listening being the most noticeable intangible assets gained through mentoring.

Communication: Mentors adapted their communication approaches to suit the characteristics of mentees. This approach includes giving positive feedback and reinforcement:

- *"I learned how I can phrase advice without sounding a bit patronising or a bit bossy"*
- *"Eventually what I ended up learning is really communication skills".*

Active Listening: The interviews highlighted improvements in the mentors' ability to actively listen:

- *“…in terms of specific skills, I have worked hard at active listening, and I think I've gotten better at active listening.”*
- *“I don't particularly do anything other than encourage active listening. I've not noticed any development in soft skills”.*
- *I felt more a bit like a therapist, I would say, which is something I never really done before because I'm an engineer”.*

This skill fostered two-way discussions, making interactions more engaging, as one participant said: *“You don't want to be the one who's always doing the talking, and for them to be sitting there as a chore waiting for you to finish so they can hang up. Just try to listen more and ask questions.”*

Empathy: Empathy was discussed by participants. This skill can relate to active listening and to the diverse backgrounds and issues, both academic and non-academic, that each mentee faces.

- *“[I have been] developing this empathy by really listening and trying to really relate to what they are feeling and what they've been through.”*
- *“Most of them came from a hardship background and it was mostly us talking about it and me relating [coming from a similar background], how I ended up at uni, and that was the foundation for all of the communication we had”.*

Organisational skills: Mentors also mentioned organisational skills, particularly in keeping track of their respective mentees with different characteristics, as one mentor described, *“…keeping track of three different people with three different lives, and three different hobbies, that was quite tricky to manage…”*.

Several professional skills appear to align with previous research. For instance, communication skills, as noted by Hryciw et al. (2013), were frequently mentioned by mentors based on their experiences. Additionally, participants reported variations in mentees' characteristics, which required them to accommodate different needs and personalities, thereby enhancing their organisational skills (Calder, 2024). Insights gained from mentors, who were able to develop empathy, indicate that this specific skill can be cultivated due to the diverse backgrounds of mature mentees (Beltman and Schaeben, 2012).

3.3 Discussion

This qualitative study sought to understand how mentors of mature students in one university in England experience mentoring. Results generally agree with the findings of Marshall et al (2021).

In order to enhance understanding of the mentor experience, Social Exchange Theory (SET) (Molm, 2006) has been applied to analyse the themes, looking at the rewards and costs for mentors. It can be seen from the themes that peer mentors gain rewards such as personal satisfaction from helping others succeed. They also receive respect and the potential development of friendships within the mentoring group.

Costs and Risks: Mentors invest time and effort in mentoring. There may be emotional costs if the relationship with the mentee is dysfunctional. Or they may feel isolated if they cannot get support from other mentees. Understanding the costs and risks can help us put in place structures that will enhance the mentoring scheme by minimising costs and maximising rewards.

One key aspect that could be improved in the further mentoring process is mentor-mentee matching, including academic background. This aspect could potentially lead to a more mutually respectful relationship and enjoyment, as explained by Gattis et al. (2017).

Our recruitment drive for mentors stressed the altruistic nature of mentoring, but the development of professional skills and personal rewards could be highlighted in future mentor recruitment drives.

The interviews highlighted the need for more support from the university or for managing expectations. While some students were keen to become friends with their mentor, many were content with a close but formal relationship and any mentor training must include information on coping with the disappointment of mentor-mentee lack of rapport and even loss of trust.

A common aspiration among mentors was to foster communication with other mentors to share experiences, common issues and possible solutions, *“It might have been interesting, after the first term, to host a mentoring lunch so that the mentors could get together and talk about it. I mean not to break any confidentiality, but to just discuss what the issues were that had come up and how they had addressed those issues.”*

It would be of interest to be able to investigate further the breakdown of trust that occurred with one mentee. At the time of writing, neither the mentor nor the mentee were able to comment further, therefore it is difficult to draw clear conclusions, but it appears that this is in line with the findings of Heirdsfield et al (2008) regarding mentor- mentee relationship forming. In future the academic contact could be checking how mentors and mentees interact regularly, in addition to the students being reminded that they can get in touch with them and ask them to mediate or mitigate conflicts.

The next phase of this project will include matching of mentors and mentees by subject topic, mentor information exchange sessions and monitoring from the researchers to ensure improved management of expectations.

4 SUMMARY AND ACKNOWLEDGEMENTS

This study underscores the importance of considering the perspectives of peer mentors when designing and implementing a mentoring programme.

Further work needs to be carried out to compare the mature student peer mentorship scheme with a standard-age mentoring scheme, to see how the age and maturity of the participants makes any difference in the effectiveness of the mentoring and the experience of the mentors. We already know that the concerns of mature students are not the same as those of younger students, so once the scheme is fully implemented in future years, better comparisons will be possible.

Keywords: *Future Readiness, Sustainable Development, Computer Science, Societal Impact, Alumni Investigation*

ABSTRACT

According to the Swedish Higher Education Act, Higher Education Institutions in Sweden must relate to Sustainable Development (SD), which also means that elements of SD must be given in courses and study programs within Swedish universities. Seen from a perspective of SD, the Higher Education Institutions should give students a preparation to contribute to the society at large, partly based on their profession, and partly through ethical, sensible, and responsible actions. Elements of

[1] *D. Einarson*
daniel.einarson@hkr.se

examination can be measured, and this especially applies to elements that are particularly linked to the specific subject given by the universities and taken by the students. What is more difficult to assess, however, is how well this affects the student's future desired skills in influencing the surrounding society in a meaningful way. This contribution aims to investigate what happens afterwards. That is, these studies focus on questions regarding how well the alumni have absorbed teaching elements regarding SD, and how they find themselves being future ready based on their previous studies.

1 INTRODUCTION

According to the Swedish Higher Education Act[2], Swedish universities must adhere to Sustainable Development (SD). In order to see that this has been followed, the Swedish Higher Education Authority[3] given a mandate in 2016 (Finnveden, et al. 2020) to evaluate this obligation via a thematic survey. Unfortunately, this survey showed that a majority of the Swedish universities did not meet the obligations concerning SD in a satisfactory manner (Finnveden, et al. 2020). Thus, the universities were requested to make significant changes, including, by highlighting SD in education. Especially, it was recommended that SD should be based on the United Nations' Agenda 2030[4], and its 17 Sustainable Development Goals (SDGs)

1.1 On Initiatives taken at Kristianstad University

Kristianstad University (HKR), Sweden, which is the home university of the authors of this contribution, was among the universities that needed to make improvements regarding SD. Several initiatives were taken at different levels of the organization. A preliminary investigation was performed to share experiences concerning how SD was approached in different disciplinary areas of the university (Argento, et al. 2020). Moreover, a higher education pedagogical (HEP) course, *Teaching for SD*, for the educators at HKR was initiated to guide and support those educators in their relation to SD and their implementation of SD into their teaching practices (Persson, Einarson and Melén 2023).

Fig. 1. A Process to Achieve Student SD Literacy

Fig. 1 illustrates the context of the HEP course, and where (Persson, Einarson and Melén 2023) addresses that course as a part of a 4-step process towards SD literacy amongst the students. The steps of Fig. 1 are further outlined as follows:

1. To meet the above-mentioned thematic evaluation, an initiative was taken to investigate the circumstances regarding SD within HKR, and where a report among other things proposed the HEP course.
2. The HEP course is designed and announced as available to take to all educators at HKR.
3. The HEP course is implemented and given to the educators. Moreover, a study is conducted to inform about the outcomes of the course in terms of

[2] UHR, The Swedish Higher Education Act (1992:1434) 2023
[3] The Swedish Higher Education Authority. 2024. https://english.uka.se/
[4] United Nations – Department of Economic and Social Affairs. 2022. https://sdgs.un.org/2030agenda

teaching practices, course/program syllabuses, and examination elements at the educators' side.

4. It is identified that to give a full picture of the efforts, there is a need for an investigation on the outcome of the students' readiness to contribute to society from a SD perspective.

Here, the leftmost arrow of Fig. 1 represents the demands put on the universities regarding SD. The rightmost arrow represents the possible impact the students/alumni have on society from a perspective of SD.

1.2 On Initiatives taken at the Dept. of Computer Science at HKR

Several initiatives have been taken at the Dept. of Computer Science, at HKR to live up to demands regarding SD in education. For instance, a one-year master program in Computer Science, open for international students, was developed to especially emphasize SD (Einarson, SEFI 2023). The structure of that program reflects on one hand, technical content, and on the other hand elements especially reflecting concepts of SD. Moreover, projects and thesis work aim to integrating skills in Computer Science-based techniques with practice in consequences on a sustainable society. Thus, students should be prepared to be ready to have positive impact on society through their core profession, and added to this, with a maturity to look at the world from the lens of ethically based actions.

Moreover, (Klonowska, Teljega and Einarson, SEFI 2023) outline of a bachelor study program in Computer Science, and where concepts of SD have been added to elements of courses of that program. The paper illuminates on how such a SD track has been built into that 3-year program, and how that track includes a progression over the study years. Here, (Klonowska, Teljega and Einarson, SEFI 2023) show how the concepts of SD were integrated with practice in Computer Science based activities, such as, programming and system building and cooperation, to introduce the students into an appropriate context. Furthermore, (Klonowska, Teljega and Einarson, SEFI 2023) reflected on students' attitudes towards SD within their study program. A survey showed that while SD was not seen as a significant subject to develop programming skills, it was still considered important that software developers were introduced to aspects of sustainability and ethical issues.

1.3 On Evaluating Future Readiness for SD

It is claimed that higher education contributes to the development of individuals, social involvement, and critical thinking (Regeringskansliet[5]) and furthermore that the higher education institutions shall ensure that the knowledge and expertise found at the higher education institution bring benefit to society (UHR, The Swedish Higher Education Act (1992:1434) 2023). This section has addressed several attempts that motivate that HKR and Computer Science at HKR live up to such benefits. The higher education institutions have the responsibility for the future readiness of the students. Courses and study programs contain the necessary elements of practice, and examinations should furthermore serve as guarantees that the students have achieved a satisfactory level of skills.

Still, as pointed out by the discussions from Fig. 1, and further elaborated on in (Persson, Einarson and Melén 2023), how well the former students, that is, the

---

[5] Regeringskansliet (Swedish Government Office). n.d. https://www.regeringen.se/regeringens-politik/hogskola-forskning-och-rymd

alumni, benefit to society is out of the borders of the university. Still, it may be essential to have an understanding of the effects of the educational system. The work of (Persson, Einarson and Melén 2023), points out a need for a larger study across the disciplinary borders to achieve such experiences. However, this contribution will address a rather narrowed down approach and restrict such a study to former students of Computer Science at HKR and limited to former bachelor students. The focus of this contribution lies in answering a question regarding how the former students have adopted their previous studies concerning SD, and how those have contributed to their working situation regarding SD.

1.4 Related work

The Higher Education Ordinance[6] is the framework in Sweden that generally describes the learning objectives that must apply within the Swedish universities. However, the relationship to SD is explained rather weakly and does not provide clear guidance for the syllabus of the university courses. In contrast to this, the global framework and network CDIO (cdio.org) for engineering educations can be mentioned. CDIO provides, e.g., a syllabus with several learning outcomes reflecting on engineering impact on SD, and furthermore guides faculties regarding approaches towards SD through the, so called, CDIO Standards. CDIO has, moreover, inspired to several works, such as, (Chea., Lim, and Chao 2022) and (Adlemo 2023), where SD is shown to be integrated in different educational contexts from CDIO perspectives. CDIO has also provided sources of inspiration at levels of alumni. For instance, (Kovacs 2022) claims that “Alumni studies are often overlooked in engineering education research, despite holding great potential for improving engineering programmes and creating the links that are missed when it comes to university-workplace transitions”. The authors illuminate on a survey where it is shown that in contrary to disciplinary skills, skills regarding ethics and sustainability amongst the alumni were considered weaker. Such results certainly may serve well as feedback to universities for improvements concerning students’ ‘soft skills’.

Furthermore, (Boone, Bromaghim, and Kapuscinsk 2023) especially elaborates on concepts, such as, Green Jobs, or Sustainability Careers, especially with a focus on environmental challenges in work life. The authors propose a set of skills (in much aligned with skills suggested by CDIO), that are desired for careers based on sustainability challenges. An interesting viewpoint of that contribution is the main perspective on skills for job, rather than for university courses. This approach is also discussed by (Salovaara 2022). Here, the author emphasizes that quite much research can be found regarding sustainability elements in education, while the qualitative results of such educational efforts have been less carefully investigated.

In the context of this contribution, it is shown that initiatives for SD in education have been made, but that there is a lack of sufficient studies of the effect on the work-operational context. Such studies may not only show how well-prepared students are but can also provide valuable feedback on the preparatory learning elements.

[6] The Swedish Higher Education Ordinance (1993:100). November 6, 2023. https://www.uhr.se/en/start/laws-and-regulations/Laws-and-regulations/The-Higher-Education-Ordinance/Annex-2/

2 METHODOLOGY

2.1 Context and Participants

In 2020, the Student Center at HKR has initiated its first general alumni survey, aimed at all HKR alumni. The objective was to gather information to improve the quality of the programs. The survey questions were tailored to primarily investigate the students' establishment on the labor market and whether they believe that their skills and abilities meet the program objectives. Since then, an alumni survey has been conducted every year, where new questions with new orientations are added. This study specifically targets the personal development aspect of the alumni from the Software Development program, encompassing the following questions:

Q1: Has the education contributed to increased **self-awareness**?

Q2: Has the education given you a better understanding of your **social relationships**?

Q3: Has the education made you aware of various **societal challenges**?

Q4: Has the education contributed to **increased societal engagement and responsibility**?

In the spring of 2024, questions were designed with a focus on personal and professional growth of our alumni (Software Development) in the light of the principles of SD they acquired during their education. A specific interested addressed the understanding on how their education had influenced their attitudes and actions towards sustainability in different aspects of their lives.

The survey of this study has addressed the following **10 questions**:

1. In your **profession**, how do you see that you took advantage of the teaching/learning elements regarding sustainable development that you received from your education?
2. How has education in sustainable development benefited you on a more **personal** level?
3. Against the background of the knowledge you gained from the education concerning sustainable development, how ready do you feel to face future adaptations based on a *sustainable development **mindset***, **professionally**?
4. Against the background of the knowledge you gained from the education concerning sustainable development, how ready do you feel to face future adaptations based on *sustainable development **mindset***, **personally**?
5. In the context of risks and innovations, how much do you see that *sustainable development **needs*** to be considered?
6. How do you acquire knowledge about which sustainability **goals** (SDGs) are relevant to you (**personally**) and your **professional** life?
7. What sources of information or strategies do you use to identify and understand the sustainability goals that best align with your **professional** activities?
8. Can you share specific methods or resources you have used to stay informed about relevant sustainability goals and how these affect your work and professional life?
9. What initiatives or projects have you been involved in that promote sustainability? What challenges have you encountered?

10. Do you have any comments / reflections?

As can be seen, the above points concern the professional approach to SD of the alumni, as well as the personal. Reasons to this are based on the roles of the universities to educate for the needs of the industry and society at large, and to build a basis for social contributions through social involvement and critical thinking.

2.2 Data collection and analysis

The data were collected from two sources, the alumni surveys administrated by the Student Centre from 2021 - 2023, and the alumni survey conducted in Spring 2024, administrated by the authors of this paper.

The response rates for the alumni surveys from Student Centre varied across the years: in 2021, there were 16 responses, accounting for 27% of the total number of examined students between 2016-2018; in 2022, there were 9 responses, representing 32% of the examined students of the year 2019; and in 2023, there were 26 responses, making up 55% of the examined students of the year 2020. Overall, there were 51 responses out of 210, indicating a response rate of approximately 24%. These surveys were mostly based on quantitative data analysis and Microsoft Excel tool were used for visualizing the results.

For the 2024 survey, 15 out 210 respondents participated, accounting for 7% of the total. This survey was based on gathering qualitative data and Microsoft Forms tool was used. Here, for the answers, we experimented with the NVivo[7] tool. Unfortunately, it did not yield satisfactory results for our intended purpose because we were interested not only in finding common patterns but also in individual responses to understand how alumni applied their knowledge of Sustainable Development in their personal and professional lives. Therefore, a detailed analysis of each answer was conducted. It is worth mentioning that in a similar study (Bohm, et al. 2023), the authors mentioned difficulties of using the tool in analyzing the survey based on qualitative data.

3 Results and Analysis

3.1 Alumni survey 2021 – 2023 – questions focused on Personal development

The questions related to personal development were classified on a scale from 0 to 4. The result is presented in Figure 2.

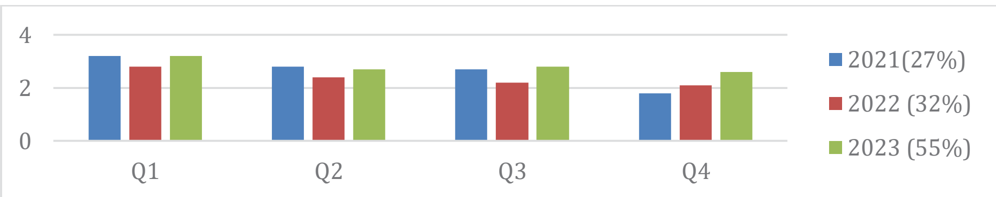

Fig 2. Result of the Personal development - from survey from 2021 - 2023

The alumni responses for questions Q1 – Q3 show relatively little variation across different study periods. A slight increase is in the last question ("increased societal engagement and responsibility"). This suggests that our efforts in collaborative and

[7] NVivo - Lumivero. n.d. https://lumivero.com/products/nvivo/.

diverse project during last years (Klonowska, Teljega and Frisk, SEFI 2023) yielded increased positive results. It also confirms that besides subject knowledge, social contacts, and collaborative project during the education, play a crucial role. This aspect is particularly significant in professions like software development.

3.2 Alumni survey 2024 – questions focused on SDG

Questions 1 to 10 and the corresponding answers were grouped in such a way that 1 to 5 report gradual agreement. The answers to questions 6 to 9 are rather of the 'either or' type, while finally question 10 concerns a pure comment on the question.

Concerning questions 1 to 5. The answers partly corresponded to a scale from 'no agreement at all', to 'meaningful', with 'potentially meaningful' in between. In addition to this, there were answers related to purely technical aspects, where this may be seen as a misunderstanding of the questions regarding sustainability being more about technical sustainability and maintainable software, rather than about SD according to Agenda 2030.

Table 1 shows the distribution of the answers where **T** stands for Technically held answer, **N** stands for No agreement, **P** stands for Potential agreement, and **M** stands for Meaningful. The rows in the table corresponds to *questions 1 to 5*. The content is then exemplified with excerpts from the answers, and where examples on answers are indexed according to **[Row,Column]**.

Table 1. Distribution of answers to questions 1 to 5

	T	N	P	M
1	7	3	2	3
2	2	4	2	7
3	1	3	3	8
4	1	2	2	10
5	3	2	2	8

Generally, the **N** column include leaving out answers, or answers of type ‘No’, ‘Nothing’, or ‘Not applicable’. While being anonymous, the survey still shows that it is in much the same persons that are behind the answers of that column (there is a similar correlation also regarding the other columns). Certainly, there is nothing right or wrong in this, it is just that SD actually have less meaning to some than to others.

One of the respondents seems to have advanced to Master Studies, where SD seems to be significant for that Master study program. Thus, that person completely responds to the **M** column. Below are exemplified some of the responses that Table 1 represents:

- **[1,T]**: In my profession, I learned many different techniques and the process of learning new programming languages from scratch. Today as a consultant for a big company, I can use these elements to adaptively learn new techniques necessary to provide customers the help they need.
- **[1,T]**: Writing tests and having technical dept in mind.

- **[1,P]**: Difficult to say. My studies gave me strong academic skills that are probably very useful in research, while they are not 1 to 1 transferable to software development. Sadly, there are usually not specific recipes on how to do professional software development in a sustainable way, and things like that need to be found out by experience.
- **[1,M]**: While sustainable development was not an integral part of my day-to-day work, the education I received has positively influenced my decision-making process, allowing me to consider sustainability aspects in my professional activities.
- **[2,T]**: Opened eyes for testing and ci\cd.
- **[2,P]**: I try to be more cautious about energy consumption and device usages.
- **[2,M]**: A lot. I became a bit more focused towards the future and the betterment of humanity.
- **[3,P]**: Well I never tested my knowledge so the question not applicable (Feel like not ready)
- **[3,M]**: I think that, given my continuation in academia, SDGs will be an omnipresent factor so I feel pretty well equipped to develop professionally with them in mind.
- **[4,P]**: Don't know, medium level most likely.
- **[4,M]**: Quite ready. Since the SDG's were talked about, I always looked for real life adaptation and to see what I can do.
- **[5,M]**: When it comes to risks and innovations, sustainability is important for several reasons, viability, resilience to risks, environmental implications, and resource efficiency among others.
- **[5,M]**: A lot. The thought is that everything we do has consequences. Better to aim for the positive consequences

Concerning 6 to 9. These questions reflect aspects such as how to acquire information about SD, and experiences around working with SD professionally. The answers can be grouped into Negative and Positive respectively, where Negative generally means that the respondents do not have SD in mind at all, and Positive stands for examining SD and having SD as a perspective in their work.

Table 2 shows the distribution of the responses where **N** stands for Negative response (not contributing) and **P** stands for Positive response (contributing). The rows answer *questions 6 to 9*. Examples of answers are given, and where these are indexed according to **[Row,Column]**.

Table 2. Distribution of answers to questions 7 to 9

	N	P
6	5	10
7	6	9
8	6	9
9	6	9

The almost complete similarity between the values for each row in Table 2 correlates broadly with how the respondents have answered. Although it is not a complete match, it is almost the same groups of respondents behind column **N** and column **P** respectively. There is thus a clarity in how SD has significance in general for the people involved in the survey. Examples of responses are included below:

- **[6,N]**: Apart from common sense, there is no real other way. SDGs are defined as admirational goals (utopian in some cases) and they are politically focused. These things have little to no power in engineering.
- **[7,P]**: To identify and understand the sustainability goals that align with my professional activities, I rely on my workplace's plans and initiatives, as well as additional information from various online resources. These tools help me stay aligned with sustainable practices within my field.
- **[8,N]**: Yes, ignore them completely and use common and experience. The organisation that I work at has it's own goals that are freely available for every employee.
- **[9,P]**: I did the paperwork for a construction company to gain a few ISO certifications that were related to sustainability.

Concerning question 10. There were 8 out of 15 responses concerning further comments or reflections, still, only 3 of those were actually contributing to the question. Examples:

- Learning and applying sustainable development principles has been enriching both professionally and personally. It's inspiring to see how even small changes can contribute to a bigger impact on our planet's health.
- I work as a consultant for a large Ehealth company and am not doing any development, so the questions are not currently relevant unfortunately.
- It would be more useful to focus on sustainable development in terms of business practices instead of learning about it in abstract as defined by UN. Reframing sustainable development as scalable, affordable, maintainable and accessible software would be more beneficial in the long term, would allow it to include software specific goals. It would also provide a channel for the real world, practical applications and examples which would help students understand and internalize the concepts. Reduced inequality means nothing on its own, having accessibility support means reaching more users which results in higher profits. Economic growth means nothing, but prioritizing long term success over short term gain is a good business practice. I could go on and on, but I think I'll end here.

4 SUMMARY AND ACKNOWLEDGEMENTS

As pointed out by, e.g., (Kovacs 2022) and (Salovaara 2022), there is a lack of research on study outcomes in the context beyond the university studies. This contribution approaches alumni skills with respect to SD literacy, according to the fourth step of Fig. 1. That step corresponds to the main research question of this paper, and more precisely, investigations regarding the level of readiness of alumni with respect to SD, on a professional basis as well as personally, and this as an effect universities' educational elements. The study behind this contribution has a focus on alumni from the Computer Science dept. of the home university of the authors. Still, the mentioned fourth step of Fig. 1, corresponds to more full-scaled studies concerning several disciplinary programs, and hopefully, this contribution may be a starting point of such. Such studies may also open for reflections on differences in alumni's attitudes towards SD with respect to disciplinary background.

To begin with, the investigations of this contribution have shown that there is a general awareness of SD amongst the alumni. Moreover, it can be seen that SD has no major role in their professional practice. This can certainly be considered natural as the programming profession itself does not directly relate to SD. It is rather at a level of project management and product development where SD can be seen as significant. The alumni behind this study have mostly not reached such levels, and thus cannot see SD as essential to their work, beyond common sense reflections. The low response rate may possibly also reflect this, a case only can be answered by future surveys.

The authors of this contribution would like to give a thanks to the Student Centre at HKR for their assistance concerning the survey. Furthermore, a special big thanks you goes to the former students, i.e., the alumni who have taken the time to respond to the survey behind these studies. Also, thanks to the anonymous peer reviewers for valuable comments on a previous version of this contribution.

It is hard to imagine a "different" Internet, but the character of the Internet as we experience it today is,
in fact, contingent on key decisions made in the past... – David D. Clark (Clark 2016)

ABSTRACT

Digital nations are embedded in a globally connected civilization largely supported by centralized technology mostly designed with an exported ideology. Our aim is to transform education to enable the conditions for regional innovation and sustainability. Engineering curriculums have a tendency to disassociate technology from politics, despite that responsible engineering requires an interdisciplinary perspective. The EPFL computer science bachelor course *CS-234* has been offering a broad but hands-on introduction to technologies for human self-organization since 2019 once per year. Unique in its own, this course blends political and computer science while creating a coherent and interdisciplinary narrative for the younger generation, i.e., connecting the dots between the evolution of governance, historical roots of democracy and design choices in state-of-the-art technologies for organization. Whereas democracy is not a technology in the conventional sense of hardware and digital software, it can be thought of as a form of social technology that structures how societies operate and make decisions. We argue that education

cannot disengage technology from politics. Educational programs that blend technology and politics may enable a path for responsible engineering the digital infrastructures that will take us from a less desirable to a preferred digital nation. We share our experience with the course CS-234 and suggest improvements based on teaching experiences and students' feedback. We believe that an interdisciplinary and evolving curriculum can help addressing some of the complex challenges that future engineers will have to face. Yet, many questions remain unanswered.

1. Introduction

The work of scientists, engineers, and other technological innovators has brought about transformative improvements for society by revolutionizing communication, information access, business innovation, and scientific progress. Consequently, many aspects of our life and work are becoming digital, and governed by algorithms and networked systems. The term digital nation has emerged as a common way to describe countries in which digital technology is integrated into all aspects of the country's social, economic, and political systems.

In digital nations, urban and rural citizens, government, academia, and the industry use technology to interact with each other generating value that should benefit everyone. However, the realization of these benefits greatly depends on the design of the digital infrastructures that support society. The architecture design can foster or hinder accountable association, economic growth, and fair competition. To illustrate, personalized content on streaming content and social media enhances user engagement and improves user experience since recommendations are aligned with user's interests. On the other hand, algorithms for personalized recommendations can increase polarization and promote the generation of echo chambers. From the perspective of democratic governance, the diversity of technological solutions weakens governmental capacity to control information flows, while, at the same time, increases decentralization and, with that, the opportunities for local governments to connect better with their citizens (OECD 2019). Given the existing challenges and risks of technologies for democratic societies, it becomes indispensable to deliberate on our approach to technological development. A relevant question for responsible engineering is: **How do we design or choose technologies that take us from a less desirable to a preferred situation?**

A modern engineer curriculum includes ethical and social responsibility, emerging technologies, academic literature, and other resources to equip future engineers amid the complex landscape of digital infrastructure. Without a solid foundation, the youth risk being misled by the very technologies meant to empower them, repeating historical mistakes. Thus, the modern curriculum benefits from educational experiences that build a space to raise questions about technology. Why did Usenet fail (Hauben 1995)? Why the Web creator wants to decentralized the web again (Hardy 2016)? What does "redecentralization" mean? Knowing how to answer the previous questions makes the difference between students who understand a power law graph from those students who understand the political powers shaping technological architectures and networks.

Integrating an evolving curriculum that balances technical skills with an understanding of technology's broader societal implications is essential for steering towards a more inclusive and equitable future. This type of education is key to ensuring engineers can thoughtfully address the challenges posed by digital advancements and contribute to a preferred societal trajectory.

Science, technology, engineering, and mathematics (STEM) assemble careers that prepare students with a solid foundation in computer science, along with problem-solving, critical thinking, and technical skills. It is hard to conceive that students can elaborate a well-founded narrative about technology with a traditional technical curriculum because technology is heavily entrenched in our social, cultural, and political behaviors. A caveat is the current disassociation between a rigorous technology education from other topics like for example political science, which are typically studied within the frame of a liberal arts curriculum.

This paper discusses why teaching decentralized technologies and self-organization brings value to STEM careers and helps developing competences for responsible engineering. In section 2, we analyze the relevance of decentralized technologies for the young generation by making the connection between some of our reading assignments with the current activism summarized with the “decentralized the web” motto. Taking the web as an example, we provide historical context on how the web evolved from a decentralized environment favoring freedom of expression and privacy towards client-server architectures that focus mostly on scalability and performance. In section 3, we argue that education cannot disengage technology from politics and discuss how to address teaching gaps, providing as an example the EPFL’s bachelor course for computer science CS-234, which blends both disciplines. Finally, we share expertise to improve the course design with multiple suggestions based on the lecturer’s last semester teaching experience.

2. Relevance of Decentralized Technologies For Democratic societies

In this section, we revisit the foundational principles of the open internet and web, providing context to grasp the evolution of technology over recent decades, as well as to recognize the challenges and their implications for democratic societies.

2.1 The strong feelings associated with decentralization and freedom

Vint Cerf and Bob Kahn, the architects behind the TCP/IP protocol suite—the foundation of the Internet—imbued their creation with a profound sense of openness and interoperability, anticipating its organic growth. The Internet, alongside Usenet and similar networks, fostered a bottom-up design, sparking a revitalization of society (Hauben 1995). In a prescient paper (Licklider and Taylor 1968), Licklider and Taylor depicted the Net as an intricate web of interconnected networks, where individuals, hardware, and software seamlessly unite to exchange computational and human resources. Their vision placed a premium on human interaction and the creative aspects of communication. They envisioned collaborative endeavors that would possess a regenerative essence—unrestricted communication, swift responsiveness, and interactive multi-access computer systems—and "open-endedness."

Recently, the web decentralization argument is enjoying a revival both as a grassroots movement and in academic environments. As the founders of redecentralization.org stated, the values tied up with the culture of an open net and web are freedom, autonomy, collaboration, and experimentation (Bolychevsky 2018). In 2015, Brewster Kahle, the founder of the Internet Archive, initiated a call for a "decentralized web" (DWeb), to put it in other words, a web that looks more like how initial pioneers like Tim Berners-Lee envisioned it (Clark 2014) (Quentin 2016). In 2016, the movement officially started at the Internet Archive, in a start-studded summit event, in which I participated together with Web architects, activist, engineers, archivist, scholars, journalists and other stakeholders to explore the technologies required to build the decentralized web. The DWeb movement raises awareness of the centralization that tech giants brought to cyberspace. Aiming at decentralizing the web, the DWeb wants to encode freedom of expression, privacy, and universal access to all knowledge.

The Web3 is a contemporary burgeoning movement that overlaps to some extent with DWeb, but its origins are traced back to blockchain technologies, cryptocurrencies, and NFTs (Tiffany 2022) (Korpal and Scott 2022). Many people use Web3 and DWeb interchangeably, and even academic researchers are not always aware of the differences in meanings carried by each movement. Both communities care about user self-determination and being in control of data (Tiffany 2022). A distinctive characteristic of the DWeb is its blockchain agnosticism. In addition, the DWeb may include technologies such as community-owned mesh networks (Panayotis et al., 2008) to build own private intranets without relying on a last-mile communication provider. The industry also exhibits a trend to democratization, decentralization, and moving to the edge with offers like IoT-based 5G mesh networks (Petterson et al. 2019) and emerging Web3 topics like decentralized physical infrastructure networks (DePIN). For others, the term Web3 is associated with hype about getting rich in pyramid schemes, and therefore, it receives more scrutiny (Weaver 2021).

Decentralization is not a cure-all, but many consider it is a valid answer to the growing concern about the extreme centralization observed in information communication technologies (ICT). The decentralization trend suggests a general expectation of a more equal Internet and more flexible technologies (open and interoperable). Particularly, peer-to-peer (p2p) technologies not only offer more resilience due to a distributed network, they raise emotions and a unique culture (Agre 2003).

The strong relationship between engineering and politics is rarely acknowledged in engineering courses. Some students, however, welcome opportunities to understand the politics that have shaped design decisions and want to learn skills that will prepare them to address or at least reduce societal challenges. This is at least justified on the enthusiasm raised by these subjects in one-to-one discussions with our students.

2.2. Contrasting the end-to-end argument and centralization

Decades ago, peer-to-peer (p2p) networks were often perceived as unreliable due to inadequate node availability, bandwidth, and other limitations. The consensus has gradually shifted towards the belief that a reliable network is essential for applications to function effectively. A notable counterargument stems from the end-to-end argument (Saltzer et al. 1984), advocating for a clear separation of responsibilities in which lower-level systems or layers should not be burdened with the expectation of providing flawless reliability. The Ethereum network can be seen as a modern system that embraces this argument. Decentralized applications (dApps) are implemented as smart contracts (Szabo 1997) that operate regardless of individual node reliability.

The tension between the end-to-end argument and centralization is at the core of many debates in technology and network policy. Advocates of the end-to-end principle argue that decentralization can lead to more resilient, user-empowered systems that are less prone to censorship and can innovate more freely. Meanwhile, centralized systems often prioritize control, which can lead to efficiencies and easier governance but may also stifle innovation and put privacy at risk.

The strong investment and development in datacenters and the cloud, the consolidation of small internet service providers (ISP) into large ISPs continued to exacerbate centralization, especially in the last two decades. Gradually, academic fellows lost their interest on decentralized p2p networks in part due to the scalability and other promises of datacenter's environments built with distributed systems and centralized governance. Many p2p systems were discontinued for various reasons, sometimes facing legal actions from the media industry and others facing business, network, and management complexities. In the end of 2010, the International Conference on Peer-to-Peer Systems (IPTPS) Workshop, a top venue for research on peer-to-peer systems, was discontinued apparently due to lack of interest (Baochun et al. 2012). With hindsight, such decision ignored that home bandwidth had a 3000-fold increase during the 1988-2011 period and that the Bitcoin network (Nakamoto 2008) started a new page in the history of p2p based systems in 2009.

In essence, the end-to-end argument promotes a vision that empowers end users and developers, fostering an environment of innovation and resilience by distributing functions and responsibilities. Centralization, while offering certain efficiencies and control, can counteract these benefits by concentrating power and potentially inhibiting the organic growth and adaptability that decentralized, end-to-end systems can offer.

2.3. The pervasive client-server architecture and centralization

The Andrew File System (AFS), a distributed file system originating in 1980 from Carnegie Mellon University, played a foundational role in shaping subsequent progress in distributed computing. Expanding on AFS's influence, its successor, Coda, significantly impacted the mobile computing domain. The chief architect of Coda underscored a comprehensive approach, emphasizing scalability, performance, operational feasibility, and security (Satyanarayanan 1992). Notably, Coda's architectural philosophy championed the concept of physical separation between clients and servers, a pivotal principle for realizing scalability, coupled with a security posture predicated on entrusting the fewest possible entities rather than relying on the security of a large number of clients. This asymmetrical client/server architecture pattern is also embedded in the World Wide Web (Berners-Lee 1996).

The trend towards security, efficiency and scalability has led engineering innovations that make human activity more productive and safer. Accordingly, STEM careers give priority to subjects that build competences for designing secure, efficient, and scalable systems, i.e., large-scale systems that respond quickly with a minimal resource consumption and can grow to handle larger workloads effectively.

3. ADDRESSING TEACHING GAPS

The skills taught in STEM careers are crucial not only for increasing students' future employability but also for enabling the industry to recruit from a pool of skilled engineers. Nevertheless, there is an urgent need to further enhance capacity building in responsible engineering and bridge technological gaps in digital nations.

3.1. Teaching technology and politics

We propose a sincere discourse about technology, one that incorporates system thinking and cross-fertilization of at least three disciplines: computer science, political science, and economics. This interdisciplinary approach is essential for our democratic institutions, which inherently blend elements of centralization and decentralization in designs that support both individual and collective goals. As our dependence on ICT increases, it becomes increasingly important to develop a critical thinking mindset to assess how digital infrastructures and technologies respect and serve society's constituents. One pertinent work in the realm of political science is Robert Dahl’s book (Dahl 2008). CS-234 students have to read some of his book chapters to learn Dahl’s criteria for democracy: effective participation, voting equality, enlightened understanding, control of the agenda, and inclusion. This is crucial not only for securing a democratic and sustainable future but also for addressing the micropolitics of everyday online life. Political scientists have raised concerns about how these dynamics, particularly those experienced in Californian-designed software, jeopardize accountable association (Schneider 2023).

To build feasible solutions, the efficiency and scalability arguments and some degree of governance centralization are reasonable engineering principles. But these principles fall short if there is not a solid system thinking framework that protects society from the potential damage that hyper-scalable technologies can directly or indirectly cause to people. Notably, the digital infrastructure colonizing our everyday life is built with an exported "California ideology" as if the scalable Californian apps understand the billions of the world and will come to liberate us from the physical tyranny of our democratic institutions and donate us a utopian apolitical digital space.

3.2. Case study: The course CS-234

Fig. 1 – Topics studied in the course CS-234 and its corresponding week. Additionally, week 1 introduces the course and week 14 is dedicated to a recap session

"It's difficult to imagine a world without Computer Science – it's anchored in all of our society's infrastructures."[1] Accordingly, the CS-234 course examines many of those infrastructures, particularly delving into voting technologies, online public forums, participatory systems, scientific peer-review, and digital money. By bringing this content to the curriculum, future engineers learn about civic tools and get prepared to deal with digital society challenges. Students learn how to explore technologies available for societal self-organization, expound key challenges and risks in using these technologies and discuss social implications of digital communication. The lectures incorporate elements considered in digital democracy: identity, economic inclusion, information flow, and democratic deliberation and choice (Bryan 2021).

This course involves a substantial amount of reading background materials, both technical and non-technical and from a variety of disciplines including computer science, social science, political science, and law. The lectures are heavily discussion-oriented requiring from both sides, lecturer and students, to deal effectively with the uncertainties of the discussion dynamics. It implements teaching engineering innovations such as project-based learning (PBL) and a flavor of a flipped classroom.

The intensive reading workload relies on the student's capacity to filter and prioritize content in their self-study hours. Students expressed feeling overwhelmed by the workload. Some students think the lecture should spend more time analyzing assigned readings. A related problem is that having this course in the third semester of a bachelor degree might present more challenges, primarily due to the lack of foundational knowledge required to fully grasp these subjects. For example, one of the assigned readings for week 6 is about "The DAO" attack. The lecture associated with this topic covers several key elements: it introduces blockchain transactions and smart contracts, explains the vulnerabilities that led to the specific attack, and discusses cryptocurrencies. Additionally, it details how smart contracts are employed to crowdsource funds and establish decentralized autonomous organizations (DAOs). The remaining time to discuss the specifics of the assigned paper reading is short.

Another encountered difficulty is the lack of a class reference book to help students finding connections between the taught subjects. The fragility of the course method is that interesting discussions require high class attendance and engagement. However, political theories and discussions about societal impacts are seen as less relevant to the student's career goal. Many students preferred to skip attendance and study along for the exam than coming to the class for having discussions with their peers.

A weekly lecture of two hours duration is limited for discussing in-depth all the topics and related technologies studied in the course (see Fig. 1). For example, the lecture dedicated to The DAO attack introduces Bitcoin and Ethereum blockchains to explain smart contracts and cryptocurrencies which are critical for the attack. To delve into the sustainability of blockchain designs we would need at least to dedicate another lecture to explain the different consensus mechanisms used in blockchains. Consensus mechanisms are studied in more advanced blockchain courses offered by master degrees. A possibly solution would be to increase the number of lecture

[1] As stated in one of the institutional EPFL webpages about the bachelor of computer science.

hours per week to have more flexibility for teaching other topics relevant to responsible engineering.

Teaching this course shall be an evolving experience to include sustainability, and emerging topics like AI with its ethical implications. The current course format also requires changes to be more resilient against environments that might alienate interdisciplinarity. At least, the course would benefit with the enrollment of more mature students at the final stage of the studies.

Additionally, we suggest reviewing the number of credits assigned for this course. Currently, CS-234 gives 5 ETCS and requires lecturing 2 hours per week. Increasing the number of credits will justify adding more lecture hours per week. We suggest change the number of credits from 5 to 8 ETCS without adding more reading workload. To put it in context, this is equivalent to the number of credits given for the course CS-358 “Making Intelligent Things”, which is another interdisciplinary course in the bachelor program. For students, the additional credits would provide a fair incentive for more robust learning and dedication to CS-234 projects. For the lecturer, the additional time would relax the time constrains for in-depth explorations of each subject.

Finally, the students have to work on a group project during various weeks with the goal of collecting solving problem for the campus community. Students have to (1) gather information about the problem, (2) propose an initial potential solution to the problem, (3) engage in discussions over both theirs’ and other teams’ proposals, (4) refine their proposal by incorporating feedback received from other groups, (5) present their final proposals, and (6) participate in an approval voting over all the proposed solutions. The assignment provides some problem suggestions such as lecture room’s capacity, housing cost, lack of internships for bachelor students, etc. Since the cases repeat every semester without a structure it is difficult to improve the assignment. Students complain about the excessive amount of feedback during the debate although handling the feedback is part of the learning activity. Besides, the lecturer finds difficult to connect this exercise with the reading assignments and lecture topics. The topics seem disconnected given the excessive freedom for suggesting problems. This assignment could improve by implementing the case study method. It is possible to create rich educational experience with crafted case studies that can be reused in various semesters. Considering the various technological transformations taking place in the campus, this course can contribute to reflect on past or ongoing transformations through the student’s perspective. The methodology would provide more incentives to prepare and debate cases in class. While the current assignment design requires that students learn to concentrate on what is relevant and ignore the noise, the case study method is a proved methodology to achieve learning outcomes efficiently.

Two well-known examples of this methodology are the Harvard Case Study and the ETH case study developed at the Department of Environmental Sciences at the Swiss Federal Institute of Technology (ETH) in Zurich (Steiner, Laws 2006). The last one requires students to investigate the problem with real-world stakeholders. Closer to the ETH case study, our students also gather information from campus to deepen the debate on certain issues. However, a single ETH case study lasts a semester with 18 hours class a week and is for advanced students in their ninth semester. To implement this method in our course, more thinking needs to be done to craft use cases that work with the limited resources of our course.

4. SUMMARY AND ACKNOWLEDGEMENTS

Future engineers will benefit from a deeper understanding of the implications of technologies. Teaching technology and politics is a reasonable interdisciplinary step towards the education of more responsible engineers. Digital nations need technologies and infrastructure that help individuals to connect, create, and improve their collective decision-making without causing harm.

We also think that more research needs to be done to better understand the risks of decoupling politics from technology. This separation may contribute to polarization, censorship, monopoly, surveillance, and other forms of authoritarianism or abuse.

To conclude, closing the distance between science and liberal arts by teaching technology and politics to bachelor students is a worthy experience that we recommend to expand outside the engineering curriculum, i.e., to political science students.

Finally, we would like to thank Prof. Bryan Ford, who designed the course CS-234 syllabus and encourage the author to teach the course in the fall of 2023-2024.

Discord platform as a dynamic resource where students can partake in discussions, request guidance on course material, join study groups, and obtain personalized assistance from experienced assistants. This independent resource is not integrated into any specific curriculum and it is available to all engineering students belonging to our university that are in need of help for their mathematics courses, This approach has demonstrated a significant positive impact on engineering education by enhancing student engagement, reducing isolation, and improving academic performance. The findings highlight the potential for teaching assistants to facilitate effective learning experiences through interactions on the user-friendly and freely accessible Discord platform.

1 INTRODUCTION

1.1 Background

The transition from high school mathematics to university mathematics is a widely acknowledged challenge internationally. This shift from being a high school student to a university student entails assuming greater responsibility for one's studies, including planning and managing one's academic workload. With larger student cohorts and less direct teacher interaction, students must adapt their learning habits and organizational skills, which significantly affects their academic performance (Jablonka et al. 2017). Self-study is a fundamental aspect of university education, yet many new students struggle to navigate this independently and find effective study techniques (Turan et al., 2022). The university learning environment differs markedly from that of high school, emphasizing the importance of students becoming self-reliant learners. University teaching often lacks the personal support students may have experienced in high school, contributing to feelings of isolation when facing academic challenges (Vinerean et al., 2023). Moreover, research indicates that the transition from secondary to tertiary education, particularly in mathematics-related subjects, is more challenging, leading to higher dropout rates compared to other fields of study. The downside of heightened autonomy is the cognitive overload experienced by learners. Studies indicate that students frequently struggle to work independently (Winsløw & Grønbæk, 2013). Additionally, the vast amount of information available on the Internet can overwhelm students cognitively (cf. Scheiter & Gerjets, 2007, pp. 291–292). Consequently, the importance of striking a balance between required autonomy and provided support has grown in recent years. Teachers must be cognizant of this situation and equipped to address it effectively (Vinerean, 2022).

1.2 Using Discord platform to offer round-the-clock study support in mathematics to engineering students

In the pursuit of academic excellence and the quest to overcome the daily challenges faced by engineering students, from balancing studies to managing stress and time constraints, a novel initiative has been launched. This pilot project, centred on a Discord server, aims to provide round-the-clock study support to engineering students. It is important to note that this service is not integrated into any specific curriculum. Instead, it is an independent resource available to all engineering students at our university seeking assistance with mathematics during the whole period of their studies.

Discord[2] is a communication platform designed primarily for gamers, but it has expanded to cater to various communities beyond gaming as well (Goes*er, 2022;* Lauricella et al., 2022). It offers text, voice, and video chat capabilities, allowing users to communicate with each other in real-time. Discord is primarily free to use. Users can create an account, join and/or create their own server, participate in text and voice chats, and use most of the platform's basic features with no charge. One of the key advantages of Discord is the ability to create servers, which serve as dedicated spaces for groups to gather and communicate. Within these servers, users can create multiple channels, both text and voice, tailored to specific topics or activities, enabling structured and organized conversations which are easy to manage (Soeiro et al., 2023; Farah & Eagle, 2021).

We redesign the Discord platform to facilitate peer-to-peer learning and mentorship, connecting students with experienced peers who have successfully navigated the mathematics courses. This dynamic resource enables students to engage in discussions, seek guidance on course content, participate in study groups, and receive personalized assistance from knowledgeable assistants during the specific courses and after that too. Such an approach aligns with findings by (Owston & York, 2018) who reported that students in blended learning courses with significant online components experienced higher satisfaction and performed better academically. This suggests that flexible and accessible educational support can indeed empower students to deepen their understanding and tackle challenging aspects of their curriculum effectively.

Moreover, the concept of “round-the-clock help” is a direct response to these unpredictable and demanding needs. The round-the-clock availability of the Discord server is crucial not only for academic pursuits but also for mental health, as it reduces the stress and anxiety associated with challenging coursework by providing a continuous outlet and support network. The importance of flexibility in learning environments, as highlighted by (Turan et al., 2022), indicates that perceived flexibility in time and content management can significantly positively affect students’ behavioural engagement and academic performance.

1.3 Related Work

Several studies have explored the use of Discord as an educational tool in various contexts, providing valuable insights into its effectiveness and implementation strategies. Bridson et al. (2022) describe their experience using Discord to provide round-the-clock help to software engineering students inside a specific course. They highlight the platform's capacity to facilitate continuous support and foster a community of learners, which aligns with the goals of our initiative for engineering students. Soeiro, David, and Neves (2023) implemented Discord in a university STEM learning environment, focusing on collective learning and engagement. Their study emphasizes the platform's potential to enhance interaction and support various pedagogical approaches. Their findings underscore the importance of creating a supportive online community, which is a critical aspect of our project as well. Heinrich et al. (2022) explored the use of Discord, Teams, and Moodle for course and cohort communication. Their research provides a comparative analysis of these platforms, offering insights into their respective strengths and limitations. Their work highlights how Discord can effectively complement other learning management

[2] About Discord | Our Mission and Values

systems to create a more dynamic and interactive learning environment. All these studies are supporting the usability and effectiveness of using Discord as a communication tool in teaching and learning. The novelty in our study is that this service is not integrated into any specific curriculum and acts as an independent resource accessible to all engineering students at our university, offering mathematics assistance throughout their entire academic journey.

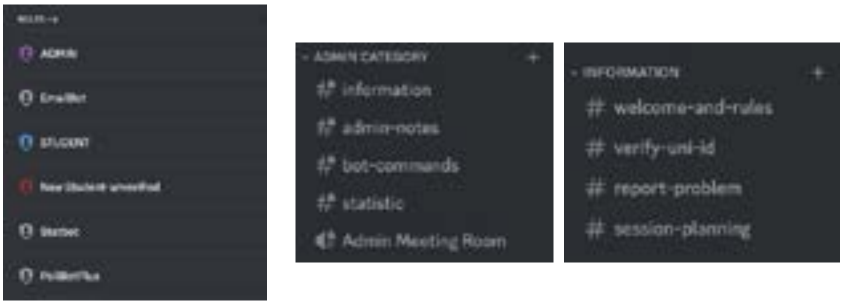
2 METHODOLOGY

2.1 Setting

The project provides support across the different mathematics courses given to both Master of Science in Engineering students and those pursuing a Bachelor's degree in Engineering Technology. The information about the project is given through verbal presentations, clarifying the project's purpose and objectives. Comprehensive information was shared through the courses on the learning management system used by the university, completed with instructions providing a link to join the server, a description and tutorial for new users on account verification and navigation on Discord server. The collective enrolment for these courses stands at approximately 300 students every year.

Two engineering students who have successfully completed the courses in question, employed as assistants at the mathematics department, operate the Discord server. They play a key role in leading and moderating the server, as well as providing direct support to other students. To ensure the quality of support offered, and to aid the student assistants in their development, an associate professor in mathematics mentors them. This mentorship includes regular meetings where the assistants can discuss educational strategies, difficult topics, and other challenges that arise.

2.2 Designing the Discord platform

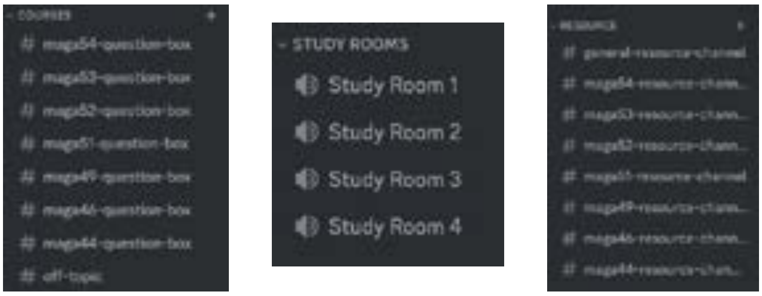


(a) (b) (c)

Figure 1 illustrate the structure of discord (a) Existing roles and bots on the discord server (b)the Admin Category and (c) the Information Category

In the Discord server, roles are segmented and assigned to each student based on their status and the permissions they hold within the server as shown in figure 1(a). The 'Admin' role is granted to helpers who have previously completed the mathematics courses. The 'New Student' role is designated for individuals who have not yet confirmed their student status, serving as a precaution to prevent spam and unauthorized individuals from joining the server. Once a student confirms their status, they are assigned the 'Student' role. This confirmation process is automated within the server using Emailbot. The server is organized into various categories to facilitate easy navigation and structuring for students who may be new to Discord.

Each category, in turn, is divided into text or voice channels. Text channels allow students to write, share images, videos, links, and react to messages. Voice channels offer a broader range of interactive opportunities, including video calls, voice calls, and screen sharing. Within the 'Admin' category, private channels exist where assistants can exchange materials, assist one another, and monitor server statistics as shown in figure 1(b). The 'Information' category features text channels such as 'Welcome' and 'Rules', which outline server guidelines, a simple tutorial on how to confirm one's identity, and a channel for students encountering verification issues as illustrated in figure 1(c). These are the only visible channels to unverified students. The 'Session Planning' channel contains scheduled sessions for the week, aimed at students who prefer to compile their questions and address them directly.



(a) (b) (c)

Figure 2 illustrate the structure of discord (a) Courses, (b) Study Rooms and (c) Resource

Another category features text channels related to the mathematics course as in figure 2(a). Here, students who are currently enrolled in the courses, as well as those who have previously taken it and are preparing for examinations, can post their questions. Polls are continuously conducted on the course content to identify topics that engineering students find challenging, enabling assistants to plan sessions where they can provide further explanations. These sessions might include using visualization tools like GeoGebra or simple diagrams to explain concepts. In the 'Study Rooms', figure 2(b), students receive personalized assistance and participate in group-discussions with their peers. This area allows for the streaming of tablet or computer screens. The 'Resources' section shown in figure 2(c) enables the sharing of external resources that have proven beneficial to assistants during their studies. This may include fundamental concepts deemed crucial for the course, guidance on utilizing mathematical handbooks, calculator functions, and more.

2.3 Research design

The research will be conducted within educational design research (McKenney & Reeves, 2018) involving several cycles as in Figure 3 where the Discord platform is re-designed according to the input from previous phases, implemented and used, and then evaluated both quantitatively and qualitatively.

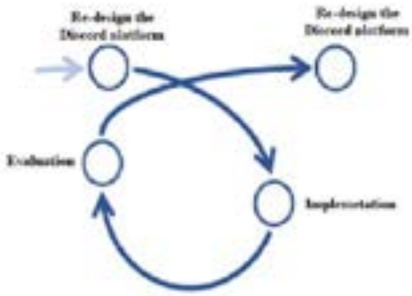


Figure 3 Continuous Improvement Cycle for Discord Platform Redesign

3 RESULTS

3.1 Engagement Statistics

The implementation of the Discord platform for round-the-clock help has seen considerable usage among engineering students. 122 verified students joined the server. There were a total of 1,145 messages sent over the study period, with an average of 52 messages per week see Figure 4(a). This consistent communication suggests a robust level of engagement with the platform for text-bases interactions.

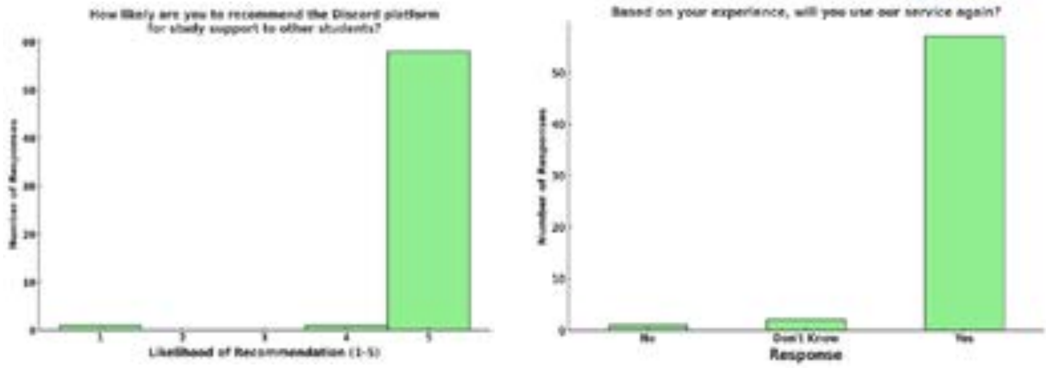
(a) (b)

Figure 4 (a) The chart displays messages sent through the text channels (courses) and (b)The chart displays the usage time of voice channels (study rooms) monitored weekly on the Discord server over the span from January 1, 2024; to June 1, 2024.

Furthermore, the voice chat usage statistics indicate a total of 566.15 hours spent in voice channels, with a weekly average of 25.7 hours. This data points to significant adoption of the platform's voice chat feature for study discussions and suggests a preference for auditory learning and collaboration among students, see Figure 4(b). Notably, 90 unique members, highlighting the widespread engagement and utilization of the voice chat feature across the students, contributed these hours.

3.2 Survey Feedback

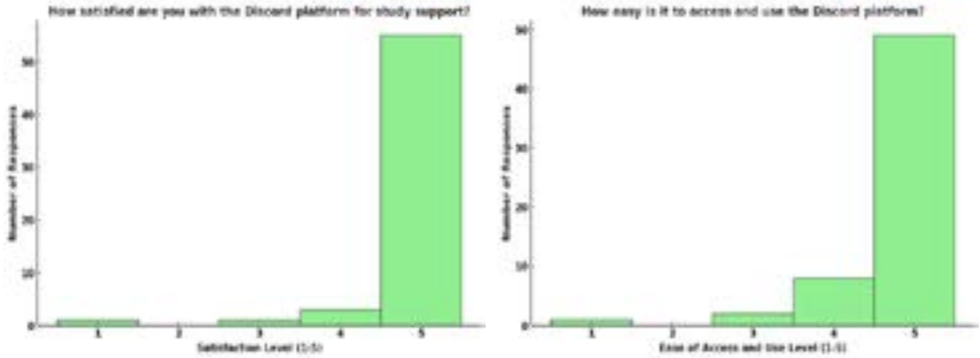
3.2.1 Quantitative



(a) (b)

Figure 5 (a) Bar graph chart showing the likelihood of survey respondents to recommend the Discord service (on a scale of 1-5 where 5 is the highest) (b) Bar graph depicting the likelihood of survey respondents reusing the Discord service.

The feedback collected from 60 respondents through a structured anonymous survey revealed that the platform was well received among the participants. One of the most striking outcomes from the survey was the high willingness to recommend the service, as 96.7% of the survey respondents indicated they would recommend the Discord study support to their peers see figure 5(a). A significant majority of 95% of respondents expressed their likelihood to reuse the service, with only 3.3% being uncertain see figure 5(b). This high level of endorsement and anticipated continued usage underscores the perceived value of the service among the students.



(a) (b)

Figure 6 (a) Bar graph showing the distribution of satisfaction levels with the study support provided by the Discord service (on a scale of 1-5 where 5 is the highest), (b) Bar graph illustrating the distribution of ease of access and use of the service.

When asked to rate their satisfaction with the study support received via the Discord server, the majority of students reported high levels of satisfaction, with the largest group - evident in the tallest bar in figure 6(a) - rating their satisfaction at the maximum level of 5 on a 5-point scale. This indicates that the support offered not only met but also often exceeded students' expectations, with 91.7% of respondents rating their satisfaction at the highest level. Ease of access and usability are critical for the success of any online platform. The survey results shown in figure 6(b) show a strong positive response, with 81.7% of students rating the ease of access and use at level 5. This reflects the user-friendly nature of the Discord platform and the effectiveness of the guidance provided to new users.

3.2.2 Qualitative

To complement the quantitative data, individual responses to the survey have been collected and analysed. These responses provide nuanced insights into the students' experiences, highlight specific aspects of the service that are particularly helpful or could be improved, and offer personal views that illustrate the impact of the service on their academic journey.

In response to the question "How has the Discord platform for study support affected your academic performance and stress levels?" students expressed a range of positive feedback. Many reported feeling more secure and less stressed due to the support provided by the platform. One student mentioned, "I feel more secure and less stressed," while another noted, "Very helpful, less stress about studies." The platform also significantly improved academic performance for several students. For instance, one student shared, "I can say that without Discord and the sessions with you, I wouldn't have understood anything in my course. Those two hours we had with you 2-3 times per week made a big difference in my studies. So a big thank you to you for giving your time and showing interest every time we came with questions." The quality of support and the availability of helpers were frequently highlighted, with students appreciating the various times and close support they received, as well as the ability to ask questions and receive good explanations. Another student reflected this sentiment by saying, "Received a lot of help from you and the discussions on the platform are also educational." Overall, the feedback indicates that the Discord platform has positively impacted students' academic performance and stress levels by providing accessible, reliable, and quality support.

In response to the question "What do you like most about the Discord platform for study support?", students provided a variety of positive feedback. Many students appreciated the instant access to help at any hour, with one student noting, "The instant access to help at any hour was a game-changer." Another student valued the sense of community, stating, "The community feeling and the shared purpose everyone brings to the platform" as a highlight. The platform's ability to reduce feelings of isolation was also mentioned, with a student sharing, "The sense of not being alone, even late at night when studying can feel overwhelming." Additionally, students praised the quality of assistance, with one commenting, "The rapid and clear explanations on tough subjects made a real difference." Overall, the feedback indicates that students highly value the accessibility, sense of community, and quality of support provided by the Discord platform for study support.

The response to “What can we improve?” provided a range of constructive suggestions. Students requested more advance notice of help sessions to aid in better planning and participation. An innovative idea was to introduce a mechanism for submitting questions anonymously to reduce anxiety. Feedback emphasized the importance of information accessibility, recommending that solutions discussed in voice chat be accompanied by screenshots posted in the chat for those who missed the live explanation. While some students felt no improvements were needed, with comments like "nothing, honestly" and "keep it up, you’re doing great," there was a concern about asking too many "silly" questions, indicating a need to foster an even more supportive atmosphere. The suggestions closed with affirmations of the platform’s value, particularly for distance learning, and a push for increased awareness of the resource. The underlying message was clear: the ethos of "students helping students" is vital and much appreciated.

4 SUMMARY AND ACKNOWLEDGEMENTS

This experience has highlighted the successful application of a Discord-based platform to provide round-the-clock study support to engineering students in mathematics courses. The platform's flexibility, accessibility, and capacity to foster a supportive community have made it an invaluable resource for students navigating the challenges of tertiary mathematics education. The positive engagement metrics and student feedback attest to the platform's effectiveness in enhancing learning outcomes and student satisfaction. Importantly, this service has significantly affected engineering education by providing a readily accessible support system that complements traditional learning methods. It empowers students to manage their academic workload more effectively, reduces feelings of isolation, and promotes continuous learning and collaboration outside of regular class hours. As an independent resource, it enhances the overall educational experience for engineering students, contributing to their academic success and well-being.

Future work will focus on implementing the suggested improvements to further enhance the platform's utility. Additionally, longitudinal studies to assess the impact of this support system on academic performance and retention rates in engineering programs could provide deeper insights into the long-term benefits of such initiatives.

Conference Key Areas: *Engineering Ethics Education, Transversal Skills,*
Keywords: *Ethics, System Thinking, Wicked Problem Mapping, Leverage Points,*

ABSTRACT

Technological advancements are expanding continuously to affect more private, societal, and environmental aspects of our lives. This raises a serious need to equip those who lead and build such technologies with the skills that apply ethical principles to guide such development. If teaching ethics can provide such guidance, for technical disciplines it is often hard to translate principles into actions. In this paper, we describe a doctoral course whose learning experience provided a group of science and engineering researchers with a toolkit for practicing ethics. This toolkit consists of a participatory approach, stimulating peer–to–peer debates; and a

[1] *laura.ferrarello@epfl.ch*

system thinking perspective, to understand the interconnectedness and causality of ethical events. With these, researchers identified one's spectrum of ethical actions that could mitigate or prevent challenges. By discussing the effectiveness of these methods, we conclude by drawing a list of recommendations for future work. This to cover the growing need to equip scientists and engineers with skills that guide the understanding of what decisions can lead to ethical actions.

1 INTRODUCTION

1.1 Teaching Ethics in Engineering and Science

Innovation is one of those societal processes that supports society in addressing challenges, by creating breakthrough solutions for the benefit of the most. Vaccines, medical and communication technologies, and new materials are just a few examples of how humanity has advanced knowledge over the years toward healthier and safer ways of living on this planet. Nonetheless, despite clear evidence of beneficial impacts, innovation has also received criticism for the exact opposite. Following the emergence of ethical dilemmas drawn from the adoption and use of new technologies and science, industries and universities have started to look at guidelines for tackling the undesired consequences deriving from the introduction of innovative solutions in society (McGinn 2022). Nonetheless, deploying ethical frameworks and principles in engineering and science is a challenge on its own because of the difficulty of translating abstract and general principles in specific tasks (Schleidgen et al. 2023; Benke, et al., 2020). Hence, a need to develop tools that guide decision–making in technical research and practice (Ibrahim et al., 2007). These would support responsible technological and scientific advancements originating from actions tackling social and environmental challenges (Kamp, 2016).

An evaluation process aimed to understand what might generate or mitigate ethical dilemmas can't rely on accountability only, as this is not enough to stimulate actions (Beu et al. 2003). Hence, the goal of the course object of this paper was to explore how holistic and systemic approaches could be methods for guiding the understanding of what actions could tackle the complexity of ethical dilemmas and inform how to best mitigate undesirable outcomes (Grewatsch et al. 2023). We argue that building skills and knowledge on preventing or mitigating the consequences of developing, and using, science and engineering innovation requires understanding ethics as complex events that can be acted upon. This happens at the decision–making level through the awareness of the role human actions play in influencing these events (Beu et al. 2003; Macklin 1967). In this paper, we describe how participatory and systemic approaches address the need to equip science and engineering research with tools for facing some of today's social and environmental challenges (Chan and Lillian 2022; Kamp 2016). By doing so, we aim to fill a gap in technical curricula.

"The Practice of Ethics for Engineering Research and Profession" is an École Polytechnique Fédérale de Lausanne (EPFL) doctoral course that has tested a toolkit to practice ethics to support engineering and science researchers in developing a critical understanding of the roles and responsibilities of human actions (Macklin 1967). This was used to generate a response based on the researchers' agency in the system of their project. The course consists of three different activities: (1) four guest lectures from CERN, Nestlé Institute of Agricultural Sciences, EPFL

Learn Centre and Climact Centre that discussed how industries or academia address ethical challenges as an opportunity for innovation; (2) presentation from seven PhDs and one postdoc from across the EPFL to debate on the ethical dilemmas in their research topics; (3) a system mapping activity involving the analysis of ethical challenges as wicked problems to identify the leverage points that would tackle ethical dilemmas related to a topic. Outcomes were presented as posters in an EPFL venue.

In the first part of this paper, we describe the course's theoretical approach; the second discusses the methodology; the third part outlines how the course's methods and activities influenced and supported the researchers in (1) thinking ethics more holistically (2) seeing ethics as a reflective exercise in support of one's critical thinking, (3) understanding how to use leverage points to address ethical dilemmas, and (4) evaluating actions that could mitigate ethical challenges, for generating innovation that meets societal and environmental goals. We conclude by discussing the toolkit's limitations and recommendations for future work.

1.2 Learning the complexity of ethical challenges

Learning how to tackle social and environmental ethical challenges in science and engineering research is a journey that would involve (1) raising awareness of possible ethical challenges (Bazerman et al. 2016), (2) understanding these as relations generating undesirable consequences (Beu et al. 2003), and (3) identifying a framework for enabling action (Schleidgen et al. 2023). The combination of these three steps forms a cognitive process that enables one to think about interventions that mitigate or prevent ethical dilemmas. The course presented in this paper aimed at creating a learning experience encompassing these three steps. Overall, the teaching was geared towards providing tools and methodologies that could form a practice of ethics in science and engineering.

With a focus on decision–making, the course adopted a constructivist approach to learning where knowledge is created from reflecting on a situation that is then compared to personal experience (Mosalanejad et al. 2020). In such an approach, reflections help draw conscious attention to the consequences of personal decisions and the responsibilities that these decisions imply in the short and long term (Campbell and Kumar 2012). In the course, decision–making was discussed through the lenses of moral and rational thinking by outlining how values and moral judgment influence actions that can cause less harm or good (Le Bar 2009; Beu et al. 2003; Macklin 1967). The focus on moral rationing outlined the rationality and irrationality of certain decisions, which vary in relation to the speed and consciousness of decision–making (Campbell and Kumar 2012; Bazerman et al. 2016). Here, biases and values have a role in evaluating ethical dilemmas; fast and slow decisions can bounce one against the other depending on the consistency decisions have with one's existing beliefs; here, values can flag any inconsistency, thus requiring a deeper and more rational reflection (Campbell and Kumar 2012). This slower and conscious thinking leads to learning, as reflecting on the consistency of thinking enables self–analysis and the review of existing knowledge (Mosalanejad et al. 2020; Bazerman et al. 2016).

In the course, raising awareness of ethical challenges was constructed over reflections stimulated by debates. Through these, we discussed moral judgment, its relation to values, and how the latter manifest a choice of how people decide to position themselves in the real world (Le Bar 2009; Beu et al. 2003).

To engage learners in getting awareness of personal positions on topics like AI or sustainability, and understanding what influences these positions, active participation had a key role (Mosalanejad et al. 2020); peer-to-peer exchange of information helped map personal lived experience to the topics discussed (Bada et al, 2015). Furthermore, theoretical ethical frameworks like Consequentialism, Deontology, and Virtue Ethics (Beu et al. 2003), were introduced within the context of real–world scenarios (e.g., collecting health data) to stimulate reflections on how ethical principles can guide the development of ethical strategies and actions (Schleidgen et al. 2023; Widdershoven, et al.,2009). The course didn't choose to follow any of these frameworks; nor it present any specific ethical principle or standard, like those attempting to regulate AI research and innovation (Jobin, et al. 2019), or the four principles in biomedical sectors (autonomy, beneficence, non-maleficence, justice) (Beauchamp & Childress, 2013). This is because its focus was on teaching an empirical process of thinking ethics as events where personal experience becomes a way to act on it. Hence, lived experiences were the vehicle used to stimulate debates and provoke reflections (Widdershoven, et al., 2009). Other activities – including the analysis, theorisation, and practice of real cases – were used to help turn theories into applied strategies (Mosalanejad et al. 2020). Such a learning journey engaged learners in reflecting on the complexity of ethics and how such a complexity can be acted upon through holistic approaches (Grewatsch et al. 2023). The wicked problem maps describe how learners acknowledged this complexity (Fig.1). With this approach, the perception of ethical challenges shifted from open dilemmas to interconnected events that can be described, discussed and, reframed. With these, theories of ethics moved to practice.

2 METHODOLOGY : THEORIES INFORMING THE PRACTICE OF ETHICS

In this section, we discuss how theoretical concepts and methods within, and outside ethical theories shaped the practice of acting upon ethical challenges. We outline the steps taken for practicing the theoretical frameworks, which consist of: (1) actively participating in the discussion of ethics, whose activities are (i) Industry expert talks and (ii) ethical challenges presentation (2.1). (2) Describing ethics as a wicked problem, whose activities are (i) system thinking and (ii) leverage points (2.2).

2.1 Develop Learning on Ethics Through Participation

As a first step, the course introduced current debate on ethics across academia and industry through the real–world perspectives of industry leaders, who presented innovative approaches to ethical challenges. The four guest lectures provided insights into navigating ethical dilemmas at the macroscale of an organisation and the microscale of individual interactions. These lectures offered examples of practical tools and strategies on data accessibility, animal rights, collaboration within heterogeneous teams and, sustainable transitions. The guest speakers set the ground for participating in discussing different views confronted on different ethical challenges through a critical perspective (Bada et al, 2015). With participation, new knowledge and subject–specific skills found their ground for development (Carlson et al. 2022; Healey 2005).

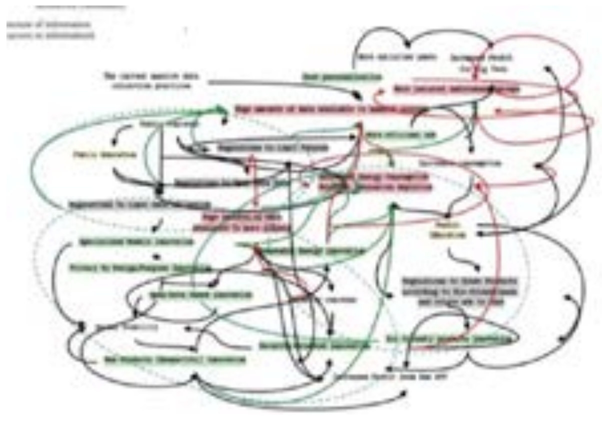
The course's second step involved learners presenting their research. Topics discussed were such as but not limited to: (i) language model ethical values (ii) environmental waste, (iii), scientific integrity: publish or perish, (iv), access to new technology, (v) security and privacy. Each of these presentations was used as boundary objects to open discussions on ethical dilemmas inherent in one's academic research (Leigh Star 2010). These peer–to–peer interactions made personal experience an active means of learning about real–life problems (Carlson et al. 2022). Indeed, presentations delved into the personal motivations driving one's research endeavours; they prompted the cohort to consider the influence of values on personal decision–making processes, reflect on the motivating factors behind their research topics, and analyse how personal, professional, and disciplinary values shape research approaches. This engaged one in a thorough examination of the ethical complexities embedded within each presentation. Debates created an intellectually stimulating environment promoting dialogue (Healey 2005; Wilson and Smetana 2011); this increased one's self–efficacy concerning the ability to discuss challenges in personal research (Bandura 1982; Beu et al. 2003); with it, learners were stimulated to act upon the information provided (Healey 2005).

Various interactive elements, such as utilising a Course Padlet for collecting reflections, further enriched the learning experience. Anticipated ethical challenges in personal research endeavours were also explored, thus contributing to a deeper understanding of the ethical dimensions of one's academic pursuits. This was stimulated by the task of formulating questions that turned learners from observers of a debate to part of the observed debate (Von Foerster 2003). For instance, the question: *"What are current (un)ethical practices that will be changed in the future?"* engaged in a live discussion on other practices that could negatively impact society. With these questions, ethical challenges were analysed through metacognition inducing a cognitive process that checks where knowledge breaks (Wilson and Smetana 2011). With these reflective exercises, participants cultivated a heightened awareness of ethical considerations in research, fostering a culture of critical inquiry and self-awareness. Formulating questions on ethical challenges moved the object of discussion to personal experience (Wilson and Smetana, 2011). This enables the mapping of new knowledge against existing one and engages in negotiating processes (Bada et al. 2015).

2.2 Ethics as a Wicked Problem: Using System Thinking and Leverage Points

The course's third step focused on system thinking; this supported the transition from theory to practise through the analysis of complex systems, i.e., the analysis of the interdependencies and feedback loops influencing the system's behaviour (Hoverstadt 2022). This method was introduced through the concept of wicked problems, i.e. a class of problems that requires the understanding of how to solve it to be able to define it. This means that to describe a wicked problem, it is necessary to list the different solutions (Rittel and Webber 1973). Using this concept for ethics was a means for recontextualising an ethical dilemma – i.e. something that implies a difficult choice to make– as a problem whose definition needs the listing of possible solutions (Lönngren and Van Poeck 2021).

From the initial participatory stage, aiming at raising awareness and stimulating active participation – i.e. participating through questions, idea sharing and by offering opinions (Masek et al. 2021) – participants were invited to use a system thinking perspective to describe the complexity of ethics (Grewatsch et al. 2023). Real–world



cases helped the cohort think holistically, i.e., to think of problems as parts of a larger whole (Hoverstadt 2022). Hence, the ethical challenges emerging from these cases were discussed as wholes emerging from the interactions of the different parts of the system. For instance, discussions on global digitalisations and sustainable transitions outlined the negative impacts on work and natural resources through exploitation. These examples contextualised the meaning of holistic thinking and extended one's understanding of the positive and negative impacts of research and innovation. The application of this approach consisted of creating maps illustrating complex issues like AI (data, privacy, robots.), sustainability (materials, processes, policies) and people (bias, profiling, behaviour, practice). This exercise was presented as a poster including (i) a description of the problem, (ii) a wicked problem map, (iii) and the leverage points map. With these maps, the theory of systems visualised the interconnected nature of problems encompassing economic, technological, social, and environmental dimensions (Buchanan 1992); leverage points, i.e. points of a system that can change the system's goal (Meadow 1997), defined where to intervene in the system, as visualised by Figure 1.

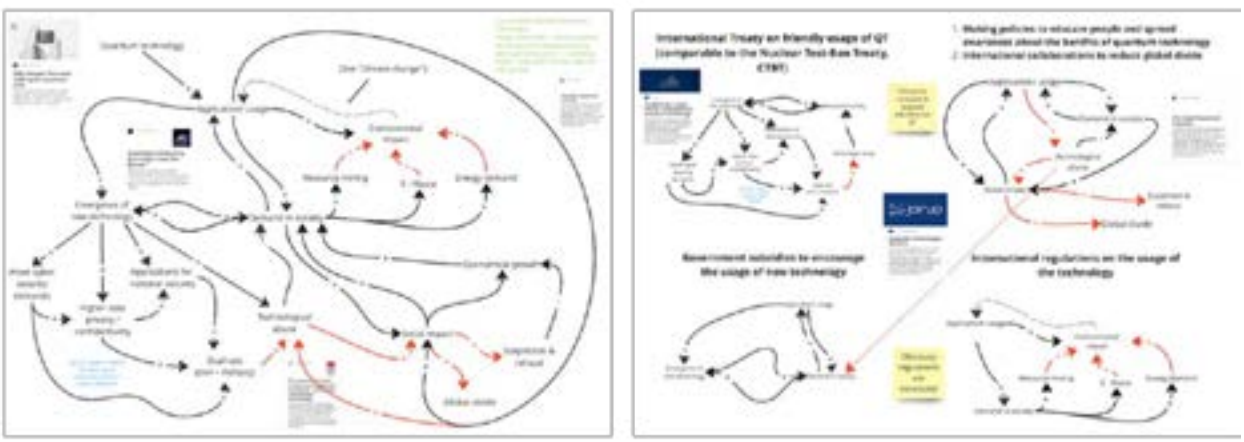


Fig. 1. The "Massive Data Collection" wicked problem map (up). Wicked Problem map and leverage point analysis on quantum technology (down)

This figure presents examples of wicked problem maps describing the ethical challenges of the massive data collection (up) and quantum technology (down). In the latter, it is outlined how quantum technology is a double-edged sword with profound social benefits, but also complicated challenges. Indeed, this technology can open revolutionary advances in computing power, cryptography and materials science, but also its use brings with it a complex web of social, environmental and ethical concerns (Possati 2023). Figure 1 illustrates this interconnectedness, where the transformative potential of this technology is faced with the complex socio-ecological and technological challenges that may arise. On the figure left side, the map describes problems that can self–stabilise and those that need leverage points for stabilisation. For example, quantum technology can have a negative impact on the environment, as it increases resource depletion and energy demand. This is a self-stabilising problem, as the technology itself is capable of providing solutions to this. On the other hand, problems related to the social impact and unethical use of the technology require leverage points for stabilisation. On the figure's right side, there are the leverage points represented through the system's feedback loops. These are classified as reinforcing or balancing loops and are graded with Meadow's twelve-point scale (1997). This classification helped the learners reflect that the leverages of the highest impact are the most difficult to realise (Dorninger 2020). For example, to avoid global inequality and make technology easily accessible to all, it was proposed the leverage of an international policy created to promote cooperation and make technology accessible to all. Preventing the misuse of technology can be leveraged by raising awareness of how to use it in the curriculum for engineering students. The map also proposes the introduction of regulations to quantum technology ethically, including relevant courses on ethics defining the use of this technology.

2.3 The Toolkit for Practising Ethics in Science and Engineering Research

In the previous sections, we described what activities developed a practice for acting upon ethical challenges. Altogether, these created a learning experience defining the toolkit for practicing ethics. Indeed, by teaching an empirical process of thinking ethics as complex events, the sequence of activities stimulated the participants' personal experiences in understanding what process can be followed to address an ethical challenge. With this toolkit, it was introduced an ethics procedural assessment based on the following steps: (1) awareness of complexity, (2) widening of opinion, (3) understanding of causality of events, and (4) points of action of highest impact. It needs to be noted that the transferability of this toolkit to other cultural contexts, disciplines, and levels of study would require further work due to the limited number of students and that this is the first course offering of this format.

3 DISCUSSION: RESULTS, LIMITATION AND RECOMMENDATIONS FOR FUTURE WORK

In this section, we first discuss the findings identified from the course's methods and related activities through the evaluation report and the learners' reflections (Table 1). We then discuss the limitations of the toolkit and make recommendations for improvement and future work (Table 2).

Table 1. Feedback on the course's methods and their application

Learners' reflection:	Evaluation report	Outcomes from application
Method: Participation & debates		
- Fostered active participation and a dynamic learning environment. - Provided a platform to express concerns and organise personal ideas. - Widened personal perspectives	- Provided numerous opportunities for dialogue and discussion - Questions and presentations helped augment one's point of view.	- Enabled to contemplate ethical issues in one's research work. - Extended the understanding of what beneficial can tackle ethical issues related to one's research work.

- Allowed to formulate open questions and engage in personal reflective exercises - Created a safe space		- Created a consultative approach.
Method: System thinking and wicked problem mapping		
- Encouraged to consider the interconnectedness of events. - Enabled to understand the opportunities one has inside the personal field of actions. - Encouraged two-way communication channels - Promoted collaborative problem-solving	Supported the understanding of how to apply its methods in research	- Allowed the application of theories and contextualise concerns - Helped describe interactions between various factors, and highlight personal influence - Widened opportunities for engaging in activities like advising in regulatory bodies - Helped understand what needs priority and efforts.

Table 2. Limitations of the toolkit for practicing ethics and recommendations for future work

Toolkit	Limitations	Recommendation
Industry talks	Some didn't enable conversation.	Guests, presentations should generate dialogue
Ethical presentations and debates	- Facilitation didn't always enable anyone's participation. - Debates relied on personal capacities of communication	- Ensure facilitation allows anyone to engage their lived experiences with the topic of discussion - The course scaling up should prioritise settings that allow equal participation in discussion. A limited number of students create safer spaces for debate.
System thinking & leverage points	More time should be allocated to this activity	- Ensure appropriate time for learning how to apply the method

4 CONCLUSIONS AND ACKNOWLEDGEMENTS

In this paper, we described a doctoral course that introduces a toolkit for practicing ethics in science and engineering research. We illustrate how this toolkit applied the course's methods for equipping researchers with skills for tackling ethical dilemmas. Thus, providing means for covering the gap in technical ethics education.

Through a participatory approach and system perspective, (1) we created a safe space of discussion enabling one to engage with the complexity of ethics; (2) we stimulated debate with peers that allowed personal introspection and the widening of opinions; (3) we enhanced one's capacity to assess the personal space of action to act and mitigate ethical dilemmas through personal experience; (4) we helped one shift the perception of ethics from open dilemmas to interconnected events that can be described, by visualising the system of an ethical challenge.

Through the learner's and evaluation report's feedback, we provided insights on the validity of the course's methods and activities and outlined the toolkit limitations. With these, we encourage future work to identify the toolkit's transportability to different cultural contexts, institutions, and levels of study. In this regard, we propose the following recommendations: (1) A debate on ethics should allow equal opportunities to participate in sharing personal experiences. (2) The number of participants needs to be at an appropriate scale to enable a safe space for discussing and engaging with ethical challenges. (3) Personal and professional lived experiences help understand the system of an ethical challenge and the personal space of agency.

The authors acknowledge the industry expert talks and all the participants of the course.

ABSTRACT

Teaching assistants are widely used at universities around the world, and they are an important part of the teaching and learning ecosystem at their institutions. They help support teachers and facilitate learning processes for students. For many teaching assistants, this work will also represent their first experience with formal teaching. Thus, it is crucial that they receive training within the field of pedagogy and didactics to prepare them for their new teaching responsibilities and ensure a consistent and high quality in their instruction. Since they are relatively inexperienced when they start working as teaching assistants, they both need to develop an understanding of the theories and methods of teaching and learning in higher education, as well as lay the foundation for a professional identity as a teacher, helping them develop sustainable teaching practices and teaching self-efficacy.

This practice paper presents the design of a teaching assistant training course at the Technical University of Denmark, which is focused on developing an understanding

[1] *A. Fornø*
aaufo@dtu.dk

of teaching and learning in higher education for the new teaching assistants, as well as facilitating their development of teaching self-efficacy.

1 INTRODUCTION

Teaching assistants are an often-used resource at universities to support teachers and help facilitate learning for students (Filz and Gurung 2013; Ren, Krishnamurthi, and Fisler 2019). The responsibilities of a teaching assistant may vary a lot depending on the course they are taking part in teaching and their collaboration with the responsible teacher. Examples of the kind of tasks teaching assistants are given responsibility for could be grading assignments, facilitating learning activities such as laboratory exercises, supervising group projects, or even being given responsibility for parts of lectures. Therefore, they play an important role in teaching and guiding students through their courses and study programmes. A common characteristic of teaching assistants is, that they are usually relatively inexperienced within the field of teaching, especially within the context of higher education. While some teaching assistants may have some more or less formal experience with teaching, for example one-on-one tutoring or similar, most teaching assistants have never stood at the front of a classroom before. Thus, their responsibilities as teaching assistants often represent their first real experience with formal teaching.

Teaching assistants are in a rather unique position as teachers given their close proximity and similarity to the students they teach, because teaching assistants are most often students themselves, and may have recently completed the same course they are now teaching (Pawlak, Irving, and Caballero 2020). Research shows that students are likely to perceive teaching assistants as more approachable, understanding and motivating (Kendall and Schussler 2012; Ren, Krishnamurthi, and Fisler 2019) which means many students may be more likely to approach a teaching assistant for help than a teacher. In other words, teaching assistants are a vital resource for universities to provide not only the much-needed capacity to accommodate the rising numbers of students in higher education (Forbes et al. 2017), but most importantly because they represent a safe and approachable source for support and learning for students. There is a huge potential then to increase student learning through the strategic use of teaching assistants. However, this potential is dependent on the teaching assistants' abilities. This underlines the importance of universities prioritising pedagogical training targeting teaching assistants, so they may be adequately prepared to take on their new teaching responsibilities. This is no simple task, as a training course will have to provide the necessary and specific knowledge and skills relevant to the diverse teaching responsibilities of teaching assistants, while also providing a pedagogical foundation for understanding teaching and learning.

Training of teaching assistants is generally under-researched, and though there are some examples to be found on the topic, many of these are often either aimed at specific disciplines (e.g. Marbach-Ad et al. 2012, or Mirza et al. 2019, or Reeves et al. 2016) or specific tasks, such as laboratory exercises (e.g. Dragisich, Keller, and Zhao 2016, or Nikolic et al. 2015). Other examples provide a framework for training teaching assistants, where the course design may require a lot of time and resources and/or big structural changes at the university in order to implement the model (e.g. Odden et al. 2023). While these very specific disciplinary course and extensive models of training may be meaningful in certain contexts, they require many resources to adapt and implement, which makes it difficult to transfer these frameworks to new teaching contexts. This practice paper, however, presents a detailed description of a course design that is easily adaptable and can help increase the proficiency of teaching assistants without using an enormous amount of resources.

This practice paper aims at providing an outline of a universally adaptable framework for a training course for inexperienced teaching assistants, called The Teaching Assistants' Education. The training course presented here has been designed as a universal crash course in pedagogy and didactics, providing an understanding of theories of learning, diverse methods for teaching and strengthening teaching assistants' teaching self-efficacy to prepare teaching assistants to provide quality teaching. Because teaching assistants can have very diverse responsibilities, the training course is also designed to accommodate teaching assistants with many different types of responsibilities. The universal design also means that the course may be transferred and adapted to different higher education contexts relatively easily, which will be elaborated more on later in the paper.

2 PREPARING THEM FOR THEIR RESPONSIBILITIES: DESIGNING A TRAINING COURSE

The Teaching Assistants' Education has been made mandatory for first-time teaching assistants to participate in, to ensures that every teaching assistant at the university has a foundation on which to base their teaching practices. The course is offered once per semester, and between 100-200 teaching assistants participate each semester. The course introduces them to the theories of teaching and learning as preparation for their new responsibilities as teaching assistants, and the course is specifically designed to provide a foundation that can support the teaching assistants as they begin the journey to develop their professional identity and competencies within teaching. This is also reflected in the learning objectives for the course:

- Describe the role of the teaching assistant in relation to students' learning and identity-building
- Explain the concepts of learning and learning processes
- Give constructive and concrete feedback to scaffold student's learning
- Choose and apply appropriate strategies to handle challenges that can occur in the work of a teaching assistant

The course consists of a full course day (6 hours), *the introduction day*, which is placed right before the beginning of a new semester. Towards the end of the semester, there is a shorter meeting (2 hours), *the follow-up meeting*, where the teaching assistants have a scaffolded discussion revolving around their individual experiences with teaching from the semester. Between the introduction day and the follow-up meeting, the teaching assistants have time to apply their new knowledge and skills in their own teaching, and alongside their work, they are required to reflect on their own practice and write a case based on their experiences, which they have to bring to the follow-up meeting. The training course is thus parallel to their teaching during the semester. Below is an illustration of the training course in relation to the academic semester:

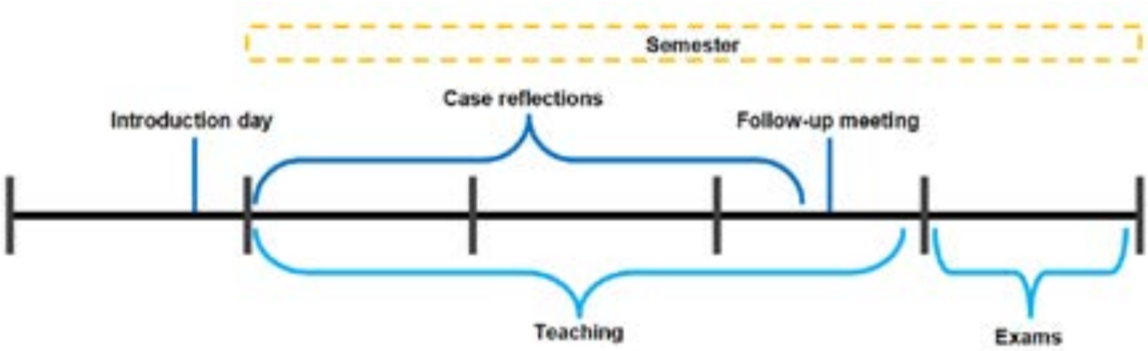

Fig. 1. Overview of the Teaching Assistants' Education

The pedagogical framework for the training course is based on an active learning philosophy and case-based learning. During the course, the teaching assistants are expected to participate in many different activities, where they will reflect on and discuss different topics, both individually, in pairs, in groups and in plenum. The purpose is to create a reflective classroom, where everybody can share experiences, ideas, and questions regarding teaching, learning and the role of teaching assistants. This creates a learner-centred classroom, where the teacher takes on a secondary role, facilitating and scaffolding the learning process of the students, which has been shown to be efficient in achieving learning outcomes (Weimer 2013; Felder and Brent 2016).

To scaffold the learning objectives and prepare the teaching assistants, the course focuses on two main aspects of the teaching assistants' role: the first aspect is about preparing them to scaffold sustainable and constructive learning processes for the students in their classrooms, and the second aspect concerns laying the foundation for their individual development of teaching self-efficacy and curiosity for further professional development. While the teaching assistants usually know which teaching activities, they will be responsible for when they are hired, they are often unprepared for how they can scaffold a constructive learning process for a full classroom. Therefore, they need to learn methods and tools for teaching to help them with the task ahead.

2.1 Understanding Teaching and Learning

Teaching assistants need both specific and cross-curricular competencies (Rico et al. 2013) in order to be able to facilitate learning processes; firstly, they need specific competencies related to their field, so they are familiar with the themes and materials of the course they are teaching. For example, if a teaching assistant helps teach a Computer Science-course where they focus on programming in Python, the teaching assistant will need to be able to, at least to a certain extent, use Python for programming, in order to support the students. Secondly, teaching assistants need cross-curricular competencies within teaching and communication, in order to employ effective teaching practices. Because teaching assistants are usually hired based on their competencies within a specific field or their high performance in a specific course, the field-specific competencies are already present when they begin working with teaching. Therefore, this training course focuses on the cross-curricular competencies within the field of teaching and learning.

In designing the training course, the diverse roles and responsibilities of teaching assistants were considered along with evidence-based teaching methods in STEM-teaching (Felder and Brent 2016). From this, four core pedagogical topics were inferred: 1) Active learning, 2) (cognitive) learning processes, 3) communication, and 4) formative and summative feedback. While teaching these topics, the course is designed to be exemplary of the same pedagogical principles in order to show how these teaching methods can be implemented in practice. Therefore, as previously mentioned, the course contains lots of varied activities and reflective exercises to scaffold the teaching assistants' learning processes. The course contains very little traditional lecturing, putting focus on the participants rather than on the teacher. The responsibility of the teacher is to support and facilitate the participants' active engagement with the course material through asking questions and providing feedback on the teaching assistants' progress.

This method of instruction has a positive effect on the learning processes of the teaching assistants, who are often curious and motivated to learn about pedagogy and didactics due to its' relevance to their work. However, these concepts can be quite foreign to them, as the teaching assistants are used to working in the field of engineering, which can be quite different from the fields of social science and humanities. As they explain it:

"*There is the hard stuff and then there is the soft stuff, and for us the soft stuff is usually the hard stuff.*" (Teaching assistant during the training course)

Therefore, the course contains careful scaffolding with exercises tied closely to teaching practice, in order to create a clear connection between pedagogical and didactical concepts, such as active learning, to the real-life practice of teaching assistants.

2.2 Scaffolding Teaching Self-efficacy and Professional Development

As previously described, teaching assistants play an important role in helping students learn, but at the same time they are rather inexperienced when it comes to teaching. Therefore, a major focus for this training course is motivating the teaching assistants for further professional development.

To address this, a part of the training course focuses on communication, scaffolding and problem-solving. Specifically, the training course seeks to support the teaching assistants in developing teaching self-efficacy, which is an important motivator to develop teaching practices for sustainable learning and has even been shown to improve the academic performance of students (Fong, Dillard, and Hatcher 2019). The concept of teaching self-efficacy is here adapted from Tinto (2017), where a model for student persistence is conceptualized, shows a connection between students' self-efficacy, their perception of curriculum and sense of belonging. Tinto describes self-efficacy in students as a belief in one's own ability to rise to (extrinsic) expectations and overcome educational challenges (Tinto 2017). Transferring the concept to teaching assistants, this means feeling confident in one's own abilities to handle challenges that may arise while teaching in a constructive manner and being able to facilitate sustainable learning processes (Fong, Dillard, and Hatcher 2019).

One of the activities during the introduction day that was specifically constructed to support the development of teaching self-efficacy is called *The Toolbox*. The purpose is to make the teaching assistants reflect on how to solve common teaching problems, so that they may be prepared if or when these problems occur in their classrooms. The Toolbox presents 7 different generalized challenges that are chosen based on cases which have previously been presented at the training course by teaching assistants. An example could be: "*How can you handle frustrated and/or unmotivated students*?". The teaching assistants are then asked to discuss each challenge and come up with solutions for handling them. Discussing these problems in a case-based way gives them a real-life feeling, and knowing the cases come from other teaching assistants lends credibility to the activity, making it highly appreciated by the teaching assistants:

"*As a new TA, I did really appreciate the opportunity to get a "toolbox" for assessing various situations, and be suited to help the students in the best possible way. I felt more prepared for the job as TA."* (Teaching assistant, from the course evaluation)

3 CEMENTING THEIR NEW SKILLS AND ASSESSMENT OF LEARNING GAINS

There is no formal exam for the training course, rather an on-going assessment takes place during the course, where the active and engaged participation of each teaching assistant counts as their exam. In order to pass the course, the teaching assistants will need to participate in all course activities. This is explicitly stated in the beginning of the course, and it is reiterated during the course, that active participation is a requirement. Therefore, passing the course is not only a question of physically being in the classroom, but also being mentally engaged in the contents and activities. The didactic design of the course and the assessment format was developed according to the model of constructive alignment, which necessitates a clear connection between the learning objectives, learning activities and the assessment of a course (Biggs and Tang 2011). The ambition of the assessment format is then to direct teaching assistants' attention towards the contents and activities of the course, and create a positive washback effect (Tsagari and Cheng 2020), motivating the teaching assistants to be more actively engaged.

Another important part of the assessment of the course is the case-discussions during the follow-up meeting, where each teaching assistant brings along a real-life case. Here, the teaching assistants show how they have used the knowledge and skills they learned during the introduction day in their teaching. During the case-discussions they are invited to analyse and reflect on their own experiences, as well as the experiences of other teaching assistants coming up with different ways of handling each situation, to deepen their understanding and insight into teaching practices. They will also practice active listening and asking questions, as well as engage in meta-discussions about the role and responsibilities of teaching assistants. This case-based activity is aligned with activities from the introduction day as well as their learning objectives, ultimately supporting the student's development of teaching competencies.

4 KEEPING THE COURSE RELEVANT

Because the tasks and responsibilities of teaching assistants are so diverse and subject to change, the content of the training course and its learning objectives are re-examined every semester using feedback from the course evaluations, as well as the cases from the Toolbox exercise. This ensures that the course is constantly kept up to date on the roles and responsibilities teaching assistants are given at the university and makes sure the content of the course is relevant and useful for future teaching assistants. Part of the revision process is reading through the cases from the teaching assistants, because it provides a detailed and valuable insight into the practices and challenges of the teaching assistants. During this process, if a new or particularly complex case shows up, they are saved and worked in to the curriculum for the upcoming semester. An example of this is, that two years ago, we received cases regarding teaching when there is a language barrier between the student and the teaching assistant. These cases created awareness of a need to prepare for handling this issue, and the case was then incorporated into the Toolbox exercise. Since the incorporation, there has been fewer teaching assistants reporting the issue.

The teaching assistants are asked to give feedback twice during the course. The first time is a short evaluation after the introduction day, where they are asked to write down something they think should be maintained on the course (for example an exercise or a topic) and something that could be developed further. Below are some examples:

Fig. 2. Excerpt from the short evaluation, Autumn 2023

This feedback serves two purposes: firstly, it immediately brings to light if there is anything that has been unclear during the introduction day that may need to be revisited or if there are some resources lacking that need to be provided for the teaching assistants. In other words, it provides an opportunity to rectify any misunderstandings quickly. Secondly, it provides valuable insight which can be used to develop and improve the course in the future, so that the content can stay relevant to teaching assistants even if their tasks and responsibilities may change.

The teaching assistants are also asked to evaluate the entire course at the end of it in a more thorough evaluation. However, there are usually around two months between the introduction day and the follow-up meeting. Thus, asking for immediate feedback after the first session is also a pragmatic decision, ensuring that feedback is given while their experiences are still fresh in their memory.

5 SUMMARY

The Teaching Assistants' Education has been offered now for more than 10 years and evaluations of the course are usually overwhelmingly positive, with teaching assistants expressing they find the course both useful and relevant. According to the feedback given by the teaching assistants, the training course facilitates positive professional development, enabling them to help further scaffold sustainable learning processes for students in close collaboration with university faculty. The teaching assistants specifically highlight the case-based activities, where they discuss real-life cases, as something that helped them gain an understanding of teaching and learning. They also describe that the course helped them feel more confident in their teaching abilities and gave them the necessary tools to handle any difficulties they encountered:

> "*I always have the results of our discussions from the introduction day in the back of my mind about how to be the best possible TA as I can. For example to be proactive when nobody's asking for help, because I can now say from experience that they often struggle with something even though they don't say it! Also be non-judgemental if they ask a supposedly "dumb" question, and instead just guide them through the problem until they understand, since everybody learns in a different pace.*" (Teaching assistant, from the course evaluation)

Implementing a training course such as this thus positively impacts the teaching self-efficacy and proficiency of teaching assistants, which in turn should have a positive impact on student learning.
Obviously, how this course design may be adapted to a different higher education context is dependent on many different factors, such as the number of new, inexperienced teaching assistants hired each year at the educational institution in question, as well as the diversity of the tasks teaching assistants are given and the resources available to support them in their professional development. The course design presented in this practice paper is designed to be flexible, so it can adapt to the dynamic landscape of higher education, and therefore it can easily be adapted to fit another context at other universities by modifying the real-life cases and questions the teaching assistants have to work with during the introduction day, as well as adding or subtracting specific teaching methods, according to their relevance for the teaching assistants in question. Considering the particularities of the context, different adaptations may be more or less meaningful. Therefore, it is important to understand the concrete needs of the teaching assistants at a given university. For example, at larger universities, which usually also have a higher number of teaching assistants, it may therefore be more meaningful to offer several, more specialised training courses for teaching assistants that are more targeted at teaching methods related to either specific scientific fields or specific tasks and responsibilities. In other cases, it may be more meaningful to adapt a more universal framework, such as the one presented in this paper, for example if a university has a relatively small number of teaching assistants or a higher diversity in responsibilities for each teaching assistant.

ABSTRACT

In this paper, we link different approaches in engineering education. On the one hand, the research in mathematics education at tertiary level, which gives a big importance to the inquiry-based learning approach, and, specifically in engineering degrees, which identifies, among others, active student learning on open-ended real-life tasks as promising innovative practices. On the other hand, the research in

montserrat.alsina@upc,edu

statistics education, where importance of inquiry is commonly accepted and which highlights the importance of the use of real and realistic data. Finally, the service-learning approach, which is clearly addressed to connect engineering education to social challenges. We present two inquiry-based activities called study and research paths, a methodology under the theoretical framework of the Anthropological Theory of the Didactic, that show the great potential of this type of teaching methodologies in engineering degrees, especially in the sense of raising questions, hands-on learning, awareness and responsibility in engineering graduates, when service-learning approach is used too.

1 INTRODUCTION

Nowadays, research in mathematics education at tertiary level gives more and more importance to inquiry-based activities. For example, the Erasmus+ PLATINUM project, carried out by eight European universities in seven countries, aims to develop an inquiry-based approach in teaching mathematics at university level related to the programmes in mathematics, science, engineering, economics, among others. (Jaworski et al. 2021)

When reviewing promising innovative mathematics teaching practices in engineering education, and the implications for curriculum reform, (Pepin et al. 2021) identify four themes that appear to address this question, being one of them “active student learning on open-ended real-life tasks and self-regulation [...] students develop their own learning trajectories, in order to overcome a ‘compartmentalized curriculum’ and atomistic approaches to learning...” (Pepin et al. 2021, p. 181-182). They also add that: “The mathematical competencies in and for engineering are developed by working on real-life professional tasks/problems/ challenges (rather than on mathematical topic areas that might or might not be used later in projects), with support and guidance from the instructor. The curriculum design involves the development or identification of complex learning tasks/challenges and their ‘monitoring’ (in terms of assessment of student learning), in addition to the provision of an infrastructure (for instructors and students) to work in such innovative environments.” (Pepin et al. 2021, p. 181-182).

The importance of inquiry in statistical education is commonly accepted, since it fosters statistical investigations (Watson 2009), statistical thinking (Pfannkuch & Wild 2004) and statistical problem-solving. According to the recommendations given by the Guidelines for Assessment and Instruction in Statistics Education (GAISE) College Report, introductory statistics courses at university level should integrate real data with a context and purpose. In addition, the desired result of all introductory statistics courses is summarised in 9 goals, being the first one: “Students should become critical consumers of statistically-based results reported in popular media, recognizing whether reported results reasonably follow from the study and analysis conducted.” (Gaise 2016, p. 8). This goal stays in line with (Gürdur et al. 2022) that states that “the engineers of the future should not only be fluent in digital technologies but also in data.” A good and critical understanding of the data can lead to changes and improve how things have been done.

On the other hand, the service-learning approach is a form of experiential education that integrates practical experience with academic knowledge, and some of its objectives are to engage students in community service projects and to foster civic values, such as ethics and social awareness. It has been widely utilized across various disciplines, including medicine, nursing, psychology, and engineering, to enhance learning outcomes and foster civic values, such as ethics and social awareness (Huda et al. 2018), (Duffy et al. 2000). Also (Jiménez-Pérez et al. 2023) claim that "service learning is seen as evaluable strategy for students to contribute to the community and fulfil their social responsibilities." In engineering education, emphasis on the application on real-world contexts is stated "Integrating service-learning into engineering education offers opportunities for students to apply technical knowledge in real-world contexts, fostering their professional development and social responsibility." (Ferri & Furlong, 2019). More specifically, Community-Based Service Learning (CBSL) is a widely adopted learning strategy in engineering that promotes social values and civic engagement among students. (Baker 2018; Huda et al. 2018; Brown and Bauer 2021).

One of the goals of our study is to show that, using the research in mathematics education about inquiry-based learning, and transferring more responsibilities to the students, so that they have a more active role in their learning process, as well as choosing topics of social impact, the learning outcomes can make an impact to the students, in terms of raising awareness on some specific topics of general interest.

2 THEORETICAL FRAMEWORK

The theoretical framework used to design this proposal is the Anthropological Framework of the Didactic (ATD) (Chevallard 2015). This framework distinguishes between two main paradigms, the paradigm of visiting works, in which students visit the works of knowledge taught by the teacher; and the paradigm of questioning the world, where questions go first and the knowledge works, among others, are used to answer these questions. Under this paradigm of questioning the world, we can find the so called *study and research paths* (SRP) (Bosch 2018). SRPs can be classified as inquiry-based activities and they start with a generating question Q_0, which is presented to the students and they, as a whole class, have to answer. In the process of finding a final answer $A^\heartsuit$, new questions arise, which can be answered using empirical data, secondary information, knowledge works...

SRPs can be described and/or analised in terms of three dialectics, called *mesogenesis*, *topogenesis* and *chronogenesis* (Barquero & Bosch 2015). The mesogenesis corresponds to the evolution of the inquiry *milieu*, that is, the incorporation of new information and partial answers and their validation to transform them into new ready-to-use knowledge tools to proceed with the inquiry. The topogenesis refers to how responsibilities will be shared between teachers and students during the different steps of the inquiry process. The chronogenesis describes the possible pace for the inquiry, that is, the progress made through the consideration of an initial question Q_0 and the new questions derived from it, as well as the intermediate answers that are found or provided. A tool to represent the chronogenesis is the so called questions and answers map (Q-A map).

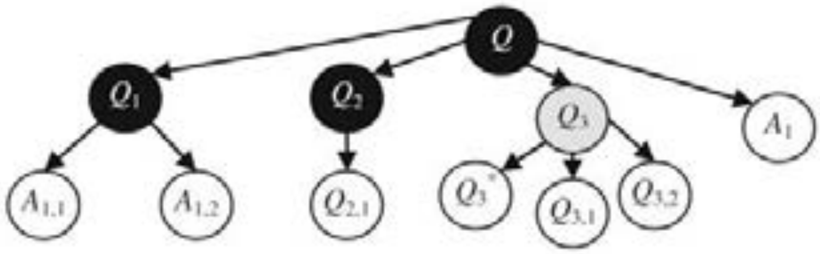

Fig. 1. An example of a question-answer map (Winsløw et al., 2013, p. 271)

Some SRPs have already been implemented in different educational levels and in different areas of mathematics education, but also in other subjects. At tertiary level, we can find some implementations that have been gathered in (García et al. 2019) and (Barquero et al. 2022), and they explain different modalities of SRPs and some commonalities and specificities in the way the three dialectics are organised. Some other SRPs have been carried out in engineering degrees (Bartolomé et al. 2019), (Florensa et al. 2018), (Queré 2022).

In the framework of the ATD, the novelty of the SRPs presented in this paper lies mainly in their articulation around social responsibility. In analyzing their development, emphasis is placed on how this aspect takes center stage, with students becoming involved and learning statistical content in an integrated manner with the practice of social and environmental responsibility.

3 DESIGN, IMPLEMENTATION AND SOME RESULTS OF THE SRPS

3.1 Design

Our proposals took place in the subject of statistics in the second semester of two consecutive years 2021-22 (Freixanet et al. 2022, 2023) and 2022-23 in the ICT Systems Engineering degree at the Escola Politècnica Superior d'Enginyeries de Manresa (EPSEM), one of the schools of the Universitat Politècnica de Catalunya UPC. Around forty students each year took the course. Four weekly sessions are devoted to the subject, two of them with the whole group, and the other two with half of the group in the computer lab. The instructional proposals were designed as SRPs, the students worked in teams of three to five students and they were given a first generating question or a topic to work on.

The theme of the first proposal (SRP1) centered around Water, with the guiding question being, "What concerns us about water in terms of sustainability?" This was closely tied to the ongoing project "AquaeSTEAM," concurrently undertaken within the school. The primary objectives of this project were to foster scientific culture and develop resources for interdisciplinary education across all levels, aligning with the Sustainable Development Goals (SDGs) outlined in the 2030 Agenda for Sustainable Development. For the second proposal (SRP2), the inquiry was focused on the electrical consumption of the EPSEM. This inquiry was introduced by the school's maintenance head. A shared focal point in both SRPs was social responsibility, aiming to raise students' awareness of the environmental impact of our actions.

The design also took into account the second goal mentioned in the GAISE report, and let the students raise the questions that were going to lead their research, they wanted to carry out. Thus, provoking a share of responsibilities between the students and the teacher in the problematisation process (Freixanet et al. 2024), that is, in finding their own generating question that would lead their own inquiry, making sure that the data provided was statistically "studiable" and actually answered their proposed question.

3.2 First steps

Although both proposals were designed as SRPs, these proposals had significant differences in the process of finding the generating question for each team. Whereas in SRP1, the students raised questions first and had to find the data that could answer them, in SRP2, the students were given some sets of data, which they first explored, which led to raise many questions, which, at the same time, and after a process, led to find the main generating question of each team. In both implementations, though, very interesting questions were raised by the students during the process of finding their own generating questions. More details are given in (Freixanet et al. 2024).

3.3 Some results

Some generating questions that were studied in SRP1 were the following:

- Team B2: To what extent does the water consumption vary if some works are carried out in bathrooms?
- Team B5: How is the water consumption of the region Vallès Occidental and how is it comparable to the consumption in Catalonia?
- Team A6: What is the water footprint of the technology of first-year ICT Systems students?
- Team B1: Has the 2020 confinement affected the level of water consumption in Barcelona?

As example of some interesting results, see Figure 2, displaying some variables.

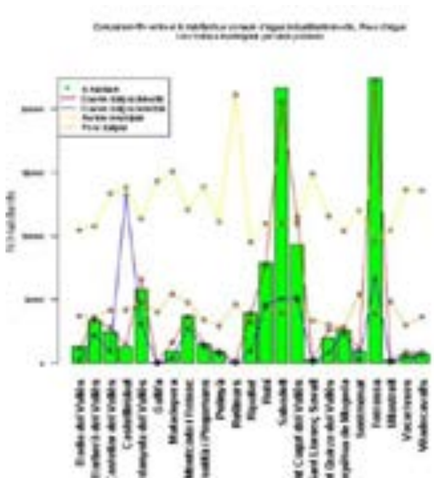

Fig. 2. Graph showing the number of inhabitants, the domestic and industrial water consumption and the price of water in each city of the region in Catalonia studied (SRP1 - Team B5)

We highlight the study carried out by team B2, in which the students proposed some changes in the bathrooms of a residence of elderly people, in order to save water, having previously asked the residence for data about water consumption, talked to some constructors and studied the water footprint.

Fig. 3. Water consumption of a residence of elderly people per month (SRP1 - Team B2)

In SRP2, some of the questions were:

- Team A1: How do morning or afternoon classes have an impact on the consumption of electricity?
- Team A3: How do temperatures affect the consumption of electricity?
- Team A4: What impact does the non-lectivity have on the consumption of electricity?
- Team B1: How does the open and closed hours and the amount of people in the school affect the consumption of electricity?
- Team B4: Does the exam period affect the consumption of electricity?

Some interesting results show, mainly, a diagnostic from which some conclusions can be withdrawn and hence, improvement proposals can be made.

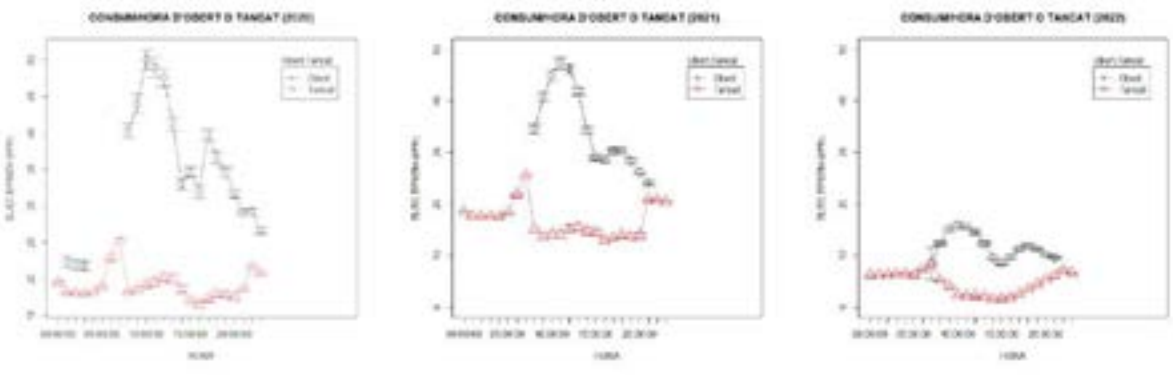

Fig. 5. Consumption of electricity of EPSEM in 2020, 2021 and 2022 when closed and opened in different years (SRP2 - Team B1)

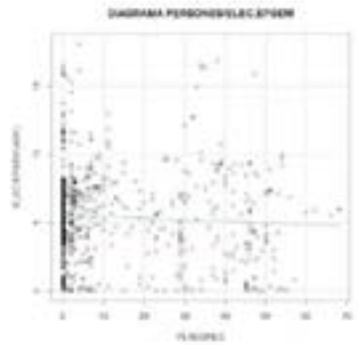

Fig. 6. Correlation between the number of people in the school and the consumption of electricity (SRP2 - Team B1)

We highlight a proposal from team B1, who encountered a lot of problems to process the data provided, which was hand-written. This data showed information about the people that entered the building on days with no classes: weekends, bank holidays, holiday periods... They suggested this control should be digitalised using the student card or a QR code. This way, the data could be analysed more easily and paper would not be used.

4 ANALYSIS AND CONCLUSIONS

Implementing inquiry-based activities, such as SRPs, in the subject of statistics provides students with the opportunity to become proficient in handling data, interrogating it, comprehending it, posing questions, being critical, making decisions, and proposing solutions. Indeed, these activities enhance students' statistical skills, which, in a world abundant with data, are essential for conducting diagnostics and formulating improvement proposals.

Analysis of the development of SRP1 confirms the key characteristics of service – learning activities. Motivation stemmed from the significance of water as a natural resource, particularly in relation to climate change, and the desire to reduce consumption and promote reuse. Social benefits included studying consumption data to raise awareness and educate, as well as generating proposals for reduction and reuse. Collaborative efforts involved external agencies such as city and county councils, environmental groups, neighbourhood associations, and public water service companies. Similar patterns were identified in the development of SRP2.

The impact on students was evaluated through a combination of academic assessment tests related to statistics and surveys and interviews focusing on their understanding of responsibility. Results indicated a positive impact on students, including enhanced learning of content and competencies, reflected in good academic performance, and increased awareness of social responsibility and personal reflection, as evidenced by survey responses and interview feedback. Furthermore, the impact on teaching staff was also positive, as they experienced simultaneous improvement in teaching effectiveness and social service engagement. Lastly, it is worth highlighting the positive impact on the institution itself, as engaging with such organizations fosters the growth of the local social network.

ABSTRACT

We showcase our 4TU Responsible Sustainability Challenge Master Honours track as a successful case of ongoing inter-university educational collaboration. The experiences of this endeavour could be used as a guiding example for similar collaborations. The organisational cooperation among the universities was evaluated through qualitative analysis based on interviews with eight involved collaborators. Our experiences show that to utilise the benefits of inter-university collaborations for both students and institutions, a careful consideration of the organisational structure is needed beforehand. It is especially important to evaluate the prerequisite conditions of the collaboration, educational alignment, and administrative tasks, as

[1] *M.S. Fuentes Bongenaar*

well as develop a suitable coordination system that would regulate the vision and the practical implications of the development and operation of the course.

1 INTRODUCTION

1.1 Interdisciplinary & Inter-university Future

The current developments in industry require engineers to work increasingly along other disciplines to understand the needs of diverse fields and specialisations (Van Den Beemt et al. 2020). The demands of industry consequently require educational institutions to further integrate interdisciplinarity within their degree programmes. This will allow students to develop and practice collaboration skills and other transversal skills necessary for understanding and working with people from other disciplines. This need is currently addressed within single universities by developing (intra-faculty) dedicated courses. However, courses shared among universities are less utilised as a learning framework for interdisciplinarity (Dimitrienko et al. 2020). The current practice paper aims to showcase one such success case of an inter-university collaboration.

Inter-university education is collaboratively developed, taught, and supported by multiple universities (Coombe 2015). This can provide an opportunity for students to engage with a wide range of disciplines, experts, teachers, and stakeholders, creating a fertile ground for the development of transversal skills (Dawson et al. 2024). Transversal skills such as critical thinking, creativity, and interpersonal skills, appear to be of crucial importance in the future engineering industry (Kovacs et al. 2020). Furthermore, by training skills on the intersection of scientific areas and increasing the number of available human and material resources, e.g. knowledge base, expertise, facilities (Dimitrienko et al. 2020), students and future employees are better equipped for the changing requirements of industry and academia (Blagorazumnaia & Trifonova 2023). However, such inter-university cooperations requires a stable ground of collaboration and clear agreements among institutions.

1.2 Development of the collaborative 4TU.Federation Master Honours track

The 4TU.Federation (4TU) is an inter-university federation of four technical universities in the Netherlands, namely Eindhoven University of Technology, Delft University of Technology, University of Twente and Wageningen University & Research, which work together in the vision of "*connecting, representing and innovating in the areas of education, research and valorisation*" (4TU.Federation 2024). The involved universities cooperate in research to build upon each other's knowledge and offer more opportunities to their students. To develop their collaboration further, the 4TU.Federation piloted an inter-university Master Honours track under the title 4TU *Responsible Sustainability Challenge (4TU.RSC)*. As a track, 4TU.RSC serves as a specialisation among the Honours programmes of the collaborating universities in which students can follow a predetermined trajectory of development centred around the dedicated topic of sustainability, in which individual components (i.e. project work, online lectures and on-site events at the universities) contribute to the overall learning goals shared by these universities. The initial idea was developed by all four universities, however, Wageningen University only partook in the initial development, as they did not offer a Master Honours programme during the time of development and could therefore not embed the track in their Honours curriculum.

In practice, 4TU.RSC is delivered as an extracurricular track for selected Master students, working on a sustainability challenge while receiving coaching, workshops, and lectures provided by educators of the three universities. The track is organised, developed, and provided under the Honours programmes of the three collaborating universities. The Honours programmes are provided for ambitious and talented students who want to do something next to their study. A key characteristic of the Honours programmes at the participating universities in this collaboration is that students must apply for them and are subsequently selected if they fit the criteria of the Honours programme of each participating university. The exact method of student recruitment and selection differ between the universities..

Since the Honours programmes are outside of the official curriculum, more experimentation with education is possible. Integrating a new course in any institution involves usually a demanding and long procedure. Additionally, Honours students are considered and selected on being motivated and able to work in complex and innovative educational structures, making them very good at handling a programme with a lot of parties, teachers, and stakeholders. These were the main considerations for the 4TU.RSC to be developed and provided by the Honours programmes.

2 METHODOLOGY

The main objective of this practice paper is to provide insight into the creation and running of inter-university education. To those ends all involved organisation staff were approached and asked to participate in an interview (appendix A). Eight semi-structured interviews were conducted with 4TU.RSC track coordinators, Honours programme managers/coordinators, educational experts, and 4TU representatives. The interviewees were involved at various stages of the preparation and/or delivery processes for each of the two running periods of 4TU.RSC. All interviewees gave their informed consent via video or voice agreement to be recorded and transcribed. The transcripts of the interviews were coded by two researchers using a deductive approach (Azungah 2018). Similar content was coded under the same code, with the count of that code increasing by one for each instance in the transcripts.

3 RESULTS

The list of codes from the transcripts could be divided into three broad categories: the requirements for, the benefits of, and the challenges in organising and running inter-university education. The following paragraphs present shortly the main categories as those were defined based on the information shared by the interviewees. Topics which were mentioned four times or more by the interviewees are included in the results within their categories:

a. *Requirements*, or the prerequisites necessary to build such a collaboration.
b. *Benefits*, or the added value of such collaborations.
c. *Challenges*, or the difficulties that such collaborations introduce.

3.1 Requirements

The first main area consisted of the requirements regarding the process of developing, initiating, and operating inter-university educational programmes. The most often mentioned requirement was alignment among Honours programme structures and institutional overarching Honours programme learning goals. Each of the 4TU universities have different structures in the Honours programmes. These differences relate to the application period, the selection criteria, and the number of credits in an Honours programme. Even the level of centralisation of the Honours programmes differs, where some universities have (a part of the) organisation on the faculty level while others maintain a university-wide programme. All these factors created a complex web of policy, scheduling issues, and requirements which the organisational team had to navigate before the track creation process could begin. The track was re-evaluated after the first year, and some strategy changes were made to be as accessible as possible for students from all universities. These changes included a restructuring of the division of credit to allow the different partner universities to take ownership over study modules which were close to their expertise.

As the content of the track, especially the learning goals and visions, needed to be aligned among the institutions and the Honours programmes, administrative complications were also introduced in the original prerequisites for setting up the collaboration. For instance, some of the collaborators defined the Master level of the learning objectives differently, had varying understanding of the appropriateness of challenge-based learning (CBL) outcomes for this educational level, and had different approval requirements for new tracks.

Given this intense administrative and aligning work, collaborative and co-creative team spirit appeared also as a prerequisite. The openness to hear other perspectives and to discuss concerns, ideas, doubts, etc. among the collaborating members made aligning the programme structure and learning goals easier. All members appeared to contribute their own expertise and knowledge and be responsible for accomplishing several tasks on behalf of the common goal. The flat hierarchy among the contributing members supported their responsibility and was the driving force towards a good collaboration. The same spirit of openness and collaboration was also extended towards the external parties throughout the whole process of preparation and operation of the track. Given the CBL character of the programme, education experts and stakeholders (e.g. companies contributing as experts from practice) were also involved in the co-creation process of the track. This diversity of expertise and points of view embedded in the programme development contributed to its extensive multidisciplinary character and enriched its knowledge database.

3.2 Benefits

The main reason of the 4TU collaboration on this track was the preparation of the students towards an inter-disciplinary future career and the understanding of differences between schools of thought within the same discipline. Interestingly, some of those benefits were also mentioned in the interviews conducted as advantages for the universities. Each institution, and their representatives, embodied a role to fulfil specific tasks. The programme required more involvement from all parties in a mostly unexplored type of collaboration. This meant that some members of the team were present and involved in elements of the track creation process where they normally would not be. This allowed for perspectives and practices to be shared, and new learning to be introduced. Hence, the interdisciplinary knowledge of the universities was equally improved.

The co-creation of this track further enhanced the network of each of the universities. The programme allowed the team members to get even more familiar with the other 4TU universities and get acquainted with professionals from diverse departments. Sharing perspectives, enriching the knowledge databases, and exchanging good practices among institutions were the most prominent benefits of the collaboration spirit that was enhanced through the development and delivery of this track. An important addition was strengthening the relationships between the Honours programmes. Given the strong ties between the programmes, enabling additional future collaborations was proposed as an important outcome of this collaboration. Finally, given the interaction with external experts and local companies as stakeholders, the network of the institutions was enriched even further in industry, allowing for other kind of collaborations and possible connection of the local students to relevant companies.

3.3 Challenges

Next to the prerequisites and benefits of this inter-university educational collaboration, there are several challenges that also need to be taken into consideration. The most named challenge is coordination. From the very beginning of this endeavour, no specific coordinator was assigned among the universities. The goal of this choice was to ensure a flat hierarchy, and equal involvement of each member. However, the cooperation between the different educational institutions, with different approaches, organisation and even teaching backgrounds, imposed complications in the collaboration. Practical matters, such as meetings, agreements and more abstract issues, such as the vision and the collaboration plans, were undetermined. Multiple interviewees suggested that clear guidance regarding important topics of the cooperation would have ensured smoother interaction, and improved cooperation.

Due to this lack of coordination, practical implications were often mentioned to arise in the collaboration between the different members. It was not always clear under whose responsibility some tasks belonged, what the planning of the track was, and which adjustments to the local programmes or promotion strategies needed to occur. This was also reflected in the student evaluations of the pilot, who provided the feedback that communication was often unclear and late. Next to coordinating among the inter-university organisational team, the local institutions needed to ensure alignment with their own curricula. Furthermore, developing such a complex interdisciplinary track required more dedication and time investment. Finally, even though the track was running under the Honours programmes of each institution, not every programme operates in the same way regarding timetables, student entry requirements, and even rules and regulations. Central coordination could offer early solutions to those matters.

Instead, to ensure solving those raising issues and dealing with the newest developments, the members of this collaboration needed to have regular meetings. Those meetings appeared to be more productive when they occurred in person. In the online meetings, several interviewees reported to have the impression of less commitment and/or lower motivation. Meetings in person appeared to be more productive and better for the team spirit. However, regular physical meetings require time and financial investment. The traveling hours of the teachers and the coordinators needed to be weighed against the increased team spirit and the successful cooperation.

4 DISCUSSION

Taking into consideration the input of the members of the organisational team of 4TU.RSC, there are some relevant conclusions that could serve as valuable guiding sources in future inter-university innovative educational projects. Thereby, it is important to underline that such collaborations are not only profitable for the students partaking in this education, but also for the educators and the institutions. Strengthening the collaboration spirit, learning from the interdisciplinary environment and the different practices and approaches of each university, as well as continuously networking with old and new stakeholders enlighten the reasons of such endeavours.

However, while preparing and delivering such inter-university courses, it is fundamental to take several implications into account. Firstly, coordination might be a key for smooth collaboration. A designated individual or group of people in this coordinating position could safeguard the vision and alignment to the local institutions, take the key decisions, arrange practical implications, such as adjustments, administrative challenges, and promotion to students, as well as decide when physical or online meetings are necessary for the best collaboration procedure. The 4TU.RSC initiators choose for a flat hierarchy structure, which led to equally successful results. The coordination tasks were adopted organically by various parties. However, having such a central role could smoothen the cooperation, especially during the development period.

Prior to initiating inter-university courses, it is important to test if the universities intending to start the course provide a good organisational foundation for such an endeavour. Meaning that the participating universities must be flexible enough to adapt to potential organisational limitations of the partnering universities. The most important factor is the evaluation of the alignment between the learning goals of such an inter-university course and the local institutional courses, as well as the administrative complications that might come along such an innovation, such as scheduling issues between universities, adjustment of educational level definitions that might be relevant for international forms of such collaborations, and more. Above that, all those prerequisites can only be successful if a collaborative and co-creative team spirit is present or can be developed among the involved members. The 4TU collaboration had a significant advantage on that front, given the already existing collaboration. Until the initiation of 4TU.RSC, the 4TU mainly focused on research and promotion of the good practices of each university. The 4TU.RSC was their first educational track developed, but the strong cooperation ties were already well established.

5 Conclusion and Acknowledgements

In conclusion, inter-university courses appear to have many advantages for both the students and the institutions. The experience of developing and providing the 4TU.RSC Honours track has shown that alignment is one of the most important factors for a successful collaboration. This must be evaluated by the participating institution, and the case of the 4TU.RSC has shown that dedicated coordination may make this process more efficient and thorough. Future attempts in establishing inter-university courses can take the present paper into account when establishing the collaboration structure. However, further longitudinal and empirical data would also be required to carefully assess the applicability of inter-university collaborations.

This study was made possible by the Honours Programme Delft of the Delft University of Technology, the Honors Academy of the Eindhoven University of Technology, Wageningen University & Research, the Honours Office at the University of Twente, the 4TU centre of Ethics, the 4TU centre of Energy, and the 4TU centre of High Tech Materials. This paper would not have been possible with the help of the teachers and coordinators of the 4TU.RSC track and our valued colleagues Luuk Buunk and Marie-Laure Snijders, who provided input, guidance, and assistance.

APPENDIX

Interview questions

Personal Data:

What was your role within the 4TU.RSC program?
Which tasks did you fulfil for the 4TU.RSC program?
During which moments were you involved in the 4TU.RSC program? (preparation 1st round, round 1 running, preparation 2nd round, round 2 running)
What expertise did you bring to the 4TU.RSC program?

Preparation Period (preparation 1st & 2nd round):

Which processes were necessary for setting up (or iterating) the 4TU.RSC program?
Who did you need to communicate with in order to organize the 4TU.RSC program?
Which were the most complicated discussion points in the development of 4TU.RSC program?
How did the teamwork/ collaboration process develop among the involved members?
What were the most valuable opportunities that 4TU / inter-university collaboration provided?

During Course Progression:

What difficulties did you experience in the cooperation/ coordination of the course?
How did you ensure the quality of the program throughout the process?
How did you ensure smooth collaboration among the involved members?
Were there points of disagreement among the involved members?
What were the most valuable opportunities that providing 4TU / inter-university education provided?

Closing & Next Steps:

How did you evaluate the cooperation with all the members?
What were the most important learning points after the completion of the cooperation?
How did you decide on the next steps (progression, next level, alternative iteration) of the program?
What would you propose for future similar inter-university collaborations?

A co-curricular approach to addressing the variation of practical skills in students from diverse backgrounds.

ABSTRACT

Responding to the diversity in practical electronics skills among first-year undergraduate students, the University of Sheffield implemented "Diamond Wednesdays," a co-curricular activity (CCA) outside the traditional curriculum. Recognizing that students arrived with varying levels of practical experience due to differences in pre-university education, including disparities in international educational backgrounds, Diamond Wednesdays sought to address this gap in an informal, technician-led environment. This initiative leverages unused laboratory time on Wednesday afternoons, a period traditionally reserved for student activities and sports, to offer optional, non-assessed sessions focused on building, testing, and troubleshooting electrical circuits. The program has demonstrated significant

[1] *J. Fullwood*
j.fullwood@sheffield.ac.uk

success since its inception in September 2019, with an increasing number of participants across various year groups, including postgraduates, seeking to refine their basic electronics skills. The introduction of remote learning options during the pandemic further expanded the reach and flexibility of Diamond Wednesdays by incorporating online resources. Feedback from participants has been overwhelmingly positive, with the initiative receiving high satisfaction ratings and qualitative praise for providing a supportive, non-judgmental space for skill development. Diamond Wednesdays is an example of the educational impact possible from empowering and utilising the expertise of the technical staff. It represents a scalable, efficient model for addressing skill disparities among engineering students, fostering a culture of collaboration between technical staff and students, and enhancing the overall educational experience without imposing additional demands on academic staff. The success of this program highlights the potential for similar co-curricular initiatives to complement traditional engineering education and support students' diverse learning needs.

1 INTRODUCTION

The Electronics and Control laboratory in the University of Sheffield's Diamond building delivers timetabled, practical classes to a range of engineering disciplines. Typical classes in the laboratory may include RLC circuits, transformers, coupled circuits and transistors. The multidisciplinary approach utilised in the laboratory (Kapranos 2018) means students attending classes in the laboratory may be enrolled in one of several degree programmes, as listed in table 1. Students arrive with different entry qualifications, different learning needs and different cultural/educational backgrounds. In aggregate, international students comprise 30% of participants in laboratory activities. Students arrive with different entry qualifications, different learning needs, and different cultural/educational backgrounds. The author's previous career in secondary (high school) education provided familiarity with the practical skills of first-year UK students. From daily interactions with students in the electronics and control lab, it is clear that the practical skills of international students are different. In aggregate, international students comprise 30% of participants in laboratory activities, and, as can be seen from Table 1, the Electronics and Electrical Engineering degree programs have a high proportion of international students.

The majority of students participating in activities in the laboratory are first- and second-year undergraduates. Despite this limited remit, the large cohort sizes (referenced in table 1) on multiple degree programmes generate substantial demands. The laboratory has a capacity of 144 seats, a high throughput, with a frequency utilisation of 84% and delivers around 63,700 student contact hours a year. Tactics to allow operation at this scale are employed, such as all students following the same activity at the same time (Di Benedetti et al. 2022). Consequently, there is little opportunity for students to spend more time than allotted to perfect or repeat prescribed tasks.

A team of five technical staff members work in the laboratory to enable the high levels of throughput. Unlike the traditional role of lab technical staff, principally concerned with equipment maintenance and safety management, the technical staff also contribute to the teaching, with contractual job titles of “teaching technicians".

In the Diamond building laboratories, there is a strong culture of integration between academic and technical staff. For example, all staff sit together in the same office, rather than having academic and technician offices physically separated, as is more common in higher education. Technical staff are empowered to make changes to laboratory delivery and encouraged to implement innovative ideas. The practice presented here is an example of how valuing technical staff contributions can lead to enhanced educational opportunities for students.

Table 1. Range of programmes and background of student in the Electronics and Control lab sorted by % of overseas students.

Programme	Cohort Size	% Overseas
Electrical and Electronic Engineering	305	65
Chemical Engineering	154	31
Computer Science and Engineering	587	29
Bioengineering	117	27
Mechanical Engineering	428	25
Aerospace Engineering	434	15
Mechatronics and Robotics	240	8
General Engineering	132	3

2 PROBLEM IDENTIFICATION

One of the first laboratory sessions for first year undergraduates is a “Workstation Lab”, designed to introduce students to using standard test equipment. Students build a circuit as the foundation of their testing. This circuit includes a prototype (breadboard) circuit and a soldered printed circuit board (PCB).

The technical staff observed that many of the undergraduate students, though knowledgeable, lacked certain basic skills in their practical electronics lab sessions. Through informal discussions with students, it was established this was due to the diversity of pre-university education. Some UK students had received less practical education during their secondary school years (age 12-18) than anticipated in the design of the teaching sessions. Many students, in particular international students, had never previously used a soldering iron and were finding great difficulty in understanding what it was for and the reasons why it is used. It was noticed that some students struggled to understand how the breadboard worked, therefore making it difficult to build the circuit accurately.

The results from the lab session assessment showed where students lacked the basic understanding of how to build prototype circuits accurately and neatly. These observations showed a lack of basic skills negatively affected the students’ progress, particularly in early lab sessions. Frustrations became obvious from both the students and the academic staff, evident in staff-student interactions.

Addressing the variation in practical skills among students of different educational and cultural backgrounds, to allow them to participate in the timetabled sessions designed with the expectation of prior experiences with these skills from previous education, present significant challenges. The already high utilisation of the lab means that additional timetabled sessions are not possible and redesigning the teaching to accommodate remedial training would consume more academic staff time resources. An innovative solution, led by technician expertise, is presented here.

3 DIAMOND WEDNESDAY

It is acknowledged in the literature that little research has been conducted in the field of co-curricular and extracurricular activities. Bartkus et al. (2012) suggest that a barrier may be the ambiguous and unclear definition of what constitutes an extracurricular activity, as no generally-accepted definition has been established in the literature. The review defines a co-curricular activity (CCA) as 'one that requires a student's participation outside of normal classroom time as a condition for meeting a curricular requirement,' which represents the work presented here. An extensive review conducted by the UK's Higher Education Academy to examine the role of extracurricular activities on students and their futures (Stuart et al., 2008) also acknowledges in the report that prior to this date, little research on extracurricular activities had been conducted. Findings of the report indicate that certain groups of students, particularly ethnic minorities, do not engage in co- or extracurricular activities. Among the report's recommendations are that 'universities need to pay attention to this unfortunate divide in the students' experience.' Participating in any form of extracurricular activity can have a positive effect on academic performance, even if the activity is not explicitly related to the field of study (Daniyal et al., 2012). A significant study in 2018 (Buckley and Lee, 2018), including a survey with 849 valid responses, analysed the impact of extracurricular activities on student experience. It was found that there are many benefits to participation in extracurricular activities, provided they do not distract too much attention from curricular activities. Very little published work can be found on the impact of co-curricular activities that are directly linked to curricular content.

Diamond Wednesdays was created as a CCA to support students with practical electronics skills. There are many engineering CCAs at the University of Sheffield. These are typically student-led teams formed to develop prototypes that compete in inter-institutional competitions. In contrast, Diamond Wednesday is technician led and focuses on the teaching of practical electronics skills such as using hand tools and the building, testing and fault finding of electrical and electronic circuitry. In all other respects, Diamond Wednesdays can mirror and take advantage of the existing paradigm of a co-curricular activity, allowing students to immediately understand its nature. It is an optional, community driven, non-assessed skills teaching session on Wednesday afternoons in the Diamond building's Electronic and Control laboratory.

The solution is innovative for two reasons. Firstly, there are no timetabled teaching sessions taking place in the laboratory on Wednesday afternoons. In the UK, higher education institutions mutually agree to avoid timetabling on Wednesday afternoons to allow for inter-university sporting fixtures to take place. This is a time when many student clubs and societies operate. Secondly, the technician-led approach to resolving the pedagogical challenge makes optimal use of their expertise and talents. It also provides a solution that avoids placing any additional burden on the academic staff.

4 ADVERTISING

As Diamond Wednesdays were not part of the formal timetable, it was necessary to raise awareness of the opportunity among students who needed support. The multidisciplinary nature of the laboratory provision presented a challenge, as students may be registered in one of several different programs. It was also necessary to promote an informal atmosphere to encourage students who may be less confident to seek further help.

It was decided that the principal mode of advertisement would be through the University's and faculty's existing social media channels, including Facebook, Instagram, and Twitter (now X). These platforms were used to highlight and publicise the work students were doing during the sessions. Social media accounts were set up for Instagram and Twitter (now X), including a hashtag of #DiamondWednesdayTUOS, to link all the posts together and allow students to respond easily.

Academic staff were encouraged to promote these sessions during lectures and tutorials and posters were strategically placed in areas where students are used to congregate.

Fig. 1. Social media posts. Left and middle from 2019. Right 2022.

5 TEACHING DESIGN

The experience gained from traditional, scheduled laboratory sessions highlighted a necessity for the provision of supplementary instruction in fundamental skills for students who initially lack the requisite competencies to achieve early success in their course. Following consultations with laboratory technicians and academic staff, consensus was reached that the most notable deficiency among students was their soldering skills. To address this skills gap, straightforward, guided activities were developed to facilitate swift and effortless skill acquisition.

These activities encompassed the use of fundamental hand tools, including side cutters and wire strippers. In alignment with the instructional needs, interactive pedagogical approaches, such as demonstrations and personalised assistance, were employed. For soldering specifically, live demonstrations of soldering were also performed for groups of (around 10) students, so they could see what to do. This was considered more appropriate than listening or reading from a worksheet, to teach a psychomotor skill (Biggs 1996).

Using the experience of the technical team, further guided worksheets and associated teaching material were produced to construct simple circuits and introduce the basic operations of a breadboard. Members of the technical team undertook trials of the instructions to pinpoint potential enhancements and acquaint themselves with the content, thereby enabling more effective assistance to students.

Fig. 2. Early version of soldering worksheets. 2018.

A series of activities, with incrementally increasing complexity, were designed. The level of required academic understanding was minimised to allow students to focus on the practical skills. The academic rigour required for an engineering programme remains in the traditional, timetabled classes and the Diamond Wednesday activities provide optional, remedial support for students requiring additional assistance. Emphasis was placed on building rather than understanding the circuits. Fabrication neatness and accuracy were the main learning outcomes, as ad-hoc and messy wiring can inhibit higher level understanding, such as fault finding.

Reflections on the approach identified two drawbacks. Firstly, the range of student ability was not reflected by any differentiation in the tasks. Some worked more quickly than others. Secondly, the demand for the sessions increased as awareness grew. The model was shown to be popular and useful, but changes in the approach were required.

6 REMOTE LEARNING

Opportunities to address these issues of differentiated content and scaling were provided during the Covid-19 pandemic. Like most higher education institutions, lab staff invested a significant amount of effort developing methods to deliver practical teaching using online learning (Bangert et al. 2022). Diamond Wednesday activities pivoted to online modes of delivery including the development of a Google Site.

Early versions of the site contained data and circuit diagrams alongside teaching notes. To facilitate more interactive remote content, an online circuit building platform was introduced. Online Laboratory sessions utilise the ‘TinkerCAD’ software, which allows students to digitally simulate building and testing circuits on breadboards.

Later developments included foundational basic knowledge content and several video clips as active demonstrations of skills and circuit building.

Following feedback and demand from students, a section on programmable circuits using ‘Arduino’ Microcontrollers was also added. Additionally, a project ideas section was introduced, enabling students to explore ways to integrate these circuits into practical applications.

One of the most popular circuits during the pandemic became the Distance Sensor. Students were given plans and diagrams of how to build a ‘social distance metre’ which proved to be popular at the time. The informal and non-assessed nature of Diamond Wednesdays allow the creation of more playful activities without compromising the rigour of the taught programmes.

7 EVALUATION

Since September 2019, 54 Diamond Wednesday (Diamond+ Electronics) face-to-face sessions have successfully taken place. In total (to date) 579 students have attended face to face. The average number of students per face-to-face session is 11, with the maximum and minimum number of attendees as 60 and 2, respectively. The breakdown per academic year can be seen in table 2.

Table 2. Student participation in Diamond Wednesday by academic year.

Aca. Year	19/20	20/21	21/22	22/23	23/24
Students	185	23	213	74	154 (projected)

In addition to the face-to-face sessions, many students interact with online material developed during the pandemic. Students have maintained contact via email, the google site and social media. Remote access from students in the UK and international was particularly apparent during the pandemic from website access data based on location, shown in figure 4.

Fig. 4. Diamond Wednesday website access based on location.

In the Diamond Building, all laboratories are equipped with a touch screen tablet to allow students to rate their satisfaction on a 5-point scale, indicated with different types of face icons.   Providing feedback is anonymous and optional. The Diamond

Wednesday sessions have received 123 responses with an average rating of 4.45 out of 5. This is significantly above the average for the Electronics and Control laboratory of 3.97 (standard error of 0.02).

There is qualitative evidence of the success of the sessions. The original purpose of Diamond Wednesday was to provide remedial, practical tuition to first year undergraduate students. There are increasing numbers of second year, third year, and postgraduate students asking for more time and opportunity to work with basic electronics to enhance their skills. It has also been observed that the teaching material for formal, timetabled classes have been adapted under the assumption that Diamond Wednesdays are an established part of the student provision.

8 Discussion

Academic staffing alongside physical estates, practical activities and differentiated, customizable curriculums are expensive. At a time when Higher Education institutions are facing significant financial pressures from reduced funding and increased inflationary costs, as well as existential threats from AI and alternative education providers, there is a pressing need to innovate how teaching is provided.

Diamond Wednesdays is an example of utilising the expertise of technical staff by empowering them to identify problems then design and implement solutions. The activities are run without needing to increase the already high workload of academic staff. By using the options, co-curricular “club” paradigm, the sessions can run at times when the estate would otherwise not be utilised. These attributions of Diamond Wednesday make it a very efficient model for teaching delivery.

The popularity and high student satisfaction of Diamond Wednesdays demonstrates its success. This is attributed to the optional nature of the teaching sessions. Students can practise, and fail, in a non-judgmental setting. While the lack of academic staff has an efficiency advantage, not having staff in the session that would typically be responsible for assessing students' performance can make authentic participation less intimidating.

The optional nature of the sessions allows students a degree of customization of their curriculum. The Diamond Wednesday sessions run, and students can choose, without obligation, to attend if they need extra support. Through advertising, students can select which activities they do or do not need in addition to in-person practical education.

Future developments are planned for Diamond Wednesday. Consideration is now being given to adapting the academic-led, timetabled teaching material based on the premise of Diamond Wednesday being available to students, with a threshold of practical skills being assumed. There is a plan to run consultation with students to gather their ideas and co-create content. Finally, spreading the co-curricular methodology to other practical skills within the Engineering faculty is under investigation.

The Diamond Wednesday Google site has been released as an open educational resource. The authors would welcome collaborations from other institutions to share and enhance the resource if it can be mutually beneficial.

ABSTRACT

Mathematics is an important part of engineering studies; however, in recent years, the way of dealing with these subjects has changed and the type of students has changed as well. As it is well known, mathematics is a tool or a set of tools to develop the future work of engineers. This study presents a pedagogical approach that allows students to acquire mathematical competences while performing a service to the community. A case study of Service-Learning and the mathematical competences involved in a statistical project are analysed here. During the academic year 2023-2024, a group of students consisting of Industrial Engineering, Statistics and Labour Relations students collaborated with the ASCOL association (association against leukaemia and blood diseases) to carry out a statistical study of the data collected by the association.

1 INTRODUCTION

1.1 Mathematical competences

In engineering studies, mathematics is above all know-how. It is more a matter of knowing a method and a way of acting than of knowing content, i.e. mathematics is a tool for the development of engineering activities and proposals.

The activities in which mathematics is involved consist of dealing with more or less complex situations in the real world that admit a very peculiar rational treatment, which many authors have called mathematization, involving appropriate symbolisation, mathematical reasoning and rigorous rational manipulation in order to reach an effective mastery of the reality being explored.

Learning (and mathematical learning in particular) is, above all, a personal activity. Indeed, part of the changes brought about by the Bologna agreement includes self-learning which challenges teachers to develop strategies that may allow students to build their knowledge autonomously. However, the task of teaching must be a collective one, since the teacher teaches (in the university context) groups of students. New teaching challenges demand new answers, far removed from memoristic expositions and merely repetitive or more or less laborious problems of the mathematical operations involved. Moreover, the teaching scenario has changed radically in recent years due to the rise of information technologies. Nowadays, the traditional classroom has become another scenario as we find ourselves in the context of ubiquitous learning.

The competences stablished by Alpers et al. during the Mathematics Working Group Seminar of the SEFI, in 2013 (Alpers et al 2013), were updated by Mogens Niss and Tomas Højgaard, which revised the concept of competence in 2019 and proposed the following definition: “Competence is someone’s insightful readiness to act appropriately in response to the challenges of given situations” (Niss and Højgaard 2019, p. 12). More specifically, “A mathematical competency is someone’s insightful readiness to act appropriately in response to a specific sort of mathematical challenge in given situations” (Niss and Højgaard 2019, p. 14).

The mathematical competencies are separated into two categories:

1. To propose and answer questions in mathematics and using mathematics.
2. Handling the language, constructs, and tools of mathematics.

These categories are further divided into the known eight competencies:

1. Mathematical thinking.
2. Problem handling.
3. Modeling mathematically.
4. Reasoning mathematically.
5. Mathematical representation.
6. Using mathematical symbols and formalisms.
7. Mathematical communication.
8. Making use of mathematical aids and tools.

To put into practice these competencies several authors have published studies and proposals developed among their students. Dias Rasteiro et al. presented a study about the last competence, with the use of Information and Communication Technology (ICT) in their classes, that was presented in the previous edition of the SEFI Annual conference (Dias Rasteiro et al. 2023). Studies about mathematical competencies is a constant in several conferences about mathematical education (Zeidmane 2012; Richtarikova 2023).

1.2 Service-Learning

In the current context several university teachers are using new methods and pedagogical approaches to make students involved in their learning process and to acquire the desired mathematical competencies. Service-Learning (SL) could be defined as a pedagogical approach that integrates academic goals with community service. It provides students with a practical and meaningful learning experience. and allows them to apply theoretical concepts in real-life situations. Findings indicate that experiences with diversity correlate with enhanced civic attitudes, intentions, and behaviours, with interpersonal interactions having a stronger impact than curricular and cocurricular diversity experiences (Bowman 2011). Jacoby (2015) emphasizes that SL not only benefits students academically, but also promotes personal development and social responsibility. Service-Learning affects academic performance, motivation, skill development, and experiential learning in students and provides significant improvements in those aspects (McNatt 2020; Muñoz-Medina et al. 2021).

Moreover, the development of Service-Learning activities increases the improvement of interpersonal skills and social awareness among students, demonstrating an increase in interpersonal competence and sensitivity to community needs (McNatt 2020). These findings underline the importance of SL as a useful pedagogical strategy to enhance the learning of future engineers. In the case of Service-Learning in mathematics courses, Queiruga-Dios et al. found that only 0.83 % of the studies related to SL in Scopus database were related to mathematics (Queiruga-Dios et al. 2021).

Real word problems provide a challenge for mathematics learners due to their requirement to translate verbal descriptions into mathematical expressions or equations. Students often find obstacles in solving word problems due to difficulties in understanding the language of mathematics and in identifying relevant problem information. Additionally, that type of real-life problems often involves multiple steps and require higher order thinking skills such as problem-solving and critical reasoning, further contributing to their complexity. This is what students address when they participate in Service-Learning challenges, they must solve a community problem, or they must do something to improve the lives of the people around them (Queiruga-Dios et al. 2023; Verschaffel 2020).

The community-based research project that involved an interdisciplinary team was a collaborative effort aimed at addressing local community needs through a multifaceted approach. Bringing together experts from diverse fields such as engineering, social sciences, statistics, and volunteers from the non-profit association, the project aimed to tackle complex issues impacting the community. By leveraging the unique expertise and perspectives of each team member, the project sought to develop innovative solutions that would not only address immediate concerns but also foster long-term sustainable development.

Throughout the project, the interdisciplinary team conducted thorough research, engaged with community stakeholders, and implemented practical interventions aimed at improving community well-being. For example, engineers may have focused on developing sustainable infrastructure solutions, while social scientists conducted surveys and interviews to better understand community dynamics and needs, and statisticians worked on the data analysis.

The interdisciplinary nature of the team allowed for a comprehensive and holistic approach to problem-solving, considering various aspects such as social, economic, and cultural factors. By collaborating across disciplines, the team was able to generate creative ideas, develop innovative strategies, and implement effective interventions that addressed the multifaceted needs of the community.

Overall, the community-based research project exemplified the power of interdisciplinary collaboration in addressing complex societal challenges and fostering positive change at the local level. Through teamwork, expertise, and community engagement, the project demonstrated how interdisciplinary approaches can lead to more inclusive, sustainable, and impactful outcomes for communities confirming what was stated by (Bowland et al. 2015).

The proposed project was to collaborate with ASCOL non-profit association in the analysis of a set of data that volunteers got from patients and their families. Thus, the goal was to analyse the results of two questionnaires conducted by the association.

2 METHODOLOGY

2.1 Materials and methods

The Service-Learning approach was used with a group of Industrial Engineering students. These students attend electrical, electronic, and automatic or mechanical engineering classes, but mathematics courses are common for all of them during their first and second years. Sophomore students from the Statistics course collaborate with students from the Statistics Degree (Data Collection Techniques for Scientific Research course) and Labour Relations Degree (Statistical Techniques of Social Research course) during the first semester of the 2023-2024 academic year. This collaboration was done in the development of SL projects. In the case of the Statistics course, this teamwork accounted for 20 % of the final mark, in Data collection for 60% and in the Statistical Techniques course for 10 %.

The total number of students from the three courses was 217, of which 53 are studying one of the Industrial Engineering degrees, 51 from the Statistics degree and 113 from the Labour Relations degree. All were offered the opportunity to take part in the project, and among the volunteers, 4 students from each degree were randomly selected. Some of the other students participated in the development of other different SL projects, such as data analysis of an NGO that distributes food to people in need, a mathematics outreach activity among elderly people, an escape game with children, etc.

The SL project follows the steps detailed in (Queiruga-Dios et al. 2023), i.e., identification of the community needs by interviewing community members, preparation and activity design (seeking additional partners to address the identified needs and determining the learning objectives related to the curriculum), implementation and development, reflection (once the service has been completed, this may lead to proposing a new project to further improve the life of the community), documentation, evaluation, and recognition (it is important to recognise the work done and the positive impact on the community). The first phase was a 3-party meeting with students-teachers-association. During this meeting teachers explained what a community service and Service-Learning project is and then the President of ASCOL described the tasks and objectives of the association and what were their needs related to the data.

Then, two working groups were set up with two members from each degree. Thus, each group was made by 6 students. It was considered appropriate to have members from all the degrees in each group to enrich them and to promote interdisciplinarity and teamwork among students that did not know each other before.

A second session was held in the ASCOL headquarters to present the place and the ASCOL volunteers and members and to share information with faculty and students about the questionnaire to be analysed by each team.

The first questionnaire was called “Survivors” and aims to find out the current situation of people who have or have had haematological cancer. Information was collected from 148 patients from different parts of Spain. The second questionnaire was a study of the needs of haematological patients, both patients and relatives. It initially consisted of 334 entries (some answers were discarded because they were not complete or did not make sense). Two MS Excel files with the answers obtained from both questionnaires and the objective of the study (try to find any conclusion from the answers) were provided. The variables to be analysed were defined by each group according to their concerns and what they considered interesting to analyse. In fact, the contact person from the association did not have a clear idea about the results that they wanted to find. That is why she proposed that each group analyse the answers and look for an interesting conclusion for patients and families.

From that moment, each group worked autonomously establishing the objective of their study and the distribution of the tasks they were going to carry out according to their knowledge of statistics.

The students of the Data Collection Techniques for Scientific Research course were responsible for cleaning the databases (coding variables, eliminating records with missing data, etc.) and converting them into SPSS format. The engineering students were responsible for carrying out a descriptive analysis of the data and creating various graphs to visualise the results. The rest of students then carried out inferential analysis of the data to explore possible relationships between the variables. The comparison of means between two independent groups was carried out with Student´s *t*-test. To analyse the association between categorical variables, the χ^2 test was applied. A significance level of 5% was used in all cases.

To make students learn about different tools, MS Excel was used for graphing and SPSS v. 23.0 for descriptive and inferential analysis in all cases.

Each of the groups presented the results of the analysis to their respective teachers and ASCOL members. They also carried out an evaluation of the Service-Learning activity in which they had participated.

3 RESULTS

This section will include the description of some results obtained from the statistical analysis of the questionnaires provided by ASCOL, as well as some of the reflections made by the students participating in the project.

After cleaning the database, the students who analysed the “Survivors” questionnaire worked with a data matrix composed of 148 individuals and 99 variables.

The database analysed by the other group consisted of 334 individuals and 51 variables after cleaning. Of the group of subjects studied, 68.3 % were patients, followed by 29.0 % family members, while the rest belonged to the categories of ex-patients, survivors and ASCOL workers. Of these, 62.0 % were female and 38.0 % men, mostly from the provinces of Valencia, La Coruña and Salamanca (Figure 1).

Fig. 1. Map describing the workplace of the participants of the study "Needs of haematology patients" (Number of respondents)

The implementation of a collaborative Service-Learning project with an association of leukaemia patients and their families provides a unique opportunity to apply and develop the mentioned mathematical competences in the following aspects:

1. Team members must apply mathematical thinking to understand the structure of the data and formulate relevant research questions related to leukaemia and its impact on families.
2. The project involves tackling complex problems related to the interpretation and analysis of the data collected. Students must plan and execute strategies to effectively organize, clean and analyse the data, as well as identify possible solutions or recommendations based on the results obtained.
3. The data collected can be used to develop mathematical models that represent the prevalence of leukaemia and its associated factors in the population studied. These models help to better understand the dynamics of the disease and its impact on families.
4. During the process of data analysis, students should apply mathematical reasoning to interpret results critically and reach informed conclusions. They must be able to identify potential errors in the analysis and evaluate the validity of the conclusions drawn.
5. Visual representation tools, such as graphs and diagrams, are used to effectively communicate the results of the study and facilitate the understanding of the information by ASCOL members and other stakeholders.
6. During statistical analysis, students use symbols and mathematical formalisms to express statistical concepts, formulas and analysis procedures. This enables them to communicate precisely and concisely the methods used in the study.
7. Students should be able to communicate the results of the study in a clear and understandable way, both in written and oral form. They should explain the statistical findings in a way that is accessible to ASCOL members, as well as to other health professionals and the public.

8. During data analysis, students use mathematical aids and tools, such as MS Excel and SPSS, to perform calculations, generate graphs and carry out statistical analyses.

In summary, carrying out a collaborative Service-Learning project with an association of leukaemia patients and families provides a valuable opportunity to apply and develop a wide range of mathematical skills in a practical and meaningful context. This interdisciplinary approach enables students to use mathematics as a powerful tool to understand and address real problems in the community.

Regarding the students' reflections on their participation in the Service-Learning project, two aspects stand out. On the one hand, students recognize that they have become more aware of the psychological needs faced by both patients and carers of people affected by haematological cancer. They also value positively their participation and the possible help they have been able to give to the association. On the other hand, they consider that their participation in the project has helped them to understand the usefulness of what they have studied in class.

Some European universities are integrating Service-Learning as part of the pedagogical methods they use. In fact, in several of them (such as the University of Salamanca), SL-based courses have been proposed. In this way the needs of the community could be addressed.

4 ACKNOWLEDGEMENTS

ABSTRACT

Teamwork is heavily used and become the norm in Engineering education across all years and disciplines. Academics running such projects/learning activities are well aware of the benefits but also the challenges of such activities, that includes for

[1] *MP Garcia-Souto*
p.garciasouto@ucl.ac.uk

example the logistics (particularly in large teams), ensuring student engagement, equal opportunities, students training and development, and fair assessment. This paper reviews six different case studies in engineering that represent the pathway taken by students in various engineering degrees at UCL. The paper identifies the main challenges faced by practitioners when running and assessing teamwork and mitigations taken to address them. In particular, we emphasise the benefits of using Individual Peer Assessment of Contribution to teamwork (IPAC), and how it helps to successfully mitigate issues that were encountered otherwise. We believe this paper will be useful for any HE lecturer in engineering (even other fields) that runs teamwork such that they improve or reinforce awareness on these challenges, see how others approach them and the impact of those approaches, potentially giving them either ideas for improvement or confirmation of their own practice. We have combined this paper with a workshop and aim to incorporate a reflection on practices at other institutions and broader range of academics.

1 INTRODUCTION

1.1 Use of teamwork in HE

While technical knowledge is still important for graduates, it needs to be paired with other experientially learnt skills such as collaboration or communication (World Economic Forum, 2023), and so skills-based learning within Engineering curricula has increase to prepare graduates for the changing post-university environment (Graham, 2018). The introduction of team projects to programmes has been a key approach to providing students with supported opportunities to learn these more experiential skills but incorporation does not come without challenges that staff will need to address. This is particularly true for large scale teaching which is common within Engineering programmes (Truscott *et a*l, 2023).

1.2 Challenges of Teaching Teamwork in Higher Education

Riebe et al (2016) in their systematic review of various case studies, categorised challenges associated with delivering and assessing teamwork in the Higher Education (HE) context into two themes, i.e., teamwork pedagogy and transaction costs.

Challenges associated with teamwork pedagogy include: (I) *Instruction strategies*, whereby educators and learners lack prior experience, view teamwork as an inefficient use of time and find moving away from tutor-centred teaching challenging (Holt et al, 1997), (II) *Curriculum design* – the degree to which team skills development is incidental or intentional in the curriculum. The intentional inclusion of teamwork training and instructions into the design phase of the curriculum is typically done using the constructive alignment model (Biggs, 1999), and this can be time and cognition intensive. (III) *Team composition*, in terms of team size, diversity, and formation, if incorrectly approached, could result in a negative learner perspective of teamwork productivity with social loafing or free riding being the main concern for learners (Hansen, 2006; Page et al, 2003; Sashittal et al, 2011; Shaw, 2004; McCorkle et al, 1999), and (IV) *Assessment* – which centres on identifying strategies for individual grading and how to address free riding as an assessment concern for learners (Freeman et al, 2002; Ohland et al., 2012).

Willamson's (1979) transaction cost theory assumes that engagement is a function of the benefits or costs derived from developing, coordinating, monitoring, participating in, interacting with, and evaluating teamwork pedagogy. In terms of teaching teamwork skills, these transaction costs may be incurred by seeking to meet employer and accrediting professional bodies' expectations (Burbach et al, 2010; Kliegl, 2013), as a function of the tutors' readiness to develop resources (Albon et al, 2014), developing strategies and interventions (Kedrowicz, 2007) and teaching teamwork skills (Jackson et al, 2014). The transaction costs also encompass how willing and ready learners are to participate in teamwork learning activities (Bacon, 2005), and available resources in institutions which promote teaching and learning teamwork (Ahern, 2007).

It is critical that engineering graduates develop an ability to work effectively within various team configurations or team types e.g. production, service, management, project, virtual, multidisciplinary, etc (Sundstrom et al., 2000); but also different team styles management e.g. consensus or voting or single leader decision making (Yang 2010). Therefore, understanding the dynamics and requirements of diverse team types is crucial for engineering graduates and educators alike. Tuckman's model (Tuckman and Jensen, 1977) introduced the five team developmental stages i.e. Forming, Storming, Norming, Performing, and Adjourning. These stages provide a dynamic framework for teaching teamwork wholistically to diverse team in varying contexts typically encountered in HE.

Various authors have attempted to address some of the teamwork challenges and developed solutions including introducing learner-team training tools and simulations (Hubbard, 2005;), role play (Crumbley et al, 1998), setting rules and accountability within the team by use of team contracts (Pertegal et al 2019, Ramdeo et al 2022) and introducing learners to the stages of teamwork using the Tuckman's (1965) model. Another popular solution has been the use of self and peer assessment, which we call hereafter IPAC (Individual Peer Assessment of Contribution to teamwork). The IPAC assessment methodology allows the learners to assess the level of contributions of each of their peers, including themselves, from which an IPAC factor or score is generated after moderation by the tutor. The IPAC can then be used in combination with the team mark to generate and individual marks for the team members that reflects the achievements of the team but also the individual contribution (Garcia-Souto, 2019). The assessment methodology is used broadly and has been reported as having significant potential to improve students' experience and engagement and reduce the temporal and efficiency related costs (Hansen, 2006; Page et al, 2003; Delaney et al, 2003; Delaney et al, 2013; Garcia-Souto et al, 2019; Seatwo, 2019).

The IPAC assessment methodology is broadly used at University College London, implemented using the IPAC system developed at our institution that makes it easy to run and insightful for staff and students (Garcia-Souto, 2019). Other universities are also using this IPAC system successfully.

Despite its challenges, teamwork remains a strong training and learning opportunity in the Higher Education (HE) engineering context. It is therefore of interest to find ways in which the challenges are managed, and the opportunities enhanced and enriched. In this paper we bring together the perspectives of 5 members of staff who lead team project units within a common HE environment. Through case studies of each practitioner's teaching activity, we bring together a list of types of challenges faced by those leading team projects and start to build a range of potential solutions or mitigations that can be used by others. We aim to widen our community of practice through a linked workshop at the 2024 SEFI conference.

2 METHODOLOGY

2.1 Selection of case studies and analysis

Six different case studies from the UCL Intergrated Engineering Programme (IEP) have been identified and analysed in this paper. The IEP is a teaching framework covering the majority of engineering undergraduate programmes within 8 engineering departments (Mitchell *et al.*, 2019). Throughout the IEP there are several team projects, both single discipline and interdisciplinary, that take place with a range of cohort sizes. The case studies included in this paper were selected because they are representative of the pathway of students within a range of engineering degrees, and they cover a range of class sizes, years of study, engineering fields, different team formations and length and weight of the project towards final degree mark. The practitioners brought together in this paper, work within a range of departments and bring different experiences and approaches to teamwork.

A thematic investigation and analysis were performed covering the selected case studies by practitioners. First the activity lead of the different case studies had a chat about their own experiences, from which a list of possible challenges cathegories was drawn by the first author. Then the lead for each case study was individually requested to reflect and elaborate in writing on each challenge, their perception of impact, describe their approach to mitigate it and how successful it was according to own perception. Finally, the first author performed thematic analysis on the written answers, that was then checked and corroborated by the other authors/case study leads. Our results show the main/common approaches that fit all cases, and also specific/local approaches based on case.

2.2 Case studies

The case studies analysed in this paper cover the pathway of engineering students at UCL from year 1 to year 4 in various disciplines and various class sizes as summarized in table 1. The IEP Challenges (case study A) is the first team project experience for all year 1 students and so students are trained and supported on developing teamwork skills (Truscott *et al*, 2021). Then the students take the "scenario projects" within their own disciplines that are a series of six one-week intensive projects spread across the first and second years (case studies B and C given as examples). At the end of the year 2, all students undertake the How to Change the World project (HtCtW) along with management students, and they work in multi-disciplinary teams, with people they have not met before. In the later years of the degree, students take a more significant team project within their own discipline (case studies E and F as examples), carrying out a significant weight towards their final degree classification.

Table 1. Case studies summary

Case	Name	Eng field	Year study	Class size	Type of teams	Team size	Proj. length	Weight (%) × ECTS
A	IEP Challenges	All	1	>900	Across 7 disciplines	5-8	7 weeks	70% × 7.5
B	Scenario Design Projects (x6)	Chem Eng	1-2	130 - 220	Within discipline	5-7	1-week full time (x6)	~25% × 7.5 (x6)
C	Scenario Design Project in BME	Biomedical Eng	2	70	Within discipline	4-5	1-week full time	25% × 7.5
D	How to Change the World (HtCtW)	All	2	>800	Across 7 disciplines	4-8	2 weeks full time	5% × year 2
E	Design group project	Chem Eng	3	130 - 200	Within discipline	5-6	3 months	45% × 15
F	Design group project	Biomedical Eng	4	20	Within discipline	4-5	6 months	90% × 22.5

3 RESULTS

The analysis was done on the teamwork nature of the activities without reference to the discipline or particulars of the case studies, making results meaningful to the wider engineering community. The challenges identified are given, as well as the proposed mitigations to solve them and how successful they were based on staff perceptions in comparison with their earlier approaches.

List of challenges:

A. Uneven student contribution/engagement and implications towards the assessment.
B. Validity of assessment: This includes concerns of whether each student gets a mark that is representative of their contribution to the teamwork. Concerns are typically felt by students, staff, external examiners, accrediting bodies when all students in a team will receive a unique mark.
C. Diversity in the team: scenarios included here are differences in students' technical knowledge and skills, differences on social skills and ways of interacting/collaborating with people, neurodiversity, differences on working patterns and responsibilities outside of the team project, differences in culture, differences on their communication skills both written and oral in English, etc.
D. Teams with SORA/EC students (SORA indicates reasonable adjustments that should be offered to a student due to long-term conditions, and EC stands for Extenuating Circumstances): Some students might have SORAs or

experience some personal issue that might affect their ability to perform in the team. Some might choose to communicate this to the team, but not all.

E. Readiness of students to do teamwork: This includes e.g. (i) ability of students to work in teams successfully, (ii) awareness of the possible diversity in a team and how to work with a diverse range of teammates, (iii) clarity on suitable students' expectations from teammates, particularly when peer assessing individual contributions, (iv) ability of the students on giving and receiving feedback in a way that is professional, critical yet constructive.
F. Team formation (rather than cohesion): Teams originally defined by tutors might be seen not to be appropriated quite early in the project. This includes (i) difficulties at the onset of the project, perhaps due to prior personal interactions between the students of academic/non-academic nature; (ii) some students might not be active in the module e.g. they are going for interruption of studies, changed their diet, etc but the module leads are not aware of it.
G. Team cohesion: Some teams can find it difficult to work together for various reasons once the project is well underway. These include clashes on personality particularly under stress, strong conflicting opinions or ideas on the desired direction of the project, differences on styles of working, or even a break-down of personal relations in or out of the project.
H. Staff workload: This includes time commitment in all aspects of the teamwork, i.e. preparation of the teams, training of students on how to do teamwork, monitoring student engagement and performance and intervening, when necessary, assessment, mitigations/arrangements needed for specific individuals/cases, and dealing with student querying/challenging their individual marks. This strongly relates to the student numbers.
I. Readiness of staff to run teamwork: Are we all ready to lead a teamwork activity? Which knowledge and skills are needed to successfully run teamwork, is there any training to close the gap?

List of mitigations per challenge:

Challenge A: Uneven student contribution/engagement -successfully mitigated

- Use the IPAC assessment methodology, so students are aware of the individual accountability to the team members, and acts as a deterrent of unjustified lack of engagement. Feedback to students from peers is valuable.
- Provide training to students in earlier years, while in 3rd/4th years need less training as they are already aware of the IPAC methodology and work expectations.
- Check points with staff are helpful, i.e. regular meetings with a member of staff, either as a team or with individual students. This is particularly common in large teamwork components in senior years, e.g. cases E/F.

Exceptional cases of very significant lack of engagement are dealt by staff, with the possibility of removing the student from the team. If the lack of engagement is justified, the staff offers deferral or alternative assessment.

Challenge B: Validity of assessment – successfully mitigated

The IPAC methodology (which includes standard tutor revision and endorsement of the marks) almost solves this challenge entirely. It is particularly useful when team dynamics are not obvious to staff. It handles students' concerns in a formal/standard way, and students are mainly comfortable with the peer assessment and happy with the methodology. It is uncommon for individual students to raise concerns with their IPAC marks, but such cases are reviewed by staff.

In long projects we recommend the use of IPAC for formative purposes at the start/middle of the project. It is an insightful "check point" for staff and it allows students to improve /continue with good practice in their project. It avoids surprising IPAC mark at the end, almost eliminating individual students that complain about their own mark.

<u>Challenge C: Diversity in the team – successfully mitigated</u>

Teams are encouraged to use the diversity and individual skills to their advantage. Particularly in year 1 (or first few times doing teamwork in HE), staff discuss with the students the value of diversity, but also train them in soft skills like communication or teamwork styles. The staff might try to balance the diversity when making the teams – this is further discussed under challenge F.

Teams write a contract at the start of the project. This engages students onto an upfront discussion on how to accommodate/take advantage of the diversity in the team. The typical student team contract reflects that students expect team members to put equal "effort" on the project as opposed to equal "output".

The IPAC assessment is used for students' self-reflection, which supports students to understand and enhance their role in the team. The feedback that each student receives from their peers often also help them to see how their teammates value them, and encouragement in the areas that could need further development.

<u>Challenge D: Teams with Summary of Reasonable Adjustments (SoRA)/ Extenuating Circumstances (EC) students- successfully mitigated</u>

- When SORA students are known to staff in advance, they are distributed across the teams. SORA/EC students are supported by staff when needed and encouraged to participate in the team project if possible.
- Team contract provides an opportunity for students to disclose personal circumstances that might be relevant in the teamwork and for the team to be aware/adjust to the needs of all individuals.
- Make clear to students, which adjustments can be applied in the teamwork for students with SORAs or ECs, and equally those that cannot be applied. Adjustments are subjected to reason, e.g. a SORA student might be given a 2-weeks extension in most of their individual assignments, but it does not apply to team submissions. SORA/EC students that cannot participate in the team project are "effectively withdrawn" from the team and a suitable alternative assessment offered.
- Projects should be feasible to completed even if missing a team member.

<u>Challenge E: Readiness of students to do teamwork - mitigated</u>

This challenge applies more significantly to year 1, when the students are new to teamwork. A significant improvement is observed from year 2 onwards. We found useful to give students training in year 1 on key aspects of teamwork, communication, conflict, etc as part of a taught year-1 module and have a team project focused on the development of teamwork skills (case study A). This sets up a strong foundation of students' skills to do teamwork. Students are also further supported/guided in following years. Marking criteria for the IPAC assessment is presented/discussed with students to clarify and standardize student expectations.

The IPAC assessment also gives students an opportunity for self-reflection and insights on their own performance by anonymous peer regarding their performance and ability to work in a team, which help them with their self-development.

There is always room for improvement by adding more training and mentorship.

Challenge F: Team formation – successfully mitigated

Team formation can be addressed in three different ways.

- Random or semirandom teams' membership. This is the common practice in large classes run across engineering degrees (case studies A and D).
- Semirandom but staff-planned such that students work with as many different students as possible within their degree. This seems to solve quite a few issues and it provides a good training to students. It is typically used in small/medium classes that run within a single degree programme (case studies B and C).
- Diversify membership: In small/medium classes undertaking a very large project within an engineering degree, teams are formed by tutors with consideration to balance gender, academic performance, cultural diversity and typically no more than 1-2 SoRA students (case studies E and F).

Observations on what works:

- Students respond more positively to team membership when the IPAC methodology is in place, even with random and diverse memberships.
- Staff might avoid putting together students with unsolvable standing conflicts due to prior/outside academia personal issues. This is particularly useful in long projects like year 3/4 design team project modules.
- Often the number of students in a team varies within a given activity. This does not seem to present a challenge provided the project can offer flexibility and is suitable to be completed by the smallest team.
- Staff monitors engagement in the early stages of the project e.g. running a formative IPAC or checking attendance to in-class events. If issues within the team are detected, staff decides in a one-to-one basis if teams/particular students just need some initial support or as last resort if some teams need to be re-adjusted. This also identifies non-active students, even if registered.

Challenge G: Team cohesion

Training and general support is provided to students, particularly in year 1. As consequence, it is rare that a team will become truly dysfunctional. However, if a team does break down as a result of external and/or internal factors, tutors provide support meeting with the team or individual students as need. Often team difficulties become significant learning experiences for team members. If the issues are significant, then this is addressed on a case-by-case basis. Dysfunctional groups are either identified by self-referral or reviewing the IPAC scores, hence it is useful and insightful to run the IPAC methodology at some point at the beginning or middle of the project even if only for formative purposes.

Challenge H: Staff workload

Team projects can require significant planning, preparation, and coordination hence staff workload is high and needs to be shared across various staff, especially in large classes. Typically, we have (1) one or two staff activity organizers that lead the planning and running of the activity, monitors and liaise with the class and deploy resources and personnel as needed; and (2) a range of PGTAs/academic staff/technical staff that support different areas of the teamwork activity and also act as supervisor for various teams. The activity organizers typically stay the same, while support personnel is more variable, specially PGTAs, and need training each year. We recommend having at least two staff members that can act as activity organizers for resilience, since it would be very challenging to replace a single activity organizer at short notice e.g. in case of illness/accident.

Challenge I: Readiness of staff to run teamwork

Teamwork seems to be typically led by self-driven staff that generally appreciate the value of teamwork for students' development and have a natural inclination to seek training and peer dialog about best practice. However, there is however no official or mandatory training. Activity leads acknowledge that staff training is needed, and often both offer training/guidance themselves to the support staff/PGTAs and refer them to relevant seminars when available. We believe that a more standard and comprehensive training for staff would be useful.

4 SUMMARY AND ACKNOWLEDGEMENTS

Based on the case studies presented, the authors believe that the IPAC is helpful in addressing some of the challenges related to the running and assessment of teamwork (challenges A, B, C D & F). It facilitates a quick and neat way of providing formative peer feedback, which students can then reflect upon to improve on future teamwork activities and submissions. In that sense, the IPAC assessment method takes a similar approach to the Tuckman's model (Tuckman and Jensen, 1977) and its stages of team development, using peer-feedback to foster the development of teamwork skills across diverse contexts. The IPAC facilitates students' assessment literacy, as they participate in aspects of the grading and helps build emotional intelligence in providing constructive feedback. The IPAC also provides students a sense of fairness in assessment and team allocation, it directly encourages constructive student engagement, and it is seen as a fair intervention for addressing free riding or uneven contributions.

Although the IPAC methodology has mitigated many of the challenges faced, it has its limitations. The IPAC marks need to be reviewed, in few cases moderated by staff, first of all because marks must be endorsed by staff but also as a student's safeguarding process especially for cases involving SoRAs and EC students. Typically, only a few cases might need moderations, and these academic judgments are based on the peer comments and available staff observations. Other important aspects to good teamwork are (i) student training and mentorship by staff; and (ii) team management tools such as the use of a student-developed team contract at the start of the project, which will encourage good communication and understanding of needs between the team members.

Thanks to the UCL Centre for Engineering Education for creating a culture of research on engineering education that has brought the authors together, and for their financial support to attend the SEFI conference.

ABSTRACT

Building a research-based curriculum across all fields of study is more important in the fast-paced, knowledge-driven world. To fully benefit from such a curriculum, engineering educators and students must recognize the significance of integrating sustainability into knowledge creation and practice, along with educational equity serving as the rationale for pedagogical design. This practice study highlights the impact of embedding sustainability research experience in two undergraduate electrical engineering courses at the University of Ottawa, Canada as a path of reinventing engineering education. In the second-year professional practice course, students learned about sustainability as a value that combines factual and ethical components through knowledge-based research. In the fourth-year power engineering course, the students investigated sustainability as a value practice in energy-related subjects through design-based research. Upon evaluation of the courses and student progress, it was evident that notable knowledge gains had been made after completing the experience. Further, this compensatory experience helped narrow the performance gap between high-achieving and low-achieving students. Surveys and feedback from students demonstrated remarkable improvements in their knowledge and competencies. The author emphasizes the significance of developing research skills for crafting usable sustainability knowledge

[1]*R. Habash*
rhabash@uottawa.ca

early on as strategic competencies in undergraduate engineering education. These competencies promote educational equity, enrich ethical design thinking, and prepare students for graduate studies and unpredictable professional careers in a changing world.

1 INTRODUCTION

Many academic institutions promote integrating research-based learning (RBL) into their various educational programs (Healey and Jenkins 2009; Dekker and Wolf 2016). RBL is a teaching methodology that emphasizes the importance of inquiry or investigation at multiple levels of education. It not only involves the use of research outcomes but also cultivates students' understanding of processes and methodologies, fostering a research-oriented culture involving both students and teachers (Noguez and Neri 2019). This enriching culture enables students to not only learn from discoveries and research methods but also actively participate in the research process to develop competencies and reflection (Wessels et al. 2021). In addition, it helps them become partners in the knowledge-creation process and the disciplinary ways of thinking and practicing (Hunter et al., 2007).

The traditional approach to RBL is for a few students only, typically juniors or seniors, to work closely with a professor on a research project outside of class in the academic year or over the summer (Hansel 2018). The chance for those students to collaborate with faculty on research can be a transformative experience. Undergraduates who participate in research internships or apprenticeships report positive outcomes, such as learning to think like a scientist, finding research exciting, and intending to pursue graduate education or research careers (Kardash 2000). The impact of such research experiences on graduation rates has not been systematically tested. Previous studies support the idea that research participation can potentially increase graduation rates and reduce equity gaps (Olivares-Donoso and González 2019). However, ensuring that all students can engage in RBL is an issue of educational equity (Hansel 2018). Therefore, a course-based undergraduate research experience (CURE) may address the inequities of the traditional RBL approach. It allows all students to engage in research, irrespective of their social backgrounds and learning preferences. This could spark students' interest in pursuing research careers and promoting diversity within the research community.

Recent literature published on undergraduate engineering research recommends the use of backward design when executing research experiences by defining the goals before the development of the course (Cooper et al. 2019). The CDIO framework, which follows a "conceive, design, implement, operate" approach, has been updated to include new educational practices such as sustainable development (SD), digital learning, simulation-based learning (SBL), engineering entrepreneurship, internationalization, research-integrated education, and industry engagement, in addition to the original core CDIO standards (Malmqvist et al. 2020). The research option recommends including one or more research experiences as part of student learning.

Although substantial evidence supports the notion that a greater number of students should engage in research, several obstacles must be addressed to achieve this goal. These obstacles include faculty time constraints, insufficient knowledge and expertise, insufficient support and mentoring, a shortage of funding, and a general lack of interest among undergraduates in conducting research (Dadipoor et al. 2019). Moreover, students have limited time to take advantage of research opportunities due to an overburdened curriculum and inadequate planning (Adebisi 2022).

This practice study introduces the initiative “course-based undergraduate sustainability research experience (CUSRE),” which was implemented in the Fall of 2023 and Winter of 2024 at the University of Ottawa, Canada. The author (instructor) opted to add a CUSRE that promotes “sustainability as a value creation and practice” to a second-year professional practice course and a fourth-year power engineering course. The two independent CUSRE modules were created to align with a standard semester structure for electrical engineering. The focus of CUSRE 1 is on knowledge-based research (KBR) while CUSRE 2 concentrates on design-based research (DBR). The study provides an overview of the courses’ pedagogical design, the CUSRE methodology, and the learning experience outcomes.

2 SUSTAINABILITY AS VALUE CREATION AND PRACTICE

The inclusion of sustainability in engineering education should be anchored in a strong philosophical endeavour. The concept of "eudaimonia," derived from Aristotelian virtue ethics and encompassing well-being, happiness, and flourishing, serves as a framework for this endeavour (Cirkony et al. 2023).

Values are enduring beliefs about what is good or desirable, encompassing personal, social, and moral considerations. They play a crucial role in ethics, which deals with human actions. Generally, values pertain to issues of human dignity and rights, cultural diversity, democracy, justice, fairness, social equity, and the rule of law (Holmes et al. 2022). Values can also be used as a measure of how useful technology is in sustainability contexts (Taebi 2016).

By presenting values as aspirational rather than solely preventative, educators can prioritize the public's well-being in ethical decision-making. According to Callard (2018), aspiration refers to the intentional and self-driven effort of individuals to enhance their worth. It encompasses a sense of purpose, envisioned outcomes, and aspirations. As this pursuit of value necessitates personal growth and development for a more gratifying existence, it facilitates sustainable transformation. Therefore, formal education should prioritize transformative learning that is inspired by aspirations.

The notion of sustainability is multifaceted and comprises both factual and value-based components, as noted by Carew and Mitchell in 2008. While sustainability can be traced back to ancient times, it has only recently gained widespread recognition as a critical issue that requires immediate attention from all stakeholders. One way to incorporate sustainability into daily actions is by using the SD Goals (SDGs). Among these stakeholders, the upcoming cohorts of engineering graduates who can play a crucial role in shaping sustainability for socio-technical development (García-Aranda et al. 2023). This requires the education system to consistently impart the necessary pedagogies for envisioning sustainability as knowledge creation and practice.

The literature provides several experiences on RBL for sustainability. Arizona State University (ASU 2024) has established a sustainability undergraduate research experience (SURE) program that provides students with research opportunities to help build career skills and enhance competitiveness for jobs and graduate school. Through the program, students improve their knowledge, skills, and experiences in exploration and discovery to develop evidence-based solutions for sustainability. Stanford University (2024) developed a sustainability undergraduate research in geoscience and engineering (SURGE) program for students from any U.S. institution interested in Earth and environmental sciences, energy, ocean sciences, or civil engineering. In 2014, the University of California at Los Angeles (UCLA 2024) founded the Undergraduate Research Scholars Program (URSP) as a signature undergraduate course of the sustainable grand challenge. The URSP unites undergraduate students across all disciplines in their research experiences in urban sustainability.

3 PEDAGOGICAL DESIGN

Canadian engineering degrees typically have a duration of four years. The School of Electrical Engineering and Computer Science at the University of Ottawa offers several degree programs including electrical engineering, computer engineering, and computer science. In addition to typical technical topics, the programs incorporate topics such as economics, entrepreneurship, and professional practice.

This study considers two undergraduate electrical engineering courses taught by the author. The second-year professional practice course (72 students) has been offered for several semesters in different formats. It covers topics like engineering ethics, leadership and entrepreneurship, sustainability, and artificial intelligence (AI) practice. The fourth-year power systems course (68 students) covers renewable energy systems, power transmission and distribution systems, and buildings. Several significant changes in the curriculum and pedagogy were implemented over the years based on student feedback and reflection on learning outcomes.

The mandate for both courses is to promote collaborative undergraduate research experience by amalgamating various learning methodologies like case-based learning (CBL), and project-based learning (PBL). The learning activities are designed to be modular and flexible, with yearly modifications to provide personalized education and discourage copying. Fig. 1 illustrates a proposed research-based curriculum for the two courses. It emphasizes the importance of the CUSRE as a catalyst for developing questions, investigating the questions, and sharing the findings. The CUSRE facilitates other compensatory learning components like hands-on research cases and projects where students work to examine phenomena and build solutions for real and often interdisciplinary problems. Tests are highly competitive and individualistic.

The learning activities of the two courses can be classified similarly to Bloom's taxonomy, starting with descriptive and analytical experiences, leading to synthetic experiences, and ultimately culminating in design and development approaches (Sleeter 2007). It is essential to note that Bloom's taxonomy is not represented as a pyramid, with a wide base of facts and a small peak of creativity, but rather as a broad wedge or straightforward table. This representation emphasizes the equal significance of analyzing, evaluating, and creating levels (Armstrong 2024). Depending on the types of competencies covered by the study, acquiring topic-specific competencies may be generally mapped as KBR for sustainability, while DBR embraces realizing solutions for sustainable real-life problems. It is important to note that most of the learning activities are group-based (two students only), which encourages participatory and compensatory education to reduce the performance gap between high-achieving and low-achieving students.

One important aspect of pedagogy design is the distinction between the planned curriculum (what is intended to be taught) and the actual curriculum (what students end up learning). Some of this difference is attributed to a "hidden curriculum" (Tormey et al. 2015) which refers to the implicit learning that occurs during implementation. Many research experiences involve the implicit development of skills that are naturally built simply by participating in the process. Sometimes students may not be aware of the experiential impact that scaffolds such research skill development.

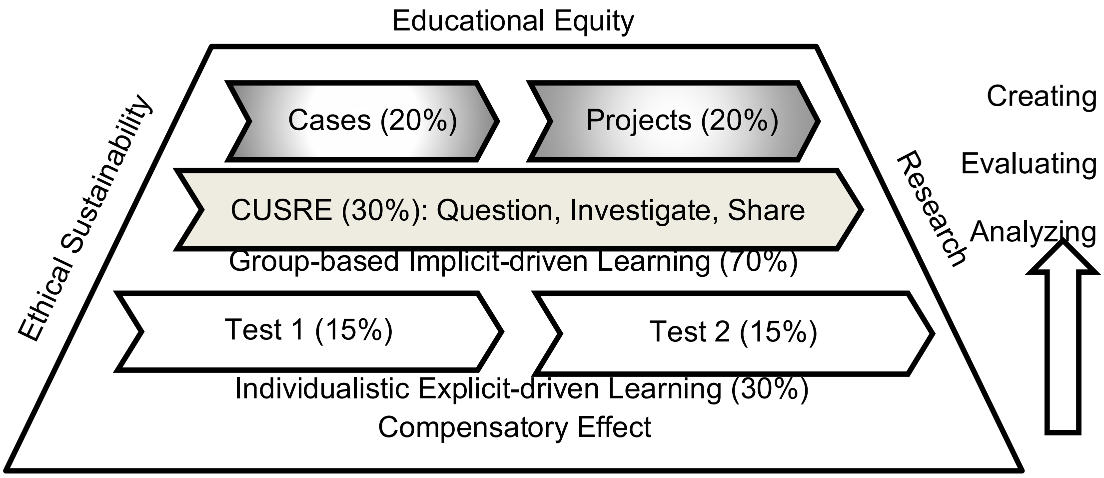

Fig. 1. The research-based curriculum for the two courses

4 CUSRE IN ENGINEERING

Engineering research differs from scientific research in that it is focused on operational knowledge (how and why of creating design concepts to solve problems), rather than factual and conceptual knowledge (understanding the fundamental principles of how phenomena work). Hence, it is vital to consider both KBR and DBR when creating undergraduate research experiences that could prove advantageous to academic institutions, faculty mentors, and students.

The inequities of the traditional RBL approach may be addressed through CURE which was initially created by McLaughlin and Coyle (2016) and evaluated by McLaughlin et al. (2017). The CURE is a course that encourages students to engage in RBL where research is embedded into the learning process. All students registered in a class investigate certain topics, use scientific practices, collaborate with others, and iterate their work. The outcomes of the research are unknown and communicated in some manner. The CURE offers the capacity to involve all students in research (Auchincloss et al., 2014) and can serve all students who enrol in a course—not only self-selecting students who seek out research internships or who participate in specialized programs. Moreover, the CURE can be integrated into introductory-level courses (Harrison et al., 2011) and thus have the potential to exert a greater influence on students' academic and career paths than research internships that occur late in an undergraduate's academic program and thus serve primarily to confirm prior academic or career choices (Hunter et al., 2007). Research internships often require an application or searching and networking to find faculty interested in involving undergraduates in research (Auchincloss et al., 2014). However, entry into a CURE is logistically straightforward where students simply can enrol in the course.

In 2023, the author structured two CUSRE modules and embedded them within the teaching and learning plan of the two courses. Educational equity sets CUSRE apart from CURE and SURE and underpins the decision to select CUSRE as the designated method for the pedagogical design of the two courses. Fig. 2 presents the two CUSRE modules that can assist in executing KBR and DBR. In the early CUSRE 1, students learn about education for SD by investigating its factual and ethical knowledge. In the advanced CUSRE 2, the students investigate how intelligent technologies contribute to the design of sustainable wind power through research replication (direct and conceptual) with a focus on design and simulation.

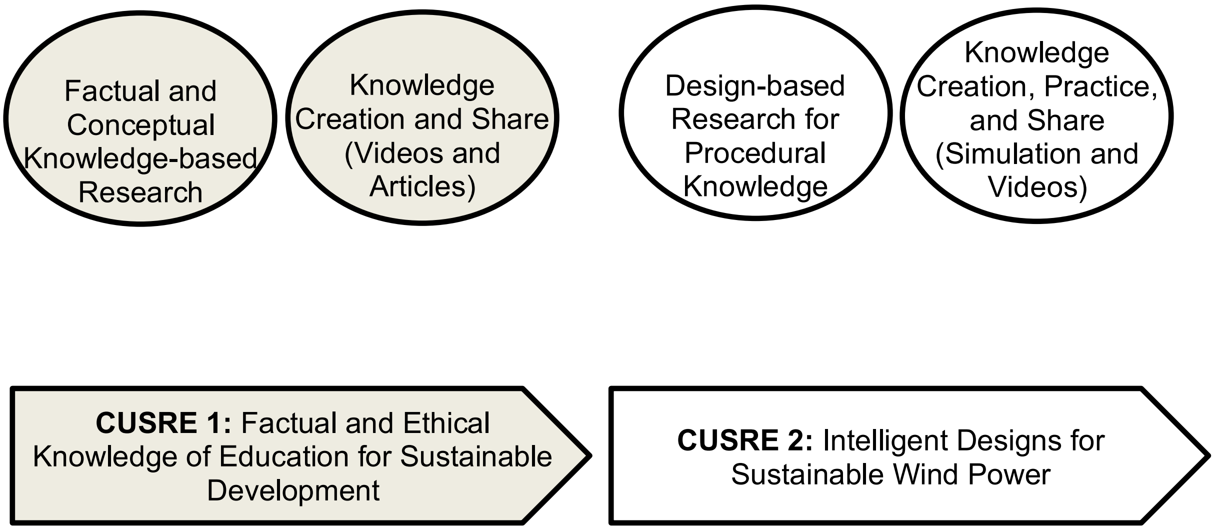

Fig. 2. Instructional design for the two CUSRE modules

In both courses, students work together in small groups to develop their research and design skills. This happens while conducting literature reviews, creating research tasks, and testing hypotheses using scientific methods and reflective problem-solving techniques. Additionally, they professionally present and share their findings through videos and articles, sometimes publishable.

Incorporating video creation, simulation, and article writing into the CUSRE modules can be a highly effective way of translating knowledge and engaging learners. In general, students exhibit value in both the creation of videos (implicit knowledge) and the subsequent simulation and article writing (explicit knowledge), which help them develop a deeper understanding of the subject matter (Habash and Abdulkadir 2023).

5 EVALUATION AND LEARNING EXPERIENCE

The intended learning objectives identified in this study are what the students are expected to learn in a course or teaching intervention. This includes the competencies the students should have acquired, or, in Bloom's terms, "what students should know or be able to do at the end of the course that they could not do before" (Bloom, 2001). The author, being the instructor, is deeply involved in the entire research-based curriculum and evaluation process. He collected empirical data through surveys and short interviews. The surveys had open-ended questions, aimed at gathering students' opinions on the courses. The students were interviewed in discussion circles and were asked questions about their thoughts and the inclusion of the CUSRE modules.

5.1 CUSRE 1: Knowledge-based Research

An anonymous survey of students of the second-year course on professional practice aimed to evaluate the effectiveness of learning materials and activities in an authentic learning environment. Data from the multiple-answer survey shows that 67% enjoyed the research cases compared to projects (40%) and tests (30%). The students preferred the CUSRE directly related to SD with 52% approval. 78% of students appreciated the opportunity to choose their topic within the CUSRE. 96% of the students valued the importance of professional social responsibilities in improving society, being active in the community, promoting racial understanding and helping others in need. For students who have been historically excluded from research experiences, there is a -11% equity gap between low-achieving and high-achieving students, but this gap is reduced to about –7%.

5.2 CUSRE 2: Design-based Research

An anonymous survey of students for the fourth-year course aimed to evaluate the effectiveness of the DBR and SBL as an approach for realizing real-life solutions that "by design" crisscross the sustainability practice space. 93% of the students were excited about the applied knowledge gained through DBR and SBL. Most of the students regarded the CUSRE as useful and successful in realizing the importance of engineering design for sustainability. 98% of the students "strongly agreed, just agreed, or slightly agreed" with the impact of the educational video creation and article writing exercise. Despite the satisfaction, this process might involve student uneasiness by being responsible for their learning tasks. For students who have been historically excluded from research experiences, there is a -9% equity gap between low-achieving and high-achieving students, but this gap is reduced to about –4%.

5.3 Feedback

An important aspect of the evaluation outcome is student fulfilment, which is correlated to but different from success as verified by student feedback and opinion about the learning experience:

"Engaging in course-based undergraduate sustainability research offers a dynamic approach to familiarize young students with contemporary engineering methodologies. The format I followed consisted of conducting a literature review, selecting a paper that aligns with the team's interests and strengths, replicating the results achieved in the paper, and finally presenting what we found to the rest of the class."

"Reflecting on this experience, I firmly believe to be a well-rounded engineer entering the workplace, you need the fundamental knowledge (math, physics, electronics, etc.) as well as perspective on research skills, sustainability, and contemporary learning methodologies."

6 Summary and Acknowledgment

One of the main challenges in engineering education has been the emphasis on the technical aspects of problem-solving and ignoring the socio-technical impact of the solutions. This requires changes in the education paradigm. However, the demanding academic plans of the technical content do not provide more room for supplementary content like sustainability. Therefore, the idea is to incorporate sustainability research in the curriculum interwoven or hidden within existing courses using methodologies like CBL, PBL, RBL, and SBL to adapt to diverse courses easily.

In this ongoing study, the classroom was viewed as a community of knowledge creation and practice where CUSRE plays an integral role in developing research competencies. It also demonstrates that incorporating research in the learning process promotes educational equity by engaging all students, irrespective of their social backgrounds and learning preferences. In addition, it reduces the performance gap between low-achieving and high-achieving students due to the compensatory effect caused by working in small groups to complete the learning tasks. Based on surveys, feedback from students, and observations of the instructor, it is recommended that classroom environments should promote social interaction and collaboration while emphasizing research skills. The curriculum structure should also strike a balance between KBR, DBR, and SBL by adopting CUSRE as a catalyst for sustainable curriculum transformation. This approach is crucial for bridging the classroom environment with professional practice to produce responsible socio-technical engineers who can resolve changing real-life problems.

Finally, the author thanks the numerous students who have taken the courses and participated in the survey and focus groups over the past year. The implementation of the CUSRE will be expanded to a third mechatronics course in the Fall of 2024.

ABSTRACT

There are many ways of integrating sustainability into engineering education. While renewing the Bachelor's Programme in Architecture, Urbanism and Building Sciences at TU Delft, The Netherlands, we discovered that these ways can easily lead to a stalemate: while there is the forward thrust of a curriculum renewal with its strict deadlines, uncertainty about useable concepts to integrate sustainability can cause delays and the avoidance of fundamental decisions. In this practice paper we give a brief overview of the ways to integrate sustainability we have considered, and explain how we subsequently chose what to do first and why. After an inventory of UNESCO's Sustainable Development Goals (SDGs) in the current courses, we reasoned that our faculty themes on sustainability were not directive enough, and that sustainability frameworks were not fully developed yet. Therefore we adopted a twofold method, top-down and bottom-up: redesigning the curriculum based on a preliminary framework, and connecting it with the SDGs in all 24 courses. This new combination did not provide a 'finished' sustainable curriculum, but does allow for follow-up steps that will update it based on fully developed frameworks and sustainable competences in the learning objectives. Our conclusion is that any method of integration may work, but that change can only start by choosing a method and going with it. Our advice is therefore nothing less than a plea for a cultural shift: to break the stalemate by choosing any way of implementing sustainability as soon as possible, in order to gradually transform education *as* sustainability.

1 INTRODUCTION

1.1 TU Delft Context

The campus vision of Delft University of Technology (TU Delft), The Netherlands, approved by the Executive Board in January 2022, includes ambitious goals on sustainability: by 2030, TU Delft will be carbon neutral, climate adaptive, circular, contributing to liveability, and demonstrating its sustainability and excellence on the campus (Van den Dobbelsteen and Van Gameren 2022). Besides sustainable campus operation and becoming climate neutral and adaptive, sustainability in education is part of this transition. Also based on literature, it is imperative that we fully integrate sustainability into our education (Weiss et al. 2021a).

Back in the 1990s, efforts were already made to introduce sustainability in education at TU Delft, with a basic course and a certificate programme. The implementation was both add-on and integrated. Research on how to implement sustainability in education was done; a combination of top-down and bottom-up was suggested (Kamp 2006).

In the years that followed, sustainability and climate education was mainly implemented bottom-up in various courses. Graham indicates in her research that this is one of TU Delft's strengths (Graham 2018). A disadvantage of the bottom-up approach is the lack of an overall view on how the competences are implemented. As in TU's own research (Kamp 2006), in literature a combination of bottom-up and top-down is preferred (Weiss et al. 2021a; Weiss et al. 2021b; Reynante 2022).

1.2 Faculty Context

At the Faculty of Architecture and the Built Environment, pursuing a high level of sustainability in education fits within the faculty's broad approach towards sustainability. This approach has been formalized in the *Sustainability Action Plan*, which was set up in 2023 (Faculty of Architecture and the Built Environment 2023a). The plan describes the faculty's ambitions and goals for primary processes (research and education) and operational processes (building exploitation, energy use, etc.).

The need for a *Sustainability Action Plan* relates to the aforementioned campus vision. The sheer size of the university as an organization, and the many differences among its faculties and services, necessitated the development of local action plans tailored to each faculty and its curricula.

In terms of education, the faculty has interpreted the campus vision's ambitious goals as a responsibility to educate students who are able to contribute to a sustainable society in a responsible way, and who are able to critically address sustainability related issues. To us, the goals set out for the university stress that our education should be fully transitioned to a sustainable default by 2030 as well.

In parallel to the *Sustainability Action Plan*, the faculty has updated its *Vision on Education* in 2023, prescribing a strong emphasis on sustainability in the curricula (Faculty of Architecture and the Built Environment 2023b). It too describes the need to critically evaluate how to shape engineering education in a changing society.

The development of these plans has led us to question how the current curricula could be updated, adjusted and reformed, to accommodate a sustainable default for education. Both the faculty's ambitions and the campus vision evoke a sense of urgency in their commitment to sustainable reform, with many calls for immediate action. Often however, there is a multitude of possible approaches for achieving the set goals. This should not lead to indecision, because taking no action is the worst option of all. With no time to waste, we seized the planned Bachelor renewal as a benchmark opportunity to start a transition towards sustainability in education.

2 THE CASE OF THE BACHELOR RENEWAL

2.1 Reasons for the Bachelor Renewal

In 2022, the Faculty of Architecture and the Built Environment decided to update and renew its Bachelor's Programme in Architecture, Urbanism and Building Sciences, after ten years of intensive use. Our dean launched a project to design an improved curriculum, to be launched in the academic year 2024-2025. Since 2022, a large group of course coordinators, teachers and students is busy preparing this.

The ambition of the broad Bachelor's Programme was – and is – to educate students to become “skilled, academic and context-aware designers of the built environment”. However, major changes have occurred since the start of the present curriculum in 2013. In the social context, the climate crisis and the housing crisis have become much more urgent. Also, the speed of digitalisation is ever increasing. In academic research and teaching methods, innovations such as blended learning and open education have led to new forms of didactics, and more importance is being given to teaching interpersonal and intrapersonal skills. The architecture discipline itself has seen a shift towards interdisciplinarity and transdisciplinarity (respectively, collaborating with other disciplines, and with society). All of this necessitated a rethinking of our programme.

2.2 Aims of the Bachelor Renewal

Our aims for the renewed Bachelor's Programme were fourfold (Faculty of Architecture and the Built Environment 2022):

1. More 'breathing space'

Making courses and the curriculum less full, improving the 'study- and teachability'

2. More academic attitude

Strengthening scientific and critical reflection, increasing freedom of choice

3. Updated content

Integrating the current 'faculty themes', increasing digital and personal skills

4. Updated didactics

Renewing teaching methods

In the remainder of this paper, we focus on ways in which relevant aspects of sustainability could be structurally embedded in the new curriculum, in relation to these four goals.

2.3 Faculty Themes

In its *Multi-Annual Plan 2021-2025*, the faculty presented a number of strategic aims or "faculty themes", all of which directly or indirectly link to sustainability (Faculty of Architecture and the Built Environment 2021). In the document, the faculty identifies three societal challenges as a basis for further action: urban inequality, climate crisis and scarcity of resources. These are followed by three perspectives: on sustainable urbanization, healthy cities, and heritage futures. Finally, the document states three strategies to be developed further: digitalization and artificial intelligence, climate adaptation and energy transition, and circularity in the built environment.

2.4 Problem Statement

Whereas it is abundantly clear that sustainability is a central concept for the faculty, it was not so clear at the outset of the Bachelor renewal how to integrate these broad themes in the renewed programme. This can easily lead to a stalemate: on the one hand there is the forward thrust of the curriculum renewal process with its strict deadlines, on the other hand, uncertainty about useable concepts to integrate sustainability can lead to the desire to take it slow and avoid fundamental decisions affecting all of our teaching. The challenge in 2022 was how to bridge this gap.

3 OVERVIEW: SUSTAINABILITY IN CURRICULA

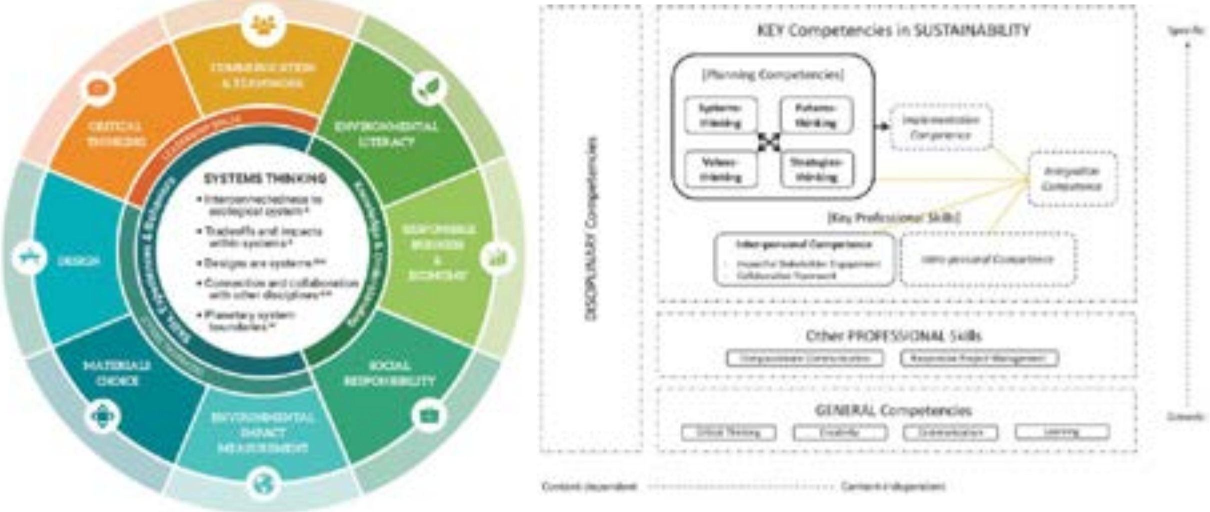
3.1 Frameworks

Twenty years ago, Sterling stated that "sustainability is not just another issue to be added to an overcrowded curriculum, but a gateway to a different view of curriculum, of pedagogy, of organisational change, of policy and particularly of ethos" (2004, 50). Sustainability can thus be implemented at different levels in education. When connecting to TU Delft's other transition goals, it is necessary to go for the highest level of implementation, redesign, education *as* sustainability, instead of education *about* sustainability, see Figure 1 (Weiss et al. 2021a).

Level		Type of ESD	Description	Pedagogical Approach
high/ very strong	redesign	education *as* sustainability	-holistic change and paradigm shift that places sustainability principles, ethics, and values at the core of the curriculum requiring the engagement of the whole person and institution -ESD is integrated into common core requirements and/or the vision of the HEI	emancipatory & transformative (third-order learning)
middle/ strong	'build-in'	education *for* sustainability	-significant changes to the curriculum by including a coherent coverage of content, values, and skills associated with sustainable development and a critical questioning of assumptions -sustainability is addressed in (interdisciplinary) programs/courses focusing on integrating sustainability issues -first linkages from ESD modules to other HEI areas such as operations/campus	
low/ weak	'bolt-on'	education *about* sustainability	-leaves current paradigm change unchallenged -sustainability concepts are added to specific disciplinary existing courses or programs (content based sustainability literacy) -minimal effort from the institution	instrumental & simplistic (first-order learning)
very weak	denial	no change	/	

Figure 1. Levels of implementing sustainability in curricula (Weiss et al. 2021a)

The usage of a framework for implementing Education for Sustainable Development (ESD) seems to be helpful (Wijnia, 2024). For our situation, we mainly looked at the Engineering for One Planet (EOP) framework and Wiek's framework, see Figure 2, left and right. Wiek's framework is the most frequently cited (Wiek and Redman 2022). This is a more general framework, with the disciplinary competencies placed next to the sustainability competencies. The Engineering for One Planet framework was developed specifically for engineering education (Anderson and Cooper 2022). It fulfils the Accreditation Board for Engineering and Technology (ABET) criteria, uses the United Nations Sustainable Development Goals (SDGs) and was prepared in collaboration with universities and industry. Knowledge on the specific implementation processes that lead to sustainable curricula still has to be developed (Weiss et al. 2021a). Wiek et al. (2011) indicate that it is more important to get started implementing ESD rather than developing the most ideal framework.



EOP framework	Wiek's framework
Model made for engineering education	General model
Disciplinary competences in the model	Competencies are largely independent of specific topics
2 levels: core and advanced	3 levels: novice, intermediate (BSc) and advanced (MSc)
Cross-referenced with engineering education and UN SDGs	Most cited research

Figure 2. Comparison of frameworks (Anderson and Cooper 2022; Wiek and Redman 2022)

3.2 Preliminary Adaptation

To fit in with TU Delft's education model, it was decided to use the EOP framework as a starting point. In 2023, a preliminary adaptation to our own educational situation has been made, see Figure 3. In the coming period, this will be further developed by a to be formed focus group. The ultimate goal is then to put this framework alongside new curricula and to see to what extent it is satisfying, can help curriculum development and needs to be updated. Educational redesign takes time to be implemented properly, and with our target there is time for improvement until 2030.

Figure 3. TU Delft Engineering for Sustainability (TUD ES) framework (own illustration based on EOP)

4 SUSTAINABILITY IN THE BACHELOR RENEWAL

4.1 Inventory

In order to check whether and where the faculty themes and sustainability could be implemented in the Bachelor renewal, an inventory of the current curriculum has been made. This started in 2022 with the report of GreenTU (GreenOffice TU Delft), in which all TU Delft education was examined and mainly looked at in outline terms, providing a general overview (GreenTU 2022). To get a better picture, research was conducted on the state of education in 2022-2023 by studying the publicly accessible information in the online Study guide. Keywords were examined and an inventory of the universally used SDGs was made using AI (see Figure 6 for all SDGs). The results were presented in the GreenDatabase. In the current Bachelor of Architecture, Urbanism and Building Sciences, a significant proportion of the courses was found to be dealing with sustainability: 10 out of 24 courses (42%), see Table 1. The courses were part of the so-called 'learning trajectories' 'Design' (ON), 'Technology' (TE) and 'Society' (MA), see Figure 4 for the curriculum.

Figure 4. Current Bachelor's Programme with 4 quarters per year (horizontal) in a 3-year curriculum (vertical) with 6 learning trajectories (see Table 1) (own illustration)

Table 1. Sustainability keywords and SDGs (for the numbers, see Figure 6) in the current programme, based on Study guide (GreenDatabase and own illustration)

Design ON (60 EC)	**Technology TE (25 EC)**	**Fundamentals GR (20 EC)**	**Representation and Form OV (15 EC)**	**Academic Skills AC (15 EC)**	**Society MA (15 EC)**
BK1ON1 11, 12, 13	BK1TE1 7, 9, 11, 13	BK1GR1	BK1OV1	BK2AC1	BK3MA1 11, 12
BK2ON2	BK1TE2	BK2GR2	BK2OV2	BK4AC2	BK4MA2 11
BK3ON3 11, 15	BK2TE3 7, 9, 11, 12	BK3GR3	BK3OV3	BK6AC3	BK6MA3 11, 12
BK4ON4 11	BK3TE4 11, 13	BK4GR4			
BK6ON5	BK4TE5 11, 12, 13				
BK6ON6 11, 12, 13, 15					
Contains 'sustainability'		Not sure		No 'sustainability'	

Next, in early 2023, the learning objectives of all courses were studied in detail by the programme coordinators. This confirmed the results of the GreenDatabase, with only one difference in the 10 courses dealing with sustainability: BK3ON3 instead of BK1ON1 in the 'Design' trajectory. However, most courses appeared to deal with sustainability only in a rather superficial way, e.g. in a subclause or as an 'add-on'.

4.2 Problems with the Faculty Themes and the TU Delft ES Framework

A major aim of the Bachelor renewal was to better embed and deepen sustainability in the programme, initially using the faculty themes. However, because these are quite abstract, thematically ordered and not linked to international examples, while the courses' learning objectives are specific and focused on assignments, the faculty themes proved difficult to use to give direction to the Bachelor renewal, in a way that is understandable also outside the faculty. Because the TUD ES framework was not fully developed during the renewal process but we did not want to delay, we adopted a twofold method, top-down and bottom-up: redesigning the curriculum based on the preliminary framework (Figure 3), and relating all courses to the SDGs.

4.3 Curriculum Redesign

First, during the first half of 2023, we redesigned the structure of the curriculum partly based on and incorporating the known knowledge, skills and attitudes from the preliminary TUD ES framework. This was one of the reasons for the fusion of the 'Academic Skills' (AC) and 'Representation and Form' (OV) trajectories into the new 'Science and Skills' (WV) trajectory, with more focus on critical thinking and personal skills, and for the introduction of the education-free and reflection-based Personal Development Week (P) twice a year (Bohm et al. 2023), see Figure 5. With these two innovations, the competences reflection & critical thinking, communication & teamwork, and social responsibility from Figure 3 are better incorporated.

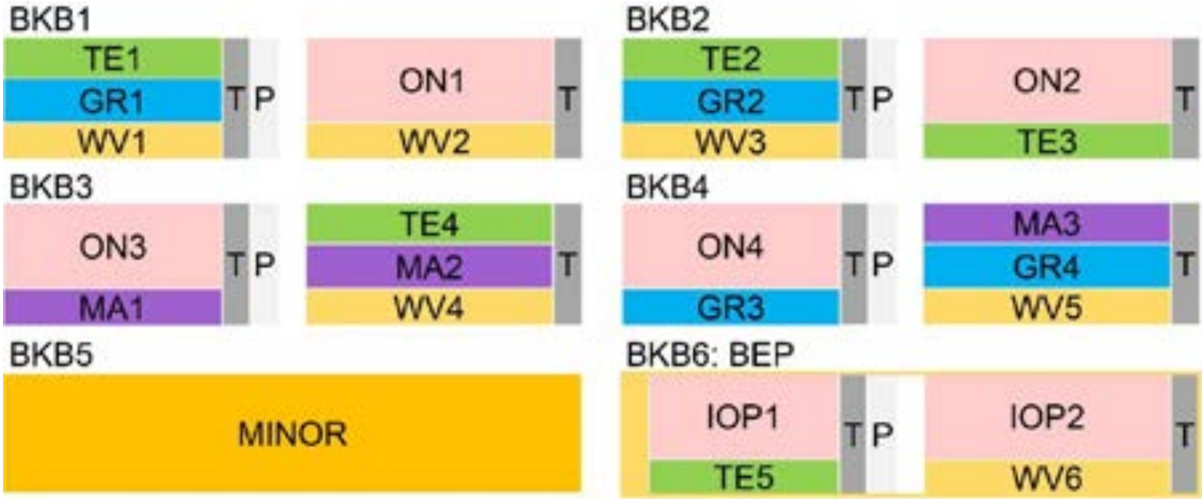


Figure 5. Renewed Bachelor's Programme starting in September 2024 (own illustration)

4.4 Sustainable Development Goals in all Renewed Trajectories and Courses

Second, we chose the SDGs as an extra framework (Beagon et al. 2022), and from summer 2023 asked all trajectory teams to what extent their renewed courses could be linked to them and steered by them. The initial question was to look at the primary (and possibly secondary) interfaces with the SDGs from the course description in development, and to interpret them broadly. For this we used the 'Wedding Cake

Model', in order to facilitate relating the SDGs to the natural and built environment, and its influencing contexts, see Figure 6 (Rockström and Sukhdev 2016).

Figure 6. SDGs Wedding Cake Model (Rockström and Sukhdev 2016)

It was explicitly not the ambition to cover all 17 SDGs with the 24 courses, as some SDGs are less related to the building domain in terms of content. Instead, the intention was to see where our programme is strongly or less connected, so an overall picture emerges.

In resolving duplications or omissions, UNESCO's publication *Education for Sustainable Development Goals* has been used (UNESCO 2017). This educational elaboration provides guidance on how to implement the SDGs in education, including suggestions for learning objectives. Besides learning objectives per SDG – subdivided into cognitive, socio-emotional and behavioural learning objectives – the publication also lists 8 generic key competences for sustainability: systems thinking, visualising multiple futures, using norms and values, strategic action, collaboration, critical thinking, self-awareness and integral problem solving. Using this, the trajectory teams started thinking about where in their courses (which) knowledge and skills about climate and sustainability could be conveyed, and how these could be captured in (assessable) learning objectives. For now, this has led to an updated version of Table 1, see Table 2, in which all courses now relate to one or more SDGs (with SDG 11 being present in 20 courses, and SDGs 1, 2 and 16 being absent).

In a future stage, the trajectory teams can fine-tune their course content as they continue to develop it during the 2024-2025 academic year, parallel to the further development of the TUD ES framework, and by using the European Commission's competence framework Greencomp (European Commission Joint Research Centre 2022). This contains 12 competences in four areas: sustainability values, complexity of sustainability, visualising a sustainable future, and pursuing sustainability.

Table 2. Sustainability keywords and SDGs (for the numbers, see Figure 6) in the renewed programme, according to the course coordinators (own illustration)

Design ON (60 EC)	Science and Skills WV (30 EC)	Technology TE (25 EC)	Fundamentals GR (20 EC)	Society MA (15 EC)
BKB1ON1 3, 6, 15	BKBWV1 4	BKB1TE1 4, 7, 13	BKB1GR1 11, 15	BKB3MA1 3, 10, 11, 13
BKB2ON2 7, 11, 12	BK1WV2 4	BKB2TE2 4, 11, 12, 13	BKB2GR2 11, 15	BKB3MA2 8, 11, 12, 17
BKB3ON3 11, 13, 15	BK2WV3 4, 11	BKB2TE3 3, 4, 6, 7, 11, 12, 13	BKB4GR3 11, 15	BKB4MA3 11, 12, 13, 17
BKB4ON4 3, 4, 5, 11	BKB3WV4 4, 11	BKB3TE4 3, 4, 7, 11, 13, 15	BKB4GR4 11,15	
BKB6IOP1 11, 17	BKB4WV5 7, 11, 14, 15	BKB6TE5 3, 4, 6, 9, 11, 12, 13, 15		
BKB6IOP2 6, 7, 11, 12	BKB6WV6 4, 11			

Contains 'sustainability'	Not sure	No 'sustainability'

5 Discussion

5.1 Conclusion

Looking back at the renewal process, and forward to the start of the renewed Bachelor's Programme in September 2024, we can conclude that our method did not provide a 'finished' sustainable curriculum at once. However, it has provided guidelines, also for other institutions, on how top-down and bottom-up approaches can be integrated: it did change the curriculum in a fundamental way, by a change of perspective on the design of a more sustainable curriculum, and on the courses' content with the SDGs; in line with the aforementioned quote of Sterling (2004).

Moreover, our method ensured that studyability (not adding more, but sometimes doing less) and teachability (a new curriculum demands a lot from staff) could receive a lot of attention. It also allows for follow-up steps from 2024-2025, that will update the curriculum in line with frameworks in development (including the TU Delft ES framework), and that will include sustainable competences in the learning objectives, while evaluating the courses and the needs of teachers and students. At the same time, our Bachelor renewal will serve as a pilot for other TU programmes.

With Wiek et al. (2011) and Weiss et al. (2021a), who indicate to get started with implementing sustainability rather than to wait for fully developed frameworks, our conclusion is that any method of integrating sustainability in engineering education may work, but that change can only start by daring to make a deliberate choice for a method and going with it. Given the implementation time, this is the first step in a process, and it will take several iterations to realise the highest level of integration.

5.2 Advice

Based on our case of the Bachelor renewal as well as on literature, our advice on integrating sustainability in engineering education is therefore nothing less than a plea for a cultural shift: to break the stalemate that may occur because of the many useable concepts, by choosing any way of implementing sustainability as soon as possible, in order to gradually transform engineering education *as* sustainability.

ABSTRACT

Since the end of 2022, ChatGPT and other chatbots continue to revolutionise the way we work, and especially in scientific and academic fields, this is both an opportunity and a challenge for both students and lecturers. Custom chatbots can also be easily created to suit specific applications and purposes. In addition, there are many other AI tools, e.g., for image and video generation and manipulation, scientific work or presentations. This study evaluates some of these AI tools besides ChatGPT with regard to different applications for academic purposes, both from the students' and lecturers' point of view. As part of an interdisciplinary project, students, in collaboration with the lecturer, selected several AI tools based on possible application scenarios and investigated the basics and functionalities of the tools. In the next step, they analysed these tools with regard to possible teaching and learning scenarios. Based on these scenarios, they used the tools to develop detailed applications in different teaching-learning scenarios to check the suitability, effectiveness and correctness and to evaluate the results. Teaching material of a dedicated lecture, including presentations, videos, textbook and more was used as demonstrator for the different AI tools.

1 INTRODUCTION

1.1 Generative AI and tools

Since end of 2022, ChatGPT and other chatbots are the most popular generative AI tools to generate and analyse text and support or even replace the writing process (Achiam 2023). These Large Language Models (LLM) were trained with an incredible amount of training data to be able to generate responses for queries, given as prompts to the tool by the user, in all kind of different domains (Chowdhury 2023). This capability of the chatbots, to generate answers based on large data sets, changes the way of writing text drastically as it reduces the creative writing process to dedicated and suitable prompting (Wu 2023). As the answers are generated by statistical processes of the LLM, the answer will not be checked for any kind of correctness and it might contain plausible yet incorrect or nonsensical information, known as hallucinations, a big challenge for the user of the tool, also in academic area, where both students and academics use chatbots to generate their text for research proposals, thesis or any other kind of documentation (Sok 2023). In academic education, generative AI can be used for active learning environments (Elsayary 2024). Besides chatbots like ChatGPT, there are many other AI tools for other purposes, like generation of images, video or presentations, scientific work, collaboration and project work and others (Bankar 2023). In addition to ChatGPT, these tools also enter the academic world and can be used by students as well as lecturers (Lee 2023, Cao 2023). In particular lecturers have to be aware of these AI tools to uses the tools themselves in a responsible and adequate manner, to be able to support students on proper use on the one hand, and to be able to check any inadequate and unallowed use on the other hand (Ghimire 2024).. Therefore, a rough knowledge and understanding of the tools is essential for lecturers as well as students.

1.2 Learning and teaching scenarios

Like chatbots (Labadze 2023, Bewersdorff 2024), other AI tools can also be used by students and lecturers to support and improve both teaching and learning and to create new learning-teaching scenarios. Always keeping in mind, that the tools might suffer from hallucinations, emphasising the importance of guided use and background knowledge about the topics. Possible application areas are listed in Tab. 1.

Table 1. Application areas for AI tools

Lecturer	Student
L1: Additional and better learning material	S1: Support in scientific work
L2: Better visualization	S2: Self-generation of questions of understanding for exam preparation
L3: Support in generation of exams	S3: Generation of presentations and material
L4: Better and more individual evaluation of learning progress of the students	S4: Summarizing learning material for exam preparation

L5: More flexibility	S5: Support in creative processes
L6: Better accessibility of learning material	

2 METHODOLOGY

2.1 Experimental setup

To take both the lecturers' and the students' point of view into account, the evaluation of AI tools for teaching-learning scenarios was done in an Interdisciplinary Project (IP). IPs with students of different bachelor and master study programs (Electrical Engineering (EE), Information Technology (IT), Multimedia and Communication for Digital Business (MCD) and Information Systems (IS)) are essential parts of the curricula of these study programs at the department of Electrical Engineering and Information Technology (FB5) at University of Applied Science Aachen. The integration of an interdisciplinary teaching approach offers dedicated advantages for the students, like better preparation for today's jobs and challenges, critical thinking about the own discipline, enhanced communication skills with other disciplines and more (Woods 2007). In addition, the combination of interdisciplinarity with project-based learning extends the competences of the students during the interdisciplinary project with regard to increased autonomy, self-management, problem analysis and communication (González-Carrasco 2016, Haack 2013). With regard to these studies, the interdisciplinarity also introduces other benefits, like different prior knowledge of the students, different expertise and technical socialization. During winter term 2023/2024 in total 25 students participated in an IP called "ChatGPT & Co – Possible applications in teaching at FB5", both bachelor and master level. After a short introduction to the topic, the students researched different AI application areas and tools that could be suitable for an analysis with regard to teaching and learning. Finally, 6 application areas were selected by the students and 6 groups were formed. During the project time, these groups worked in a self-organized way with bi-weekly status meetings with all groups and the lecturer. The tasks for the groups were:

- Analyse the technical background of the tools
- Get familiar with the tool
- Identify possible applications for teaching and learning
- Develop real scenarios, e.g. for a dedicated module
- Evaluate and rate the results

2.2 Selected tools

In total, more than 10 different AI application areas were found by the students to be interesting for teaching or learning. Out of these, 6 were selected for detailed analysis in 6 groups. Due to limited space, this paper focusses on two AI application areas – PDF chatbots and image and video generation – and on the results of the analysis with regard to teaching and learning. The complete results of all 6 groups, including generation of presentations, scientific work and research and project management, can be requested from the author.

3 RESULTS

3.1 PDF chatbots

PDF chatbots are AI tools similar to ChatGPT to directly interact or chat with dedicated pdf documents to provide pdf processing capabilities including summarization, generation of question and answers, citing sources from the pdf.

Unlike chatbots like ChatGPT, they act on the pdf documents provided by the user instead on their own database. There are many different PDF chatbots available, commercial tools like ChatPDF or pdf.ai, open source tools, or you can create your own pdf chatbot. As most teaching material is provided and is available in form of pdf documents, PDF chatbots and their capabilities will be an important tool for academic use. Typical uses cases for students and lecturers are listed in Tab. 2.

Table 2. Uses cases for PDF chatbots

Lecturer	**Student**
Create questions & answers	Summarize learning material
Create exercises and labs	Generate questions & answers
Summarize books and scientific texts	Solve exercises and labs
Check answers and solutions	Get feedback for own work
Understand use of chatbots by students	Support with language problems
Create exams	Prepare for exam
Create feedback	

As clearly visible in Tab. 2, PDF chatbots change the way of interaction with the learning material, both for lecturers and students. For lecturers, PDF chatbots can improve the quality and the quantity of learning material, e.g., by providing focussed summaries, and increase the variety and flexibility of training material like exercises.

For students, PDF chatbots can be positive and negative with regard to their own learning success. In best case, the PDF chatbot can act as a training partner for better understanding of the teaching material, e.g., by asking dedicated questions for unclear topics, generating executive summaries, or even generate additional questions for better understanding. Also, the preparation for exams can be improved. On the other hand, PDF chatbots can tempt students to neglect real understanding and instead rely solely on the chatbot's answers without engaging intensively with the material. This topic is difficult in two ways: the students miss real understanding, and, in case of wrong answers, e.g., due to hallucination of the PDF chatbot or bad prompting, learn false facts.

To analyse the student's use cases, the complete teaching material of a dedicated module – sensors and actuators – was used, a complete set of presentations (about 500 slides), a textbook (about 200 pages), data sheets, exercises and lab material. The analysis used several different PDF chatbots – ChatPDF, Bingchat, PDFgear and pdf.ai – and covered uses cases like questions of understanding, generation of exercises and solutions, searching for details in data sheets, explanations, and more. The generated material was checked afterwards by the lecturer with regard to correctness and completeness.

As a result, questions of understanding were answered correctly by the PDF chatbots in most cases, just minor errors were introduced. Solutions to exercises, in particular for calculation tasks, were sometimes correct, but mostly incorrect. Either the equations used were wrong, or the calculating path, or the calculation itself. Students should therefor refrain from using PDF chatbots for calculations and solving exercises, at least they should be aware that the solution might be wrong and should be just a first hint for an own solution. The capability to summarize pdfs differ between the tools under investigation. The quality of the summary depends on proper and detailed prompting, and the length of the summary. the more detailed the summary should be, the shorter the input should be. Again, the student should be able to judge the quality of the summary. PDF chatbots can generate questions very well, the corresponding answers are, like for the first point, mostly correct for questions of understanding and often wring for calculations. Fig. 1 summarizes the results in form of a SWOT analysis.

Fig. 1. SWOT analysis of PDF chatbots

3.2 Image & video tools

Image and video processing tools are important and powerful AI tools in general (Singh 2023). Based on proper prompting, they can generate images and videos in different styles, manipulate and edit images and videos, convert text to image/video and vice versa, or video to video. For teaching and learning scenarios, these capabilities offer a wider range of applications for image and video processing tools like synthesia or runwayml, e.g., generation of dedicated images for visualization, increase the creativity and the variety of learning material, add subtitles to videos or generate explanatory videos. Form these applications, two were selected for more detailed analysis with regard to teaching and learning, creation of an explanatory video, and adding subtitle to an existing video.

For generating subtitles for an existing video, the AI tool reduces the noise of the video to increase the quality of the sound and performs an acoustic modelling to understand connections between phonemes heard. Afterwards a language modelling understands the text and in a final step, this text is reworked and corrected. To generate the subtitles in another language, e.g., for foreign students, the text can be downloaded in an .srt-file with timestamps. Afterwards it can be translated using ChatGPT for example and reinserted into the .srt-fil, which can be imported by a video player in the end resulting in a video with multilingual subtitles. These steps were done using the existing videos of the module sensors and actuators. After getting used to the AI video processing tool, the effort to generate subtitles is very low and it just takes about two minutes to generate subtitles in German for one of the videos of the modul of about 25 minutes. To generate multilingual subtitles, the extra steps for translation are currently manual and take some time, but still the effort is rather low. In future, these steps can be automated using an API instead. A screenshot of the video with English subtitles is depicted in Fig. 2. Due to the simplicity and speed of generation it can be done by either the lecturer, or by the students for individual settings and languages.

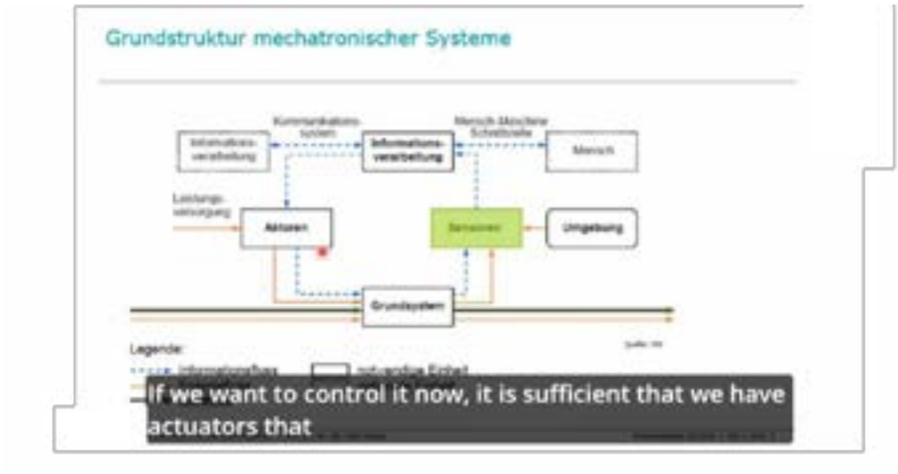

Fig. 2. English subtitles for a German video

The possibility of adding (multilingual) subtitles to videos increases the accessibility for several groups of students significantly. For foreign students, the translation of the subtitles to their mother tongue keeping the original language of the slides and the speech, can support their technical learning outcome as well as their understanding of the original teaching language. For students with hearing impairment subtitles will significantly increase the possibility for understanding the teaching material and improve their learning outcome. Or they can use the generated text instead.

Another application area of image and video AI tools is the creating of additional teaching material, e.g., in form of explanatory videos using avatars. Starting point for generation of explanatory videos is a script that should be presented in the video. This script is analysed by the AI tool to understand the context and to determine semantics and pronunciation. In the following prosody modelling step the AI tool understands the intonation and rhythm of the text and uses it to model pitches and durations. In the speech synthesis step, a trained neural network finally generates the actual speech based on the speech patterns and modelling.

As an application example, the written installation instructions for a lab were converted into an explanatory video using the tool synthesia. In a first step, the written instruction was converted to a script on different slides within synthesia. Afterwards, the features of the video can be adapted to the requirements, e.g., the animation style, language, avatar and gestures, speech. In Fig.3 a screenshot of the generated explanatory video is shown. The effort for the generation of the videos is rather low. Main task is to generate the script in the first step. The selection of the video features is a matter of training and doesn't need much time. The generation of the video itself is rather time consuming, for a video of about 30 s it took roughly 8 minutes to generate the video.

Explanatory videos increase the variety of learning material and provide an additional approach for the students as they can enable an easier access to dedicated topics. Hence, these explanatory videos don't require much effort for the lecturer, but can support and relieve the professor with simple descriptions and explanations.

Fig. 3. Screenshot of explanatory video

3.3 Evaluation of PDF chatbots and image & video tools

The results of the analysis above can be mapped to the application areas of Tab. 1, as depicted in Tab. 3. Even just two types of AI tools, PDF chatbots and image & video tools, can significantly contribute to the improvement of the teaching and learning material, increase the accessibility of the material, promote more inclusive engineering curricula and provide a higher degree of flexibility and individualization, simplifying the work for both lecturers as well as students and increasing the individual learning outcome of the students.

Table 3. Mapping of results to application areas

Group	**PDF chatbots**	**Image & video tools**
Lecturer	L1, L3, L4, L5	L1, L2, L4, L5, L6
Students	S1, S2, S4	S3, S5

4 SUMMARY AND ACKNOWLEDGEMENTS

This paper summarizes some of the results of an Interdisciplinary Project with regard to AI tools for teaching and learning, focussing on two AI applications. Both AI applications, PDF chatbots and video generation, were shortly introduced and important results were presented. PDF chatbots can support lecturers to improve their teaching material. For students, the use of PDF chatbot has some pros and cons and students should be aware of these to use the PDF chatbots sensibly, purposefully and correctly. Video generation tools can significantly improve the teaching and learning material and can be very helpful in terms of accessibility for foreign students and students with disabilities.

The careful use of AI tools is highly recommended, and in particular lecturers have to have a profound knowledge of these tools and their application.

The author would like to thank the students of the IP for their creativity and excellent cooperation. The complete results of the project can be requested by the author.

ABSTRACT

In response to students' over-engineered designs in a biological engineering capstone course, the authors formulated a teaching partnership among communication, engineering, and library science instructors. We outline service design methodology as the framework for a teaching intervention in our partnered courses and then provide examples of instruction stemming from our respective areas of expertise. Our goal is to show how our multidisciplinary teaching collaboration improves the engineering curriculum while intersecting several ABET student learning outcomes. This teaching team was particularly attentive to centering people or users to educate engineers in a way that deters user dissatisfaction and environmental waste. We include one team's coursework as a case study for how this unique pedagogical framework improves student learning and simultaneously forwards their awareness of sustainability in engineering.

1 INTRODUCTION: PROBLEM & TEACHING INTERVENTION OVERVIEW

Picture a table-sized mobile phone charger whose surface automatically detects the device's location and charges it. Although this technology is fairly innovative, it lacks purpose for users. Outlet-based chargers are the norm, and while this technology design removes a user's need to be close to an outlet, it's unclear why a user would purchase a large, expensive charger over a readily available, less expensive one. A design like this one suffers from *over-engineering*, a process by which engineers design a product that is "unnecessarily complicated" ("Over-Engineered" 2024).

Over-engineered designs fail to prompt social and environmental sustainability. One example comes from a prominent German automotive manufacturer, who added 78 optional extras over 20 years, despite that "the number of customers purchasing these add-on components remained steady at only one in six for the same time period" (Bryant and Wrigley 2014, 78). Likewise, engineering designs that do not meet user needs also fail to meet sustainability goals, such as "the presence of high occupancy vehicle (HOV) lanes in Atlanta, Georgia for two decades has had little noticeable effect on congestion and driver behavior, particularly on willingness to carpool" (Guerra and Shealy 2018). Because the problem of over-engineering begins partially in the undergraduate engineering curriculum and sustainability is one way of contending with it, we argue for educating engineers to learn concepts and practices that deter such dissatisfaction and waste.

Therefore, our teaching team included service design methodology as a pedagogical framework for improving the learning outcomes in a senior biological engineering capstone course where students prototype and test physical designs. Five years ago, our multidisciplinary teaching team began a collaborative curriculum approach, combining communication and biological engineering expertise. Our instruction approach *authentically integrates* communication in the engineering curriculum (Reave 2004) with the goal of providing students with a situated learning experience (Artemeva, Logie, and St-Martin 1999) through a hands-on engineering design project. We accomplished this by adding a new engineering communication course, ENGRC 4590, to the curriculum that is partnered with BEE 4590: Physical Design in Biological Engineering. Two years ago, Christina Sheley, a library scientist, joined our team to provide information literacy instruction in the communication course to improve students' research skills so they could better define their problem, user, technology, and broader contexts before and during the design process.

First, we describe the current state of engineering design education, and second, we define service design methodology as the framework for a teaching intervention in our partnered courses. From there, we summarize the engineering student outcomes supported by our collaborative teaching partnership and offer examples from each respective instructor's area of expertise. Throughout we include a case study of one team's coursework as an illustration of how this unique pedagogical framework improves student learning and simultaneously forwards their awareness of sustainability in engineering. Upon examining the students' projects from 2023, we observed their heightened understanding of user needs which ultimately led to more sustainably conscientious and usable designs.

1.1 Engineering Design Curriculum Structure
